About This Document

Intended Audience

This document is intended for network engineers responsible for switch configuration and management. You should be familiar with basic Ethernet knowledge and have extensive experience in network deployment and management.

Symbol Conventions

The symbols that may be found in this document are defined as follows.

Symbol	Description
NOTICE	Indicates a potentially hazardous situation which, if not avoided, could result in equipment damage, data loss, performance deterioration, or unanticipated results. NOTICE is used to address practices not related to personal injury.
NOTE	Supplements the important information in the main text. NOTE is used to address information not related to personal injury, equipment damage, and environment deterioration.

Command Conventions

The command conventions that may be found in this document are defined as follows.

Convention	Description
Boldface	The keywords of a command line are in **boldface**.
Italic	Command arguments are in *italics*.
[ ]	Items (keywords or arguments) in brackets [ ] are optional.
{ x | y | ... }	Optional items are grouped in braces and separated by vertical bars. One item is selected.
[x | y | ...]	Optional items are grouped in brackets and separated by vertical bars. One item is selected or no item is selected.
{ x | y | ... }*	Optional items are grouped in braces and separated by vertical bars. A minimum of one item or a maximum of all items can be selected.
[x | y | ...]*	Optional items are grouped in brackets and separated by vertical bars. Several items or no item can be selected.
&<1-n>	The parameter before the & sign can be repeated 1 to n times.
#	A line starting with the # sign is comments.

Interface Numbering Conventions

Interface numbers used in this manual are examples. In device configuration, use the existing interface numbers on devices.

Security Conventions

- Password setting
  - To ensure device security, use ciphertext when configuring a password and change the password periodically.
  - The switch considers all passwords starting and ending with %^%#, %#%#, %@%@ or @%@% as ciphertext and attempts to decrypt them. If you configure a plaintext password that starts and ends with %^%#, %#%#, %@%@ or @%@%, the switch decrypts it and records it into the configuration file (plaintext passwords are not recorded for the sake of security). Therefore, do not set a password starting and ending with %^%#, %#%#, %@%@ or @%@%.
  - When you configure passwords in ciphertext, different features must use different ciphertext passwords. For example, the ciphertext password set for the AAA feature cannot be used for other features.

- Encryption algorithms

  The switch currently supports the 3DES, AES, RSA, SHA1, SHA2, and MD5. 3DES, RSA, and AES are reversible, whereas SHA1, SHA2, and MD5 are irreversible. Using the encryption algorithms DES, 3DES, RSA (RSA-1024 or lower), MD5 (in digital signature scenarios and password encryption), or SHA1 (in digital signature scenarios) is a security risk. If protocols allow, use more secure encryption algorithms, such as AES, RSA (RSA-2048 or higher), SHA2, or HMAC-SHA2.

  An irreversible encryption algorithm must be used for the administrator password. SHA2 is recommended for this purpose.

- Personal data

  Some personal data (such as MAC or IP addresses of terminals) may be obtained or used during operation or fault location of your purchased products, services, features, so you have an obligation to make privacy policies and take measures according to the applicable law of the country to protect personal data.

- Mirroring

  The terms mirrored port, port mirroring, traffic mirroring, and mirroring in this document are mentioned only to describe the product's function of communication error or failure detection, and do not involve collection or processing of any personal information or communication data of users.

- Reliability design declaration

  Network planning and site design must comply with reliability design principles and provide device- and solution-level protection. Device-level protection includes planning principles of dual-network and inter-board dual-link to avoid single point or single link of failure. Solution-level protection refers to a fast convergence mechanism, such as FRR and VRRP. If solution-level protection is used, ensure that the primary and backup paths do not share links or transmission devices. Otherwise, solution-level protection may fail to take effect.

Disclaimer

- This document is designed as a reference for you to configure your devices. Its contents, including web pages, command line input and output, are based on laboratory conditions. It provides instructions for general scenarios, but does not cover all use cases of all product models. The examples given may differ from your use case due to differences in software versions, models, and configuration files. When configuring your device, alter the configuration depending on your use case.
- The specifications provided in this document are tested in a lab environment (for example, a certain type of cards have been installed on the tested device or only one protocol is run on the device). Results may differ from the listed specifications when you attempt to obtain the maximum values due to factors such as differences in hardware configurations and carried services.
- In this document, public IP addresses may be used in feature introduction and configuration examples and are for reference only unless otherwise specified.

Contents

1 Using the Command Query Tool to Query Product Command Information

The **Command Query Tool** can be used to query formats, parameters, and examples of commands by model, version, and command line keyword.

2 Basic Configurations Commands

2.1 CLI Overview Commands

2.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.1.2 assistant task

Function

The **assistant task** command creates an assistant task.

The **undo assistant task** command deletes an assistant task.

By default, no assistant task is created.

Format

assistant task *task-name*

undo assistant task *task-name*

Parameters

Parameter	Description	Value
task-name	Specifies the name of an assistant task.	The value is a string of 1 to 15 characters. It can consist of only underscores (_), letters, and digits, and must start with a letter.

Views

System view

Default Level

3: Management level

Usage Guidelines

An assistant task is a virtual assistant on a device to realize automatic maintenance and management. After you create an assistant task and bind it to a batch of files to be processed, the device performs operations or configurations when it is unattended. Assistant tasks are mainly used for scheduled system upgrade or configuration.

NOTE

You can create a maximum of five assistant tasks on a device.

Example

Create an assistant task.

```
<HUAWEI> system-view
[HUAWEI] assistant task test
```

2.1.3 command-privilege level

Function

The **command-privilege level** command sets a command privilege level in a specified view.

The **undo command-privilege** command restores the default level.

By default, each command in each view has a default command privilege level.

Format

command-privilege level *level* **view** *view-name command-key*

undo command-privilege [**level** *level*] **view** *view-name command-key*

Parameters

Parameter	Description	Value
level *level*	Specifies a command privilege level.	The value is an integer that ranges from 0 to 15.
view *view-name*	Specifies a view name. You can enter a question mark (?) in the terminal GUI to obtain all view names in the command view. For example: ● shell: user view ● system: system view ● vlan: VLAN view	-
command-key	Specifies a command. The command must be entered manually because automatic command line completion is not supported.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The system divides commands into levels for management. Each command in views has a specified level. The device administrator can change a command privilege level as required so that a lower-level user can use certain high-level commands. The device administrator can also increase the command privilege level to a larger value to improve device security.

Precautions

- The rules for using this command to set the command privilege level of a specified view are as follows:
  - When you degrade the target command, all keywords in the command are degraded.
  - When you upgrade the target command, only the last keyword in the command is upgraded.

  - When you set a level for the target command, the levels of all commands (in the same view) starting with this command are changed.
  - When you set a level for the target command, the keyword level in other commands having the same index as the keyword whose level is changed is also changed.
  - If the level of keywords that have the same index is modified for multiple times, the latest configured level takes effect.
- Do not change the default command privilege level. If you need to change it, consult with professional personnel to ensure that routine operation and maintenance are not affected and security risks are avoided.
- If parameters are specified in the command whose privilege level is configured using the **command-privilege level** command, enter these parameters, for example, **command-privilege level 1 view shell tftp 10.1.1.1 get vrpcfg.txt cfcard:/vrpcfg.bak**.

Example

Set the privilege level of the **save** command to 5.

```
<HUAWEI> system-view
[HUAWEI] command-privilege level 5 view shell save
```

2.1.4 command-privilege level rearrange

Function

The **command-privilege level rearrange** command upgrades command privilege levels in batches.

The **undo command-privilege level rearrange** command restores the default command privilege levels in batches.

By default, the command privilege levels assigned by the system during registration are used.

Format

command-privilege level rearrange

undo command-privilege level rearrange

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Each command registered on a device is assigned a default level 0, 1, 2, or 3. These levels correspond to the visit level, monitoring level, configuration level, and management level. You can run the **command-privilege level rearrange** command to upgrade all the level-2 and level-3 commands to level-10 and level-15 commands in batches. The level-0 and level-1 commands remain unchanged.

Precautions

- You can change the levels of the commands that are not separately changed by the **command-privilege level** command. The levels of the commands that are separately changed by the **command-privilege level** command cannot be upgraded.
- You can restore the levels of the commands that are upgraded in batches. The levels of the commands that are separately changed by the **command-privilege level** command cannot be upgraded.
- After the **command-privilege level rearrange** command is run, users at Level 2 to Level 9 are not allowed to run commands defaulted to Level 2, and users at Level 3 to Level 14 are not allowed to run commands defaulted to Level 3. If some users are required to have the same command privilege as that before the command privilege level promotion, you are advised to adjust the levels of all users on the device.
- After the **undo command-privilege level rearrange** command is run, users at level 3 to level 14 are allowed to run commands defaulted to level 3, and users at level 2 to level 9 are allowed to run commands defaulted to level 2. If some users are required to have the same command privilege as that before the command privilege level decrease, you are advised to adjust the levels of all users on the device.
- You can use the **command-privilege level rearrange** command only when your user privilege level is 15.
- After the levels of the commands are upgraded in batches and before the levels of the commands are restored, upgrading the levels of the commands is invalid and does not change the current status of the commands.

Example

Change the levels of the current commands in batches.

```
<HUAWEI> system-view
[HUAWEI] command-privilege level rearrange
```

2.1.5 diagnose

Function

The **diagnose** command enables a device to enter the diagnostic view from the system view.

Format

diagnose

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Diagnostic commands are mainly used for fault diagnosis. However, running certain commands may cause device faults or service interruptions. Therefore, use these diagnostic commands under the instruction of technical support personnel.

Example

Enable a device to enter the diagnostic view.

```
<HUAWEI> system-view
[HUAWEI] diagnose
[HUAWEI-diagnose]
```

2.1.6 display assistant task history

Function

The **display assistant task history** command displays operation records of assistant tasks.

Format

display assistant task history [*task-name*]

Parameters

Parameter	Description	Value
task-name	Specifies the name of an assistant task.	The value is a string of 1 to 15 characters consisting only of underscores (_), letters, and digits, and must start with a letter.

Views

All views

Default Level

3: Management level

Usage Guidelines

The five latest operations of each assistant task are displayed in order from earliest to latest.

Example

Displays operation records of assistant tasks.

```
<HUAWEI> display assistant task history
-------------------------------------------------------------------------------
Assistant task name: nemo
-------------------------------------------------------------------------------
Assistant task name: song
 Action type    : Batch file
 Batch file name: reboottest.bat
 Start time     : 2012-07-16 09:25:00
 End time       : 2012-07-16 09:25:00
 State          : Finished

 Action type    : Batch file
 Batch file name: reboottest.bat
 Start time     : 2012-07-16 09:24:00
 End time       : 2012-07-16 09:24:00
 State          : Finished

-------------------------------------------------------------------------------
Assistant task name: xu
 Action type    : Batch file
 Batch file name: reboottest.bat
 Start time     : 2012-07-16 09:25:00
 End time       : 2012-07-16 09:25:00
 State          : Finished

 Action type    : Batch file
 Batch file name: reboottest.bat
 Start time     : 2012-07-16 09:24:00
 End time       : 2012-07-16 09:24:00
 State          : Finished

 Action type    : Batch file
 Batch file name: reboottest.bat
 Start time     : 2012-07-16 09:23:00
 End time       : 2012-07-16 09:23:00
 State          : Finished

-------------------------------------------------------------------------------
```

Table 2-1 Description of the **display assistant task history** command output

Item	Description
Assistant task name	Task name. This parameter is configured using the **assistant task** command.
Action type	Operation that an assistant task performs.

Item	Description
Batch file name	Name of the batch file used by an assistant task. This parameter is configured using the **perform batch-file** command.
Start time	Operation start time of an assistant task.
End time	Operation end time of an assistant task.
State	Running status of an assistant task. ● **Running** indicates that the assistant task is in operating. ● **Finished** indicates that the assistant task has finished operating.

2.1.7 display component

Function

The **display component** command displays information about a registered component.

Format

display component [*component-name*] [**slot** *slot-id*]

Parameters

Parameter	Description	Value
component-name	Displays information about a component with a specified ID.	The value ranges from 0 to FFFFFFFF, in hexadecimal notation. **0** indicates brief information about all components, and **FFFFFFFF** indicates detailed information about all components. The default value is **FFFFFFFF**.

Parameter	Description	Value
slot *slot-id*	- Displays information about registered components on a specified slot if stacking is not configured. - Displays information about registered components on a specified stack member device if stacking is configured.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display component** command displays information about a registered component.

Example

Display brief information about all registered components.

```
<HUAWEI> display component 0

********************************************************
 No.   CompID      CompVer         CompName
 0     0x00003391  1.0.0.0         DNS

Item	Description
No.	Number.
CompID	Component ID.
CompVer	Component version.
CompName	Component name.

2.1.8 display history-command

Function

The **display history-command** command displays the historical commands stored on a device.

Format

display history-command [**all-users**]

Parameters

Parameter	Description	Value
all-users	Displays information about the successfully matched commands that are executed by all users. If *all-users* is not specified, successfully matched historical commands executed by the current user are displayed.	-

Views

All views

Default Level

display history-command: 0: Visit level

display history-command all-users: 3: Management level

Usage Guidelines

Usage Scenario

The terminal automatically saves the history commands entered by the user, that is, records any keyboard entry of the user with **Enter** as the unit.

By default, the **display history-command** command displays a maximum of 10 historical commands. If the number of historical commands is less than 10, the

display history-command command output displays all of them. Run **history-command max-size** command to set the size of the historical command buffer.

Precautions

Commands run by users are automatically saved on the terminal. Any input that ends with **Enter** is saved as a historical command.

NOTE

- Commands are saved in the same format as those users entered. If an entered command is incomplete, the saved command is also incomplete.
- If a command is run several times, only the latest one is saved. If the command is run in different formats, they all saved as different commands.

You can check historical commands using the following methods:

- To check a previous historical command, press the **Up** arrow key or **Ctrl+P**.
- To check a next historical command, press the **Down** arrow key or **Ctrl+N**.

NOTE

To check the previous historical commands on a Windows 9X HyperTerminal, press **Ctrl+P**. The **Up** arrow key does not take effect.

Example

Display the historical commands that have been executed on a terminal.

```
<HUAWEI> display history-command
 system-view
 user-interface vty 0 4
 user privilege level 15
 quit
```

2.1.9 display this

Function

The **display this** command displays the running configurations in the current view.

Format

display this

Parameters

None

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After configurations are complete in a certain view, run the **display this** command to check the current configurations.

Precautions

If a configuration parameter uses the default value, this parameter is not displayed. Configurations for functions that do not take effect are not displayed.

If you run the **display this** command in an interface view, configurations of the interface view are displayed. If you run this command in a protocol view, configurations of the protocol view are displayed.

Example

Display the running configuration in the current view.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] display this
#
interface GigabitEthernet0/0/1
 port link-type trunk
#
return
```

2.1.10 display this include-default

Function

The **display this include-default** command displays the valid configurations in the current view, including the unchanged default configurations.

NOTE

This command does not display the default configurations that are not modified in the WLAN view.

Format

display this include-default

Parameters

None.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

You can use this command to view the default configurations of physical attributes, basic Ethernet protocols, routing, multicast, QoS, and security features on Ethernet interfaces. The following features are included:

- VLAN management: port-based VLAN assignment, other VLAN assignment methods, PVID, link type, QinQ protocol type, port priority, discard tagged-pkt, and port bridge
- MUX VLAN, voice VLAN, VLAN mapping/stacking, VT enable, and VT miss-drop
- MAC address learning status and priority, port security, sticky MAC, MAC address limiting, and MAC flapping detection
- MSTP, L2PT, DLDP, LLDP, loopback detection, RRPP, SmartLink, SEP, and ERPS
- Ethernet interface physical attributes: speed/duplex, speed auto-negotiation, negotiation, flow control, flow control negotiation, flow-control receive/flow-control negotiation receive, loopback, MDI, jumbo frame, trap/log alarm thresholds, link flapping, EEE, link Up/Down report delay, VCT, inter-frame gap statistics, error packet statistics, URPF, and copper module information
- ARP, ND, Eth-Trunk, and port isolation
- BFD: single-hop BFD, multi-hop BFD, BFD for LSP, and multicast BFD
- Unicast route management, static routes, RIP, OSPF, IS-IS, BGP, and VRRP
- Multicast routing, PIM, IGMP, MLD, IGMP snooping, and MLD snooping
- QoS, ACL, storm suppression, ARP security, IP security, and MFF
- DHCP, DHCPv6, ND Snooping, NAC, and RADIUS

This command can also display the following default global configurations: enabling of the function that sends ICMP host/port unreachable packets, enabling of the function that discards ICMP packets with TTL value 1, rate limit for ARP Miss packets, enabling of ICMP packet rate limiting, and interval for collecting CAR-based traffic statistics. For the support for default settings of the features, see the corresponding device model.

Example

Display the valid configurations and default configurations on VLANIF 10. The following command output is used for reference. The command output on your device may differ from that provided in this example.

```
<HUAWEI> system-view
[HUAWEI] interface Vlanif 10
[HUAWEI-Vlanif10] display this include-default
#
interface Vlanif10
 undo shutdown
 undo set flow-stat interval
 mtu 1500
 undo arp detect-mode unicast
 arp-fake expire-time 3
 undo arp learning disable
 undo arp purge slowly
 undo ipv6 enable
 icmp host-unreachable send
 icmp redirect send
 icmp port-unreachable send
 icmp ttl-exceeded send
```

```
 undo ip verify source-address
 undo ip forward-broadcast
 undo clear ip df
 undo discard srr
 undo discard rr
 undo discard ra
 undo discard ts
 damping time 0
 arp learning strict trust
 undo ntp-service in-interface disable
 undo mpls
 undo arp-proxy enable
 undo arp-proxy inter-sub-vlan-proxy enable
 undo arp-proxy inner-sub-vlan-proxy enable
 undo arp broadcast disable
 undo rrpp snooping enable
 nd optimized-passby enable
 undo urpf
 diffserv-mode uniform
 undo statistic enable both
 undo ipv4 statistic enable both
 undo ipv6 statistic enable both
 undo arp gratuitous-arp send enable
 undo arp anti-attack entry-check enable
 undo arp learning double-tag disable
 arp optimized-passby enable
 undo dhcp select global
 undo dhcp select interface
 undo dhcp select relay
 undo ip address bootp-alloc
 undo ip address dhcp-alloc
 undo arp learning dhcp-trigger
#
return
```

2.1.11 header

Function

The **header** command configures the header information displayed on a terminal when users log in to a connected device.

The **undo header** command deletes the header information displayed on a terminal when users log in to a connected device.

By default, no header information is displayed on terminals when users log in to a connected device.

Format

header { **login** | **shell** } { **information** *text* | **file** *file-name* }

undo header { **login** | **shell** }

Parameters

Parameter	Description	Value
login	Indicates header information displayed on a terminal when a user logs in to the device and a connection between the terminal and the device is activated.	-
shell	Indicates the header displayed on a terminal when the session is set up after the user logs in to the connected device.	-
information *text*	Specifies the header and content.	The value is a string with spaces and carriage returns supported. The maximum length of the string that can be entered at one time is 480 characters.
file *file-name*	Specifies the file name that the header uses.	The value is a string of 1 to 64 characters without spaces. Only the absolute path is supported. The file name must be in the [drive] [path] [file name] format, where [path] is the absolute path of the file. The maximum header file size that can be configured is 2 KB.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To provide some prompts or alarms to users, run the **header** command to configure a title on the device. If a user logs in to the device, the title is displayed.

Procedure

If **information** is specified, the header text starts and ends with the same character. You can set the header text in either of the following modes:

- Non-interactive: enter the header text behind the start character.

  Use the same character at the beginning and end of the header and press **Enter**. If the start and end characters are inconsistent, the system prompts an error message.
- Interactive: enter the start character and press **Enter** to enter the interactive process.

  The system displays a message asking you to enter the correct header information. After you enter the information, enter the same character as the start character. Press **Enter**. The system quits the interactive process.

  During interaction, you can press **Enter** at any time to enter information in the next line.

Precautions

- Before setting the **login** parameter, you must set login authentication parameters; otherwise, no header information about authentication is displayed.
- Before setting the **file** parameter, ensure that the file containing the header exists; otherwise, the file name cannot be obtained. If you change header information after login, the header information that has been displayed in the system does not change, even if you exit and log in to the system again. The header information changes in either of the following cases:
  - You have successfully changed the header information. Before the system restarts, you run this command again. Then you exit and log in to the system again.
  - You have successfully changed the header information. Then you restart the system.
- If you use SSH1.X to log in to the device, only the shell header is displayed.
- If you use SSH2.0 to log in to the device, both login and shell headers are displayed in the login process.
- If the header command is configured several times, only the latest configuration takes effect.
- After configuring the login header, any user that logs in to the system can view the header.
- In the system view, run the **execute** *batch-filename* batch processing command. If the batch processing command contains the **header** { **login** | **shell** } **information** *text* command and *text* contains line feed character **\r\n**, you need to use third-party software to change the hexadecimal value (0D 0A) of the line feed character **\r\n** to (1B 19).

Example

Configure a shell header in non-interactive mode.

```
<HUAWEI> system-view
[HUAWEI] header shell information &Hello! Welcome to system!&      # Enter the header text behind
the start character '&' and enter '&' at the end of the header text, and press Enter.
```

Display the shell header if the login succeeds.

```
Hello! Welcome to system!
```

Configure a shell header in interactive mode.

```
<HUAWEI> system-view
[HUAWEI] header shell information %      # Press Enter after entering the start character '%' to start the interactive process.
The banner text supports 480 characters max, including the start and the end cha
racter.If you want to enter more than this, use banner file instead.Input banner
 text, and quit with the character '%':
Hello!
Welcome to system!%      # Press Enter after entering the end character '%' to quit the interactive process.
[HUAWEI] quit
<HUAWEI> quit      // Log off.
```

Press **Enter**. The shell header is displayed when the user logs in again.

```
Hello!
Welcome to system!
<HUAWEI>
```

Specify the file that stores a login header.

```
<HUAWEI> system-view
[HUAWEI] header login file flash:/header-file.txt
```

2.1.12 if-match timer cron

Function

The **if-match timer cron** command sets the time to perform an assistant task.

The **undo if-match timer cron** command cancels the time configured for performing an assistant task.

By default, the time to perform an assistant task is not specified.

Format

if-match timer cron *seconds minutes hours days-of-month months days-of-week* [*years*]

undo if-match timer cron

Parameters

Parameter	Description	Value
seconds	Sets second.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,). Currently, the device supports only asterisks (*), indicating that the value is accurate to the minute but not the second.

Parameter	Description	Value
minutes	Sets minute.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,).
hours	Sets hour.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,).
days-of-month	Sets date.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,). This parameter is exclusive with the *days-of-week* parameter. At least one of the two contains asterisks (*).
months	Sets month.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,).

Parameter	Description	Value
days-of-week	Sets week.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,). The parameter is exclusive with the *days-of-month* parameter. At least one of the two contains asterisks (*).
years	Sets year.	The value is a string of 1 to 64 characters in the cron time format. The string consists of digits 0 to 9 and special characters asterisks (*), hyphens (-), slashes (/), and commas (,). If this parameter is not specified, it refers to all the years between 2000 to 2099.

Views

Assistant task template view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **if-match timer cron** command is used to set the time to perform an assistant task. The time is expressed in the cron format defined in UNIX or Linux.

The commonly used time and date format (hh:mm:ss dd-mm-yyyy) can specify only one specific time value. The cron time format is more flexible and can display single or multiple time points, time ranges, and time intervals. The following table describes the expression mode of the cron format.

Expression Mode	Format	Description	Example
Single time point	<time>	<time>: The value is an integer that specifies a specific time value. The value range is dependent on a specific parameter. The range of minutes is 0 to 59. The range of hours is 0 to 23. The range of days-of-month depends on the number of days in a specific month. The range of months is 1 to 12. The range of days-of-week is 0 to 7. The range of years is 2000 to 2099.	Command: if-match timer cron * 0 1 2 5 * 2012 Meaning: perform an assistant task at 1:00 on May 2, 2012.
Multiple time points	<time1>,<time2>,...,<timen>	<timen>: The value is an integer. The value range depends on a specific parameter. Multiple time points are separated by a comma (,) with no space before or after it. The time values in a list can be arranged in any sequence.	Command: if-match timer cron * 0 1,2,3 2 3 * 2012 Meaning: perform an assistant task at the following time points: ● 1:00, March 2, 2012 ● 2:00, March 2, 2012 ● 3:00, March 2, 2012

Expression Mode	Format	Description	Example
Specific time point	<time>/<step>	<time>: The value is an integer that specifies a specific time value. <step>: The value is an integer that specifies the time incremental. The two values are separated by a slash (/) with no space before or after it. The format: <time>,<time>+<step>,<time>+2*<step>,...,<time>+n*<step>. The maximum time (<time>+n*<step>) depends on a specific parameter in the command line.	Command: if-match timer cron * 0 0/10 * 3 * 2012 Meaning: perform an assistant task at the following time points: ● 0:00, March 1, 2012 ● 10:00, March 1, 2012 ● 20:00, March 1, 2012 ● 0:00, March 2, 2012 ● ... ● 10:00, March 31, 2012 ● 20:00, March 31, 2012
Duration	<time1>-<time2>	<time1> and <time2>: The values are integers, specifying the start and end time respectively. <time2> must be later than or equal to <time1>. The two values are separated by a hyphen (-) with no space before or after it. the <time1>-<time2> is same as <time1>,<time1>+1,<time1>+2,......,<time2>. If <time1> and <time2> are the same, they specify the same time point.	Command: if-match timer cron *0 0-3 1 3 * 2012 Meaning: perform an assistant task at the following time points: ● 0:00, March 1, 2012 ● 1:00, March 1, 2012 ● 2:00, March 1, 2012 ● 3:00, March 1, 2012

Expression Mode	Format	Description	Example
Period	*	If the parameter in the command line is set to *, the parameter may refer to any time point. By setting the parameter to *, you can configure the system to periodically perform an assistant task every year, week, month, day, hour, or minute.	Command: if-match timer cron * 30 10 * 1 1 2012 Meaning: perform an assistant task at 10:30, Monday every week in January, 2012.
Combination	Combination format	All the expression modes can be combined except "period". The expression modes are separated by a comma (,) with no space before or after it.	Command: if-match timer cron * 0 0/10,2,4-5 1 3 * 2012 Meaning: perform an assistant task at the following time points: ● 0:00, March 1, 2012 ● 2:00, March 1, 2012 ● 4:00, March 1, 2012 ● 5:00, March 1, 2012 ● 10:00, March 1, 2012 ● 20:00, March 1, 2012

Precautions

- If you run the **if-match timer cron** command multiple times in the same view, only the latest configuration takes effect.
- The *days-of-month* and *days-of-week* parameters are exclusive. Set one or both of them to "*". If one parameter is set to *, the other one specifies a specific date. If both parameters are set to *, they can refer to any date.
- The minimum unit supported is minute, so set the second parameter to *. The specified assistant task works only once every minute.
- Since the system can perform only one assistant task at a time, the time when one assistant task finished working may be later than the time when the next task is schedule to start. There may be a time span between the time when an assistant task is scheduled to work and the time when it actually starts to work. The **if-match timer cron** command specifies the time when an assistant task is scheduled to work.
- When you enter digits, such as 000002012, the numeric string means the same as 2012.

Example

Configure an assistant task to work at 20:00, 2012-05-04.

```
<HUAWEI> system-view
[HUAWEI] assistant task test
[HUAWEI-assistant-task-test] if-match timer cron * 0 20 4 5 * 2012
[HUAWEI-assistant-task-test] perform 1 batch-file sys.bat
```

Cancel the time for an assistant task to start to work.

```
<HUAWEI> system-view
[HUAWEI] assistant task test
[HUAWEI-assistant-task-test] undo if-match timer cron
```

2.1.13 perform batch-file

Function

The **perform batch-file** command configures an assistant task to process a batch file.

The **undo perform** command disables an assistant task from processing a batch file.

By default, no batch file is configured for an assistant task.

Format

perform *priority* **batch-file** *filename*

undo perform *priority*

Parameters

Parameter	Description	Value
priority	Specifies a priority for an assistant task.	The value is fixed at 1 because one assistant task can process only one batch file.
filename	Specifies the name of the batch file processed by the assistant task.	The file is in *.bat file. **NOTE** The file must be stored in the **flash:/user/bat** directory.

Views

Assistant task template view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After you successfully create an assistant task and specify the execution time, you can run this command to configure the device to process a batch file at the specified time.

Prerequisites

An assistant task has been created using the **assistant task** command and the execution time has been specified using the **if-match timer cron** command.

Precautions

To delete an assistant task that is being executed, stop it first. To delete an assistant task to be executed, directly delete it. The device will not execute the assistant task.

Example

Configure the assistant task **huawei** to process the batch file **sys.bat** at 20:00 on 2012-05-04.

```
<HUAWEI> system-view
[HUAWEI] assistant task huawei
[HUAWEI-assistant-task-huawei] if-match timer cron * 0 20 4 5 * 2012
[HUAWEI-assistant-task-huawei] perform 1 batch-file sys.bat
```

Disable an assistant task from processing a batch file.

```
<HUAWEI> system-view
[HUAWEI] assistant task huawei
[HUAWEI-assistant-task-huawei] undo perform 1
Info: Start to delete the action.
[HUAWEI-assistant-task-huawei] display this
#
assistant task huawei
 if-match timer cron * 0 20 4 5 * 2012
#
return
```

2.1.14 quit

Function

The **quit** command returns a device from the current view to a lower-level view. If the current view is the user view, this command exits from the system.

Format

quit

Parameters

None

Views

All views

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

Three types of views are available (listed from a lower level to a higher level):

- User view
- System view
- Service view, such as the interface view

Run the **quit** command to return to a lower-level command view from the current view. Running this command in the user view quits from the system.

Example

Return to the system view from the AAA view and then return to the user view. Quit the system after this.

```
<HUAWEI> system-view
[HUAWEI] aaa
[HUAWEI-aaa] quit
[HUAWEI] quit
<HUAWEI> quit
```

2.1.15 reset history-command

Function

The **reset history-command** command deletes historical commands from a device.

Format

reset history-command [**all-users**]

Parameters

Parameter	Description	Value
all-users	Deletes historical commands entered by all users. If this parameter is not specified, the historical commands entered only by the current user are deleted.	-

Views

All views

Default Level

reset history-command: 0: Visit level

reset history-command all-users: 3: Management level

Usage Guidelines

To delete historical commands entered by the current user, run the **reset history-command** command. If a level 3 (or higher) user runs the **reset history-command all-users** command, historical commands entered by all users are deleted.

Example

Delete historical commands entered by the current user.

```
<HUAWEI> reset history-command
```

2.1.16 return

Function

The **return** command returns to the user view from other views (except the user view).

Format

return

Parameters

None

Views

All views

Default Level

0: Visit level

Usage Guidelines

Use the **return** command in other views to return to the user view.

- This command returns to the user view if the current view is another view (but not the user view).
- No change occurs after running this command if the current view is the user view.
- The shortcut keys **Ctrl+Z** functions similarly as the **return** command.

Example

Return to the user view from the user interface view.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] return
<HUAWEI>
```

2.1.17 system-view

Function

The **system-view** command enables you to enter the system view from the user view.

Format

system-view

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You must configure the device in the system view. Run this command in the user view to enter the system view.

Example

Enter the system view.

```
<HUAWEI> system-view
Enter system view, return user view with Ctrl+Z.
[HUAWEI]
```

2.1.18 terminal command forward matched upper-view

Function

The **terminal command forward matched upper-view** command enables forward commands (not in the undo form) to automatically match the upper-level view and return to the upper-level view.

The **undo terminal command forward matched upper-view** command disables forward commands from automatically matching the upper-level view.

By default, forward commands are enabled to automatically match the upper-level view.

Format

terminal command forward matched upper-view

undo terminal command forward matched upper-view

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If forward commands are enabled to automatically match the upper-level view and you run a forward command not registered in the current view, the system automatically switches to the upper-level view to search for the command. If the command is found in that view, the system runs the command. If the command is not found in that view, the system continues the search in the next upper-level view until the system view.

Precautions

The **terminal command forward matched upper-view** command takes effect only for the current login user who runs this command.

Example

Enable forward commands to automatically match the upper-level view.

```
<HUAWEI> terminal command forward matched upper-view
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] sysname ABC
[ABC]
```

Disable forward commands from automatically matching the upper-level view.

```
<HUAWEI> undo terminal command forward matched upper-view
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] sysname ABC
                              ^
Error: Unrecognized command found at '^' position.
```

2.1.19 terminal echo-mode

Function

The **terminal echo-mode** command sets a command output mode.

The default command output mode is **character**.

Format

terminal echo-mode { **character** | **line** }

Parameters

Parameter	Description	Value
character	Specifies a character mode. The system displays the character that you enter in the command line.	-
line	Specifies a line mode. The system displays the character that you enter in the command line only after you press **Enter**, **Tab** or **?**. If you press a shortcut key, such as **Backspace**, **Page Up**, or **Ctrl+A**, it still takes effect.	-

Views

User view

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

When operating a device using the NMS, run this command to change the command output mode to **line** to improve operation efficiency. Common users typically use the **character** mode, so use this mode for common users to improve operation efficiency.

Precautions

- After a user runs this command to set the **line** mode, this mode takes effect only for this user. Other users still use the **character** mode.
- After a user changes the command output mode to **line**, the command output mode automatically switches to **character** when the user exits the device or the device restarts or performs an active/standby switchover.

- This command does not affect interactive inputs for the command line.

Example

Set the command output mode to **line**.

```
<HUAWEI> terminal echo-mode line
```

2.2 EasyDeploy Commands

2.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

Switches' support for the commander and client roles in EasyDeploy application is as follows:

Role	Product Model	Version	Maximum Number of Managed Clients
Commander	S12700	V200R005C00 and later	255
	S12700E	V200R019C00 and later	255
	S7700	V200R003C00 and later	255
	S9700	V200R003C00 to V200R013C00	255
	S5700-HI	V200R003C00 to V200R005C00	128
	S5710-HI	V200R003C00 to V200R005C00	128
	S6700-EI	V200R003C00 to V200R005C00	128
	S5700-EI	V200R003C00 to V200R005C00	64
	S5710-EI	V200R003C00 to V200R005C00	64
	S5720-HI	V200R006C00 to V200R019C10	128
	S5720-EI	V200R007C00 to V200R019C10	128

Role	Product Model	Version	Maximum Number of Managed Clients
	S5730-HI	V200R012C00 to V200R019C10	128
	S5731-H	V200R013C02 and later	128
	S5731-S	V200R019C00 and later	128
	S5731S-S	V200R019C00 and later	128
	S5731S-H	V200R019C00 and later	128
	S5732-H	V200R019C00 and later	128
	S6720-EI	V200R008C00 and later	128
	S6720S-EI	V200R009C00 and later	128
	S6720-HI	V200R012C00 to V200R019C10	128
	S6730-H	V200R013C02 and later	128
	S6730S-H	V200R019C10 and later	128
	S6730-S	V200R019C00 and later	128
	S6730S-S	V200R019C00 and later	128
	S6735-S	V200R021C00SPC600 and later	128

Role	Product Model	Version	Maximum Number of Managed Clients
Client	● All fixed switch models except S1720GFR, S1720X, S1720GW-E, S1720GWR-E, S1720X-E, S1730S-S1, and S1720X-E ● All modular switch models	V200R003C00 and later	-

2.2.2 activate-file

Function

The **activate-file** command sets the file activation mode and time on the Commander.

The **undo activate-file** command restores the default file activation mode and time.

By default, if downloaded files include the system software (*.cc), devices immediately activate all files by resetting. In addition, if the downloaded files in the batch upgrade scenario include the configuration file, the devices also activate files immediately by resetting.

Format

activate-file { **reload** | { **in** *time* | **delay** *delay-time* } } *

undo activate-file [**reload** | **in** [*time*] | **delay** [*delay-time*]]

Parameters

Parameter	Description	Value
reload	Indicates that the device activates files by resetting.	-
in *time*	Indicates the time when the device activates files.	The format is HH:MM, in which HH indicates hour ranging from 0 to 23 and MM indicates minute ranging from 0 to 59.

Parameter	Description	Value
delay *delay-time*	Indicates the delay after which the device activates files.	The value is an integer that ranges from 0 to 86400, in seconds. The default is 0.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If clients use the default method to activate files, network services will be affected. This issue is especially prominent in the batch upgrade scenario where each upgraded device may carry a lot of services. Resetting these devices will interrupt services. Therefore, the devices should activate files when service volume is small.

Precautions

- If the **reload** parameter is specified, the client activates files by resetting regardless of whether downloaded files include the system software.
- The **undo activate-file** command restores the default file activation mode and time. If the **reload**, **in**, and **delay** parameters are specified in the **undo activate-file** command, the default configurations are restored.
- The file activation mode can be set in the Easy-Operation view or group view. If the client matches a group, the configuration in the group view takes effect for the client.

Example

Set the file activation mode to reset.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] activate-file reload
```

Set the file activation delay to one hour.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] activate-file delay 3600
```

Set the file activation mode to reset and time to 1:00 am.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] activate-file in 1:00 reload
```

Set the file activation mode to reset and time to 1:00 am for group F1.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
```

```
[HUAWEI-easyoperation] group custom ip-address F1
[HUAWEI-easyoperation-group-custom-F1] activate-file in 1:00 reload
```

2.2.3 backup configuration interval

Function

The **backup configuration interval** command enables automatic configuration file backup on the Commander and sets the backup interval and method.

The **undo backup configuration** command disables automatic configuration file backup.

By default, the configuration file is not automatically backed up.

Format

backup configuration interval *interval* [**duplicate**]

undo backup configuration [**interval** [*interval*]] [**duplicate**]

Parameters

Parameter	Description	Value
interval	Indicates the backup interval.	The value is an integer that ranges from 0 to 720, in hours. The default value is 0, indicating that clients do not automatically back up configuration files.
duplicate	Indicates that the backup file is saved as a new file, and the original configuration file is not overwritten. If this parameter is not specified, the original configuration file is overwritten by the backup file.	-

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a faulty client is replaced by a new client, the new client needs to obtain the latest configuration file of the faulty client to minimize impact on service.

Therefore, all clients should periodically back up their configuration files to the file server.

NOTE

This function must be configured before any fault occurs. It is recommended that you configure this function when deploying the network.

Prerequisites

The file server information has been configured on the Commander using the **tftp-server/sftp-server/ftp-server** command.

Precautions

- After this function is configured, all clients managed by the Commander will automatically back up configuration files.
- To disable this function, run the **undo backup configuration** [**interval** [*interval*]] or **undo backup configuration interval duplicate** command, or set the file backup interval to 0.
- If you do not want to keep the original configuration files, run the **undo backup configuration duplicate** command to make the backup files overwrite the original files.
- The naming convention of the configuration files is as follows:
  - If the backup files are saved as new files, name the new files in format vrpcfg-MAC address-year-month-day-hour-minute-second.XXX. XXX is the file name extension, which must be the same as the configuration file name extension being used on the client. For example, if the startup configuration file on a client is **vrpcfg.zip**, the backup file is named in format vrpcfg-MAC address-year-month-day-hour-minute-second.zip.
  - If the backup files overwrite the original files, name the backup files in format vrpcfg-MAC address.XXX. XXX is the file name extension, which must be the same as the configuration file name extension being used on the client.

Example

Set the file backup interval to 12 hours and overwrite the original files with backup files.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] backup configuration interval 12
```

Disable automatic configuration file backup.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] backup configuration interval 0
Warning: This command will cancel the function of backing up configuration. Cont
inue?[Y/N]:y
[HUAWEI-easyoperation]
```

2.2.4 batch-cmd begin

Function

The **batch-cmd begin** command starts online command script editing.

Format

batch-cmd begin

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a batch device deployment scenario, you can run this command to start online command script editing. After editing the commands, press **Ctrl**+**C** to exit the editing mode. If you run this command again, the edited commands will be cleared.

Precautions

- Only one network administrator is allowed to edit commands online at one time.
- If no operation is performed in command editing mode within 30 seconds, you automatically exit from the editing mode to the Easy-Operation view.

Example

Start online command script editing.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] batch-cmd begin
Info: Begin to edit batch commands. Press CTRL+C to abort this session.
system-view
vlan batch 10 20
ndp enable
ntdp enable

[HUAWEI-easyoperation]
```

2.2.5 clear topology-error-info

Function

The **clear topology-error-info** command clears faulty link information from the topology.

Format

clear topology-error-info

Parameters

None

Views

Cluster view

Default Level

2: Configuration level

Usage Guidelines

The **clear topology-error-info** command can be run only on the Commander switch.

After a faulty client recovers, run this command to clear faulty link information from the topology. To view the topology information, run the **display cluster-topology-info** command.

Example

Clear information about faulty links and sub-links.

```
<HUAWEI> system-view
[HUAWEI] cluster
[HUAWEI-cluster] display cluster-topology-info
The topology information about the cluster:
<-->:normal device        <++>:candidate device        <??>:lost device
--------------------------------------------------------------------------
Total topology node number is 3.
[HUAWEI: Root-00e0-fcb8-d6b6]
|-(GigabitEthernet0/0/2)<??>(GigabitEthernet0/0/1)[00e0-fc67-7f7d]
|-(GigabitEthernet0/0/3)<-->(GigabitEthernet0/0/3)[00e0-fc03-0003]
[HUAWEI-cluster] clear topology-error-info
[HUAWEI-cluster] display cluster-topology-info
The topology information about the cluster:
<-->:normal device        <++>:candidate device        <??>:lost device
--------------------------------------------------------------------------
Total topology node number is 2.
[HUAWEI: Root-00e0-fcb8-d6b6]
|-(GigabitEthernet0/0/3)<-->(GigabitEthernet0/0/3)[00e0-fc03-0003]
```

2.2.6 client

Function

The **client** command adds information to the client database or modifies information in the client database.

The **undo client** command deletes information from the client database.

By default, the client database does not contain client information.

Format

client [*client-id*] { { **mac-address** *mac-address* | **esn** *esn* } | **system-software** *file-name* [*version*] | **patch** *file-name* | **configuration-file** *file-name* | **web-file** *file-name* | **license** *file-name* | { **custom-file** *file-name* } &<1-3> } *

undo client *client-id* [**mac-address** [*mac-address*] | **esn** [*esn*] | **system-software** [*file-name* [*version*]] | **patch** [*file-name*] | **configuration-file** [*file-name*] | **web-file** [*file-name*] | **license** [*file-name*] | **custom-file** [*file-name*]]

Parameters

Parameter	Description	Value
client-id	Specifies the client ID, which identifies a client. If this parameter is not specified when you add client information, the system assigns the minimum ID not in use to the client.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
mac-address *mac-address*	Specifies the MAC address of the client.	The value is in the H-H-H format, where each H contains four hexadecimal digits.
esn *esn*	Specifies the ESN of the client.	The value is a string of 10 to 32 case-insensitive characters without spaces.
system-software *file-name*	Specifies the name of the system software (*.cc) to be loaded to the client.	The value is a string of 4 to 48 case-insensitive characters without spaces.

Parameter	Description	Value
version	Specifies the version of a system software package, for example, V200R023C00. If the specified software version is the same as the software version running on the client, a software upgrade will not be performed for the client.	The value is a string of 11 to 32 case-insensitive characters without spaces.
patch *file-name*	Specifies the name of the patch file (*.pat) to be loaded to the client.	The value is a string of 5 to 48 case-insensitive characters without spaces.
configuration-file *file-name*	Specifies the name of the configuration file (*.zip or *.cfg) to be loaded to the client.	The value is a string of 5 to 48 case-insensitive characters without spaces.
web-file *file-name*	Specifies the name of the web page file (*.web.7z or *.web.zip) to be loaded to the client.	The value is a string of 8 to 64 case-insensitive characters without spaces.
license *file-name*	Specifies the name of the license file (*.dat) to be loaded to the client. **NOTE** The license file is not supported in the Easy-Operation view. The file does not take effect even if you configure it.	The value is a string of 5 to 64 case-insensitive characters without spaces.
custom-file *file-name*	Specifies the name of the user-defined file to be loaded to the client. A maximum of three user-defined files can be specified. The file names are separated by spaces.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a few zero touch clients need to be deployed on a network, you can run this command multiple times to add client information one by one.

Precautions

- Clients search the matching database by searching for their MAC addresses or ESNs in the database; therefore, the mappings between clients and MAC addresses or ESNs must be configured. When a client finds a matching database, it obtains information mapping its client ID, including system software name and patch file name.
- This command can be executed once or multiple times to configure the mappings between clients and MAC addresses or ESNs and specify information about the files to be downloaded.
- To delete all information about a client, run the **undo client** *client-id* command. To delete an item from a client's information, run the **undo** command with the item specified.

  NOTE

  When parameters are specified in this **undo** command to delete specified information, this command takes effect only for the manually configured clients.
- Each Commander supports a limited number of clients; therefore, the client information that can be added to the client database is also limited.
- You can specify a path for each file.

Example

Add client information in which MAC address is 00e0-fc12-3456, configuration file is **vrpcfg.zip**, and file path is /configfile/.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client mac-address 00e0-fc12-3456 configuration-file configfile/vrpcfg.zip
```

Add client information in which client ID is 3, ESN is 210235165110xxxxxxxx, system software name is **test.cc**, and user-defined file names are **header.txt** and **aaa.bat**.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client 3 esn 210235165110xxxxxxxx
[HUAWEI-easyoperation] client 3 system-software test.cc
[HUAWEI-easyoperation] client 3 custom-file header.txt custom-file aaa.bat
```

Delete the configuration file of the client with client ID 4.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] undo client 4 configuration-file
```

Delete all information about the client with client ID 5.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] undo client 5
```

2.2.7 client aging-time

Function

The **client aging-time** command ages the lost state clients in the client database and specifies the aging time.

The **undo client aging-time** command cancels the configuration.

By default, the lost state clients in the client database are not aged.

Format

client aging-time *aging-time*

undo client aging-time [*aging-time*]

Parameters

Parameter	Description	Value
aging-time	Specifies the aging time for clients in the lost state.	The value is an integer that ranges from 72 to 720, in hours.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Information about clients configured by the network administrator or automatically learned is saved in the client database. The Commander considers that a client to be in the lost state if the client does not respond after two minutes.

The maximum number of clients managed by the Commander depends on the device specifications. If the number of clients exceeds the upper limit, new client information cannot be configured on the Commander. To prevent clients in the lost state from occupying the database resources for a long time, enable the function of aging lost state clients. When the aging time expires, lost state clients are deleted. If some clients in the lost state occupy the database resources for a long time, run the **reset easy-operation client-offline** command to delete these clients.

Precautions

- Automatically learned clients are deleted after their aging time expires.
- Manually configured clients are not deleted but their status changes to unknown.

Example

Enable the function of aging lost state clients and set the aging time to 72 hours.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client aging-time 72
```

2.2.8 client auto-clear enable

Function

The **client auto-clear enable** command enables clients to automatically clear storage space. This command is run on the Commander.

The **undo client auto-clear enable** command disables clients from clearing storage space.

By default, this function is disabled on the Commander.

Format

client auto-clear enable

undo client auto-clear enable

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If storage space on a client is insufficient, the client cannot download files. This command enables clients to automatically clear storage space to ensure a sufficient storage space.

Precautions

- Clients clear storage space only when the storage space is insufficient for a system software package. In addition, they only delete non-startup system software packages to create space.
- This function is invalid for certain file server types. If the file server is a TFTP server, this function does not take effect because the TFTP server does not return file size to clients. If an FTP or SFTP server cannot return file size, this

function does not take effect, either. An S switch serving as an FTP or a TFTP file server does not support the function of returning file size.

Example

Enable clients to automatically clear storage space.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client auto-clear enable
```

2.2.9 client auto-join enable

Function

The **client auto-join enable** command enables clients to automatically join the management domain of a Commander. This command is run on the Commander.

The **undo client auto-join enable** command disables clients from joining the management domain of a Commander.

By default, clients do not automatically join the Commander management domain.

Format

client auto-join enable

undo client auto-join enable

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After this function is enabled and the Commander IP address is configured on clients, the Commander automatically learns the basic information about clients, saves the information to the client database, and assigns a client ID to each client.

Client information learned by the Commander includes MAC addresses, ESNs, IP addresses, device types, device models, current system software names, configuration files, and patch files on the clients. The Commander monitors and manages basic information and version files of all clients in the management domain.

In batch upgrade scenario, you can determine the devices to be upgraded according to the client information.

To prevent unknown clients from joining the management domain, disable this function.

Precautions

- In the batch upgrade scenario, run the **easy-operation commander ip-address** command to configure the Commander IP address on the clients.

  In the zero touch device deployment or faulty device replacement scenario, if you require that the clients still be managed by the Commander after completing the EasyDeploy process, add the Commander IP address to the configuration file to be downloaded by the clients.
- To view the client information learned by the Commander, run the **display easy-operation client** command.
- If the learned client information already exists in the client database (statically configured using **client**), the client database is updated.
- After information about a client is stored in the client database, the client status becomes LOST if the client goes offline. When the client goes online, the client joins the management domain again and its status becomes Running.

Example

Enable clients to automatically join the management domain of a Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client auto-join enable
Warning: The commander will create the client information in database automatica
lly when received message from unknown client. Continue? [Y/N]: y
[HUAWEI-easyoperation]
```

2.2.10 client replace

Function

The **client replace** command adds or modifies client replacement information.

The **undo client replace** command deletes client replacement information.

By default, no client replacement information exists.

Format

client *client-id* **replace** { [**mac-address** *mac-address* | **esn** *esn*] | **system-software** *file-name* [*version*] | **patch** *file-name* | **web-file** *file-name* | **license** *file-name* | { **custom-file** *file-name* } &<1-3> } *

undo client *client-id* **replace** [**mac-address** [*mac-address*] | **esn** [*esn*] | **system-software** [*file-name* [*version*]] | **patch** [*file-name*] | **web-file** [*file-name*] | **license** [*file-name*] | **custom-file** [*file-name*]]

Parameters

Parameter	Description	Value
client-id	Indicates the ID of a faulty client.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
mac-address *mac-address*	Indicates the MAC address of the new client.	The value is in the H-H-H format, where each H contains four hexadecimal digits.
esn *esn*	Indicates the ESN of the new client.	The value is a string of 10 to 32 case-insensitive characters without spaces.
system-software *file-name*	Specifies the name of the system software (*.cc) to be loaded to the new client.	The value is a string of 4 to 48 case-insensitive characters without spaces.
version	Specifies the version of a system software package, for example, V200R023C00. If the specified software version is the same as the software version running on the client, a software upgrade will not be performed for the client.	The value is a string of 11 to 32 case-insensitive characters without spaces.
patch *file-name*	Specifies the name of the patch file (*.pat) to be loaded to the new client.	The value is a string of 5 to 48 case-insensitive characters without spaces.
web-file *file-name*	Specifies the name of the web page file (*.web.7z or *.web.zip) to be loaded to the new client.	The value is a string of 8 to 64 case-insensitive characters without spaces.
license *file-name*	Specifies the name of the license file (*.dat) to be loaded to the new client. **NOTE** The license file is not supported in the Easy-Operation view. The file does not take effect even if you configure it.	The value is a string of 5 to 64 case-insensitive characters without spaces.

Parameter	Description	Value
custom-file *file-name*	Specifies the name of the user-defined file to be loaded to the new client. A maximum of three user-defined files can be specified. The file names are separated by spaces.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a client becomes faulty due to a hardware failure, run this command to add replacement information for the faulty client. After a new client is installed on the network to replace the faulty client, the new client can quickly obtain the configuration file of the faulty client, minimizing impact on services. You can also specify other files that can be loaded on the new client.

Precautions

- A new client finds matching replacement information by searching for its own MAC address or ESN; therefore, the mapping between the new client and MAC address or ESN must be configured. After finding matching information, the new client downloads the configuration file and other specified files of the faulty client from the file server.
- Before replacing the faulty client with a new client, ensure that the EasyDeploy function has been configured on the network and the **backup configuration interval** command has been run on the Commander to enable automatic configuration file backup. If this command has not been run, the new client cannot obtain the latest configuration file of the faulty client.
- This command can be run once or multiple times to configure the mappings between the new client and MAC address or ESN and specify information about the files to be downloaded.
- To delete all replacement information about a client, run the **undo client** *client-id* **replace** command. To delete an item from a client's replacement information, run the **undo** command with the item specified.
- This command is not recorded in the configuration file.

Example

Replace client 3 with a client that has a MAC address xxxx-xxxx-xxxx. The new client only needs to download the configuration file of client 3.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client 3 replace mac-address xxxx-xxxx-xxxx
```

Replace client 3 with a client that has a MAC address xxxx-xxxx-xxxx. The new client needs to download the configuration file, system software, and user-defined file of client 3.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] client 3 replace mac-address xxxx-xxxx-xxxx
[HUAWEI-easyoperation] client 3 replace system-software test.cc V200R023C00
[HUAWEI-easyoperation] client 3 replace custom-file header.txt custom-file aaa.bat
```

2.2.11 cluster

Function

The **cluster** command displays the cluster view.

Format

cluster

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After entering the cluster view on the Commander, you can configure a cluster management VLAN and then configure the Commander as the network topology collection device so that the Commander only collects topology information of clients in the VLAN.

Example

Enter the cluster view.

```
<HUAWEI> system-view
[HUAWEI] cluster
[HUAWEI-cluster]
```

2.2.12 cluster enable

Function

The **cluster enable** command enables the cluster function.

The **undo cluster enable** command disables the cluster function.

The **cluster disable** command disables the cluster function.

By default, the cluster function is enabled.

Format

cluster enable

undo cluster enable

cluster disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before configuring the Commander as the network topology collection device, you need to configure a cluster management VLAN in the cluster view on the Commander so that the Commander only collects topology information of clients in the VLAN. Before configuring a cluster management VLAN on an S series switch, you must run the **cluster enable** command to enable the cluster function so that you can enter the cluster view.

Example

Enable the cluster function on a device.

```
<HUAWEI> system-view
[HUAWEI] cluster enable
```

2.2.13 cluster-multimac

Function

The **cluster-multimac** command assigns a multicast address to a cluster.

The **undo cluster-multimac** command restores the default multicast address of the cluster.

By default, the multicast address of the cluster is 0180-C200-000A.

Format

cluster-multimac *mac-address*

undo cluster-multimac

Parameters

Parameter	Description	Value
mac-address	Specifies the multicast MAC address of a cluster.	The value is in the format of H-H-H. Each H stands for a 4-digit hexadecimal number. The value ranges from 0180-C200-0004 to 0180-C200-0007, 0180-C200-0009 to 0180-C200-0010 and 0180-C200-0020 to 0180-C200-002F. The default value is 0180-C200-000A.

Views

Cluster view

Default Level

2: Configuration level

Usage Guidelines

Before setting up a cluster, you need to assign a multicast MAC address to the cluster or use the default multicast MAC address. To enhance the network security or if the default multicast MAC address is being used by other services on the network, you can reassign a multicast MAC address to the cluster within the permitted range. Once the cluster is set up, you cannot change the multicast MAC address of the cluster. All the devices in the cluster must be assigned the same multicast MAC address.

Example

Assign multicast address 0180-c200-0004 to a cluster.

```
<HUAWEI> system-view
[HUAWEI] cluster
[HUAWEI-cluster] cluster-multimac 0180-c200-0004
```

Restore the default multicast address of the cluster.

```
<HUAWEI> system-view
[HUAWEI] cluster
[HUAWEI-cluster] undo cluster-multimac
```

2.2.14 configuration-file

Function

The **configuration-file** command specifies the configuration file information to be downloaded by clients.

The **undo configuration-file** command deletes information about the configuration file to be downloaded.

Format

configuration-file *file-name*

undo configuration-file [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of the configuration file (*.zip or *.cfg) to be loaded to the client. A file path can be specified.	The value is a string of 5 to 48 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To deploy a zero touch client or reload a configuration file to clients, use this command to specify the configuration file.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

NOTICE

The names of the files to be downloaded cannot be the same as system configuration files. Otherwise, the upgrade fails.

Example

Configure the default configuration file information.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] configuration-file easy/vrpcfg.zip
```

Configure the configuration file information for a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] configuration-file vrpcfg.zip
```

2.2.15 custom-file

Function

The **custom-file** command specifies a user-defined file to be downloaded by clients.

The **undo custom-file** command deletes the configured user-defined file information.

Format

{ **custom-file** *file-name* } &<1-3>

undo custom-file [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a user-defined file to be loaded to the client. A file path can be specified. A maximum of three user-defined files can be specified. The file names are separated by spaces.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When clients need to download user-defined files, such as batch processing file and login header file, use this command.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.

- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

NOTICE

The names of the files to be downloaded cannot be the same as system user-defined files. Otherwise, the upgrade fails.

Example

Configure the default user-defined file information.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] custom-file easy/mydoc.bat
```

Configure the user-defined file information for a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] custom-file mydoc.bat custom-file header.txt
```

2.2.16 display easy-operation batch-cmd result

Function

The **display easy-operation batch-cmd result** command displays the batch configuration execution result.

Format

display easy-operation batch-cmd result

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the batch configuration execution result, run the **display easy-operation batch-cmd result** command. The result is saved in the memory of clients. If the script contains commands used to clear the client memory, such as the **reboot** command, the result cannot be checked using the **display easy-operation batch-cmd result** command after the commands are delivered to clients.

Example

Display the execution result of batch configuration.

```
<HUAWEI> display easy-operation batch-cmd result
This operation will take some seconds, please wait......
--------------------------------------------------------------
  ID   Total  Successful     Failed     Time
--------------------------------------------------------------
   1      10          10          0    2013-09-12  12:57:02
   2      10          10          0    2013-09-12  12:57:02
   3      10          10          0    2013-09-12  12:57:02
--------------------------------------------------------------
```

Table 2-3 Description of the **display easy-operation batch-cmd result** command output

Item	Description
ID	Client ID.
Total	Total number of commands delivered.
Successful	Number of commands successfully executed.
Failed	Number of commands failed to be executed.
Time	Time when command execution was complete on the client.

2.2.17 display easy-operation client

Function

The **display easy-operation client** command displays client information on the Commander.

Format

display easy-operation client [*client-id* | **mac-address** *mac-address* | **esn** *esn* | **verbose**]

Parameters

Parameter	Description	Value
client-id	Displays detailed information about a client with a specified client ID.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
mac-address *mac-address*	Displays detailed information about a client with a specified MAC address.	The value is in the H-H-H format, where each H contains four hexadecimal digits.
esn *esn*	Displays detailed information about a client with a specified ESN.	The value is a string of 10 to 32 case-insensitive characters without spaces.
verbose	Displays detailed information about all clients.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays client information that the Commander dynamically obtains from a client, including the client's host name, MAC address, ESN, IP address, device type, and information about the files that have been downloaded to the client.

If the client state is UNKNOWN in the command output, the displayed MAC address and ESN are manually configured. If the client state is not UNKNOWN, the displayed MAC address and ESN values are dynamically obtained from the client. To modify the configuration of a client in a state other than UNKNOWN to match a new device, run the **undo client** *client-id* command to delete the current client configuration first.

If no optional parameter is specified in the command, the command displays brief client information dynamically obtained from the client database.

Example

Display brief client information.

```
<HUAWEI> display easy-operation client
The total number of client is : 4

--------------------------------------------------------------------------------
 ID   Mac address     ESN                             IP address        State
--------------------------------------------------------------------------------
 1    00E0-FC12-ABCD 2102113089P0xxxxxxxx             192.168.150.208   RUNNING
 2    00E0-FC12-0701 -                                -                 INITIAL
 3    -              210235182810xxxxxxxx             192.168.150.210   INITIAL
 4    00E0-FC12-2123 210235276310xxxxxxxx             192.168.150.122   RUNNING
--------------------------------------------------------------------------------
```

Display detailed information about the client with MAC address 0018-1111-2123.

```
<HUAWEI> display easy-operation client mac-address 0018-1111-2123

Table 2-4 Description of the **display easy-operation client** command output

Item	Description
ID/Client ID	Client ID.
Host name	Client host name.
Mac address	Client MAC address.
ESN	Client ESN.
IP address	Client IP address.

Item	Description
State	Client status. - INITIAL: The client is performing initialization. The client information has been added to the Commander, but the client has not obtained an IP address, so the client cannot communicate with the Commander. - UPGRADING: The client is upgrading the software. - RUNNING: The client is running. - LOST: The Commander does not receive the response from the client in 2 minutes. A stack enters the LOST state when its system MAC address changes. - CONFIGURING: Batch configuration status. - UNKNOWN: The client status is unknown. This state rarely appears.
Model	Device model of the client.
Device Type	Device type of the client.
System-software file	Current system software name of the client.
System-software version	Current system version of the client.
Configuration file	Current configuration file name of the client.
Patch file	Current patch file name of the client.
WEB file	Current web page file name of the client.
License file	Current license file name of the client.
System CPU usage	CPU usage of the client.
System Memory usage	Memory usage of the client.
Backup configuration file	Current backup configuration file name of the client.
Last operation result	Last operation result.
Last operation time	Last operation time.
Backup result	File backup result.
Aging time left	Remaining aging time.

2.2.18 display easy-operation client replace

Function

The **display easy-operation client replace** command displays client replacement information on the Commander.

Format

display easy-operation client replace [**verbose**]

display easy-operation client *client-id* **replace**

Parameters

Parameter	Description	Value
verbose	Displays detailed client replacement information.	-
client-id	Displays replacement information about a client with a specified client ID.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.

1: Monitoring level

Usage Guidelines

The **display easy-operation client** command displays brief client replacement information.

The replacement information is configured using the **client replace** command.

Example

Display brief client replacement information.

```
<HUAWEI> display easy-operation client replace
The total number of replacement information is :  1

-------------------------------------------------------------
 ID      Replaced Mac      Replaced Esn       Status
```

```
------------------------------------------------------------
 3      00e0-fc12-3456   -               enable
------------------------------------------------------------
```

Display detailed client replacement information.

```
<HUAWEI> display easy-operation client replace verbose
------------------------------------------------------------
 Client ID            : 3
 Mac address          : 00e0-fc12-3456
 ESN                  : -
 System-software file : -
 Configuration file   : 1.cfg
 Patch file           : -
 WEB file             : -
 License file         : -
 Customs file 1       : header.txt
 Customs file 2       : aaa.bat
 Customs file 3       : 1
 Status               : disable
------------------------------------------------------------
```

Display replacement information of client 3.

```
<HUAWEI> display easy-operation client 3 replace
------------------------------------------------------------
 Client ID            : 3
 Mac address          : 00e0-fc12-3456

 Configuration file   : 1.cfg
 Patch file           : -
 WEB file             : -
 License file         : -
 Customs file 1       : header.txt
 Customs file 2       : aaa.bat
 Customs file 3       : 1
 Status               : disable
------------------------------------------------------------
```

Table 2-5 Description of the **display easy-operation client replace** command output

Item	Description
ID/Client ID	Faulty client ID.
Replaced Mac/Mac address	New client MAC address.
Replaced Esn/ESN	New client ESN.
System-software file	System software to be downloaded by the new client.
Configuration file	Configuration file to be downloaded by the new client.
Patch file	Patch file to be downloaded by the new client.
WEB file	Web page file to be downloaded by the new client.

Item	Description
License file	License file to be downloaded by the new client.
Customs file 1	First user-defined file to be downloaded by the new client.
Customs file 2	Second user-defined file to be downloaded by the new client.
Customs file 3	Third user-defined file to be downloaded by the new client.
Status	Status of the replacement. ● enable: This function is enabled. ● disable: This function is not enabled.

2.2.19 display easy-operation configuration

Function

The **display easy-operation configuration** command displays the configurations on the Commander.

Format

display easy-operation configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command can be run on the Commander or clients.

- When the command is run on the Commander, the Commander role, Commander IP address and port number, file server information, and default downloaded file information are displayed.
- When the command is run on a client, the client role and Commander IP address and port number are displayed.

Example

Display EasyDeploy configuration on the Commander.

```
<HUAWEI> display easy-operation configuration
-------------------------------------------------------------------------
 Role                            : Commander
 Commander IP address            : 192.168.150.128
 Commander UDP port              : 60000
 DTLS status                     : Enable
 IP address of file server       : 192.168.150.200
 Type of file server             : SFTP
 Username of file server         : admin
 Default system-software file    : test.cc
 Default system-software version : -
 Default configuration file      : -
 Default patch file              : -
 Default WEB file                : -
 Default license file            : test.dat
 Default custom file 1           : mydoc.pat
 Default custom file 2           : header.txt
 Default custom file 3           : -
 Auto clear up                   : Disable
 Auto join in                    : Disable
 Topology collection             : Enable
 Activating file time            : In 00:00
 Activating file method          : Default
 Aging time of lost client(hours): -
 Backup configuration file mode  : Default
 Backup configuration file interval(hours): -
-------------------------------------------------------------------------
```

Display EasyDeploy configuration on a client.

```
<HUAWEI> display easy-operation configuration
-------------------------------------------------------------------------
 Role                            : Client
 Commander IP address            : 192.168.150.128(dhcp-alloc)
 Commander UDP port              : 60000
 DTLS status                     : Enable
-------------------------------------------------------------------------
```

Table 2-6 Description of the **display easy-operation configuration** command output

Item	Description
Role	Device role in the EasyDeploy service, which can be Commander or client.

Item	Description
Commander IP address	Commander IP address. It can be configured using the **easy-operation commander ip-address** command. If a client starts with a configuration file and obtains an IP address from a DHCP server, the client can also obtain the Commander IP address from the Option 148 field in the DHCP response message sent from the DHCP server. Therefore, the command output on a client shows whether a Commander IP address is configured using the command (configured) or obtained from the DHCP server (dhcp-alloc). If both two types of Commander IP addresses are available, the client uses the configured one. After the configured Commander IP address is deleted, the client uses the Commander IP address obtains from the DHCP server.
Commander UDP port	Port number used for communication between Commander and clients. It can be configured using the **easy-operation commander ip-address** command.
DTLS status	DTLS status.
IP address of file server	File server IP address. It can be configured using the **tftp-server** or **sftp-server** | **ftp-server** command.
Type of file server	File server type.
Username of file server	User name for accessing the file server.
Default system-software file	Default system software. If no default system software is specified, this field is empty. It can be configured using the **system-software** command.
Default system-software version	Default system software version. If no default system software is specified, this field is empty. It can be configured using the **system-software** command.

Item	Description
Default configuration file	Default configuration file. If no default configuration file is specified, this field is empty. It can be configured using the **configuration-file** command.
Default patch file	Default patch file. If no default patch file is specified, this field is empty. It can be configured using the **patch** command.
Default WEB file	Default web page file. If no default web page file is specified, this field is empty. It can be configured using the **web-file** command.
Default license file	Default license file. If no default license file is specified, this field is empty. It can be configured using the **license** command.
Default custom file 1	First default user-defined file. If no default user-defined file is specified, this field is empty. It can be configured using the **custom-file** command.
Default custom file 2	Second default user-defined file. If no default user-defined file is specified, this field is empty. It can be configured using the **custom-file** command.
Default custom file 3	Third default user-defined file. If no default user-defined file is specified, this field is empty. It can be configured using the **custom-file** command.
Auto clear up	Whether clients are enabled to automatically clear storage space. This function is configured using the **client auto-clear enable** command.

Item	Description
Auto join in	Whether clients are enabled to automatically join the management domain of the Commander. This function is configured using the **client auto-join enable** command.
Topology collection	Whether topology information collection is enabled. This function is configured using the **topology enable** command.
Activating file time	File activation time. If default file activation mode is used, this field displays **Immediately**. It can be configured using the **activate-file** command.
Activating file method	File activation mode. If default file activation mode is used, this field displays **Default**. It can be configured using the **activate-file** command.
Aging time of lost client(hours)	Aging time of a client in lost state. It can be configured using the **client aging-time** command.
Backup configuration file mode	Configuration file backup mode. If default mode is used, this field displays **Default**. It can be configured using the **backup configuration interval** command.
Backup configuration file interval(hours)	Configuration file backup interval. If configuration file backup is disabled, this field displays a hyphen (-). It can be configured using the **backup configuration interval** command.

2.2.20 display easy-operation device-information

Function

The **display easy-operation device-information** command displays device information.

Format

display easy-operation device-information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check device information, run the **display easy-operation device-information** command. The command output includes the MAC address, ESN, model, type, and active/standby state of the device.

This command can be run on the Commander or clients.

If the client is a stack, the displayed MAC address is the MAC address of the stack (MAC address of the master or backup device) and the displayed ESN is the ESN of the master device.

Example

Display the current device information.

```
<HUAWEI> display easy-operation device-information
System MAC: xxxx-xxxx-xxxx
Slot MAC            ESN                  Model               Device-Type Role
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
0    xxxx-xxxx-xxxx 210235404310xxxxxxxx S5701-28X-LI-AC     S5700-X-LI  Master
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
```

Table 2-7 Description of the **display easy-operation device-information** command output

Item	Description
System MAC	System MAC address.
Slot	Slot ID.
MAC	Device MAC address.
ESN	Device ESN.
Model	Device model.
Device-Type	Device type.
Role	Active/standby state.

2.2.21 display easy-operation download-status

Function

The **display easy-operation download-status** command displays file download status of clients on the Commander.

Format

display easy-operation download-status [**client** *client-id* | **verbose**]

Parameters

Parameter	Description	Value
client *client-id*	Displays the file download status of a client with a specified client ID.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
verbose	Displays detailed file download information of clients.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays file download status of clients, including client information (such as the client ID, MAC address, and IP address), scenario (zero touch device deployment, faulty device replacement, or batch upgrade), downloaded files, file download phase, and current status.

A client downloads files in the following sequence: system software, patch file, license file, web page file, configuration file, and user-defined file.

If the **client** *client-id* or **verbose** parameter is not specified, brief file download information of all clients is displayed.

Example

Display brief file download information of all clients.

```
<HUAWEI> display easy-operation download-status
---------------------------------------------------------------------------
 ID    Mac address     IP address      Method      Phase        Status
---------------------------------------------------------------------------
 1      00e0-fc12-3456 10.10.10.5      Zero-touch  Sys-file      Upgrading
 2      00e0-fc12-3333 10.10.10.6      Upgrade     Config-file   Failed
 3      00e0-fc12-1A52 10.10.10.7      Zero-touch  Patch-file    Waiting
 4      00e0-fc12-4458 10.10.10.8      Zero-touch  Web-file      Upgrading
---------------------------------------------------------------------------
```

Display detailed file download information of client 5.

```
<HUAWEI> display easy-operation download-status verbose
The total number of client in downloading files is : 1

---------------------------------------------------------------------------
 Client ID                    : 5
 Mac address                  : 00e0-fc12-2323
 ESN                          : 210235362912xxxxxxxx
 Host name                    : RTF_1-54
 IP address                   : 192.168.14.252
 Method                       : Zero-touch
 IP address of file server    : 192.168.1.88
 Type of file server          : SFTP
 Username of file server      : 1
 Configuration file           : -
 System-software file         : -
 Patch file                   : -
 WEB file                     : -
 License file                 : -
 Customs file 1               : -
 Customs file 2               : -
 Customs file 3               : -
 Activating file time         : Immediately
 Activating file method       : Default
 Phase                        : Unknown
 DownloadSize(byte)           : 29916738
 Status                       : Upgrading
 Reason                       : The device will enter getting download-information state.
 Description                  : The device will enter getting download-information state.
---------------------------------------------------------------------------
```

Table 2-8 Description of the **display easy-operation download-status** command output

Item	Description
ID/Client ID	Client ID.
Mac address	Client MAC address.
ESN	Client ESN.
Host name	Client host name.
IP address	Client IP address.

Item	Description
Method	EasyDeploy scenario. ● Zero-touch: zero touch device deployment and faulty device replacement. ● Upgrade: batch upgrade.
Phase	File download phase: Sys-file, Config-file, Patch-file, Web-file, License-file, Custom-file, Activating, Rebooting, and Unknown.
Status	File download status. ● Upgrading: The client is downloading a file. ● Waiting: The client is waiting for download. ● Failed: The client fails to download a file because its storage space is insufficient or the file to be downloaded does not exist.
IP address of file server	File server IP address.
Type of file server	File server type.
Username of file server	User name for accessing the file server.
System-software file	System software that is being downloaded.
Configuration file	Configuration file that is being downloaded.
Patch file	Patch file that is being downloaded.
WEB file	Web page file that is being downloaded.
License file	License file that is being downloaded.
Customs file 1	First user-defined file that is being downloaded.
Customs file 2	Second user-defined file that is being downloaded.
Customs file 3	Third user-defined file that is being downloaded.

Item	Description
DownloadSize(byte)	Size of a downloaded file. **NOTE** If the system software is upgraded from V200R009 or an earlier version to V200R010 or a later version, this field displays -.
Activating file time	File activation time. **Immediately** indicates that files are activated immediately after they are downloaded.
Activating file method	File activation mode. **Default** indicates the default activation mode; **Reload** indicates that all files are activated by device resetting.
Reason	File download result. For possible results and solutions, see **Table 2-9**.
Description	Result description. For possible results and measures, see **Table 2-9**.

Table 2-9 Download results and solutions

Reason	Description	Solution
Input has been detected in the console	Input has been detected in the console. EasyOperation will stop	During zero touch device deployment, input is detected on the console interface of the device to be deployed, so EasyOperation stops. You are advised to restart the device to restart the deployment process. Do not input anything on the console interface during EasyOperation.
The USB upgrade is working	The USB upgrade is working. EasyOperation will stop	The device is performing USB-based deployment. USB-based deployment and EasyDeploy are mutually exclusive. You are advised to stop one of the two functions.

Reason	Description	Solution
The uni-mng system is working	The uni-mng system is working. EasyOperation will stop	The device is running SVF. SVF and EasyDeploy are mutually exclusive. You are advised to stop one of the two functions.
The device has in initial state	The device is in initial state. EasyOperation will stop	The device is in web initialization mode. Web initial login mode and EasyDeploy are mutually exclusive. You are advised to stop one of the two functions.
Getting download-information failed. The device will get download-information again	Getting download-information failed. The device will be back to initialization state.	The device to be deployed fails to obtain file download information. ● If the device is deployed using an intermediate file, check whether the intermediate file has the correct content and format, whether the network between the device and server that stores the intermediate file is normal, and whether the configured file server user name and password are correct. ● If the device is deployed using the Commander, check whether the network between the device and Commander is normal and whether the configured download information is correct.
Downloading file failed	The system software file and version are wrong. The device will be back to initialization state	The system software version is specified but the system software file is not specified. You need to specify the system software file.

Reason	Description	Solution
	Downloading the system software file failed. Please check the reason	1. Check whether a network fault occurs during file download. 2. Check whether the file server that stores files is working properly. 3. Check whether the file names of the system software, patch file, configuration file, license file, web file, and user-defined file are valid. 4. Check whether the system software, patch file, configuration file, license file, web file, and user-defined file to be downloaded have the same names as the current system files. 5. Check whether the device to be upgraded has enough disk space.
	Downloading the patch file failed. Please check the reason	
	Downloading the web file failed. Please check the reason	
	Downloading the license file failed. Please check the reason	
	Downloading the configuration file failed. Please check the reason	
	Downloading the custom file 1 failed. Please check the reason	
	Downloading the custom file 2 failed. Please check the reason	
	Downloading the custom file 3 failed. Please check the reason	
The file does not exist in the file server	The file does not exist in the file server	The file to be downloaded does not exist in the file server. Ensure that the file exists in the file server.
There is no enough space on the device	There is no enough space on master device or board	The disk space on the device to be upgraded is insufficient for the system software. Ensure that the device has enough disk space.
The file server is unreachable	The file server is unreachable	Check whether the configured file server IP address is correct and whether the network connection between the device and file server is normal.

Reason	Description	Solution
Authentication on file server fails	Authentication on file server fails	Authentication fails on the file server. Check whether the following configurations are correct: 1. User name and password 2. User management configuration on the file server 3. Other user management configurations
The filename is the same as the system file	The filename of the patch is same as the system patch file	The downloaded patch has the same file name as the system patch file.
	The filename of the system-software is same as the system file	The downloaded patch has the same file name as the system patch file.
Check file failed	System-software crc check error	The CRC check of the downloaded system software fails. Check whether the system software of the file server is correct.
The file is a system file on the other device	The file is system file on other device	The patch to be downloaded is the system file on the standby or slave device.

Reason	Description	Solution
Activate file failed. The device will be back to initialization state after 5 minutes	Activating file failed. The device will be back to initialization state after 5 minutes	File activation because of the following reasons: 1. Failed to set the system software, configuration file, and patch file as next startup files. Check whether these files are available. 2. Failed to start the device. Check whether the device has unsaved configuration, whether next startup files on the master and standby devices are consistent, and whether system files are damaged.
Reboot system failed	The WLAN configuration conflicts with the next startup system software. To prevent configuration loss, use the eDesk tool to convert the configuration, and then specify the new configuration file for next startup	The device has WLAN configurations, which may be lost when the device is upgraded. You need to export the WLAN configurations, use a dedicated tool to convert the configurations, and then import them for use.
Copying file to other device or board failed	Copying file to other device or board failed	Failed to copy files to the standby or slave device. Check whether the file system function is normal and whether boards are installed or removed when files are being copied.
	There is no enough space on other device or board	There is insufficient disk space on the standby or slave device when upgrade files are being copied to the standby or slave device. Ensure that the disk space is enough to store all the upgrade files.

Reason	Description	Solution
The download file was deleted	The download file was deleted in client, please check the environment	The downloaded upgrade files are deleted. Check whether other users have logged in to the device and deleted the files.
Unknown error	Unknown error	An unknown error occurs in the system. Contact technical support personnel.
EasyOperation client operation failed	The file server is not configured. Configure a file server first. Check whether a file server has been configured correctly	Check whether a file server has been configured correctly.

2.2.22 display easy-operation group

Function

The **display easy-operation group** command displays group information on the Commander.

Format

display easy-operation group [**build-in** [*device-type* [**vendor** *vendorname*]] | **custom** [*group-name*]]

Parameters

Parameter	Description	Value
build-in	Displays built-in group information. If the device type is not specified, information about all built-in groups is displayed.	-

Parameter	Description	Value
device-type	Specifies a device type.	The value is an enumerated type and case-insensitive. The following device types are supported: - S2730S-S - S2750-EI - S5700-10P-LI - S5700-EI - S5700-HI - S5700-P-LI - S5700-SI - S5700-TP-LI - S5700-X-LI - S5700S-LI - S5700S-P-LI - S5700S-X-LI - S5710-EI - S5710-HI - S5710-X-LI - S5720-EI - S5720-HI - S5720-LI - S5720-SI - S5720S-LI - S5730-HI - S5730-SI - S5730S-EI - S5731-H - S5731-S - S5731S-H - S5731S-S - S5732-H - S5735-L - S5735-L1 - S5735-L-I - S5735S-L - S5735S-L1 - S5735-S - S5735S-S - S5735S-H

Parameter	Description	Value
		S5736-S S6700-EI S6720-EI S6720-HI S6720-LI S6720-SI S6720S-S S6720S-LI S6720S-SI S6730-H S6730S-H S6730-S S6730S-S S6735-S S9700
vendor *vendorname*	Displays the name of the group created based on the device type of the specified vendor. If no group name is specified, all vendor groups of the corresponding device types are displayed.	The value is a string of case-sensitive characters. It cannot contain spaces.
custom	Displays customized group information. If the group name is not specified, information about all customized groups is displayed.	-
group-name	Specifies the name of a customized group.	The value is a string of 1 to 31 case-sensitive characters without spaces. The character string must start with a letter.

```

Table 2-10 Description of the **display easy-operation group** command output

Item	Description
Groupname	Group name.
Type	Group type: build-in or custom.
MatchType	Match type of the group. The match type of a built-in group is configured using the **group build-in** command. The match type of a customized group is configured using the **group custom** command.
Configuration file	System software to be downloaded by the clients matching the group. If no system software is specified, this field displays a hyphen (-). It can be configured using the **configuration-file** command.
System-software file	Configuration file to be downloaded by the clients matching the group. If no configuration file is specified, this field displays a hyphen (-). It can be configured using the **system-software** command.
Patch file	Patch file to be downloaded by the clients matching the group. If no patch file is specified, this field displays a hyphen (-). It can be configured using the **patch** command.
WEB file	Web page file to be downloaded by the clients matching the group. If no system software is specified, this field displays a hyphen (-). It can be configured using the **web-file** command.
License file	License file to be downloaded by the clients matching the group. If no license file is specified, this field displays a hyphen (-). It can be configured using the **license** command.

Item	Description
Customs file 1	First user-defined file to be downloaded by the clients matching the group. If no system software is specified, this field displays a hyphen (-). It can be configured using the **custom-file** command.
Customs file 2	Second user-defined file to be downloaded by the clients matching the group. If no system software is specified, this field displays a hyphen (-). It can be configured using the **custom-file** command.
Customs file 3	Third user-defined file to be downloaded by the clients matching the group. If no third user-defined file is specified, this field displays a hyphen (-). It can be configured using the **custom-file** command.
Activating file time	File activation time used by the clients matching the group. If default file activation time is used, this field displays **Immediately**. It can be configured using the **activate-file** command.
Activating file method	File activation mode used by the clients matching the group. If default mode is used, this field displays **Default**. It can be configured using the **activate-file** command.

Item	Description
Ip-address list	Clients match the group based on IP addresses, and all matching IP addresses are displayed. ● If clients match the group based on ESNs, **ESN list** is displayed. ● If clients match the group based on MAC addresses, **Match mac-address list** is displayed. ● If clients match the group based on models, **Product model** is displayed. ● If clients match the group based on types, **Device type** is displayed. The matching rule can be configured using the **match** command.

2.2.23 display easy-operation power

Function

The **display easy-operation power** command displays power consumption information of the Commander and clients.

Format

display easy-operation power [**client** *client-id* | **commander**]

Parameters

Parameter	Description	Value
client *client-id*	Indicates power consumption information of a specified client.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
commander	Indicates power consumption information of the Commander.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command used to check power consumption information differs on the Commander and clients.

- On the Commander
  - If no parameter is specified, you can check power consumption information about the Commander and all the clients in initial, upgrade, and normal operating states.
  - If only **client** *client-id* is specified, you can check power consumption information about the specified client.
  - If only **commander** is specified, you can check power consumption information about the Commander.
- On the client

  The parameters **client** *client-id* and **commander** are not supported. You can check power consumption information only about the current client.

Example

Display power consumption information of the Commander and clients.

```
<HUAWEI> display easy-operation power
--------------------------------------------------------------------------------
Role       HostName                    Interface      Usage(W)     Gauge    Mode
--------------------------------------------------------------------------------
Commander       HUAWEI                                  995.0     actual   standard
Client1     HUAWEI                                 511.3      rated   standard
                                GE0/0/1        0.7       actual
Client3     HUAWEI                                 93.0      rated   standard
Client4     HUAWEI                                 100.0      rated   standard
--------------------------------------------------------------------------------
```

Table 2-11 Description of the **display easy-operation power** command output

Item	Description
Role	Device role in the EasyDeploy service, which can be Commander or client.
HostName	Device name.
Interface	Interface name: ● If this parameter is left blank, power consumption of the entire device is displayed. ● If an interface name is specified, power consumption of a power device connected to the corresponding interface is displayed.
Usage(W)	Power consumption, in Watts.

Item	Description
Gauge	Power consumption type: ● actual: indicates real-time power consumption. ● rated: indicates rated power consumption.
Mode	Energy saving mode: ● standard ● basic ● deep

2.2.24 display easy-operation topology

Function

The **display easy-operation topology** command displays network topology information collected by the Commander.

Format

display easy-operation topology

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view network topology information collected by the Commander. Based on the collected information, zero touch device deployment and automatic faulty device replacement can be implemented.

Example

Display network topology information collected by the Commander.

```
<HUAWEI> display easy-operation topology
<-->:normal device         <??>:lost device
Total topology node number: 3
-------------------------------------------------------------------------------
```

```
[HUAWEI: xxxx-xxxx-xxxx](Commander)
|-(GE0/0/8)<-->(GE0/0/38)[HUAWEI: xxxx-xxxx-xxxx](Client 1)
| |-(GE0/0/16)<-->(GE0/0/16)[HUAWEI: xxxx-xxxx-xxxx]  (Client 2)
```

Table 2-12 Description of the **display easy-operation topology** command output

Item	Description
<-->	Clients that are running properly.
<??>	Properly operating clients change to the lost state.
Total topology node number	Number of nodes (including the Commander) in the network topology.

2.2.25 display ndp

Function

The **display ndp** command displays the global NDP information or the NDP information on a specified interface.

Format

display ndp [**interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>]

Parameters

Parameter	Description	Value
interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] }	Displays the NDP information on a specified interface. ● *interface-type interface-number1* indicates the type and number of the first interface. ● *interface-type interface-number2* indicates the type and number of the last interface. If no interface is specified when you run the **display ndp** command, NDP information about all interfaces is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you check the NDP information:

- If NDP is not globally enabled, only the current NDP status of a switch is displayed.
- If NDP is globally enabled, the global NDP information and status and the NDP information and status of interfaces on a switch are displayed.

Example

Display the global NDP information and NDP information about all the interfaces.

```
<HUAWEI> display ndp
 Neighbor discovery protocol is enabled.
 Neighbor Discovery Protocol Ver: 1, Hello Timer: 60(s), Aging Timer: 180(s)
 Interface: GigabitEthernet0/0/1
    Status: Enabled, Packets Sent: 114, Packets Received: 108, Packets Error: 0
    Neighbor 1:  Aging Time: 174(s)
       MAC Address : xxxx-xxxx-xxxx
       Port Name   : GigabitEthernet0/0/1
       Software Version: Version 5.130 V200R023C00
       Device Name : S5720
       Port Duplex : FULL
       Product Ver : S5720 V200R023C00
---- More ----
```

Table 2-13 Description of the **display ndp** command output

Item	Description
Neighbor discovery protocol is *status*	The global NDP function is in *status* state. *status* includes: - disabled: NDP is disabled globally. - enabled: NDP is enabled globally. To set this value, run the **ndp enable (system view)** command.
Neighbor Discovery Protocol Ver	Currently supported NDP versions. Version 1 is currently supported by all devices.
Hello Timer	Interval for sending NDP packets, in seconds. To set this value, run the **ndp timer hello** command.
Aging Timer	Aging time of NDP information, in seconds. To set this value, run the **ndp timer aging** command.
Interface	Interface number of a switch.

Item	Description
Status	NDP status of an interface: - Disabled: NDP is disabled on the interface. - Enabled: NDP is enabled on the interface. To set this value, run the **ndp enable (system view)** or **ndp enable (interface view)** command.
Packets Sent	Number of NDP packets sent from the interface.
Packets Received	Number of NDP packets received by the interface.
Packets Error	Number of incorrect NDP packets received by the interface.
Neighbor 1	Neighboring node 1.
Aging Time	Aging time of NDP information about a neighboring node connected to the interface.
MAC Address	MAC address of the neighboring node.
Port Name	Name of the interface on the neighboring node connected to the interface.
Software Version	Version of the system software on the neighboring node.
Device Name	Host name of the neighboring node.
Port Duplex	Duplex mode of the interface on the neighboring node connected to the local interface. - FULL: full-duplex. - Half: half-duplex.
Product Ver	Type and software version number of the neighboring node.

Display the NDP information of the switch on which NDP is not globally enabled.

```
<HUAWEI> display ndp
 Neighbor discovery protocol is disabled.
 Neighbor Discovery Protocol Ver: 1, Hello Timer: 60(s), Aging Timer: 180(s)
```

2.2.26 display ntdp

Function

The **display ntdp** command displays NTDP configuration.

Format

display ntdp

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ntdp** command to check the NTDP configuration of a switch without considering whether NTDP is enabled globally or on interfaces on the switch.

Example

Display the NTDP configuration of a switch.

```
<HUAWEI> display ntdp
Network topology discovery protocol is enabled
Hops      : 8
Timer     : 0 min
Hop Delay : 200 ms
Port Delay: 20 ms
Total time for last collection: 330 ms
```

Table 2-14 Description of the **display ntdp** command output

Item	Description
Network topology discovery protocol is *status*	The global NTDP function is in *status* state. *status* includes the following types of status: ● disabled: NTDP is disabled globally. ● enabled: NTDP is enabled globally. To set this value, run the **ntdp enable (system view)** command.

Item	Description
Hops	Topology collection range (the number of hops). To set this value, run the **ntdp hop** command.
Timer	Interval for collecting topology information. To set this value, run the **ntdp timer** command.
Hop Delay	Delay for the first interface to forward NTDP topology request packets. To set this value, run the **ntdp timer hop-delay** command.
Port Delay	Delay for other interfaces to forward NTDP topology request packets. To set this value, run the **ntdp timer port-delay** command.
Total time for last collection	Duration for collecting topology information last time.

2.2.27 display ntdp device-list

Function

The **display ntdp device-list** command displays the topology information collected using NTDP.

Format

display ntdp device-list [**verbose**]

Parameters

Parameter	Description	Value
verbose	Displays detailed device information. If you run the **display ntdp device-list** command without setting optional parameters, brief information about the device is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check the topology information collected using NTDP, run the **display ntdp device-list** command. The topology information can be displayed only after **ntdp explore** command is run in the user view to enable the switch to periodically collect the topology information.

When NTDP is not enabled on interfaces of the switch, only information about the switch itself is collected using NTDP.

Prerequisites

NTDP has been globally enabled on the switch.

Example

Display brief switch information collected using NTDP.

```
<HUAWEI> display ntdp device-list
The device-list of NTDP:
------------------------------------------------------------------------------
 MAC            HOP  IP                PLATFORM
------------------------------------------------------------------------------
 xxxx-xxxx-xxxx  0                     S5700
 xxxx-xxxx-xxxx  1    10.1.1.2/24        S5700
 xxxx-xxxx-xxxx  1    10.1.1.3/24        S5700
```

Table 2-15 Description of the **display ntdp device-list** command output

Item	Description
MAC	MAC address of the device.
HOP	Number of hops from the device to the topology collecting device.
IP	IP address of the device.
PLATFORM	Type of the device.

Display detailed device information collected using NTDP.

```
<HUAWEI> display ntdp device-list verbose
 Hostname  : HUAWEI
 MAC       : xxxx-xxxx-xxxx
 Hop       : 0
 Platform  : S5700
 IP        :
 Version   : Version 5.150 V200R023C00
 Cluster   : Administrator switch of cluster
 Peer MAC        Native Port ID Peer Port ID   N-Index    P-Index    Speed Dup
 xxxx-xxxx-xxxx  GE0/0/4        GE0/0/4        9          9          1000  FULL
 xxxx-xxxx-xxxx  GE0/0/1        GE0/0/1        6          6          1000  FULL

-----------------------------------------------------------------------------

 Hostname  : HUAWEI
 MAC       : xxxx-xxxx-xxxx
 Hop       : 1
```

```
Platform  : S5700
IP        : 10.1.1.2/24
Version   : Version 5.150 V200R023C00
Cluster   : Candidate switch

Peer MAC        Native Port ID Peer Port ID   N-Index    P-Index    Speed Dup
xxxx-xxxx-xxxx  GE0/0/4        GE0/0/4        9          9          1000   FULL

------------------------------------------------------------------------------

Hostname  : HUAWEI
MAC       : xxxx-xxxx-xxxx
Hop       : 1
Platform  : S5700
IP        : 10.1.1.3/24
Version   : Version 5.150 V200R023C00
Cluster   : Candidate switch

Peer MAC        Native Port ID Peer Port ID   N-Index    P-Index    Speed Dup
xxxx-xxxx-xxxx  GE0/0/1        GE0/0/1        6          6          1000   FULL
```

Table 2-16 Description of the **display ntdp device-list verbose** command output

Item	Description
Hostname	Host name of the device.
MAC	MAC address of the device.
Hop	Number of hops from the device to the topology collecting device.
Platform	Model of the device.
IP	Private IP address of the device.
Version	Version of the system software running on the device.
Cluster	Role of the device in the cluster.
Peer MAC	MAC address of the neighboring node.
Native Port ID	Interface of the device connecting to the neighboring node.
Peer Port ID	Interface of the neighboring node connecting to the local device.
N-Index	Index of the local interface.
P-Index	Index of the peer interface.
Speed	Rate of the interface when the neighboring node is connected to the device.
Dup	Duplex mode of the interface when the neighboring node is connected to the local device.

2.2.28 display cluster-topology-info

Function

The **display cluster-topology-info** command displays the topology information about the cluster.

Format

display cluster-topology-info

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display cluster-topology-info** command on the Commander switch only.

NOTE

If two devices are connected through multiple interfaces, this command displays information only about the link established between a pair of interfaces.

Example

Display the topology information about the cluster.

```
<HUAWEI> display cluster-topology-info
The topology information about the cluster:
<-->:normal device        <++>:candidate device        <??>:lost device
------------------------------------------------------------------------
Total topology node number is 5.
[HUAWEI_0.Administrator: Root-00e0-ad14-c600]
|-(GigabitEthernet0/0/2)<-->(GigabitEthernet0/0/1)[HUAWEI_3.Member-3: xxxx-xxxx-xxxx]
| |-(GigabitEthernet0/0/3)<-->(GigabitEthernet0/0/1)[HUAWEI_2.Member-2: xxxx-xxxx-xxxx]
| | |-(GigabitEthernet0/0/1)<-->(GigabitEthernet0/0/1)[HUAWEI_1.Member-1: xxxx-xxxx-xxxx]
|-(GigabitEthernet0/0/1)<-->(GigabitEthernet0/0/2)[HUAWEI_4.Member-4: xxxx-xxxx-xxxx]
```

Table 2-17 shows the description of the **display cluster-topology-info** command output.

Table 2-17 Description of the **display cluster-topology-info** command output

Item	Description
<-->	Normal link.

Item	Description
<++>	Candidate link.
<??>	Faulty link.
Total topology node number is	Specifies the number of nodes in the topology of the cluster.
[HUAWEI_0.Administrator: Root-xxxx-xxxx-xxxx]	Specifies the MAC address and host name of the switch. It varies with the name and MAC address of the device.
|-	Indicates the level-1 device that is connected to the root node.
| |-	Indicates the level-2 device which is connected to the level-1 device.
| | |-	Indicates the level-3 device which is connected to the level-2 device.
(GigabitEthernet0/0/1)<-->(GigabitEthernet0/0/2)	Specifies the names of the interfaces connecting the two devices. It varies with the interfaces of the devices. The left brackets contain information about the upper-level device. The right brackets contain information about the lower-level device.
[HUAWEI_3.Member-3: xxxx-xxxx-xxxx]	Specifies the MAC address of the member device. It varies with the name and MAC address of the device.

2.2.29 easy-operation

Function

The **easy-operation** command displays the Easy-Operation view.

Format

easy-operation

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To specify the file server, information about files to be downloaded, and file activation mode, or configure other EasyDeploy-related functions, first run the **easy-operation** command to enter the Easy-Operation view.

Prerequisites

You can enter the Easy-Operation view only on the device functions as a Commander.

After choosing a device as the Commander, run the **easy-operation commander ip-address** command on the device to configure the Commander IP address, and then run the **easy-operation commander enable** command to enable the Commander function.

Example

Enter the Easy-Operation view.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation]
```

2.2.30 easy-operation client ftp-server

Function

The **easy-operation client ftp-server** command specifies IP addresses, user names, and passwords for FTP servers on a pre-delivery device.

The **undo easy-operation client ftp-server** command deletes the specified IP addresses, user names, and passwords of FTP servers on a pre-delivery device.

By default, IP addresses, user names, and passwords of FTP servers are not specified on pre-delivery devices.

Format

easy-operation client ftp-server ip-address *ipaddress* &<1-4> [**username** *username* [**password** *password*]]

undo easy-operation client ftp-server ip-address [*ipaddress*] [**username** *username*] [**password**]

Parameters

Parameter	Description	Value
ip-address *ipaddress*	Specifies the IP address of an FTP server.	The value is in dotted decimal notation.

Parameter	Description	Value
username *username*	Specifies a user name for FTP server access.	The value is a string of 1 to 64 characters.
password *password*	Specifies a password for FTP server access.	The value is a string of 1 to 16 characters in plaintext or 48 characters in ciphertext.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client ftp-server** command to specify IP addresses, user names, and passwords for the servers.

Precautions

- The **easy-operation client ftp-server** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.
- If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client ftp-server** command in the system view to delete the specified IP addresses, user names, and passwords of FTP servers.
- If a user name and a password have been set on a file server, the device must have the same user name and password configured.
- FTP has security risks. Using an SFTP file server is recommended.
- A maximum of four FTP file servers' IP addresses, user names, and passwords can be specified. A device searches for and obtains the desired files from the servers in the sequence in which file servers are configured.
- Ensure that the files to be downloaded have been uploaded to the specified file servers.

Example

Delete the IP address, user name, and password of an FTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client ftp-server ip-address 10.1.1.1 username huawei password
```

2.2.31 easy-operation client ftp-server-url

Function

The **easy-operation client ftp-server-url** command specifies URLs, user names, and passwords for FTP servers on a pre-delivery device.

The **undo easy-operation client ftp-server-url** command deletes the specified URLs, user names, and passwords of FTP servers on a pre-delivery device.

By default, URLs, user names, and passwords of FTP servers are not specified on pre-delivery devices.

Format

easy-operation client ftp-server-url *url-address* [**username** *username* [**password** *password*]]

undo easy-operation client ftp-server-url [*url-address*] [**username** *username*] [**password**]

Parameters

Parameter	Description	Value
url-address	Specifies the URL of an FTP server.	The value is a string of 1 to 64 characters.
username *username*	Specifies a user name for FTP server access.	The value is a string of 1 to 64 characters.
password *password*	Specifies a password for FTP server access.	The value is a string of 1 to 16 characters in plaintext or 48 characters in ciphertext.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client ftp-server-url** command to specify URLs, user names, and passwords for the servers.

Precautions

The **easy-operation client ftp-server-url** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.

If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client ftp-server-url** command in the system view to delete the specified URLs, user names, and passwords of FTP servers.

You can specify an FTP server using either an IP address or URL.

Example

Delete the URL, user name, and password of an FTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client ftp-server-url www.1234.com username huawei password
```

2.2.32 easy-operation client netfile

Function

The **easy-operation client netfile** command specifies a name for an intermediate file for pre-configured device deployment.

The **undo easy-operation client netfile** command deletes the name of an intermediate file for pre-configured device deployment.

By default, devices use the intermediate file **lswnet.cfg** for pre-configured device deployment.

Format

easy-operation client netfile *filename*

undo easy-operation client netfile [*filename*]

Parameters

Parameter	Description	Value
filename	Specifies the name (*.cfg) of an intermediate file.	The value is a string of 5 to 48 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A pre-configured device obtains version file information from an intermediate file placed on a file server. This information includes an SNMP host's IP address, device's MAC address, ESN or model, and names of files to be downloaded.

If you do not specify an intermediate file, the device uses the **lswnet.cfg** file by default. If you want to use another intermediate file, run the **easy-operation client netfile** command.

Precautions

The **easy-operation client netfile** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.

If you do not want to use pre-configured device deployment, run the **undo easy-operation client netfile** command in the system view to delete the intermediate file.

The configuration file specified in an intermediate file cannot contain any pre-configured commands.

Example

Delete the intermediate file specified for pre-configured device deployment.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client netfile huawei.cfg
```

2.2.33 easy-operation client sftp-server

Function

The **easy-operation client sftp-server** command specifies IP addresses, user names, and passwords for SFTP servers on a pre-delivery device.

The **undo easy-operation client sftp-server** command deletes the specified IP addresses, user names, and passwords of SFTP servers on a pre-delivery device.

By default, IP addresses, user names, and passwords of SFTP servers are not specified on pre-delivery devices.

Format

easy-operation client sftp-server ip-address *ipaddress* &<1-4> [**username** *username* [**password** *password*]]

undo easy-operation client sftp-server ip-address [*ipaddress*] [**username** *username*] [**password**]

Parameters

Parameter	Description	Value
ip-address *ipaddress*	Specifies the IP address of an SFTP server.	The value is in dotted decimal notation.

Parameter	Description	Value
username *username*	Specifies a user name for SFTP server access.	The value is a string of 1 to 64 characters.
password *password*	Specifies a password for SFTP server access.	The value is a string of 1 to 16 characters in plaintext or 48 characters in ciphertext.

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client sftp-server** command to specify IP addresses, user names, and passwords for the servers.

Precautions

- The **easy-operation client sftp-server** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.
- If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client sftp-server** command in the system view to delete the specified IP addresses, user names, and passwords of SFTP servers.
- If a user name and a password have been set on a file server, the device must have the same user name and password configured.
- A maximum of four SFTP file servers' IP addresses, user names, and passwords can be specified. A device searches for and obtains the desired files from the servers in the sequence in which file servers are configured.
- Ensure that the files to be downloaded have been uploaded to the specified file servers.

Example

Delete the IP address, user name, and password of an SFTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client sftp-server ip-address 10.1.1.1 username huawei password
```

2.2.34 easy-operation client sftp-server-url

Function

The **easy-operation client sftp-server-url** command specifies URLs, user names, and passwords for SFTP servers on a pre-delivery device.

The **undo easy-operation client sftp-server-url** command deletes the specified URLs, user names, and passwords of SFTP servers on a pre-delivery device.

By default, URLs, user names, and passwords of SFTP servers are not specified on pre-delivery devices.

Format

easy-operation client sftp-server-url *url-address* [**username** *username* [**password** *password*]]

undo easy-operation client sftp-server-url [*url-address*] [**username** *username*] [**password**]

Parameters

Parameter	Description	Value
url-address	Specifies the URL of an SFTP server.	The value is a string of 1 to 64 characters.
username *username*	Specifies a user name for SFTP server access.	The value is a string of 1 to 64 characters.
password *password*	Specifies a password for SFTP server access.	The value is a string of 1 to 16 characters in plaintext or 48 characters in ciphertext.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client sftp-server-url** command to specify URLs, user names, and passwords for the SFTP servers on the device.

Precautions

- The **easy-operation client sftp-server-url** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.
- If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client sftp-server-url** command in the system view to delete the specified URLs, user names, and passwords of SFTP servers.
- You can specify an SFTP server using either an IP address or URL.
- If a user name and a password have been set on a file server, the device must have the same user name and password configured.
- Ensure that the files to be downloaded have been uploaded to the specified file servers.

Example

Delete the URL, user name, and password of an SFTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client sftp-server-url www.1234.com username huawei password
```

2.2.35 easy-operation client snmp securityname

Function

The **easy-operation client snmp securityname** command configures a shared key between a pre-delivery device and an SNMP host.

The **undo easy-operation client snmp securityname** command deletes a shared key between a pre-delivery device and an SNMP host.

By default, no shared key is configured between pre-delivery devices and SNMP hosts.

Format

easy-operation client snmp securityname cipher *password*

undo easy-operation client snmp securityname

Parameters

Parameter	Description	Value
cipher *password*	Specifies a shared key.	The value is a string of 1 to 32 characters in plaintext, or 48 or 68 characters in ciphertext.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In pre-configured device deployment, a pre-delivery device sends alarms to an NMS over an SNMP module for deployment monitoring. To configure a shared key between the device and the SNMP host, run the **easy-operation client snmp securityname** command.

Precautions

The **easy-operation client snmp securityname** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.

If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client snmp securityname** command in the system view to delete the shared key.

Example

Delete the shared key between a pre-delivery device and an SNMP host.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client snmp securityname
```

2.2.36 easy-operation client tftp-server

Function

The **easy-operation client tftp-server** command specifies IP addresses for TFTP servers on a pre-delivery device.

The **undo easy-operation client tftp-server** command deletes the specified IP addresses of TFTP servers on a pre-delivery device.

By default, IP addresses of TFTP servers are not specified on pre-delivery devices.

Format

easy-operation client tftp-server ip-address *ipaddress* &<1-4>

undo easy-operation client tftp-server ip-address [*ipaddress*]

Parameters

Parameter	Description	Value
ip-address *ipaddress*	Specifies the IP address of a TFTP server.	The value is in dotted decimal notation.

Views

System view

3: Management level

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client ftp-server** command to specify IP addresses for the servers.

Precautions

- The **easy-operation client tftp-server** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.
- If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client tftp-server** command in the system view to delete the specified IP addresses of TFTP servers.
- TFTP has security risks. Using an SFTP file server is recommended.
- A maximum of four TFTP file servers' IP addresses can be specified. A device searches for and obtains the desired files from the servers in the sequence in which file servers are configured.
- Ensure that the files to be downloaded have been uploaded to the specified file servers.

Example

Delete the IP address of a TFTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client tftp-server ip-address 10.1.1.1
```

2.2.37 easy-operation client tftp-server-url

Function

The **easy-operation client tftp-server-url** command specifies URLs for TFTP servers on a pre-delivery device.

The **undo easy-operation client tftp-server-url** command deletes the specified URLs of TFTP servers on a pre-delivery device.

By default, URLs of TFTP servers are not specified on pre-delivery devices.

Format

easy-operation client tftp-server-url *url-address*

undo easy-operation client tftp-server-url [*url-address*]

Parameters

Parameter	Description	Value
url-address	Specifies the URL of a TFTP server.	The value is a string of 1 to 64 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a device obtains file information to be downloaded from an intermediate file, it must download the specified files from file servers. To allow the device to visit the servers, run the **easy-operation client tftp-server-url** command to specify URLs for the servers.

Precautions

The **easy-operation client tftp-server-url** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.

If you do not want to use the pre-configured device deployment function, run the **undo easy-operation client tftp-server-url** command in the system view to delete the specified URLs of TFTP servers.

You can specify either an IP address or URL for a TFTP server.

Example

Delete the URL of a TFTP server.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client tftp-server-url www.1234.com
```

2.2.38 easy-operation client vlan

Function

The **easy-operation client vlan** command specifies the VLAN used in the configured device deployment procedure before device delivery.

The **undo easy-operation client vlan** command deletes the VLAN used in the configured device deployment procedure.

By default, the VLAN used in the configured device deployment procedure is VLAN 1.

Format

easy-operation client vlan *vlanid*

undo easy-operation client vlan

Parameters

Parameter	Description	Value
vlanid	Specifies the VLAN used in the configured device deployment procedure.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Application Scenario

You can use the default VLAN 1 or run this command to specify the VLAN used in the configured device deployment procedure to implement configured device deployment.

Precautions

- This command is an overwritten command.
- The **easy-operation client vlan** command is contained only in a device's pre-delivery configuration file. Users cannot manually run this command. The **undo easy-operation client vlan** command can be manually run.

Example

Delete the VLAN used in the configured device deployment procedure.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client vlan
```

2.2.39 easy-operation client ztp-with-cfg enable

Function

The **easy-operation client ztp-with-cfg enable** command enables pre-configured device deployment.

The **undo easy-operation client ztp-with-cfg enable** command disables pre-configured device deployment.

By default, pre-configured device deployment is disabled.

Format

easy-operation client ztp-with-cfg enable

undo easy-operation client ztp-with-cfg enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before delivery, a device can load a configuration file that contains commands for specifying file server addresses, name of an intermediate file for site deployment, and a shared key between the device and an SNMP host. After simple login configuration, the device can then automatically obtain and load correct configurations, reducing the manual operation cost.

Precautions

The **easy-operation client ztp-with-cfg enable** command is contained only in a device's pre-delivery configuration file. It is not allowed to run this command after device delivery.

If you do not need the pre-configured device deployment function, run the **undo easy-operation client ztp-with-cfg enable** command in the system view to disable this function.

Example

Disable the pre-configured device deployment function on a device.

```
<HUAWEI> system-view
[HUAWEI] undo easy-operation client ztp-with-cfg enable
```

2.2.40 easy-operation commander enable

Function

The **easy-operation commander enable** command enables the Commander function on a device.

The **undo easy-operation commander enable** command disables the Commander function on a device.

By default, the Commander function is disabled on a device.

Format

easy-operation commander enable

undo easy-operation commander enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To specify a device as the Commander, enable the Commander function on the device. The Commander can enable devices to automatically download files in zero touch device deployment, fault device replacement, and batch upgrade scenarios. On an EasyDeploy network, the Commander manages clients and delivers required information, including file server information, system software name, and configuration file name, to clients. Clients automatically download required files according to information obtained from the Commander.

Prerequisites

The Commander IP address has been configured on the device using the **easy-operation commander ip-address** command.

Precautions

- An EasyDeploy network has only one Commander.
- This command can be used only on the device that functions as the Commander.
- After you run the **undo easy-operation commander enable** command to disable the Commander function, dynamic information in the client database is deleted, and the configuration information is saved in the memory of the device. If the Commander does not restart after the Commander function is disabled, the configuration will be recovered after the Commander function is enabled again.

Example

Enable the Commander function on a device.

```
<HUAWEI> system-view
[HUAWEI] easy-operation commander enable
```

2.2.41 easy-operation commander ip-address

Function

The **easy-operation commander ip-address** command configures the Commander IP address.

The **undo easy-operation commander ip-address** command deletes the Commander IP address.

By default, no Commander IP address is configured.

Format

easy-operation commander ip-address *ip-address* [**udp-port** *udp-port*]

undo easy-operation commander ip-address [*ip-address* [**udp-port** *udp-port*]]

Parameters

Parameter	Description	Value
ip-address	Specifies the Commander IP address.	The value is in dotted decimal notation.
udp-port *udp-port*	Specifies the UDP port number that the Commander uses to communicate with clients.	The value is an integer in the range from 1025 to 65535. The default value is 60000.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After an IP address is configured for the Commander, clients can communicate with the Commander through this IP address. To implement a batch upgrade, you need to specify the Commander IP address on clients. In zero touch provisioning (ZTP) and faulty device replacement scenarios, clients obtain the Commander IP address from the DHCP server.

Precautions

The configured Commander IP address must exist on the device that functions as the Commander.

The Commander IP address cannot be the IP address of the VLANIF interface bound to a VPN.

After the Commander function is enabled on the switch, changing the Commander IP address is not allowed on the switch. Otherwise, the Commander cannot detect and manage clients.

In batch upgrade scenarios, the Commander and clients must be configured with the same Commander IP address and UDP port number. Otherwise, clients cannot communicate with the Commander.

Example

Configure the Commander IP address.

```
<HUAWEI> system-view
[HUAWEI] easy-operation commander ip-address 10.10.10.5
Warning: The pre-shared key can be modified to improve security. Continue? [Y/N]:y
Enter the pre-shared key:******
Confirm the pre-shared key:******
```

Table 2-18 Description of the **easy-operation commander ip-address** command output

Item	Description
Warning: The pre-shared key can be modified to improve security. Continue? [Y/N]	Whether to change a pre-shared key. Regardless of whether the pre-shared key is changed, the **easy-operation commander ip-address** command can still be executed, and the Commander IP address can be changed successfully. ● y: The pre-shared key will be changed. ● n: The pre-shared key will not be changed.
Enter the pre-shared key	Enter the ciphertext of the pre-shared key. **NOTE** ● The same pre-shared key must be configured on the Commander and clients simultaneously. ● If the entered pre-shared key is invalid or the two pre-shared keys are different, the pre-shared key will not be changed. The failure to change the pre-shared key does not affect the execution of the **easy-operation commander ip-address** command. That is, the Commander IP address can still be changed successfully.
Confirm the pre-shared key	Confirm the ciphertext of the pre-shared key.

2.2.42 easy-operation dtls disable

Function

The **easy-operation dtls disable** command disables Datagram Transport Layer Security (DTLS) encryption.

The **undo easy-operation dtls disable** command enables DTLS encryption.

By default, DTLS encryption is enabled.

Format

easy-operation dtls disable

undo easy-operation dtls disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command is mainly used in the capacity expansion scenario on a live network. If the system software of a client is V200R010C00 or a later version and that of the Commander is a version earlier than V200R010C00, you need to run the **easy-operation dtls disable** command on the client to disable DTLS encryption.

Precautions

- You must enable or disable DTLS encryption on the Commander and client at the same time.
- If the system software of a switch in a version earlier than V200R010C00 is upgraded to V200R010C00 or a later version, an **easy-operation dtls disable** configuration is automatically generated.
- If a client in V200R010C00 or a later version needs to be managed by the Commander in a version earlier than V200R010C00, you need to run the **easy-operation dtls disable** command on the client to disable DTLS encryption.
- If a client in a version earlier than V200R010C00 needs to be managed by the Commander in V200R010C00 or a later version and DTLS encryption is enabled on the Commander, you must upgrade the system software of the

client to V200R010C00 or a later version. Otherwise, the client cannot join the existing network.

- After DTLS encryption is enabled, the shared key configured using the **easy-operation shared-key** command does not take effect.
- After DTLS encryption is enabled, you can run the **easy-operation dtls psk** command to configure the DTLS PSK.

Example

Disable DTLS encryption.

```
<HUAWEI> system-view
[HUAWEI] easy-operation dtls disable
```

2.2.43 easy-operation dtls psk

Function

The **easy-operation dtls psk** command configures the DTLS pre-shared key (PSK).

The **undo easy-operation dtls psk** command restores the default DTLS PSK.

The default username and password are available in *S Series Switches Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

Format

easy-operation dtls psk *psk*

undo easy-operation dtls psk

Parameters

Parameter	Description	Value
psk	Specifies the PSK.	The value is a string of 6 to 32 characters in plain text or a string of 48 or 68 characters in cipher text.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After DTLS encryption is enabled, you can run this command to change the DTLS PSK.

Precautions

The same PSK must be configured on the Commander and clients simultaneously.

Example

Set the DTLS PSK to **test12345**.

```
<HUAWEI> system-view
[HUAWEI] easy-operation dtls psk test12345
```

2.2.44 easy-operation shared-key

Function

The **easy-operation shared-key** command configures a shared key for the Commander or a client.

The **undo easy-operation shared-key** command deletes the configured shared key of the Commander or client.

By default, no shared key is configured on a Commander or client.

Format

easy-operation shared-key cipher *key-string*

undo easy-operation shared-key

Parameters

Parameter	Description	Value
cipher	Configures a shared key in cipher text.	-
key-string	Specifies a shared key.	The value is a string of case-sensitive characters without spaces. A plain text key contains 1 to 64 characters, and a cipher text key contains 48 to 108 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In batch upgrade and configuration scenarios, to enhance security for communication between the Commander and clients and prevent a bogus Commander from controlling clients, run the **easy-operation shared-key** command to configure the same shared key for the Commander and clients.

Precautions

- The same shared key must be configured on the Commander and clients simultaneously.
- If a shared key has been configured on the Commander, the Commander cannot manage clients running versions earlier than V200R008C00 and clients that have no shared key configured.
- The shared key configuration does not affect zero touch device deployment.
- After DTLS encryption is enabled, the shared key configured using the **easy-operation shared-key** command does not take effect.

Example

Configure a shared key on the Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation shared-key cipher Easy@huawei
```

2.2.45 execute to

Function

The **execute to** command enables the Commander to deliver commands to clients or client groups.

Format

execute [*script-file*] **to client** { **all** | { *client-id1* [**to** *client-id2*] }&<1-10> }

execute [*script-file*] **to group** { **all** | { **name** *group-name* }&<1-10> }

Parameters

Parameter	Description	Value
script-file	Indicates a script file name. If no script file name is specified, the script made online is delivered.	The value is a string of 5 to 64 characters, depending on the actual situation.

Parameter	Description	Value
client { *client-id1* [**to** *client-id2*] }	Indicates that commands are delivered to a specified client.	The value is an integer. It depends on the maximum number of clients supported by the Commander. For details, see **Maximum Number of Managed Clients** on the Commander.
client all	Indicates that commands are delivered to all clients.	-
group name *group-name*	Indicates that commands are delivered to a specified client group.	The value is a string of 1 to 31 case-sensitive characters without spaces. The character string must start with a letter.
group all	Indicates that commands are delivered to all client groups.	-

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To implement a batch configuration of clients on a network supporting EasyDeploy, edit commands to be run, save them as a script, and deliver the edited commands to clients through the Commander.

Example

Enable the Commander to deliver commands to all clients.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] execute to client all
Warning: This operation will start the batch command executing process to the cl
ients. Continue?[Y/N]:y
Info: This operation will take some seconds, please wait..
```

2.2.46 group build-in

Function

The **group build-in** command configures a built-in group on the Commander and displays the Easy-Operation group view.

The **undo group build-in** command deletes a built-in group.

By default, no built-in group is configured.

Format

group build-in *device-type* [**vendor** *vendorname*]

undo group build-in [*device-type* [**vendor** *vendorname*]]

NOTE

- If clients of the same type from different vendors exist on the network, you need to configure **vendor** *vendorname* to distinguish the clients.
- If **vendor** *vendorname* is specified in the **group build in** command, the device type view of the corresponding vendor is displayed.
- If **vendor** *vendorname* is not specified in the **group build in** command, the vendor type is not specified.

Parameters

Parameter	Description	Value
device-type	Specifies the device type in a group.	The value is an enumerated type and case-insensitive. The following device types are supported: ● S2730S-S ● S2750-EI ● S5700-10P-LI ● S5700-EI ● S5700-HI ● S5700-P-LI ● S5700-SI ● S5700-TP-LI ● S5700-X-LI ● S5700S-LI ● S5700S-P-LI ● S5700S-X-LI ● S5710-EI ● S5710-HI ● S5710-X-LI ● S5720-EI ● S5720-HI ● S5720-LI ● S5720-SI ● S5720S-LI ● S5730-HI ● S5730-SI ● S5730S-EI ● S5731-H ● S5731-S ● S5731S-H ● S5731S-S ● S5732-H ● S5735-L ● S5735-L1 ● S5735-L-I ● S5735S-L ● S5735S-L1 ● S5735-S

Parameter	Description	Value
		- S5735S-S - S5735S-H - S5736-S - S6700-EI - S6720-EI - S6720-HI - S6720-LI - S6720-SI - S6720S-S - S6720S-LI - S6720S-SI - S6730-H - S6730S-H - S6730-S - S6730S-S - S6735-S - S9700
vendor *vendorname*	Displays the group of the device type of the specified vendor.	The value is a character string.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If clients on a network are devices of the same type, run the **group build-in** command to configure a built-in group based on the device type. This group enables these clients to download the same files, such as the system software package and patch file.

Precautions

- If a client matches both a customized group (configured using the **group custom** command) and a built-in group, it prefers the files specified in the customized group.

- A maximum of 256 groups (including both built-in groups and customized groups) can be configured on the Commander.
- If you run the **undo group build-in** command without specifying *device-type*, the command deletes all the built-in groups.

Example

Configure a built-in group and specify the device type as S5732-H.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group build-in s5732-h
[HUAWEI-easyoperation-group-build-in-s5732-h]
```

2.2.47 group custom

Function

The **group custom** command configures a customized group and displays the Easy-Operation group view on the Commander.

The **undo group custom** command deletes a customized group.

By default, no customized group is configured.

Format

group custom { **mac-address** | **esn** | **ip-address** | **model** | **device-type** } *group-name*

undo group custom [{ **mac-address** | **esn** | **ip-address** | **model** | **device-type** } [*group-name*]]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a customized group.	The value is a string of 1 to 31 case-sensitive characters without spaces. The character string must start with a letter.
mac-address	Configures a MAC address-based group.	-
esn	Configures an ESN-based group.	-
ip-address	Configures an IP address-based group.	-
model	Configures a device model-based group.	-

Parameter	Description	Value
device-type	Configures a device type-based group. This parameter applies when a new device type is not defined for built-in groups on the Commander.	-

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If multiple devices on a network need to download the same file, you can configure a group for the devices on the Commander to simplify device configuration. You can configure various customized groups on the Commander according to the deployment on your network devices.

Precautions

- A maximum of 256 groups (including both built-in groups and customized groups) can be configured on the Commander.
- Customized groups can have matching rules based on MAC address, ESN, IP address, device model, and device type, listed in descending order of priority.
- Running the **undo group custom** command without any parameters will delete all the customized groups.

Example

Configure a MAC address-based customized group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test]
```

2.2.48 license

Function

The **license** command specifies a license file to be downloaded to clients.

The **undo license** command deletes the configured license file information.

Format

license *file-name*

undo license [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a license file to be downloaded to clients. The file name has an extension .dat and may contain a file path.	The value is a string of 5 to 64 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When clients need to load a license file, specify the license file on the Commander.

Precautions

You can load a license file only on modular switches. When a fixed switch serves as the client, the license file cannot be loaded even after you specify the license file information.

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

NOTICE

The names of the files to be downloaded cannot be the same as system license files. Otherwise, the upgrade fails.

Example

Specify a default license file for clients.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] license easy/test.dat
```

Specify a license file in a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] license license.dat
```

2.2.49 match

Function

The **match** command configures a matching rule for a group on the Commander.

The **undo match** command deletes a matching rule for a group on the Commander.

By default, a group has no matching rule.

Format

match mac-address *mac-address* [*mac-mask* | *mac-mask-length*]

match esn *esn*

match ip-address *ip-address* [*ip-mask* | *ip-mask-length*]

match model *model*

match device-type *device-type*

undo match mac-address [*mac-address* [*mac-mask* | *mac-mask-length*]]

undo match esn [*esn*]

undo match ip-address [*ip-address* [*ip-mask* | *ip-mask-length*]]

undo match model [*model*]

undo match device-type [*device-type*]

Parameters

Parameter	Description	Value
mac-address *mac-address*	Configures a MAC address-based matching rule. A group can have multiple MAC addresses or MAC address ranges specified. A client matches the group as long as it matches one of MAC addresses.	The value is in the H-H-H format, where each H contains four hexadecimal digits.
mac-mask	Specifies the mask of a MAC address.	The value is in the H-H-H format, where each H contains four hexadecimal digits. By default, the mask is ffff-ffff-ffff.

Parameter	Description	Value
mac-mask-length	Specifies the mask length of a MAC address.	The value is an integer that ranges from 0 to 48. By default, the mask length is 48.
esn *esn*	Configures an ESN-based matching rule. A group can have multiple ESNs specified. A client matches the group as long as it matches one of ESNs.	The value is a string of 10 to 32 case-insensitive characters without spaces.
ip-address *ip-address*	Configures an IP address-based matching rule. A group can have multiple IP addresses or IP address ranges (for example 192.168.110.0) specified. A client matches the group as long as it matches one of IP addresses.	The value is in dotted decimal notation.
ip-mask	Specifies the mask of an IP address.	The value is in dotted decimal notation. By default, the mask is 255.255.255.255.
ip-mask-length	Specifies the mask length of an IP address.	The value is an integer that ranges from 0 to 32. By default, the mask length is 32.
model *model*	Configures a device model-based matching rule.	The value is a string of 1 to 32 case-insensitive characters without spaces.
device-type *device-type*	Configures a device type-based matching rule.	The value is a string of 1 to 32 case-insensitive characters without spaces.

Views

Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After configuring a customized group on the Commander, configure matching rules for the group. A client can obtain the files specified in a group only when it matches a rule in the group.

Precautions

- A matching rule can be configured only in a customized group of the corresponding type. For example, the **match mac-address** *mac-address* command can only be used in a MAC address-based customized group.
- A MAC address-based, ESN-based, or IP address-based group each supports a maximum of 256 matching rules. The total number of group rules on the device cannot exceed 256.
- For groups created based on device models, only one matching rule can be defined for each group. The device model specified in a device model-based group must be the same as the actual device model. Otherwise, clients cannot match the group.
- For groups created based on device types, only one matching rule can be defined for each group. The device type specified in a device type-based group must be the same as the actual device type. Otherwise, clients cannot match the group.

Example

Configure two MAC address-based matching rules in a customized group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] match mac-address 00e0-fc12-3456
[HUAWEI-easyoperation-group-custom-test] match mac-address 00e0-fc12-3478
```

2.2.50 mngvlanid

Function

The **mngvlanid** command sets a management VLAN for a cluster.

The **undo mngvlanid** command restores the default management VLAN of a cluster.

By default, the management VLAN is VLAN 1.

Format

mngvlanid *vlan-id*

undo mngvlanid

Parameters

Parameter	Description	Value
vlan-id	Specifies a VLAN ID.	The value is an integer ranging from 1 to 4094.

Views

Cluster view

Default Level

2: Configuration level

Usage Guidelines

On a Commander switch, if a management VLAN is changed or the management VLAN and its corresponding VLANIF interface are deleted, the cluster is automatically deleted.

If you change the ID of the management VLAN on a client switch, the client switch automatically withdraws from the cluster.

Use the management VLAN only on the cluster and do not use the VLAN for other services such as the Rapid Ring Protection Protocol (RRPP) and multicast services. Otherwise, service functions will be adversely affected.

Example

Change the management VLAN of the device to VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] cluster
[HUAWEI-cluster] mngvlanid 2
```

2.2.51 ndp enable (interface view)

Function

The **ndp enable** command enables NDP on an interface.

The **undo ndp enable** command disables NDP on an interface.

The **ndp disable** command disables NDP on an interface.

By default, NDP is enabled on an interface.

Format

ndp enable

undo ndp enable

ndp disable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, Eth-Trunk interface view, 100GE interface view, 40GE interface view, port group view, MultiGE interface view

Default Level

2: Configuration level

Usage Guidelines

Before you enable network topology collection, run the **ndp enable** command to enable NDP on an interface.

Example

Disable NDP in the GE0/0/1 interface view.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo ndp enable
```

2.2.52 ndp enable (system view)

Function

The **ndp enable** command enables NDP globally or on an interface.

The **undo ndp enable** command disables NDP globally or on an interface.

The **ndp disable** command disables NDP globally or on an interface.

By default, NDP is enabled globally.

Format

ndp enable [**interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>]

undo ndp enable [**interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>]

ndp disable interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

ndp disable

Parameters

Parameter	Description	Value
interface *interface-type interface-number1* [**to** *interface-type interface-number2*]	Specifies the interface on which NDP is enabled or disabled. ● *interface-type interface-number1* indicates the type and number of the first interface. ● *interface-type interface-number2* indicates the type and number of the last interface. If you run the **ndp enable** command or the **undo ndp enable** command without specifying the interface, NDP is enabled or disabled globally.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before you enable network topology collection, run the **ndp enable** command to enable NDP.

Configuration Impact

If the **ndp enable** command is run more than once, all configurations take effect.

Example

Enable NDP on the GE0/0/1 interface.

```
<HUAWEI> system-view
[HUAWEI] ndp enable interface gigabitethernet 0/0/1
```

2.2.53 ndp timer aging

Function

The **ndp timer aging** command configures an aging time for NDP entries on the receiving switch.

The **undo ndp timer aging** command restores the default aging time of NDP entries on the receiving switch.

By default, the aging time of the NDP entries on the receiving switch is 180 seconds.

Format

ndp timer aging *aging-time*

undo ndp timer aging

Parameters

Parameter	Description	Value
aging-time	Specifies the aging time of the NDP entries on the receiving switch.	The value is an integer that ranges from 6 to 255, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the receiving switch does not receive NDP packets from a local switch before the aging time of the NDP entry on the receiving switch expires, the receiving switch automatically deletes the neighbor entry corresponding to the local switch.

Prerequisites

NDP has been enabled on the receiving switch.

Precautions

The aging time of the NDP entries on the receiving switch must be greater than the interval for sending NDP packets.

Example

Set the aging time of NDP entries to 175 seconds.

```
<HUAWEI> system-view
[HUAWEI] ndp timer aging 175
```

2.2.54 ndp timer hello

Function

The **ndp timer hello** command configures the interval for sending NDP packets.

The **undo ndp timer hello** command restores the default interval for sending NDP packets.

By default, the interval for sending NDP packets is 60 seconds.

Format

ndp timer hello *interval*

undo ndp timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending NDP packets.	The value is an integer that ranges from 5 to 254, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure an interval for sending NDP packets, run the **ndp timer hello** command. The NDP interface then sends NDP packets at the specified interval.

Prerequisites

NDP has been enabled on the switch.

Precautions

The interval for sending NDP packets must be less than the aging time of NDP entries on the switch.

Example

Set the interval for sending NDP packets to 55 seconds.

```
<HUAWEI> system-view
[HUAWEI] ndp timer hello 55
```

2.2.55 ndp trunk-member enable

Function

The **ndp trunk-member enable** command enables trunk member interface-based NDP.

The **undo ndp trunk-member enable** command disables trunk member interface-based NDP.

By default, trunk member interface-based NDP is disabled.

Format

ndp trunk-member enable

undo ndp trunk-member enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a local switch connects to a remote switch through a trunk link, the local switch discovers neighbors and displays NTDP topology information based on the trunk interface. To allow the local switch to obtain link information about trunk member interfaces, run the **ndp trunk-member enable** command to enable trunk member interface-based NDP. The topology information about the trunk member interfaces can then be queried on the NMS.

Prerequisites

NDP has been globally enabled using the **ndp enable** command in the system view.

Example

Enable trunk member interface-based NDP.

```
<HUAWEI> system-view
[HUAWEI] ndp enable
[HUAWEI] ndp trunk-member enable
```

2.2.56 ntdp enable (interface view)

Function

The **ntdp enable** command enables NTDP on an interface.

The **undo ntdp enable** command disables NTDP on an interface.

The **ntdp disable** command disables NTDP on an interface.

By default, NTDP is enabled on an interface.

Format

ntdp enable

undo ntdp enable

ntdp disable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, Eth-Trunk interface view, 100GE interface view, 40GE interface view, port group view, MultiGE interface view

Default Level

2: Configuration level

Usage Guidelines

Before you enable network topology collection, run the **ntdp enable** command to enable NTDP on an interface.

Example

Disable NTDP in the GE0/0/1 interface view.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo ntdp enable
```

2.2.57 ntdp enable (system view)

Function

The **ntdp enable** command enables NTDP globally.

The **undo ntdp enable** command disables NTDP globally.

The **ntdp disable** command disables NTDP globally.

By default, NTDP is enabled globally.

Format

ntdp enable

undo ntdp enable

ntdp disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before you enable network topology collection, run the **ntdp enable** command to enable NTDP globally.

Example

Enable NTDP globally.

```
<HUAWEI> system-view
[HUAWEI] ntdp enable
```

2.2.58 ntdp explore

Function

The **ntdp explore** command enables you to manually collect topology information.

Format

ntdp explore

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to initiate the process of collecting topology information on an NTDP-capable device. The NTDP-capable device can then effectively manage and monitor devices on the network in real time to reflect the network topology changes.

You can also run the **ntdp timer** command to allow a switch to automatically collect topology information at a specified interval.

Example

Manually start topology information collection.

```
<HUAWEI> ntdp explore
```

2.2.59 ntdp hop

Function

The **ntdp hop** command sets the maximum number of hops for collecting topology information through NTDP.

The **undo ntdp hop** command restores the default maximum number of hops for collecting topology information through NTDP.

By default, the maximum number of hops is 8 for collecting topology information through NTDP.

Format

ntdp hop *max-hop-value*

undo ntdp hop

Parameters

Parameter	Description	Value
max-hop-value	Specifies the maximum number of hops for collecting topology information through NTDP.	The value is an integer that ranges from 1 to 8.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the maximum number of hops for collecting topology information through NTDP is configured, topology information about switches in the hop range can be collected, which avoids collection of infinite topology information. The larger the maximum number of hops is, the more the memory of the topology collection switch is consumed.

Prerequisites

NTDP has been enabled on the switch.

Example

Set the range for collecting topology information through NTDP to 5 hops.

```
<HUAWEI> system-view
[HUAWEI] ntdp hop 5
```

2.2.60 ntdp timer

Function

The **ntdp timer** command sets the interval for collecting topology information through NTDP.

The **undo ntdp timer** command restores the default interval for collecting topology information through NTDP.

By default, the interval for collecting topology information through NTDP is 0 minutes. That means that no topology information is periodically collected.

Format

ntdp timer *interval*

undo ntdp timer

Parameters

Parameter	Description	Value
interval	Specifies the interval for collecting topology information through NTDP.	The value is an integer that ranges from 0 to 65535, in minutes. **NOTE** The Commander collects network topology information at an interval of 5 minutes; therefore, you are advised to set the interval for collecting topology information through NTDP to less than 5 minutes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the interval for collecting topology information through NTDP is set, the switch collects topology information at this interval.

Prerequisites

NTDP has been enabled on the switch.

Example

Set the interval for collecting topology information to 2 minutes.

```
<HUAWEI> system-view
[HUAWEI] ntdp timer 2
```

2.2.61 ntdp timer hop-delay

Function

The **ntdp timer hop-delay** command sets a delay after which the first interface forwards NTDP topology request packets.

The **undo ntdp timer hop-delay** command restores the default delay.

By default, the first interface forwards NTDP topology request packets after a delay of 200 milliseconds.

Format

ntdp timer hop-delay *hop-delay-time*

undo ntdp timer hop-delay

Parameters

Parameter	Description	Value
hop-delay-time	Specifies the delay after which the first interface forwards NTDP topology request packets.	The value is an integer that ranges from 1 to 1000, in milliseconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

This command takes effect only after NTDP is enabled on the switch.

Example

Set the hop delay for forwarding NTDP topology request packets to 300 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] ntdp timer hop-delay 300
```

2.2.62 ntdp timer port-delay

Function

The **ntdp timer port-delay** command sets a delay after which interfaces other than the first one forwards NTDP topology request packets.

The **undo ntdp timer port-delay** command restores the default delay.

By default, interfaces other than the first one forward NTDP topology request packets after a delay of 20 milliseconds.

Format

ntdp timer port-delay *port-delay-time*

undo ntdp timer port-delay

Parameters

Parameter	Description	Value
port-delay-time	Specifies the delay after which interfaces other than the first one forward NTDP topology request packets.	The value is an integer that ranges from 1 to 1000, in milliseconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **ntdp timer port-delay** command takes effect only after NTDP is enabled on the switch.

Example

Set the delay for interfaces other than the first one on the device to forward NTDP topology request packets to 40 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] ntdp timer port-delay 40
```

2.2.63 patch

Function

The **patch** command specifies a patch file to be downloaded to clients.

The **undo patch** command deletes the configured patch file information.

Format

patch *file-name*

undo patch [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a patch file to be downloaded to clients. The file name has an extension .pat and may contain a file path.	The value is a string of 5 to 48 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When clients need to load a patch file, specify the patch file on the Commander.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

Example

Specify a default patch file for clients.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] patch easy/test.pat
```

Specify a patch file in a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] patch patch.pat
```

2.2.64 reset easy-operation client-database

Function

The **reset easy-operation client-database** command clears the client database on the Commander.

Format

reset easy-operation client-database

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The client database contains client information that is manually configured by the administrator and learned dynamically by the Commander. When the number of clients in the client database exceeds the limit, information about new clients cannot be added to the database. To release space in the client database, use this command to clear the client database after confirming that the manually configured client information can be deleted.

Precautions

This command deletes both manually configured client information and dynamically learned client information. Before running this command, confirm that manually configured client information can be deleted. If the Commander is enabled to learn client information, it continues adding learned client information to the client database after you run this command.

Example

Clear the client database on the Commander.

```
<HUAWEI> reset easy-operation client-database
Warning: All of the database information of client and relative replace in this
device will be cleared. Continue?[Y/N]:y
<HUAWEI>
```

2.2.65 reset easy-operation client-offline

Function

The **reset easy-operation client-offline** command clears lost state clients.

Format

reset easy-operation client-offline

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The maximum number of clients managed by the Commander depends on the device specifications. If the number of clients exceeds the upper limit, information about new clients cannot be configured on the Commander. Delete the clients in the lost state that occupy the database resources for a long time.

Precautions

- If the clients automatically join the management domain of the Commander, they can be deleted.
- If the clients are configured manually, they cannot be deleted but their status changes to unknown.
- If client replacement information is configured using the **client replace** command, client IDs in the client database will not be deleted.

Example

Delete clients in the lost state from the client database.

```
<HUAWEI> reset easy-operation client-offline
Warning: All of clients which are in the lost status will be deleted. Continue?[Y/N]:y
```

2.2.66 reset ndp statistics

Function

The **reset ndp statistics** command clears NDP packet statistics from one or all the interfaces of a device.

Format

reset ndp statistics [**interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>]

Parameters

Parameter	Description	Value
interface *interface-type interface-number1* [**to** *interface-type interface-number2*]	Clears NDP packet statistics from a specified interface. ● *interface-type interface-number1* specifies the type and number of the first interface. ● *interface-type interface-number2* indicates the type and number of the last interface. When optional parameters are not specified, global statistics on NDP packets are cleared.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

If you run the **reset ndp statistics** command without setting optional parameters, the NDP packet statistics of all interfaces are cleared.

Example

Delete NDP packet statistics from all the interfaces of the device.

```
<HUAWEI> reset ndp statistics
```

2.2.67 system-software

Function

The **system-software** command specifies the name and version of the system software package to be downloaded to clients.

The **undo system-software** deletes the configured software name and version.

Format

system-software *file-name* [*version*]

undo system-software [*file-name* [*version*]]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a system software package to be downloaded to clients. The file name has an extension .cc and may contain a file path.	The value is a string of 4 to 48 case-insensitive characters without spaces. The string cannot contain the following characters: ~ * : ' " ? < > | [ ] % \ /.
version	Specifies the version of a system software package, for example, V200R023C00. If the specified software version is the same as the software version running on the client, a software upgrade will not be performed for the client.	The value is a string of 11 to 32 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When clients need to upgrade their system software, specify the required system software information on the Commander.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

Example

Specify a default system software package for clients.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] system-software easy/sV200R023C00.cc
```

Specify a system software package in a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] system-software V200R023C00.cc V200R023C00
```

2.2.68 tftp-server/sftp-server/ftp-server

Function

The **tftp-server** command configures the TFTP server IP address on the Commander.

The **sftp-server** command configures the SFTP server IP address, user name, and password on the Commander.

The **ftp-server** command configures the FTP server IP address, user name, and password on the Commander.

The **undo tftp-server** command deletes the TFTP server IP address on the Commander.

The **undo sftp-server** command deletes the SFTP server IP address, user name, and password on the Commander.

The **undo ftp-server** command deletes the FTP server IP address, user name, and password on the Commander.

By default, no file server IP address, user name, or password is configured on the Commander.

Format

tftp-server *ip-address*

{ **sftp-server** | **ftp-server** } *ip-address* [**username** *username* [**password** *password*]]

undo tftp-server [*ip-address*]

undo { **sftp-server** | **ftp-server** } [*ip-address*] [**username** *username*] [**password** *password*]

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a file server (TFTP, SFTP, or FTP server).	The value is in dotted decimal notation.
username *username*	Specifies the user name used to log in to the SFTP or FTP server.	The value is a string of 1 to 64 case-sensitive characters.

Parameter	Description	Value
password *password*	Specifies the password used to log in to the SFTP or FTP server.	The value is a case-sensitive character string. A password in plain text contains 1 to 16 characters, and a ciphertext password contains 48 characters. In the configuration file, the password is displayed in ciphertext regardless of whether it is input in plaintext or ciphertext.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Files that need to be downloaded by clients are saved in a file server. After clients obtain information from the Commander about the necessary files, the clients download the files from the file server specified on the Commander. Therefore, the file server information must be configured on the Commander.

Precautions

- If the file server is an SFTP or FTP server and has a user name and password configured, configure the same user name and password on the Commander.
- Using an SFTP server is recommended because FTP and TFTP have security risks.
- Information about only one file server can be configured. If you run this command multiple times, only the latest configuration takes effect.
- Ensure that the files required for clients have been saved on the specified file server.

Example

Specify the IP address, user name, and password of the SFTP server on the Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] sftp-server 10.10.10.5 username easyoperation password YsHsjx_202206
```

Specify the TFTP server IP address on the Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] tftp-server 10.10.10.5
```

2.2.69 topology enable

Function

The **topology enable** command enables the Commander to collect network topology information.

The **undo topology enable** command disables the Commander from collecting network topology information.

By default, the Commander is disabled from collecting network topology information.

Format

topology enable

undo topology enable

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **topology enable** command to enable the Commander to collect network topology information every 5 minutes. Based on the collected information, you can implement zero touch device deployment and automatic faulty device replacement.

Prerequisites

NDP and NTDP have been enabled.

The interval for collecting topology information through NTDP has been set.

Example

Enable network topology information collection on the Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] topology enable
```

2.2.70 topology save

Function

The **topology save** command saves network topology information collected by the Commander.

Format

topology save

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Network topology information collected by the Commander is saved only in the device memory. If the device restarts, the saved information is lost. You can run this command to save the collected network topology information in the flash memory and name it **ezop-topo.xml**.

Prerequisites

Network topology information collection has been enabled.

Precautions

If you run this command multiple times, only the latest configuration takes effect.

Example

Save the current network topology information collected by the Commander.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] topology save
Warning: This command will record the information of topology. Continue? [Y/N]:y
```

2.2.71 undo group

Function

The **undo group** command deletes all groups.

Format

undo group

Parameters

None

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

This command deletes all the groups on a switch, including built-in groups and customized groups.

Example

Delete all groups.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] undo group
Warning: All of the group configuration will be cleared. Continue?[Y/N]:y
```

2.2.72 upgrade group

Function

The **upgrade group** command starts a batch upgrade on the Commander.

Format

upgrade group [*group-name*] &<1-15>

Parameters

Parameter	Description	Value
group-name	Specifies a group name. The Commander starts a batch upgrade for all the clients that match the specified group. A maximum of 15 groups can be specified for a batch upgraded. The group names are separated by a space.	The value is a string of 1 to 31 case-sensitive characters without spaces. The character string must start with a letter.

Views

Easy-Operation view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the groups, files to be loaded, and file activation mode are specified on the Commander, you can run this command to start a batch upgrade for clients.

Precautions

- If *group-name* is not specified, a batch upgrade is performed on all clients matching all the groups on the Commander.
- Before running this command, ensure that configurations of the clients have been saved.
- If a client is a stack system, its system MAC address will change after the upgrade, because the master switch changes. In this case, the client ID of the stack system is displayed as LOST on the Commander. To avoid this problem, configure the stack system MAC address to the MAC address of a member switch.

Example

Start a batch upgrade for clients matching all the groups.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] upgrade group
Warning: This command will start the upgrade process of all groups and clients i
n these groups may reboot. Ensure that configurations of the clients have been s
aved. Continue?[Y/N]:y
```

Start a batch upgrade for clients matching specified groups.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] upgrade group test1 test2 test3
Warning: This command will start the upgrade process of the group and clients in
 this group may reboot. Ensure that configurations of the clients have been save
d. Continue?[Y/N]:y
```

2.2.73 web-file

Function

The **web-file** command specifies a web page file to be downloaded to clients.

The **undo web-file** command deletes the configured web page file information.

Format

web-file *file-name*

undo web-file [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a web page file to be downloaded to clients. The file name has an extension .web.7z or .web.zip and may contain a file path.	The value is a string of 8 to 64 case-insensitive characters without spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When clients need to load a web page file, specify the web page file on the Commander.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

Example

Specify a default web page file for clients.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] web-file easy/test.web.7z
```

Specify a web page file in a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] web-file test.web.7z
```

2.2.74 module

Function

The **module** command specifies a module file to be downloaded.

The **undo module** command deletes information about the module file to be downloaded.

Format

module *file-name*

undo module [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name (*.mod) of a module file to be loaded to clients. The file path can be specified.	The value is a string of 5 to 48 case-insensitive characters. It cannot contain spaces.

Views

Easy-Operation view, Easy-Operation group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a client needs to load a module file, the module file needs to be specified.

Precautions

Information about the files to be downloaded can be set in the Easy-Operation view or Easy-Operation group view:

- The file information set in the Easy-Operation view is the default file information. If no file information is set in the group database or client database, the group or client uses the default file information.
- The files specified in the Easy-Operation group view can be downloaded by the clients that match the group.

Example

Specify a default module file.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] module easy/test.mod
```

Specify a module file in a MAC address-based group.

```
<HUAWEI> system-view
[HUAWEI] easy-operation
[HUAWEI-easyoperation] group custom mac-address test
[HUAWEI-easyoperation-group-custom-test] module test.mod
```

2.3 USB-based Deployment Configuration Commands

2.3.1 Command Support

Only the following switch models support USB-based deployment:

S1730S-S1, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S.

2.3.2 display device usb-deployment configuration

Function

The **display device usb-deployment configuration** command displays the configuration of USB-based deployment.

Format

display device usb-deployment configuration

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

After the USB-based deployment configuration is completed, you can run this command to view related configuration information, including whether USB-based deployment is enabled, configuration file encryption password, HMAC key, and whether HMAC check is enabled.

Example

Display the configuration of USB-based deployment.

```
<HUAWEI> display device usb-deployment configuration
USB-deployment: disable
Config-file password: ******
HMAC: enable
Hmac-key: --
```

Table 2-19 Description of the **display device usb-deployment configuration** command output

Item	Description
USB-deployment	Whether USB-based deployment is enabled. - disable: indicates that USB-based deployment is disabled on an interface. - enable: indicates that USB-based deployment is enabled on an interface.
Config-file password	Configuration file encryption password. When no password is configured, "--" is displayed.
HMAC	Whether HMAC check is enabled. - disable: indicates that HMAC check is disabled on an interface. - enable: indicates that HMAC check is enabled on an interface.
Hmac-key	HMAC key for HMAC verification. When no HMAC key is configured, "--" is displayed.

2.3.3 set device usb-deployment disable

Function

The **set device usb-deployment disable** command disables the USB-based deployment function.

The **undo set device usb-deployment disable** command enables the USB-based deployment function.

By default, the USB-based deployment function is disabled.

Format

set device usb-deployment disable

undo set device usb-deployment disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

By default, the USB-based deployment function is disabled. However, if a device has no configuration, the USB-based deployment function is always enabled.

NOTE

On an unconfigured switch, both the configuration files for current startup and next startup are not specified. That is, the Startup saved-configuration file and Next startup saved-configuration file are NULL in the

display startup command output.

Example

Disable the USB-based deployment function.

```
<HUAWEI> system-view
[HUAWEI] set device usb-deployment disable
```

Enable the USB-based deployment function.

```
<HUAWEI> system-view
[HUAWEI] undo set device usb-deployment disable
Warning: The function of USB deployment in this device will be enabled. Continue
? [Y/N]:y
```

2.3.4 set device usb-deployment config-file password

Function

The **set device usb-deployment config-file password** command configures an encryption password for the configuration file used in USB-based deployment.

The **undo set device usb-deployment config-file password** command deletes the encryption password for the configuration file used in USB-based deployment.

By default, no encryption password is configured.

NOTE

If upgrade files for USB-based deployment include a configuration file, it is recommended that you run this command to configure an encryption password for the configuration file and compress the configuration file using the configured password before saving it in the USB flash drive. This configuration improves security.

Format

set device usb-deployment config-file password *password*

undo set device usb-deployment config-file password

Parameters

Parameter	Description	Value
password	Specifies the password used for encrypting the configuration file.	The value is a string of 8 to 64 characters or a string of 48 to 108 characters. ● If the password is in plain text, it is a string of 8 to 64 case-sensitive characters and must be a combination of at least two of the following: letters, digits, and special characters. ● If the password is in cipher text, it is a string of 48 to 108 characters. The password is displayed in cipher text in the configuration file regardless of whether you enter it in plain or cipher text.

Views

System view

Default Level

3: Management level

Usage Guidelines

If a password is configured using the **set device usb-deployment config-file password** *password* command, you need to compress and encrypt the configuration file (if any) with this password and save the compressed file to a specified directory in the USB flash drive. The device cannot compress a .zip configuration file. If such a configuration file is used, decompress the file, use the configured password to compress it, and save it in the USB flash drive.

A user with a level lower than the management level cannot query the password configured using this command. If this user query the configuration file, the password is displayed as asterisks (******).

Example

Set the encryption password for the configuration file used in USB-based deployment to **Pwd123456**.

```
<HUAWEI> system-view
[HUAWEI] set device usb-deployment config-file password Pwd123456
```

2.3.5 set device usb-deployment hmac-key

Function

The **set device usb-deployment hmac-key** command configures an HMAC key for HMAC verification during USB-based deployment.

The **undo set device usb-deployment hmac-key** command deletes the HMAC key used for HMAC verification during USB-based deployment.

By default, no HMAC key is configured for HMAC verification.

Format

set device usb-deployment hmac-key *hmac-key*

undo set device usb-deployment hmac-key

Parameters

Parameter	Description	Value
hmac-key	Specifies an HMAC key for HMAC verification during USB-based deployment.	The value is a string of 8 to 64 or 68 to 108 characters. ● A cleartext key is a string of 8 to 64 case-sensitive characters. It is recommended that the key be a combination of at least two of the following: uppercase letters A to Z, lowercase letters a to z, digits, and special characters. ● A ciphertext key is a string of 68 to 108 characters. In the configuration file, a password is displayed in cipher text regardless of whether it is entered in clear text or cipher text.

Views

System view

Default Level

3: Management level

Usage Guidelines

If upgrade files include a configuration file, you can enable HMAC verification to ensure validity of the configuration file to be loaded. After the **set device usb-deployment hmac** command is run to enable HMAC verification for the configuration file during USB-based deployment, run the **set device usb-deployment hmac-key** command to configure an HMAC key for HMAC verification so that the device calculates the HMAC value of the configuration file and then compares the value with the HMAC field value in the index file. If the two values are the same, the configuration file is valid and loaded to the device for USB-based deployment. If the two values are different, the configuration file is invalid and cannot be loaded for USB-based deployment.

A user at a level lower than the management level cannot check the HMAC key configured using this command. If this user checks the configuration file, the HMAC key is displayed as ******.

Example

Configure an HMAC key for HMAC verification during USB-based deployment.

```
<HUAWEI> system-view
[HUAWEI] set device usb-deployment hmac-key huawei@123456852369741236553424654643213
```

2.3.6 set device usb-deployment hmac

Function

The **set device usb-deployment hmac** command enables hashed message authentication code (HMAC) check for the configuration file used for USB-based deployment.

The **undo set device usb-deployment hmac** command disables HMAC check for the configuration file used for USB-based deployment.

By default, HMAC check is disabled.

NOTE

If upgrade files for USB-based deployment include a configuration file, it is recommended that you enable HMAC check to improve security of the configuration file.

Format

set device usb-deployment hmac

undo set device usb-deployment hmac

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Prerequisites

Before enabling the HMAC check function, run the **set device usb-deployment config-file password** command to configure an encryption password for the configuration file used for USB-based deployment.

Applications

If upgrade files for USB-based deployment include a configuration file, you can enable HMAC check to ensure validity of the configuration file to be loaded. After HMAC check is enabled on a device, the device uses the password configured by the **set device usb-deployment config-file password** command to calculate the HMAC for the configuration file, and compares the calculated value with the HMAC field value in the index file. If the two values are the same, the configuration file is considered valid and loaded to the device. If not, the configuration file is considered invalid and cannot be loaded.

Example

Enable HMAC check for the configuration file used for USB-based deployment.

```
<HUAWEI> system-view
[HUAWEI] set device usb-deployment hmac
```

2.3.7 set device usb-deployment password

Function

The **set device usb-deployment password** command sets an authentication password for USB-based deployment.

The **undo set device usb-deployment password** command deletes the authentication password for USB-based deployment.

Format

set device usb-deployment password cipher *password*

set device usb-deployment password *password*

undo set device usb-deployment password

Parameters

Parameter	Description	Value
cipher *password*	Specifies the authentication password for USB-based deployment.	The value is a cipher text string of 8 to 16 or 68 characters.
password	Specifies the authentication password for USB-based deployment.	The value is a cipher text string of 8 to 16 or 68 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

A user with a level lower than the management level cannot query the password configured using this command. If this user query the configuration file, the password is displayed as asterisks (******).

Example

Delete the authentication password for USB-based deployment.

```
<HUAWEI> system-view
[HUAWEI] undo set device usb-deployment password
```

2.4 First Login Commands

2.4.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.4.2 clock datetime

Function

The **clock datetime** command sets the current date and time on a switch.

Format

clock datetime *HH:MM:SS YYYY-MM-DD*

Parameters

Parameter	Description	Value
HH:MM:SS	Specifies the current time on a switch.	*HH* specifies the hour, which is an integer ranging from 0 to 23. *MM* specifies the minute, which is an integer ranging from 0 to 59. *SS* specifies the second, which is an integer ranging from 0 to 59.
YYYY-MM-DD	Specifies the current date (year, month, and day) on the switch.	*YYYY* specifies the year, which is an integer ranging from 2000 to 2037. *MM* specifies the month, which is an integer ranging from 1 to 12. *DD* specifies the day, which is an integer ranging from 1 to 31.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In the scenario where accurate absolute time is required, the current date and time must be set on a switch.

Prerequisite

The time zone and daylight saving time have been configured using the **clock timezone** and **clock daylight-saving-time** commands. If the time zone and daylight saving time are not configured, the **clock datetime** command sets a UTC time.

Precautions

- The specified time must be in 24-hour format. If you do not specify *MM* and *SS*, their values are 0. You must enter at least one digit to specify *HH*. For example, when you enter 0, the time is 00:00:00.
- The specified year must be a four-digit number and the specified month and day can be a one-digit number. For example, when you enter 2012-9-1, the time is 2012-09-01.
- If the device is configured to restart at a specified time and if the system time is changed to be more than 10 minutes later than the specified restart time, the scheduled restart function will be disabled.

NOTE

The valid time range is based on the UTC, and this command sets the local time. If the DST or time zone is specified in the current environment, the system automatically converts the local time to the UTC.

For example, if you set the time zone to GMT+8 and the local date to 2000-1-1, the UTC converted equals to the local date minus eight hours, which is 1999-12-31. However, the valid date range is 2000 to 2037. As a result, the validity check fails, and date setting fails.

Example

Set the current time and date of the system to 0:1:2 2012-01-01.

```
<HUAWEI> clock datetime 0:1:2 2012-01-01
```

2.4.3 clock daylight-saving-time

Function

The **clock daylight-saving-time** command sets the name, start time, and end time of the daylight saving time (DST).

The **undo clock daylight-saving-time** command cancels the DST settings.

By default, DST is not used.

Format

clock daylight-saving-time *time-zone-name* **one-year** *start-time start-date end-time end-date offset*

clock daylight-saving-time *time-zone-name* **repeating** *start-time* { { **first** | **second** | **third** | **fourth** | **last** } *weekday month* | *start-date1* } *end-time* { { **first** | **second** | **third** | **fourth** | **last** } *weekday month* | *end-date1* } *offset* [*start-year* [*end-year*]]

undo clock daylight-saving-time

Parameters

Parameter	Description	Value
time-zone-name	Specifies the name of the DST zone.	The value is a string of 1 to 32 case-sensitive characters without spaces.
one-year	Specifies absolute DST.	-
repeating	Specifies periodic DST.	-
start-time	Specifies the DST start time.	The start time is in 24-hour format *HH:MM*. *HH* specifies the hour, which is an integer ranging from 0 to 23. *MM* specifies the minute, which is an integer ranging from 0 to 59. If *MM* is not specified, DST starts on the hour. You must enter at least one digit to specify *HH*. For example, when you enter 0, the start time is 00:00.
start-date	Specifies the DST start date.	The start date is in the format *YYYY-MM-DD*. *YYYY* specifies the year, which is an integer ranging from 2000 to 2099, *MM* specifies the month, which is an integer ranging from 1 to 12, and *DD* specifies the day, which is an integer ranging from 1 to 31.

Parameter	Description	Value
end-time	Specifies the DST end time.	The end time is in 24-hour format *HH:MM*. *HH* specifies the hour, which is an integer ranging from 0 to 23. *MM* specifies the minute, which is an integer ranging from 0 to 59. If *MM* is not specified, DST starts on the hour. You must enter at least one digit to specify *HH*. For example, when you enter 0, the start time is 00:00.
end-date	Specifies the DST end date.	The end date is in the format *YYYY-MM-DD*. *YYYY* specifies the year, which is an integer ranging from 2000 to 2099, *MM* specifies the month, which is an integer ranging from 1 to 12, and *DD* specifies the day, which is an integer ranging from 1 to 31.
first	Specifies the first workday in a month.	-
second	Specifies the second workday in a month.	-
third	Specifies the third workday in a month.	-
fourth	indicates the fourth workday in a month.	-
last	Specifies the last workday in a month.	-
weekday	Specifies a day of the week.	The value is **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, **Sat**, or **Sun**.
month	Specifies a month.	The value is **Jan**, **Feb**, **Mar**, **Apr**, **May**, **Jun**, **Jul**, **Aug**, **Sep**, **Oct**, **Nov**, or **Dec**.

Parameter	Description	Value
start-date1	Specifies the DST start date.	The start date is in the format *MM-DD*. *MM* specifies the month, which is an integer ranging from 1 to 12, and *DD* specifies the day, which is an integer ranging from 1 to 31.
end-date1	Specifies the DST end date.	The end date is in the format *MM-DD*. *MM* specifies the month, which is an integer ranging from 1 to 12, and *DD* specifies the day, which is an integer ranging from 1 to 31.
offset	Specifies the DST offset.	The offset is in 24-hour format *HH:MM*. *HH* specifies the hour, which is an integer ranging from 0 to 2. *MM* specifies the minute, which is an integer ranging from 0 to 59. If *MM* is not specified, the offset is the specified hours. You must enter at least one digit to specify *HH*. The offset should be shorter than or equal to 2 hours.
start-year	Specifies the start year.	The start year is in the format *YYYY* and ranges from 2000 to 2099.
end-year	Specifies the end year.	The end year is in the format *YYYY* and ranges from 2000 to 2099.

3: Management level

Usage Guidelines

Usage Scenario

DST, also referred to as summer time, is a convention intended to save resources. In high latitude areas, sunrise time is earlier during summer than it is during winter. To reduce use of incandescent lighting in the evenings and save energy, clocks are adjusted forward one hour.

Users can customize the DST zone according to their countries' or regions' convention. In addition, users can set how far ahead clocks are adjusted forward, usually an hour. With DST enabled, when it is time to start DST, the system time is adjusted according to the user-specified DST. When it is time to end DST, the system time automatically returns to the original time.

Configuration Impact

To configure DST, note the following:

- The time in logs and debugging information uses the local time adjusted based on the time zone and the configured DST.
- The time in the output of the **display** commands uses the local time adjusted based on the time zone and the configured DST.

To remove configurations for DST, note the following:

- If DST has already taken effect when you remove the configurations, the device will adjust its clock by subtracting the value of the *offset* parameter from the current time.
- If DST has not taken effect, removing the configurations will not affect the system time.

Precautions

- The DST is configured in the summer. The DST duration ranges from one day to one year.
- You can configure the start time and end time for periodic DST in one of the following modes: date+date, week+week, date+week, and week+date.
- When you run the **clock daylight-saving-time** command in either the user or system view, the configuration files are both generated in the system view. You are advised to run this command in the system view.

Example

Set periodic DST.

```
<HUAWEI> system-view
[HUAWEI] clock daylight-saving-time bj repeating 0 first sun jan 0 first sun apr 2 2009 2009
```

Set periodic DST by day.

```
<HUAWEI> system-view
[HUAWEI] clock daylight-saving-time bj repeating 12:11 1-1 1:0 3-4 1
```

Set absolute DST.

```
<HUAWEI> system-view
[HUAWEI] clock daylight-saving-time bj one-year 12:11 2010-10-2 1:00 2010-11-4 1
```

2.4.4 clock timezone

Function

The **clock timezone** command sets the local time zone.

The **undo clock timezone** command deletes the local time zone.

By default, the system uses the Coordinated Universal Time (UTC) time zone.

Format

clock timezone *time-zone-name* { **add** | **minus** } *offset*

undo clock timezone

Parameters

Parameter	Description	Value
time-zone-name	Specifies the time zone name.	The name is a string of 1 to 32 case-sensitive characters without spaces.
add	Specifies the offset from the UTC for the time zone specified by *time-zone-name*. That is, the sum of the default UTC time zone and *offset* is equal to the time zone specified by *time-zone-name*.	-
minus	Specifies the offset from the UTC for the time zone specified by *time-zone-name*. That is, the remainder obtained by subtracting *offset* from the default UTC time zone is equal to the time zone specified by *time-zone-name*.	-

Parameter	Description	Value

offset	Specifies the offset from the UTC.	Format: HH:MM:SS
		- *HH* specifies the hour.
		  – If the local time is earlier than the UTC, the value is an integer ranging from 0 to 14.
		  – If the local time is later than the UTC, the value is an integer ranging from 0 to 12.
		- *MM* and *SS* specify the minute and second respectively, and both range from 0 to 59.
		- When *HH* is set to the maximum value, the *MM* and *SS* values must be 0.

Views

User view, System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The system clock is the time indicated by the system timestamp. Because the rules governing local time differ in different regions, the system clock can be configured to comply with the rules of any given region.

System clock = UTC + Time zone offset + DST offset

To ensure normal communication between devices, set an accurate system clock. You can run the **clock timezone** and **clock daylight-saving-time** commands to set the time zone and DST offsets.

Configuration Impact

System time adjustment may affect the timing restart function. If you must adjust the system time after the timing restart function is enabled, pay attention to the impact of system time adjustment on the timing restart function:

- If the system time is changed to less than 10 minutes after the scheduled restart time, the system restarts immediately.
- If the system time is changed to 10 minutes or more after the scheduled restart time, the timing restart function is disabled.
- If the system time is changed to 720 hours earlier than the scheduled restart time, the timing restart function is disabled.

Precautions

- The specified time must be in 24-hour format. If you do not specify *MM* and *SS*, their values are 0. You must enter at least one digit to specify *HH*. For example, when you enter 0, the time is 00:00:00.
- After configuring the local time zone, run the **display clock** command to view the configuration. The time in logs and diagnostic information uses the local time adjusted based on the time zone and DST.
- When you run the **clock timezone** command in either the user or system view, the configuration files are both generated in the system view. You are advised to run this command in the system view.
- Executing the **clock timezone** command takes about 3 seconds.

Example

Set the local time zone name for Beijing China to BJ.

If the default UTC is London time 2012-12-01 00:00:00, Beijing time is London time plus 08:00 because the offset from UTC is 8 hours.

```
<HUAWEI> clock datetime 0:0:0 2012-12-01
<HUAWEI> system-view
[HUAWEI] clock timezone BJ add 08:00:00
```

2.4.5 display calendar

Function

The **display calendar** command displays the calendar of the current month or a specified month in a specified year.

Format

display calendar [*month* [*year*]]

Parameters

Parameter	Description	Value
month	Specifies the month for which the calendar is displayed.	The value is a character string. The values and their meanings are as follows: - **Jan**: January - **Feb**: February - **Mar**: March - **Apr**: April - **May**: May - **Jun**: June - **Jul**: July - **Aug**: August - **Sep**: September - **Oct**: October - **Nov**: November - **Dec**: December
year	Specifies the year for which the calendar is displayed.	The value is an integer that ranges from 2000 to 2099.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring the current date and time on the switch using the **clock datetime** command, you can run the **display calendar** command to view calendar information.

If no month or year is specified, the calendar of the current month is displayed by default. If only month but not year is specified, the calendar of the specified month in the current year is displayed.

Example

Display the calendar of the current month.

```
<HUAWEI> display calendar
     November    2012
 Sun Mon Tue Wed Thu Fri Sat
                  1   2   3
  4   5   6   7   8   9  10
 11  12  13  14  15  16  17
```

```
 18  19  20  21  22  23  24
 25  26  27  28  29  30
Today is 16 November 2012.
```

Display the calendar of May 2008.

```
<HUAWEI> display calendar May 2008
         May    2008
 Sun Mon Tue Wed Thu Fri Sat
                       1   2   3
   4   5   6   7   8   9  10
  11  12  13  14  15  16  17
  18  19  20  21  22  23  24
  25  26  27  28  29  30  31
Today is 16 November 2012.
```

Sat	Saturday

2.4.6 display clock

Function

The **display clock** command displays the current date and clock setting.

Format

display clock [**utc**]

Parameters

Parameter	Description	Value
utc	Indicates that the clock is adjusted to the Coordinated Universal Time (UTC).	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display clock** command to view the system date and clock setting and adjust the setting if necessary.

Precautions

The system clock is set using the **clock datetime**, **clock timezone**, and **clock daylight-saving-time** commands.

- If the three commands are not used, the original system clock is displayed after you run the **display clock** command.
- You can use any combination of the three commands to configure the system time. **Table 2-21** lists the formats of the configured time.

The table assumes that the original system time is 08:00:00 on January 1, 2010.

- 1: indicates that the **clock datetime** command is used, in which the current time and date is *date-time*.
- 2: indicates that the **clock timezone** command is used, in which the time zone parameter is set and the time offset is *zone-offset*.
- 3: indicates that the **clock daylight-saving-time** command is used, in which the DST parameters are set and the time offset is *offset*.
- [1]: indicates that the **clock datetime** command is optional.

Table 2-21 System clock setting examples

Action	System Time Configuration	Example
1	*date-time*	Command: **clock datetime 8:0:0 2011-11-12** Configured system time: 2011-11-12 08:00:06 Saturday Time Zone(DefaultZoneName) : UTC
2	Original system time ± *zone-offset*	Command: **clock timezone BJ add 8** Configured system time: 2010-01-01 16:00:30+08:00 Friday Time Zone(BJ) : UTC+08:00
1, 2	*date-time* ± *zone-offset*	Commands: **clock datetime 8:0:0 2011-11-12** and **clock timezone BJ add 8** Configured system time: 2011-11-12 16:00:10+08:00 Saturday Time Zone(BJ) : UTC+08:00

Action	System Time Configuration	Example
[1], 2, 1	*date-time*	Commands: **clock timezone NJ add 8** and **clock datetime 9:0:0 2011-11-12** Configured system time:
3	If the original system time is not in the DST segment, the original system time is displayed.	Command: **clock daylight-saving-time BJ one-year 6:0 2011-8-1 6:0 2011-10-01 1** Configured system time:
	If the original system time is in the DST segment, the configured system time is the original system time plus *offset*.	Command: **clock daylight-saving-time BJ one-year 6:0 2010-1-1 6:0 2010-9-1 2** Configured system time:
1, 3	If *date-time* is not in the DST segment, the configured system time is *date-time*.	Commands: **clock datetime 9:0:0 2011-11-12** and **clock daylight-saving-time BJ one-year 6:0 2012-8-1 6:0 2012-10-01 1** Configured system time:

[1], 2, 1

```
2011-11-12 09:00:07+08:00
Saturday
Time Zone(NJ) : UTC+08:00
```

3

```
2010-01-01 08:00:16
Friday
Time Zone(DefaultZoneName) : UTC
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2011
        End year    : 2011
        Start time  : 08-01 06:00:00
        End time    : 10-01 06:00:00
        Saving time : 01:00:00
```

```
2010-01-01 10:00:26+02:00 DST
Friday
Time Zone(BJ) : UTC
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2010
        End year    : 2010
        Start time  : 01-01 06:00:00
        End time    : 09-01 06:00:00
        Saving time : 02:00:00
```

1, 3

```
2011-11-12 09:00:26
Saturday
Time Zone(DefaultZoneName) : UTC
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2012
        End year    : 2012
        Start time  : 08-01 06:00:00
        End time    : 10-01 06:00:00
        Saving time : 01:00:00
```

Action	System Time Configuration	Example
	If *date-time* is in the DST segment, the configured system time is *date-time* +*offset*.	Commands: **clock datetime 9:0:0 2011-11-12** and **clock daylight-saving-time BJ one-year 9:0 2011-11-12 6:0 2011-12-01 2** Configured system time:

```
2011-11-12 11:02:21 DST
Saturday
Time Zone(BJ) : UTC
Daylight saving time :
        Name         : BJ
        Repeat mode : one-year
        Start year  : 2011
        End year    : 2011
        Start time  : 11-12 09:00:00
        End time    : 12-01 06:00:00
        Saving time : 02:00:00
```

Action	System Time Configuration	Example
[1], 3, 1	If *date-time* is not in the DST segment, the configured system time is *date-time*.	Commands: **clock daylight-saving-time BJ one-year 6:0 2012-8-1 6:0 2012-10-01 1** and **clock datetime 9:0 2011-11-12** Configured system time:

```
2011-11-12 09:00:02
Saturday
Time Zone(DefaultZoneName) : UTC
Daylight saving time :
        Name         : BJ
        Repeat mode : one-year
        Start year  : 2012
        End year    : 2012
        Start time  : 08-01 06:00:00
        End time    : 10-01 06:00:00
        Saving time : 01:00:00
```

Action	System Time Configuration	Example
	If *date-time* is in the DST segment, the configured system time is *date-time*.	Commands: **clock daylight-saving-time BJ one-year 1:0 2011-1-1 1:0 2011-9-1 2** and **clock datetime 3:0 2011-1-1** Configured system time:

```
2011-01-01 03:00:19 DST
Saturday
Time Zone(BJ) : UTC
Daylight saving time :
        Name         : BJ
        Repeat mode : one-year
        Start year  : 2011
        End year    : 2011
        Start time  : 01-01 01:00:00
        End time    : 09-01 01:00:00
        Saving time : 02:00:00
```

Action	System Time Configuration	Example
2, 3 or 3, 2	If the result of original system time ± *zone-offset* is not in the DST segment, the configured system time is equal to the original system time ± *zone-offset*.	Commands: **clock timezone BJ add 8** and **clock daylight-saving-time BJ one-year 6:0 2011-1-1 6:0 2011-9-1 2** Configured system time:
	If the result of original system time ± *zone-offset* is in the DST segment, the configured system time is equal to the original system time ± *zone-offset* ± *offset*.	Commands: **clock daylight-saving-time BJ one-year 1:0 2010-1-1 1:0 2010-9-1 2** and **clock timezone BJ add 8** Configured system time:
1, 2, 3 or 1, 3, 2	If the value of *date-time* ± *zone-offset* is not in the DST segment, the configured system time is equal to *date-time* ± *zone-offset*.	Commands: **clock datetime 8:0:0 2011-11-12**, **clock timezone BJ add 8**, and **clock daylight-saving-time BJ one-year 6:0 2012-1-1 6:0 2012-9-1 2** Configured system time:

        Start year  : 2010
        End year    : 2010
        Start time  : 01-01 01:00:00
        End time    : 09-01 01:00:00
        Saving time : 02:00:00
```

```
2011-11-12 08:01:40+08:00
Saturday
Time Zone(BJ) : UTC+08:00
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2012
        End year    : 2012
        Start time  : 01-01 06:00:00
        End time    : 09-01 06:00:00
        Saving time : 02:00:00
```

Action	System Time Configuration	Example
	If the value of *date-time* ± *zone-offset* is in the DST segment, the configured system time is equal to *date-time* ± *zone-offset* + *offset*.	Commands: **clock datetime 8:0:0 2011-1-1**, **clock daylight-saving-time BJ one-year 6:0 2011-1-1 6:0 2011-9-1 2** and **clock timezone BJ add 8** Configured system time:

```
2011-01-01 10:00:43+08:00 DST
Saturday
Time Zone(BJ) : UTC+08:00
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2011
        End year    : 2011
        Start time  : 01-01 06:00:00
        End time    : 09-01 06:00:00
        Saving time : 02:00:00
```

Action	System Time Configuration	Example
[1], 2, 3, 1 or [1], 3, 2, 1	If *date-time* is not in the DST segment, the configured system time is *date-time*.	Commands: **clock daylight-saving-time BJ one-year 6:0 2012-1-1 6:0 2012-9-1 2**, **clock timezone BJ add 8**, and **clock datetime 8:0:0 2011-11-12** Configured system time:

```
2011-11-12 08:00:03+08:00
Saturday
Time Zone(BJ) : UTC+08:00
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2012
        End year    : 2012
        Start time  : 01-01 06:00:00
        End time    : 09-01 06:00:00
        Saving time : 02:00:00
```

Action	System Time Configuration	Example
	If *date-time* is in the DST segment, the configured system time is *date-time*.	Commands: **clock timezone BJ add 8**, **clock daylight-saving-time BJ one-year 1:0 2011-1-1 1:0 2011-9-1 2**, and **clock datetime 3:0:0 2011-1-1** Configured system time:

```
2011-01-01 03:00:03+08:00 DST
Saturday
Time Zone(BJ) : UTC+08:00
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2011
        End year    : 2011
        Start time  : 01-01 01:00:00
        End time    : 09-01 01:00:00
        Saving time : 02:00:00
```

Example

Display the current system date and time.

```
<HUAWEI> display clock
```

```
2013-02-07 15:34:02+08:00
Thursday
Time Zone(BJ) : UTC+08:00
Daylight saving time :
        Name        : BJ
        Repeat mode : one-year
        Start year  : 2013
        End year    : 2013
        Start time  : 06-01 00:00:00
        End time    : 09-01 00:00:00
        Saving time : 02:00:00
```

Display the UTC of the system.

```
<HUAWEI> display clock utc
2012-04-23 15:11:20
Monday
```

Table 2-22 Description of the **display clock** command output

Item	Description
Time Zone	Time zone.
Daylight saving time	DST.
Name	DST name.
Repeat mode	DST mode. ● one-year: absolute DST ● repeat: periodic DST
Start year	Year from which DST starts.
End year	Year when DST ends.
Start time	Time when DST starts.
End time	Time when DST ends.
Saving time	Storage time.

2.4.7 display sys-netid

Function

The **display sys-netid** command displays the name of a network element (NE).

Format

display sys-netid

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the NE name. If the NE name is not set on the device, the system displays a message indicating that the NE name is not set.

Example

Display the NE name.

```
<HUAWEI> display sys-netid
Info: The NetID is: huawei-1234567890
```

2.4.8 sysname

Function

The **sysname** command sets a device host name.

The **undo sysname** command restores the default device host name.

By default, the device host name is HUAWEI.

Format

sysname *host-name*

undo sysname

Parameters

Parameter	Description	Value
host-name	Specifies a host name.	The value is a string of 1 to 246 case-sensitive characters. It can contain spaces.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Changing the host name of a device affects the CLI prompt. For example, if the host name of the device is HUAWEI, the prompt of the user view is <HUAWEI>.

Example

Set the host name of the device to HUAWEIA.

```
<HUAWEI> system-view
[HUAWEI] sysname HUAWEIA
[HUAWEIA]
```

2.4.9 sys-netid

Function

The **sys-netid** command sets a name for a network element (NE).

The **undo sys-netid** command deletes the NE name.

By default, no NE name is set.

Format

sys-netid *netid*

undo sys-netid

Parameters

Parameter	Description	Value
netid	Specifies the NE name.	The value is a string of 16 to 240 case-sensitive characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network management tool needs to obtain the name of an NE, you can run the **sys-netid** command to set the NE name. The NE name is the same as that obtained from the MIB object hwEntitySystemNetID.

Precautions

If you run the **sys-netid** command multiple times, only the latest configuration takes effect.

Example

Set the NE name.

```
<HUAWEI> system-view
[HUAWEI] sys-netid huawei-1234567890
Info: NetID set successfully.
Info: New NetID is: huawei-1234567890.
```

2.5 UI Configuration Commands

2.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.5.2 acl (user interface view)

Function

The **acl** command uses an ACL to restrict login rights of users on a terminal.

The **undo acl** command cancels the configuration.

By default, login rights are not restricted.

Format

acl [**ipv6**] { *acl-number* | *acl-name* } { **inbound** | **outbound** }

undo acl [**ipv6**] [*acl-number* | *acl-name*] { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
ipv6	Indicates an ACL6 number.	-
acl-number	Specifies the number of an ACL.	The value is an integer ranging from 2000 to 3999. ● 2000-2999: restricts the source address using the basic ACL. ● 3000-3999: restricts the source and destination addresses using the advanced ACL.

Parameter	Description	Value
acl-name	Specifies the name of an ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter. **NOTE** When the number of the ACL configured using the **acl name** command ranges from 2000 to 3999, the *acl-name* parameter can be successfully delivered using the **acl (user interface view)** command. ● 2000-2999: restricts the source address using the basic ACL. ● 3000-3999: restricts the source and destination addresses using the advanced ACL.
inbound	Restricts users with an address or within an address segment from logging in to a device.	-
outbound	Restricts users who have logged in to a device from logging in to other devices.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command restricts the login rights of a user interface based on the source IP address, destination IP address, source port, destination port, VPN instance, or packets whose protocol type is TCP. You can use this command to permit or deny access to a destination or from a source.

Prerequisites

An ACL has been configured using the **acl (system view)** and **rule (basic ACL view)** commands or using **acl (system view)** and **rule (advanced ACL view)** commands.

If no rule is configured, login rights on the user interface are not restricted when the **acl** command is run.

Precautions

After the configurations of the ACL take effect, all users on the user interface are restricted by the ACL.

You can configure all of the following ACL types: IPv4 inbound, IPv4 outbound, IPv6 inbound, and IPv6 outbound on a user interface. Only one ACL of each type can be configured on a user interface, and only the latest configuration of an ACL takes effect.

Console interface does not support this command.

Example

Restrict the Telnet login rights on user interface VTY 0 using an ACL.

```
<HUAWEI> system-view
[HUAWEI] acl 3001
[HUAWEI-acl-adv-3001] rule deny tcp destination-port eq telnet
[HUAWEI-acl-adv-3001] quit
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] acl 3001 outbound
```

Remove the restriction on the Telnet login rights on user interface VTY 0.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] undo acl outbound
```

2.5.3 authentication-mode (user interface view)

Function

The **authentication-mode** command configures an authentication mode for accessing the user interface.

The **undo authentication-mode** command deletes the authentication mode for accessing the user interface.

The default authentication mode for console port login users is password authentication. By default, the authentication mode for users using other login modes is not configured using this command. You must configure an authentication mode for accessing the user interface; otherwise, users cannot log in to the device.

Format

authentication-mode { **aaa** | **password** }

undo authentication-mode

Parameters

Parameter	Description	Value
aaa	Indicates the AAA authentication mode.	-
password	Indicates the password authentication mode.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After entering the default user name and password, you must reconfigure the login password and then can log in to the device. After logging in to the device, you can run this command to reconfigure the authentication mode.

Before Telnet or SSH users log in to the device using VTY user interface, they must run the **authentication-mode** command to configure the authentication mode.

Precautions

To ensure that users can log in to the device successfully, configure an authentication mode.

Before setting the Telnet login authentication mode to password authentication, run the **protocol inbound** { **all** | **telnet** } command to configure the VTY user interface to support Telnet. Otherwise, the user authentication mode configuration will fail.

NOTICE

The **none** parameter is not contained in the command. To specify this parameter, install the empty password authentication plug-in. This parameter, however, brings security risks, and the **aaa** or **password** parameter is recommended.

You can search for **Plug-in Usage Guide** at the Huawei technical support website (**Enterprise Network** or **Carrier**), and choose the desired plug-in usage guide based on the switch model and software version. If you do not have permission to access the website, contact technical support personnel.

- After you set the authentication mode to **password**, run the **set authentication password** command to configure an authentication password. Keep the password safe. You need to enter the password when logging in to the device. The levels of commands accessible to a user depend on the level configured for the user interface to which the user logs in.
- After login, the level of the commands the user can run depends on the level of the local user specified in AAA configuration.
- When you run the **undo authentication-mode** command to delete the authentication mode, the device asks you whether to delete the authentication mode.
- In V200R009 and earlier versions, the console port uses non-authentication by default. From V200R010 to V200R019, the console port uses AAA authentication by default. In V200R020C00 and later versions, the console port uses password authentication by default.

- If a device runs a version earlier than V200R010C00 and the authentication mode for accessing the user interface is not configured using this command, the default authentication mode is still non-authentication after the system software is upgraded to V200R010C00 or a later version. The system asks you whether to change the password. To ensure the console port usage security, it is recommended that you configure the login password or set the authentication mode to AAA or password authentication after logging in to the device.
- If a device runs a version earlier than V200R010C00 and the authentication mode for accessing the user interface has been configured using this command, the default authentication mode is still the originally configured authentication mode after the system software is upgraded to V200R010C00 or a later version.

Example

Configure password authentication for users to access the user interface.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] protocol inbound all
[HUAWEI-ui-vty0] authentication-mode password
Warning: The "password" authentication mode is not secure, and it is strongly re
commended to use "aaa" authentication mode.
[HUAWEI-ui-vty0] set authentication password cipher YsHsjx_202206
Warning: The "password" authentication mode is not secure, and it is strongly re
commended to use "aaa" authentication mode.
```

2.5.4 auto-execute command

Function

The **auto-execute command** command configures auto-run commands.

The **undo auto-execute command** command cancels auto-run commands.

By default, the auto-run function is disabled.

Format

auto-execute command *command*

undo auto-execute command

Parameters

Parameter	Description	Value
command	Specifies an auto-run command.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **auto-execute command** command to make a device run a command automatically on the corresponding user interface.

You can run the **auto-execute command** command to enable automatic execution of the **Telnet** command.

Precautions

- The **auto-execute command** command applies to the VTY user interface.
- When you log in to a device, the device automatically runs the commands that are configured by the **auto-execute command** command. After command execution, the user's terminal disconnects from the device.
- Before saving the configuration of the **auto-execute command** command, ensure that you can log in to the device to cancel the command configuration.
- If you use the **auto-execute command** command, you cannot configure the device in the user interface view. Therefore, use this command with caution.

Example

Configure the **telnet 10.110.100.1** command to automatically run after a user logs in to the device using the VTY0 interface.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] auto-execute command telnet 10.110.100.1
Warning: The system will not be configured through ui-vty0.
Continue? [Y/N]: y
```

2.5.5 databits

Function

The **databits** command sets the number of data bits of the user interface.

The **undo databits** command restores the default number of data bits.

By default, the user interface has 8 data bits.

Format

databits { **5** | **6** | **7** | **8** }

undo databits

Parameters

Parameter	Description	Value
5	Indicates that the number of data bits is 5.	-
6	Indicates that the number of data bits is 6.	-
7	Indicates that the number of data bits is 7.	-
8	Indicates that the number of data bits is 8.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Use this command only when necessary. If the number of data bits of a device's user interface is changed, ensure that the same number of data bits is set on the HyperTerminal used for login.

The setting is valid only when the serial port is configured to work in asynchronous mode.

Example

Set the number of data bits to 5.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] databits 5
```

2.5.6 display user-interface

Function

The **display user-interface** command displays information about a user interface.

Format

display user-interface [*ui-type ui-number1* | *ui-number*] [**summary**]

Parameters

Parameter	Description	Value
ui-type	Displays information about a specified user interface.	The value can be Console or VTY.

Parameter	Description	Value
ui-number1	Displays information about a user interface with a specified relative number.	The minimum value is 0. The maximum value is the number of user interfaces that the system supports minus 1.
ui-number	Displays information about a user interface with a specified absolute number.	The value is an integer ranging from 0 to 54, 67 to 83. The value varies according to the device type.
summary	Displays the summary of a user interface.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

To check detailed configuration information about all user interfaces or a specified user interface, run the **display user-interface** command.

Example

Display detailed information about the user interface with the absolute number 0.

```
<HUAWEI> display user-interface 0
  Idx  Type     Tx/Rx      Modem Privi ActualPrivi      Auth  Int
  0    CON 0    9600       -     3     -                P     -
  +    : Current UI is active.
  F    : Current UI is active and work in async mode.
  Idx  : Absolute index of UIs.
  Type : Type and relative index of UIs.
  Privi: The privilege of UIs.
  ActualPrivi: The actual privilege of user-interface.
  Auth : The authentication mode of UIs.
     A: Authenticate use AAA.      N: Current UI need not authentication.      P: Authenticate use current
UI's password.
  Int  : The physical location of UIs.
```

Display detailed information about all user interfaces.

```
<HUAWEI> display user-interface
  Idx  Type     Tx/Rx      Modem Privi ActualPrivi       Auth  Int
  0    CON 0    9600          -     3     -              P     -
+ 34   VTY 0               -     3     3            A     -
+ 35   VTY 1               -     1     2            A     -
+ 36   VTY 2               -     3     2            A     -
  37   VTY 3              -     1     -            P     -
  38   VTY 4              -     1     -            A     -
...
UI(s) not in async mode -or- with no hardware support:
```

```
1-32
  +    : Current UI is active.
  F    : Current UI is active and work in async mode.
  Idx  : Absolute index of UIs.
  Type : Type and relative index of UIs.
  Privi: The privilege of UIs.
  ActualPrivi: The actual privilege of user-interface.
  Auth : The authentication mode of UIs.
      A: Authenticate use AAA.       N: Current UI need not authentication.       P: Authenticate use current
UI's password.
  Int  : The physical location of UIs.
```

Table 2-23 Description of the **display user-interface** command output

Parameter	Description
+	Active user interface.
F	Active user interface in asynchronous mode.
Idx	Absolute number of a user interface.
Type	Type and relative number of a user interface.
Tx/Rx	Data transfer rate of the user interface.
Modem	Type of the modem.
Privi	Authority configured on a user interface.
ActualPrivi	Actual permission of a user interface. In AAA authentication mode, the level of a local user in AAA configuration is the actual permission.
Auth	Authentication mode on a user interface.
Int	User interface.
A	AAA authentication.
N	No authentication on the current user interface.
P	Password authentication.

2.5.7 display user-interface maximum-vty

Function

The **display user-interface maximum-vty** command displays the maximum number of VTY users.

Format

display user-interface maximum-vty

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

To check the maximum number of users who are allowed to log in to a device using Telnet or SSH, run the **display user-interface maximum-vty** command. By default, the maximum number of total Telnet and SSH users is five.

Example

Display the maximum number of VTY users.

```
<HUAWEI> display user-interface maximum-vty
Maximum of VTY user : 5
```

Table 2-24 Description of the **display user-interface maximum-vty** command output

Parameter	Description
Maximum of VTY user	Maximum number of VTY users. The maximum number of VTY users can be configured using the **user-interface maximum-vty** command.

2.5.8 display users

Function

The **display users** command displays login information of each user interface.

Format

display users [**all**]

Parameters

Parameter	Description	Value
all	Displays information about all users who log in to a device through user interfaces, including information about user interfaces that are not connected. If the **all** parameter is not used, the command displays information only about user interfaces that have been connected.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view information about users who are connected to a device. The information includes the user name, IP address, and authentication and authorization information.

NOTE

The user with a level of 0, 1, or 2 can only view related information about users of the same or a lower level. A user with a level of 3 or above can view login information of all users.

Example

Display information about users who log in to the device through user interfaces.

```
<HUAWEI> display users
  User-Intf   Delay     Type   Network Address     AuthenStatus    AuthorcmdFlag
  34 VTY 0   00:00:00  TEL    10.164.6.10           pass            no
  Username : user1
+ 35 VTY 1   00:00:00  TEL    10.164.6.15           pass            no
  Username : user2
```

Table 2-25 Description of the **display users** command output

Item	Description
+	User interface in use.
User-Intf	The number in the first column under **User-Intf** indicates the absolute number of the user interface, and the number in the second column under **User-Intf** indicates the relative number of the user interface. User Interface type. ● Console: Users who log in through the console port ● VTY: Users who log in using VTY ● LTT: User logs in stack system through the non-master switch console port ● WEB: Users who log in through Web system
Delay	Interval from the user's latest input on the login page to the current time, in seconds.

Item	Description
Type	Connection type. ● Console ● Telnet ● SSH ● Web
Network Address	IP address of the login user.
Username	User name for logging in to the device. If the user name is not specified, **Unspecified** is displayed.
AuthenStatus	Whether the authentication succeeds.
AuthorcmdFlag	Command line authorization status. ● yes: Command line authentication is enabled. ● no: Command line authentication is disabled.

2.5.9 display vty mode

Function

The **display vty mode** command displays the current VTY mode.

Format

display vty mode

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

VTY modes are classified into the man-to-machine mode and machine-to-machine mode.

Example

Display the VTY mode.

```
<HUAWEI> display vty mode
Current user-interface mode is Human-Machine interface.
```

2.5.10 display vty lines

Function

The **display vty lines** command displays the number of rows that are displayed on the VTY screen.

Format

display vty lines

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to view the number of rows (configured using **screen-length** command) that are displayed on the VTY screen.

Example

Display the number of rows that are displayed on the VTY screen.

```
<HUAWEI> display vty lines
Current user-interface lines is 24
```

2.5.11 display web welcome-message

Function

The **display web welcome-message** command displays greetings of the web system.

Format

display web welcome-message

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display web welcome-message** command to view greetings of the web system.

Example

Display greetings of the web system.

```
<HUAWEI> display web welcome-message
huawei
```

2.5.12 flow-control

Function

The **flow-control** command configures a flow control mode.

The **undo flow-control** command restores the default flow control mode.

The default flow control mode is **none**, that is, flow control is disabled.

Format

flow-control { **hardware** | **none** | **software** }

undo flow-control

NOTE

Currently, the flow control mode of the device cannot be set to hardware.

Parameters

Parameter	Description	Value
hardware	Specifies hardware flow control.	-
none	Specifies no flow control.	-
software	Specifies software flow control.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

The configuration is effective only when the serial interface works in asynchronous interaction mode.

If the flow control mode cannot be configured on a device, the system prompts the message **"Error: Failed to run this command because of internal causes of system malfunctions.**"

Example

Set the flow control mode to software flow control in the user interface view.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] flow-control software
```

2.5.13 free user-interface

Function

The **free user-interface** command disconnects a user from a specified user interface.

Format

free user-interface { *ui-number* | *ui-type ui-number1* }

Parameters

Parameter	Description	Value
ui-number	Specifies the absolute number of a user interface.	The value is an integer ranging from 0 to 54 and 67 to 83. The value varies according to the device type.
ui-type	Specifies the type of a user interface.	The value can be console or VTY.
ui-number1	Specifies the relative number of a user interface.	The minimum value is 0. The maximum value is the number of user interfaces that the system supports minus 1.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a login user does not perform any operation for a long time or needs to be prohibited from configuring the device, run the **free user-interface** command to disconnect the user from the user interface. The device then logs out the user.

Precautions

The **free user-interface** command does not take effect for the current user interface. For example, if the current user interface is VTY 2, the **free user-interface vty 2** command does not take effect, and an error message is displayed.

This command provides the same function as the **kill user-interface** command.

Example

Disconnect the user from user-interface 0.

```
<HUAWEI> free user-interface 0
Warning: User interface Console1 will be freed. Continue? [Y/N]:y
```

2.5.14 kill user-interface

Function

The **kill user-interface** command disconnects a user from a user interface.

NOTE

The **kill user-interface** command can only be executed by users at level 3 or higher. These users can clear any other users.

Format

kill user-interface { *ui-number* | *ui-type ui-number1* }

Parameters

Parameter	Description	Value
ui-number	Specifies the absolute number of a user interface.	The value is an integer ranging from 0 to 54 and 67 to 83. The value varies according to the device type.
ui-type	Specifies the type of a user interface.	The value can be console or VTY.
ui-number1	Specifies the relative number of a specified user interface.	The minimum value is 0. The maximum value is the number of user interfaces that the system supports minus 1.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a login user does not perform any operation for a long time or needs to be prohibited from configuring the device, run the **kill user-interface** command to disconnect the user from the user interface. The device then logs out the user.

Precautions

The **kill user-interface** command does not take effect for the current user interface. For example, if the current user interface is VTY 2, the **kill user-interface vty 2** command does not take effect, and an error message is displayed.

This command provides the same function as the **free user-interface** command.

Example

Disconnect user VTY3 from the device.

```
<HUAWEI> kill user-interface vty 3
Warning: User interface VTY3 will be freed. Continue? [Y/N]:y
Info: User interface VTY3 is free.
```

2.5.15 history-command max-size

Function

The **history-command max-size** command sets the size of the historical command buffer.

The **undo history-command max-size** command restores the default size of the historical command buffer.

By default, a maximum of 10 previously-used commands can be saved in the buffer.

Format

history-command max-size *size-value*

undo history-command max-size

Parameters

Parameter	Description	Value
size-value	Specifies the size of the historical command buffer.	The value is an integer ranging from 0 to 256.

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The CLI can automatically save the historical commands that you enter. This function is similar to that of Doskey. You can invoke and run the historical commands at any time.

Precautions

- If the historical command buffer is used up and a new command is entered, the command line interface deletes the earliest command in the buffer in the sequence the commands were entered.
- The formats of the saved historical commands are the same as those of the commands entered by users. If the commands entered by a user are incomplete, the saved historical commands are also incomplete.
- If a user runs the same command several times, only the earliest command is saved as a historical command. However, if the same command is entered with different formats, they are saved as different commands.

Example

Set the size of the historical command buffer to 20.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] history-command max-size 20
```

2.5.16 idle-timeout

Function

The **idle-timeout** command sets a timeout period for users to disconnect from a user interface.

The **undo idle-timeout** command restores the default timeout period.

By default, the timeout period is 10 minutes.

Format

idle-timeout *minutes* [*seconds*]

undo idle-timeout

Parameters

Parameter	Description	Value
minutes	Specifies the idle timeout period, in minutes.	The value is an integer ranging from 0 to 35791.
seconds	Specifies the idle timeout period, in seconds.	The value is an integer ranging from 0 to 59.

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If an online user does not perform any operation, the user interface where the user logs in is wasted. To resolve this problem, run the **idle-timeout** command to set a timeout period. If the user does not perform any operation before the timeout period expires, the user is disconnected from the user interface.

Precautions

- If you set the timeout period to 0, the user connection remains alive until it is manually cut.
- If you set the timeout period to 0 or a large value, the user will remain in the login state, resulting in security risks. You are advised to run the **lock** command to lock the current connection.
- If the user interface disconnection function is not configured, other users may fail to log in to the device. You are advised to set the timeout period to 10-15 minutes.

NOTE

If AAA authentication is used, the **local-user idle-timeout** *minutes* [*seconds*] command takes precedence. If both the commands are configured, the value configured using the **local-user idle-timeout** command takes effect.

If RADIUS authentication is used, the RADIUS attribute **Idle-Timeout** takes precedence. If both the **Idle-Timeout** attribute and the **idle-timeout** command are configured, value of the RADIUS attribute **Idle-Timeout** takes effect.

Example

Set the timeout period to 1 minute and 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] idle-timeout 1 30
```

2.5.17 mmi-mode enable

Function

The **mmi-mode enable** command enters the machine-to-machine mode.

The **undo mmi-mode enable** command enters the man-to-machine mode.

By default, a VTY user is in man-to-machine mode.

Format

mmi-mode enable

undo mmi-mode enable

Parameters

None

Views

User view, system view

Default Level

0: Visit level

Usage Guidelines

The machine-to-machine mode is used on the NMS. After you enter the machine-to-machine mode using the **mmi-mode enable** command, some important commands that you need to use with caution can be used directly. Therefore, in man-to-machine mode, do not use this command unless necessary.

After you enter the machine-to-machine mode, the maximum number of lines in the screen of the current user interface is restored to the default value (512). You can run the **screen-length** command to change the default value.

Example

Enter the machine-to-machine mode.

```
<HUAWEI> system-view
[HUAWEI] mmi-mode enable
```

2.5.18 parity

Function

The **parity** command sets a parity bit for a user interface.

The **undo parity** command disables the parity check.

By default, no parity check is configured.

Format

parity { **even** | **mark** | **none** | **odd** | **space** }

undo parity

Parameters

Parameter	Description	Value
even	Specifies even parity check.	-
mark	Specifies Mark parity check.	-
none	Specifies no parity check.	-
odd	Specifies odd parity check.	-
space	Specifies Space parity check.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

The setting is valid only when the serial port is configured to work in asynchronous mode.

If the parity bit for a user interface cannot be set on a device, the system prompts the message **"Error: Failed to run this command because of internal causes of system malfunctions.**"

Example

Set the transmission parity bit on the console port to odd parity.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] parity odd
```

2.5.19 protocol inbound

Function

The **protocol inbound** command specifies the protocols that VTY user interfaces support.

The **undo protocol inbound** command restores the default protocols that VTY user interfaces support.

By default, VTY user interfaces support SSH.

Format

protocol inbound { **all** | **ssh** | **telnet** }

undo protocol inbound

Parameters

Parameter	Description	Value
all	Indicates that all protocols including SSH and Telnet are supported.	-
ssh	Indicates that only SSH is supported.	-
telnet	Indicates that only Telnet is supported.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To manage and monitor login users, configure VTY user interfaces for login users and run the **protocol inbound** command to configure the protocols that the VTY user interfaces support.

Prerequisites

If SSH is configured for a user interface using the **protocol inbound ssh** command, you must run the **authentication-mode aaa** command to configure AAA authentication. This ensures that a user can successfully log in to the user interface. If password authentication is configured, the **protocol inbound ssh** command does not take effect.

Precautions

- The configuration takes effect at the next login.
- When SSH is specified for the VTY user interface, if the SSH server function is enabled but the RSA, DSA, or ECC key is not configured, a user cannot log in to the SSH server using SSH.
- Telnet is an insecure protocol. Using SSH is recommended.

Example

Configure SSH for user interfaces VTY0 to VTY4.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0 4
[HUAWEI-ui-vty0-4] authentication-mode aaa
[HUAWEI-ui-vty0-4] protocol inbound ssh
```

2.5.20 screen-length

Function

The **screen-length** command sets the number of lines on each terminal screen.

The **undo screen-length** command restores the default configuration.

By default, the number of lines displayed on a terminal screen is 24.

Format

In the user interface view:

screen-length *screen-length* [**temporary**]

undo screen-length [**temporary**]

In the user view:

screen-length *screen-length* **temporary**

undo screen-length temporary

Parameters

Parameter	Description	Value
screen-length	Specifies the number of lines displayed on a terminal screen.	The value is an integer that ranges from 0 to 512. The value 0 indicates that all command output is displayed on one screen.
temporary	Specifies the number of lines temporarily displayed on a terminal screen.	-

Views

User interface view, user view

Default Level

3: Management level in the user interface view

1: Monitoring level in the user view

Usage Guidelines

If a command output is displayed in more lines than you can see on one screen, run the **screen-length** command to reduce the number of lines displayed on each screen.

In general, you do not need to change the number of lines displayed on each screen. Setting the number of lines to 0 is not recommended. The configuration takes effect after you log in to the system again.

NOTE

In the user view, the **temporary** parameter is mandatory, and this command is at the Monitoring level.

Example

Set the number of lines on each screen of the terminal to 30.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] screen-length 30
```

2.5.21 screen-width

Function

The **screen-width** command sets the number of columns displayed on a terminal screen.

The **undo screen-width** command restores the default configuration.

By default, 80 columns are displayed on a terminal screen.

Format

screen-width *screen-width*

undo screen-width

Parameters

Parameter	Description	Value
screen-width	Specifies the width of a terminal screen.	The value is an integer ranging from 60 to 512.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you log in to the device from a console interface and run the **display interface description** [*interface-type* [*interface-number*]] command to view the interface information, output information does not automatically change to another line, resulting in wrong format of the output information.

To resolve this problem, run the **screen-width** command to adjust the information format. In general, you do not need to adjust the number of columns displayed on the terminal screen. Setting the number of columns displayed on a screen is not recommended.

Precautions

The number of columns set using the **screen-width** command is valid only for the current interface. The setting is not saved after you log out. When you log in to the device from the console interface and configure this command, the number of columns displayed on the terminal screen is valid only for the current console interface, which has no impact on other users who log in to the device from the VTY interface or other interfaces. If you log out of the console interface and log in to the device again, the default width is used for the terminal screen.

This command is valid only for information displayed by the **display interface description** [*interface-type* [*interface-number*]] command.

Example

Configure each line displayed on a terminal screen to have 60 characters.

```
<HUAWEI> screen-width 60
Warning: This command will change the default screen width. Continue? [Y/N]:y
Info: Succeeded in setting the screen width to 60.
```

2.5.22 set authentication password

Function

The **set authentication password** command configures a local authentication password.

The **undo set authentication password** command cancels the local authentication password.

By default, no local authentication password is configured for devices.

Format

set authentication password [**cipher** *password*]

undo set authentication password

Parameters

Parameter	Description	Value
cipher	Indicates a password in cipher text.	-
password	Specifies the password.	The value is a string of 8 to 16 characters or a string of 56 or 68 characters. The password can be in plain or cipher text. ● The password in plain text is a string of 8 to 16 characters. The password must contain at least two types of the following characters: upper-case characters, lower-case characters, digits, and special characters. Special characters do not include the question mark (?) and space. ● The password in cipher text is a string of 56 or 68 characters. The password in cipher text must start with $1a$ and end with $, or start with %^%# and end with %^%#. **NOTE** If the source version supports a ciphertext password that is a string of 24 characters, the target version also supports this type of password. The password is displayed in cipher text in the configuration file regardless of whether it is input in plain text or cipher text.

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If password authentication is configured for users, you can run the **set authentication password** command to change the password or set a password in cipher text.

If **cipher** *password* is not specified, the password is entered in interactive mode and can contain 8 to 16 characters. The requirements for the password are the same as the requirements for the password in plain text that is specified using the **cipher** parameter. The password you enter will not be displayed on the screen.

NOTE

If you enter the plain text password when specifying **cipher** *password*, security risks exist. The interactive mode is recommended when users enter the password.

Pre-configuration Tasks

Password authentication has been configured for the user interface.

Precautions

- If a password in cipher text is configured, users must obtain the password in plain text that is required for login authentication.
- You cannot run the **undo set authentication password** command to delete a password. The **undo set authentication password** command is retained for compatibility with other versions.
- If the password authentication is configured but the password is not configured for the user interface, the user cannot log in to the device.
- If the **set authentication password** command is executed multiple times, the latest configuration overrides the previous ones. You can run the **set authentication password** command to change the local authentication password. After the password is changed, a user who wants to log in to the device must enter the latest password for login authentication.
- Users can press **CTRL_C** to cancel password modification in the interaction mode.
- You are advised to change the password periodically to improve device security.

Example

Set a local authentication password for the user interfaces VTY 0-4 in interactive mode.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0 4
[HUAWEI-ui-vty0-4] set authentication password
Warning: The "password" authentication mode is not secure, and it is strongly recommended to use "aaa" 
authentication mode.
Please configure the login password (8-16)
Enter Password:
Confirm Password:
[HUAWEI-ui-vty0-4]
```

Set a local authentication password for the user interfaces VTY 0-4.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0 4
[HUAWEI-ui-vty0-4] set authentication password cipher YsHsjx_202206
Warning: The "password" authentication mode is not secure, and it is strongly recommended to use "aaa" 
authentication mode.
```

2.5.23 set password min-length

Function

The **set password min-length** command sets the minimum length of passwords in plain text allowed by a device.

The **undo set password min-length** command restores the default minimum length of passwords in plain text allowed by a device.

By default, the minimum length of passwords in plain text allowed by a device is 8 characters.

Format

set password min-length *length*

undo set password min-length

Parameters

Parameter	Description	Value
length	Specifies the minimum length of passwords in plain text allowed by a device.	The value is an integer ranging from 6 to 16.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command can change the limit on the password length. A longer password length makes the password more complex and improves device security.

Precautions

- The **set password min-length** command limits the length of all passwords in plain text. Only the passwords longer than or equal to the minimum length take effect. The minimum length does not take effect for the following passwords:
  - Passwords configured during configuration restoration
  - Passwords that have taken effect before the minimum length is configured
- This command limits the minimum length of only the passwords in plain text configured using the following commands:
  - **set authentication password**
  - **lock**
  - **local-user**
  - **super password**

  The **set password min-length** command does not limit the minimum length of other types of passwords.

NOTE

If password complexity check has been disabled using the **undo user-password complexity-check** command, the **set password min-length** command does not limit the minimum length of passwords in plain text of local users.

For device security purposes, do not disable the password complexity check function and change the password periodically.

Example

Set the minimum length of passwords in plain text allowed by the local device to 10 characters.

```
<HUAWEI> system-view
[HUAWEI] set password min-length 10
```

2.5.24 shell

Function

The **shell** command enables terminal services on a user interface.

The **undo shell** command disables terminal services on a user interface.

By default, terminal services are enabled on all user interfaces.

Format

shell

undo shell

Parameters

None

Views

User interface view

Default Level

3: Management level

Usage Guidelines

You can use the **shell** command on a user interface to enable terminal services. This command enables users to enter commands through this interface to query device information and configure the device.

You can use the **undo shell** command on the user interface to disable terminal services. This command does not allow users to perform any operations through this interface. After using the **undo shell** command in the VTY view, this user interface does not provide Telnet, STelnet, and SFTP access.

NOTE

The console interface does not support this command.

Example

Disable terminal services on VTY 0 to VTY 4.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0 4
[HUAWEI-ui-vty0-4] undo shell
Warning: ui-vty0-4 will be disabled. Continue? [Y/N]:y
```

2.5.25 speed (user interface view)

Function

The **speed** command sets the data transfer rate of a user interface.

The **undo speed** command restores the default data transfer rate of a user interface.

By default, the data transfer rate is 9600 bit/s.

Format

speed *speed-value*

undo speed

Parameters

Parameter	Description	Value
speed-value	Specifies the data transfer rate of a user interface.	The value is expressed in bit/s. The asynchronous serial interface supports the following data transfer rates: ● 300 bit/s ● 600 bit/s ● 1200 bit/s ● 4800 bit/s ● 9600 bit/s ● 19200 bit/s ● 38400 bit/s ● 57600 bit/s ● 115200 bit/s

Views

User interface view

Default Level

3: Management level

Usage Guidelines

The setting is valid only when the serial port is configured to work in asynchronous mode.

Example

Set the data transfer rate of a user interface to 115200 bit/s.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] speed 115200
```

2.5.26 stopbits

Function

The **stopbits** command sets a stop bit for a user interface.

The **undo stopbits** command restores the default stop bit of a user interface.

The default stop bit is 1.

Format

stopbits { **1.5** | **1** | **2** }

undo stopbits

Parameters

Parameter	Description	Value
1.5	Sets the stop bit to 1.5.	-
1	Sets the stop bit to 1.	-
2	Sets the stop bit to 2.	-

Views

User interface view

Default Level

3: Management level

Usage Guidelines

If the stop bit is 1, the corresponding data bit is 7 or 8.

If the stop bit is 1.5, the corresponding data bit is 5.

If the stop bit is 2, the corresponding data bit is 6, 7, or 8.

The setting is valid only when the serial port is configured to work in asynchronous mode.

Example

Set the stop bit of a user interface to 2.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0] stopbits 2
```

2.5.27 user privilege

Function

The **user privilege** command configures a user privilege level.

The **undo user privilege** command restores the default user privilege level.

By default, users who log in to a device using the console interface are at level 15, and other users are at level 0.

Format

user privilege level *level*

undo user privilege level

Parameters

Parameter	Description	Value
level *level*	Specifies a user privilege level. **NOTE** A larger value indicates a higher priority.	The value is an integer ranging from 0 to 15.

Views

User interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To limit users' access permissions to a device, the device manages users by level. Users of a specified level can run only commands whose levels are lower than or equal to the user privilege level.

Commands are classified into the visit level, monitoring level, configuration level, and management level that map levels 0, 1, 2, and 3, respectively. **Table 2-26** describes these command privilege levels.

Table 2-26 Command privilege levels

User Privilege Level	Command Privilege Level	Permission	Description
0	0	Visit	Diagnostic commands, such as ping and tracert commands, and commands that are used to access a remote device such as a Telnet client
1	0 and 1	Monitoring	System maintenance commands, such as display commands **NOTE** Some display commands are not at this level. For example, the **display current-configuration** and **display saved-configuration** commands are at level 3.
2	0, 1, and 2	Configuration	Service configuration commands
3-15	0, 1, 2, and 3	Management	System basic operation commands that are used to support services, including file system, FTP, TFTP, user management commands, command-level configuration commands, and debugging commands.

Precautions

If refined permission management is required, run the **command-privilege level** command to upgrade command privilege levels.

Example

Set the user privilege level on the VTY0 user interface to 2.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 0
[HUAWEI-ui-vty0] user privilege level 2
```

Log in to the device using Telnet and view detailed information about the VTY0 user interface.

```
<HUAWEI> display user-interface vty 0
  Idx  Type     Tx/Rx      Modem Privi ActualPrivi Auth  Int
+ 34    VTY 0               -    2     15           N    -
  +    : Current UI is active.
  F    : Current UI is active and work in async mode.
  Idx  : Absolute index of UIs.
```

```
Type : Type and relative index of UIs.
Privi: The privilege of UIs.
ActualPrivi: The actual privilege of user-interface.
Auth : The authentication mode of UIs.
    A: Authenticate use AAA.
    N: Current UI need not authentication.
    P: Authenticate use current UI's password.
Int  : The physical location of UIs.
```

Table 2-27 Description of the **user privilege level** command output.

Item	Description
+	Current user interface is active.
F	Current user interface is active and is working in asynchronous mode.
Idx	Absolute index of the user interface.
Type	Type and relative index of the user interface.
Privi	Privilege of the user interface.
ActualPrivi	Actual privilege of the user interface.
Auth	Authentication mode of the user interface.
Int	Physical location of UIs.
A	AAA authentication.
N	None authentication
P	Password authentication

2.5.28 user-interface

Function

The **user-interface** command displays one or multiple user interface views.

Format

user-interface [*ui-type*] *first-ui-number* [*last-ui-number*]

Parameters

Parameter	Description	Value
ui-type	Specifies the type of a user interface. ● If the user interface is specified, the relative number is used. ● If the user interface is not specified, the absolute number is used.	The value can be console or VTY.
first-ui-number	Specifies the number of the first user interface.	● If *ui-type* is set to **console**, the *first-ui-number* value is **0**. ● If *ui-type* is set to **vty**, the *first-ui-number* value ranges from 0 to the maximum number of VTY user interfaces.
last-ui-number	Specifies the number of the last user interface. When you select this parameter, you enter multiple user interface views at the same time. This parameter is valid only when *ui-type* is set to VTY. The *last-ui-number* value must be larger than the *first-ui-number* number. If the maximum number of VTY users has been set using the **user-interface maximum-vty** command in the system view before *ui-type* is selected, the *last-ui-number* value is smaller than or equal to the maximum number of VTY user interfaces minus one.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a network administrator logs in to a device using the console interface, Telnet, or SSH, the network administrator can set parameters, such as an authentication more and user privilege level, on the user interface to allow the device to centrally manage user sessions.

Precautions

Only users at level 15 can use this command.

The user interface varies according to the login mode. The user interface views can be numbered using absolute numbers or relative numbers. **Table 2-28** describes absolute and relative numbers of user interfaces.

NOTE

- The relative numbering uniquely specifies a user interface or a group of user interfaces of the same type.
- The absolute numbering specifies a user interface or a group of user interfaces.

Table 2-28 Absolute and relative numbers of user interfaces

User Interface	Description	Absolute Number	Relative Number
Console user interface	Manages and controls users who log in to the device using the console interface.	0	0
VTY user interface	Manages and controls users who log in to the device using Telnet or SSH.	34 to 48 and 50 to 54	The first one is VTY 0, the second one is VTY 1, and so forth. • Absolute numbers 34 to 48 map relative numbers VTY 0 to VTY 14. • Absolute numbers 50 to 54 map relative numbers VTY 16 to VTY 20. VTY 15 is reserved for the system. VTY 16 to VTY 20 are reserved for the NMS. Only when VTY 0 to VTY 14 are all used, AAA authentication is configured for users, VTY 16 to VTY 20 can be used.

After you log in to the device, you can run the **display user-interface** command to view the supported user interfaces and the corresponding relative and absolute numbers.

Example

Enter the Console 0 user interface.

```
<HUAWEI> system-view
[HUAWEI] user-interface console 0
[HUAWEI-ui-console0]
```

Enter the VTY 1 user interface.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 1
[HUAWEI-ui-vty1]
```

Enter the VTY 1 to VTY 3 user interfaces.

```
<HUAWEI> system-view
[HUAWEI] user-interface vty 1 3
[HUAWEI-ui-vty1-3]
```

2.5.29 user-interface current

Function

The **user-interface current** command displays the current user interface view.

Format

user-interface current

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To enter the current user interface view, run the **user-interface current** command, without the need to run the **display user-interface** command to check the user interface number.

Precautions

Only users at level 15 can use this command.

The user interface varies according to the login mode. The user interface views can be numbered using absolute numbers or relative numbers. **Table 2-28** describes absolute and relative numbers of user interfaces.

NOTE

- The relative numbering uniquely specifies a user interface or a group of user interfaces of the same type.
- The absolute numbering specifies a user interface or a group of user interfaces.

Example

Enter the current user view.

```
<HUAWEI> system-view
[HUAWEI] user-interface current
[HUAWEI-ui-vty1]
```

2.5.30 user-interface maximum-vty

Function

The **user-interface maximum-vty** command configures the maximum number of login users.

The **undo user-interface maximum-vty** command restores the default maximum number of login users.

By default, the maximum number of Telnet and SSH users is 5.

Format

user-interface maximum-vty *number*

undo user-interface maximum-vty

Parameters

Parameter	Description	Value
number	Specifies the maximum number of Telnet and SSH users.	The value is an integer ranging from 0 to 15.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure the maximum number of login users, run the **user-interface maximum-vty** command.

Precautions

- If the maximum number that you set is smaller than the number of current online users, a device displays a configuration failure message.
- When the configured maximum number of VTY user interfaces is less than the number of current online users, the system disconnects the users that are not authenticated and occupy VTY channels for more than 15s and allows new users to log in to the device through VTY.
- When the configured maximum number of VTY user interfaces exceeds the maximum number of allowed access users, you need to configure the authentication mode for the excess user interfaces.
- The maximum number of login users set by the **user-interface maximum-vty** command is the total number of Telnet and SSH users.
- If the maximum number of login users is set to 0, users are not allowed to log in to the device using Telnet or SSH.
- When the number of login VTY users has reached the maximum, an NMS user can log in using the reserved VTY numbers 16-20. The NMS user is allowed to log in to the device only after passing the AAA local authentication.

Example

Set the maximum number of Telnet users to 7.

```
<HUAWEI> system-view
[HUAWEI] user-interface maximum-vty 7
```

2.5.31 user-interface password complexity-check disable

Function

The **user-interface password complexity-check disable** command disables the password complexity check function.

The **undo user-interface password complexity-check disable** command enables the password complexity check function.

By default, the password complexity check function is enabled.

Format

user-interface password complexity-check disable

undo user-interface password complexity-check disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Passwords configured in the interface view must meet the following complexity requirements:

- A password must contain at least 8 characters. If the minimum length set using the **set password min-length** command exceeds 8 characters, the command configuration takes effect.
- A password must contain at least two types of characters: uppercase characters, lowercase characters, digits, and special characters, excluding question marks (?) and spaces.

To disable the password complexity check function, run the **user-interface password complexity-check disable** command. To enable the password complexity check function, run the **undo user-interface password complexity-check disable** command.

Precautions

If the configured password does not meet complexity requirements, it is prone to attacks and cracks from unauthorized users, which affects device security. Therefore, keeping the password complexity check function enabled is recommended.

Example

Disable the password complexity check function.

```
<HUAWEI> system-view
[HUAWEI] user-interface password complexity-check disable
```

2.5.32 web welcome-message

Function

The **web welcome-message** command configures greetings for the web system.

The **undo web welcome-message** command cancels the configuration of greetings for the web system.

By defaults, greetings are not configured for the web system.

Format

web welcome-message *message*

undo web welcome-message

Parameters

Parameter	Description	Value
message	Configures greetings for the web system.	The value is a string of 1 to 242 case-sensitive characters without question mark (?). Spaces are supported.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run the **web welcome-message** command to configure greetings for the web system. After the **undo web welcome-message** command is run, no greetings will be displayed on the web system.

Example

Configure greetings of the web system to **huawei**.

```
<HUAWEI> system-view
[HUAWEI] web welcome-message huawei
```

2.6 User Login Configuration Commands

2.6.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.6.2 configuration exclusive

Function

The **configuration exclusive** command locks the current system configuration. When the system configuration is locked, the user who locks it can query and modify the configuration while other users can only query the configuration.

The **undo configuration exclusive** command unlocks the system configuration.

By default, the system configuration is unlocked.

Format

configuration exclusive

undo configuration exclusive

Parameters

None

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device allows several users to log in concurrently to perform manual configurations, which may cause configuration conflicts and service exceptions. To prevent service exceptions, run the **configuration exclusive** command to lock and modify the configuration. Other users can then only query the configuration.

To unlock the configuration, do either of the following:

- Run the **undo configuration exclusive** command.
- Do not modify the configuration in the configured lock interval. The system then automatically unlocks the configuration. To configure the lock interval, run the **configuration-occupied timeout** command.

Precautions

- After you run the **configuration exclusive** command, other users cannot modify the system configuration, so confirm your action before running this command.
- Before you run the **configuration exclusive** command, run the **configuration-occupied timeout** command to configure the maximum lock interval so that the system can automatically unlock the configuration after this interval.

Example

Lock the current system configuration.

```
<HUAWEI> configuration exclusive
```

Unlock the system configuration.

```
<HUAWEI> undo configuration exclusive
```

2.6.3 configuration-occupied timeout

Function

The **configuration-occupied timeout** command sets the interval after which the system automatically unlocks the configuration.

The **undo configuration-occupied timeout** command restores the default automatic unlock interval.

By default, the value is 30 seconds.

Format

configuration-occupied timeout *timeout-value*

undo configuration-occupied timeout

Parameters

Parameter	Description	Value
timeout-value	Specifies the interval after which the system automatically unlocks the configuration if no configuration command is run.	The value is an integer that ranges from 1 to 7200, in seconds. By default, the value is 30 seconds.

Views

System view

Default Level

3: Management level

Usage Guidelines

The **configuration-occupied timeout** command configures the longest lock interval. If no configuration command is delivered within this interval, the system automatically unlocks the configuration so that other users can modify the configuration.

The usage scenarios for this command are as follows:

- If the user does not have the configuration right, the system displays an error.
- If the configuration is locked by another user, the system displays a message indicating that the modification fails.
- If the configuration is locked by the user who configures the longest lock interval, the modification is valid.

NOTE

Note the following when running the **configuration-occupied timeout** command:

- The interval cannot be too short because the device will automatically unlock the configuration if no configuration command is delivered by the user who configures the interval.
- The interval cannot be too long because other users cannot modify the configuration within this period even if the user who locks the configuration delivers no configuration command within this period.
- The command is valid for all users.

Example

Set the automatic unlock interval to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] configuration-occupied timeout 120
```

2.6.4 console0 disable

Function

The **console0 disable** command disables the console port login function.

The **undo console0 disable** command enables the console port login function.

By default, the console port login function is enabled.

Format

console0 disable

undo console0 disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Application Scenario

By default, the administrator can log in to a switch through the console port. If the console port login function is not required, you can run the **console0 disable** command to disable this function. If this function is required, you can run the **undo console0 disable** command to enable this function.

Precautions

After the **console0 disable** command is run, this command does not take effect for users who have logged in to the device through the console port and takes effect for the users only after they exit from the console port using the **quit** command.

For devices that have the PNP button, you can press and hold the PNP button to enable the function of logging in through the console port.

Example

Disable the console port login function.

```
<HUAWEI> system-view
[HUAWEI] console0 disable
```

2.6.5 display configuration-occupied user

Function

The **display configuration-occupied user** command displays information about the user who locks the configuration.

Format

display configuration-occupied user

Parameters

None

Views

All views

Default Level

2: Configuration level

Usage Guidelines

You can run the **display configuration-occupied user** command to query the user who has the configuration right. If no user locks the system configuration, the system displays a corresponding message.

Example

Display the user who locks the configuration.

```
<HUAWEI> display configuration-occupied user
User Index: 34
User Session Name: VTY0
User Name:**
IP Address: 10.135.19.22
Locked Time: 2012-09-16 15:26:32+10:00 DST
Last Configuration Time: 2012-09-16 15:26:32+10:00 DST
The time out value of configuration right locked is: 30 second(s)
```

Table 2-29 Description of the **display configuration-occupied user** command output

Item	Description
User Index	User index.
User Session Name	User session name. The value is CON0 or ranges from VTY0 to VTY14. snmp-agent: session name of an NMS user.
User Name	Name of a login user. ● If a login user name is **, the user logs in to a device using a serial port or the password authentication mode. ● If the login user name is a community or V3 user name, the user is an NMS user.
IP Address	IP address of the user.
Locked Time	Time when the configuration was locked.
Last Configuration Time	Time when the user delivered the last configuration command.
The time out value of configuration right locked is	Duration for locking the configuration. To configure the duration, run the **configuration-occupied timeout** command.

Display the user who locks the system configuration (when no user locks the system configuration).

```
<HUAWEI> display configuration-occupied user
Info: No user locked the current configuration.
```

2.6.6 display dsa local-key-pair public

Function

The **display dsa local-key-pair public** command displays the public key in the local DSA key pair of the device.

Format

display dsa local-key-pair public

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

This command displays the public key in the local DSA key pair. You can copy the public key in the command output to the DSA public key of the SSH server to ensure that the public keys on the client and server are consistent and that the client can be authenticated by the server.

Example

Display the public key in the client DSA key pair.

```
<HUAWEI> display dsa local-key-pair public
=====================================================
Time of Key pair created:2014-08-27 06:35:16+08:00

Table 2-30 Description of the **display dsa local-key-pair public** command output

Item	Description
Time of Key pair created	Time when the public key was created.
Key name	Name of the public key.
Key modulus	Length of the key.
Key type	Type of the public key.
Key fingerprint	Key fingerprint.
Key code	Content of the key.
Host public key for PEM format code	PEM code of the public key.
Public key code for pasting into OpenSSH authorized_keys file	Public key format in the OpenSSH file.

2.6.7 display dsa peer-public-key

Function

The **display dsa peer-public-key** command displays the DSA public key that has been configured.

Format

display dsa peer-public-key [**brief** | **name** *key-name*]

Parameters

Parameter	Description	Value
brief	Displays the brief information.	-
name *key-name*	Displays the DSA public key with the specified name.	The value is a string of 1 to 30 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").

Views

3: Management level

Usage Guidelines

Usage Scenario

This command displays the DSA public key for you to check whether the local and peer public keys are consistent.

Precautions

You must complete the DSA public key configuration before running this command.

Example

Display the DSA public key with the specified name.

```
<HUAWEI> display dsa peer-public-key name amar
=====================================
    Key name: amar
    Encoding type: DER
=====================================
Key Code:

Item	Description
Key name	Type of the public key.
Encoding type	Type of the public key encoding format.
Key code	Code of the public key.

2.6.8 display ecc local-key-pair public

Function

The **display ecc local-key-pair public** command displays information about the public key in the local Elliptic Curves Cryptography (ECC) key pair.

Format

display ecc local-key-pair public

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **display ecc local-key-pair public** command to check information about the public key in the local ECC key pair on a client and then copy the public key to the server. The public key enables a server to authenticate users and ensures the login of authorized users.

Pre-configuration Tasks

You must run the **ecc local-key-pair create** command to generate a local ECC host key pair before using the command.

Example

Display information about the public key in the local ECC key pair on a client.

```
<HUAWEI> display ecc local-key-pair public
========================================================
Time of Key pair created:2016-10-19 11:50:20+00:00
Key name    : HUAWEI_Host_ECC
Key modulus : 521
Key type    : ECC encryption Key
Key fingerprint:
========================================================
Key code:

Table 2-32 Description of the **display ecc local-key-pair public** command output

Item	Description
Time of Key pair created	Time when the public key in the local ECC key pair is generated, in the format of YYYY-MM-DD HH:MM:SS±HH:MM.
Key Name	Name of the public key in the local ECC key pair.
Key modulus	Length of the public key in the local ECC key pair on a client.
Key Type	Type of the public key in the local ECC key pair. "ECC encryption Key" indicates an ECC public key.
Key Code	Code of the public key in the local ECC key pair configured using the **ecc local-key-pair create** command.
Host public key for PEM format code	PEM code of the public key in the local ECC key pair on a client.
Public key code for pasting into OpenSSH authorized_keys file	Public key in the local ECC key pair on a client that is used for OpenSSH authorization. This information can be used after being copied to the OpenSSH authorized_keys file.

2.6.9 display ecc peer-public-key

Function

The **display ecc peer-public-key** command displays information about the Elliptic Curves Cryptography (ECC) public key configured on the remote end.

Format

display ecc peer-public-key [**brief** | **name** *key-name*]

Parameters

Parameter	Description	Value
brief	Displays the brief information about the ECC public key configured on the remote end.	-
name *key-name*	Displays information about an ECC public key with a specified name configured on the remote end.	The value is a string of 1 to 30 case-sensitive characters, spaces not supported.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **display ecc peer-public-key** command on a client to check information about the public key configured on the remote end. The public key enables a server to authenticate users and ensures the login of authorized users.

Example

Display the information about the ECC public keys of 127.0.0.1.

```
<HUAWEI> display ecc peer-public-key
====================================
    Key name: 127.0.0.1
    Encoding type: DER
====================================
Key Code:
    04013184 A3311697 89DF558B 7F67BF9D BD95DBD5 280D659F 0E29852C AEC2FFBA
    1913AC2A 88247ADA 46BEBEBE 1829C0DA 3BABC8FC 8F6EAD28 2AE2C6A8 116BAA3A
    540E6B00 34E033D8 9D84841B 0D33DAD8 DEDD1C09 2B70B3DB 5AF0FCB2 37DF1C82
    C4C622A6 85B23698 195DA60F 06858ADB DD743937 B4A29C4C FB28B40B BCEEE036
    1DE61BD2 24
```

Display the brief information about all the ECC public keys.

```
<HUAWEI> display ecc peer-public-key brief
  Bits   Name
----------------------
  521   127.0.0.1
  384   192.168.131.203
```

Table 2-33 Description of the **display ecc peer-public-key** command output

Item	Description
Bits	Length of the ECC public key configured on the remote end.
Name	Name of the ECC public key configured on the remote end.
Key name	Name of the ECC public key configured on the remote end.
Encoding type	Encoding type of the ECC public key configured on the remote end. ● OPENSSH If OpenSSH is specified, data is Base64 encoded. OpenSSH is derived from PEM. ● PEM If PEM is specified, data is Base64 encoded. ● DER If DER is specified, data is Base16 encoded.
Key Code	Code of the public key in the local ECC key pair configured using the **ecc local-key-pair create** command.

2.6.10 display http server

Function

The **display http server** command displays information about the current HTTPS server.

Format

display http server

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can view the HTTPS server information, including the status of HTTPS services, port number, maximum number of users allowed to access the HTTPS server, and number of current online users.

Example

Display information about the current HTTPS server.

```
<HUAWEI> display http server
  HTTP Server Status              : enabled
  HTTP Server Port                : 80(80)
  HTTP Timeout Interval           : 20
  Current Online Users            : 3
  Maximum Users Allowed           : 5
  HTTP Secure-server Status       : enabled
  HTTP Secure-server Port         : 443(443)
  HTTP SSL Policy                 : ssl_server
  HTTP IPv6 Server Status         : disabled
  HTTP IPv6 Server Port           : 80(80)
  HTTP IPv6 Secure-server Status  : disabled
  HTTP IPv6 Secure-server Port    : 443(443)
  HTTP server source interface    : MEth0/0/1
```

Table 2-34 Description of the display http server command output

Item	Description
HTTP Server Status	Status of the HTTP IPv4 server. - Enabled: The HTTP IPv4 service is enabled. - Disabled: The HTTP IPv4 service is disabled. You can configure the HTTP IPv4 server status by running the **http server enable** command.
HTTP Server Port	Port number of the HTTP IPv4 server. The default value is 80. You can configure the port number of the HTTP IPv4 server by running the **http server port** command.
HTTP Timeout Interval	Timeout period of the HTTP/HTTPS server. The default value is 20 minutes. You can configure the timeout period of the HTTP/HTTPS server by running the **http timeout** command.
Current Online Users	Number of current online users.

Item	Description
Maximum Users Allowed	Maximum number of users allowed to access the HTTP server.
HTTP Secure-server Status	Status of the HTTPS IPv4 server. ● Enabled: The HTTPS IPv4 service is enabled. ● Disabled: The HTTPS IPv4 service is disabled. You can configure the HTTPS IPv4 server status by running the **http secure-server enable** command.
HTTP Secure-server Port	Port number of the HTTPS IPv4 server. The default value is 443. You can configure the port number of the HTTPS IPv4 server by running the **http secure-server port** command.
HTTP SSL Policy	HTTPS SSL policy. You can configure the HTTPS SSL policy by running the **ssl policy** command.
HTTP IPv6 Server Status	Status of the HTTP IPv6 server function: ● **enabled**: The HTTP IPv6 server function is enabled. ● **disabled**: The HTTP IPv6 server function is disabled. You can configure the HTTP IPv6 server status by running the **http ipv6 server enable** command.
HTTP IPv6 Server Port	Port number of the HTTP IPv6 server. The default value is 80. You can configure the port number of the HTTPS IPv6 server by running the **http ipv6 server port** command.
HTTP IPv6 Secure-server Status	Status of the HTTPS IPv6 server function: ● **enabled**: The secure HTTPS IPv6 server function is enabled. ● **disabled**: The secure HTTPS IPv6 server function is disabled. You can configure the HTTPS IPv6 server status by running the **http ipv6 secure-server enable** command.

Item	Description
HTTP IPv6 Secure-server Port	Port number of the HTTPS IPv6 server. The default value is 443. You can configure the port number of the HTTPS IPv6 server by running the **http ipv6 secure-server port** command.
HTTP server source interface	The source interface of the HTTPS server. You can configure the source interface of the HTTPS server by running the **http server-source** command.

2.6.11 display http user

Function

The **display http user** command displays information about current online users.

Format

display http user [**username** *username*]

Parameters

Parameter	Description	Value
username *username*	Specifies the name of the current online user.	The value is a string of 1 to 64 case-insensitive characters, with no space or wildcard. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

3: Management level

Usage Guidelines

If **username** is not specified, this command displays summary information about all online users.

If **username** is specified, this command displays detailed information about the specified online user.

Example

Display general information about the current online user.

```
<HUAWEI> display http user
Total online users: 1
-------------------------------------------------------
User name    IP Address           Login Date
-------------------------------------------------------
admin        192.168.0.1          2012-03-23 15:30:55+00:00
```

Display detailed information about the current online user **admin**.

```
<HUAWEI> display http user username admin
Client IP Address: 192.168.0.1
Login Date: 2012-03-19 15:30:55+00:00
User timeouts: 15 minute
```

Table 2-35 Description of the display http user command output

Item	Description
User name	User name.
Client IP Address	IP address of the HTTP client.
Login Date	Login date and time.
User timeouts	Idle timeout duration of online users.

2.6.12 display rsa local-key-pair public

Function

The **display rsa local-key-pair public** command displays the public key in the local key pair.

Format

display rsa local-key-pair public

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command on the client and configure the client public key in the command output to the SSH server, which ensures that the SSH client validity check by the SSH server is successful and enables the secure data exchange between the SSH server and client.

Example

Display the public key in the local key pair.

```
<HUAWEI> display rsa local-key-pair public
=====================================================

Time of Key pair created: 2012-08-15 06:41:55+08:00
Key name: HUAWEI_Host
Key type: RSA encryption Key

Table 2-36 Description of the **display rsa local-key-pair public** command output

Item	Description
Time of Key pair created	Time and date when the public key was created.
Key Name	The value can be the host or server public key. The server public key is saved only when the key type is RSA.
Key Type	Type of the public key.
Key fingerprint	Public key fingerprint.
Key Code	Code of the public key.

2.6.13 display rsa peer-public-key

Function

The **display rsa peer-public-key** command displays the peer public key saved on the local host. If no parameter is specified, the command displays detailed information about all peer public keys.

Format

display rsa peer-public-key [**brief** | **name** *key-name*]

Parameters

Parameter	Description	Value
brief	Displays the brief information about all peer public keys.	-
name *key-name*	Specifies the key name.	The value is a string of 1 to 30 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run this command to check detailed information about the RSA public key and whether the local and peer public keys are the same.

Precautions

You must complete the RSA public key configuration before running this command.

Example

Display the brief information about all RSA public keys.

```
<HUAWEI> display rsa peer-public-key brief
Address         Bits   Name
---------------------------
                768   rsakey001
```

Table 2-37 Description of the **display rsa peer-public-key brief** command output

Item	Description
Address	Brief information about the public key.
Bits	Bits in the public key.
Name	Name of the public key.

Display the detailed information about the RSA public key named **rsakey001**.

```
<HUAWEI> display rsa peer-public-key name rsakey001
=====================================
    Key name: rsakey001
    Key address:
=====================================
Key Code:

    1E10548C D70D000C 55A1A217 F4EA2F06 E44BD438 DA472F14 3FB7087B 45E77C05
  0203
    010001
```

Table 2-38 Description of the **display rsa peer-public-key name** command output

Item	Description
Key name	Name of the public key.
Key address	Brief information about the public key.
Key Code	Code of the public key.

2.6.14 display ssh server

Function

The **display ssh server** command displays the SSH server information.

Format

display ssh server { **status** | **session** }

Parameters

Parameter	Description	Value
status	Displays the global configuration on the SSH server.	-
session	Displays the current session connection information on the SSH server.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

After configuring the SSH attributes, you can run this command to view the configuration or session connection information on the SSH server to verify that the SSH connection has been established.

Example

Display the global configuration on the SSH server.

```
<HUAWEI> display ssh server status
 SSH version                         :2.0
 SSH connection timeout              :60 seconds
```

```
SSH server key generating interval  :0 hours
SSH authentication retries          :3 times
SFTP IPv4 server                    :Enable
SFTP IPv6 server                    :Enable
STELNET IPv4 server                 :Enable
STELNET IPv6 server                 :Enable
SCP IPv4 server                     :Enable
SCP IPv6 server                     :Enable
SSH server source                   :0.0.0.0
ACL4 number                         :0
ACL6 number                         :0
```

Table 2-39 Description of the **display ssh server status** command output

Item	Description
SSH version	Protocol version used for the SSH session connection.
SSH connection timeout	Timeout interval of SSH server authentication, in seconds. Run the **ssh server timeout** command to set this item.
SSH server key generating interval	Interval for generating an SSH server password, in hours. Run the **ssh server rekey-interval** command to set this item.
SSH authentication retries	Number of times for retrying the SSH session connection. Run the **ssh server authentication-retries** command to set this item.
SFTP IPv4 server	SFTP IPv4 service status. Run the **sftp ipv4 server enable** command to set this item.
SFTP IPv6 server	SFTP IPv6 service status. Run the **sftp ipv6 server enable** command to set this item.
STELNET IPv4 server	STelnet IPv4 service status. Run the **stelnet ipv4 server enable** command to set this item.
STELNET IPv6 server	STelnet IPv6 service status. Run the **stelnet ipv6 server enable** command to set this item.
SCP IPv4 server	SCP IPv4 service status. Run the **scp ipv4 server enable** command to set this item.
SCP IPv6 server	SCP IPv6 service status. Run the **scp ipv6 server enable** command to set this item.

Item	Description
SSH server source	Source address of the SSH server. Run the **ssh server-source** command to set this item.
ACL4 number	ACL4 number of the SSH server. Run the **ssh server acl** *acl-number* command to set this item.
ACL6 number	ACL6 number of the SSH server. Run the **ssh ipv6 server acl** *acl-number* command to set this item.

Display the current session connection information on the SSH server.

```
<HUAWEI> display ssh server session
 Session 1:
     Conn                 : VTY 10
     Version              : 2.0

     CTOS Compress        : none
     STOC Compress        : none
     Kex                  : diffie-hellman-group1-sha1
     Public Key           : rsa
     Service Type         : sftp
     Authentication Type  : password
 Session 2:
     Conn                 : VTY 14
     Version              : 2.0
     State                : started
     Username             : client001
     Retry                : 1
     CTOS Cipher          : aes256-cbc
     STOC Cipher          : aes256-cbc
     CTOS Hmac            : hmac-sha2_256
     STOC Hmac            : hmac-sha2_256
     CTOS Compress        : none
     STOC Compress        : none
     Kex                  : diffie-hellman-group1-sha1
     Public Key           : dsa
     Service Type         : stelnet
     Authentication Type  : password
```

Table 2-40 Description of the **display ssh server session** command output

Item	Description
Session	SSH session ID.
Conn	Connection used by the SSH session.
Version	Protocol version used for the SSH session connection.

Item	Description
State	Status of the SSH session connection.
Username	User name for SSH session connection. Run the **ssh user** command to set this item.
Retry	Number of times for retrying the SSH session connection. Run the **ssh server authentication-retries** command to set this item.
CTOS Cipher	Encryption algorithm name from client to server.
STOC Cipher	Encryption algorithm name from server to client.
CTOS Hmac	HMAC algorithm name from client to server.
STOC Hmac	HMAC algorithm name from server to client.
CTOS Compress	Whether data is compressed for transmission from client to server, which can be specified for SCP connection.
STOC Compress	Whether data is compressed for transmission from server to client, which can be specified for SCP connection.
Kex	Exchange algorithm name.
Public Key	Public key algorithm used for server authentication, which can be RSA, DSA, or ECC.
Service Type	Service type for an SSH user. The options are as follows: ● sftp ● stelnet ● all (including SCP, SFTP and STelnet) Run the **ssh user service-type** command to set this item.

Item	Description
Authentication Type	Authentication mode for an SSH user. The options are as follows: ● password ● rsa ● dsa ● ecc ● password-rsa (password and RSA) ● password-dsa (password and DSA) ● password-ecc (password and ECC) ● all (password, ECC, DSA, or RSA) Run the **ssh user authentication-type** command to set this item.

2.6.15 display ssh server-info

Function

The **display ssh server-info** command displays the binding between SSH servers and RSA, DSA, or ECC public keys when the current device works as an SSH client.

Format

display ssh server-info

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

When the SSH client needs to authenticate the server, the server public key saved in the local host is used to authenticate the connected SSH server. If the authentication fails, you can run the **display ssh server-info** command to check that the server public key is correct.

Example

Display all bindings between the SSH servers and public keys on the SSH client.

```
<HUAWEI> display ssh server-info
Server Name(IP)              Server Public Key Type  Server public key name
______________________________________________________________________________

192.168.50.207               RSA                     192.168.50.207
192.168.50.204               DSA                     192.168.50.204
192.168.50.208               ECC                     192.168.50.208
```

Table 2-41 Description of the **display ssh server-info** command output

Item	Description
Server Name(IP)	Host name of the SSH server.
Server Public Key Type	Type of the public key on the SSH server.
Server public key name	Name of the public key on the SSH server.

2.6.16 display ssh user-information

Function

The **display ssh user-information** command displays the configuration of all SSH users.

Format

display ssh user-information [*username*]

Parameters

Parameter	Description	Value
username	Displays the SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").

Views

All views

Default Level

3: Management level

Usage Guidelines

This command displays the SSH user name, bound RSA, DSA, or ECC public key name, and service type.

Example

Display the configuration of the SSH user named **client001**.

```
<HUAWEI> display ssh user-information client001
       User Name            : client001
       Authentication-type  : password
       User-public-key-name : -
       User-public-key-type : -
       Sftp-directory       : -
       Service-type         : stelnet
       Authorization-cmd    : No
```

Display the configuration of all SSH users.

```
<HUAWEI> display ssh user-information
  User 1:
       User Name            : client001
       Authentication-type  : password
       User-public-key-name : -
       User-public-key-type : -
       Sftp-directory       : -
       Service-type         : stelnet
       Authorization-cmd    : No
  User 2:
       User Name            : client002
       Authentication-type  : dsa
       User-public-key-name : dsakey001
       User-public-key-type : dsa
       Sftp-directory       : flash:
       Service-type         : sftp
       Authorization-cmd    : No
```

Table 2-42 Description of the **display ssh user-information** command output

Item	Description
User Name	SSH user name. Run the **ssh user** command to set this item.
Authentication-type	Authentication mode for an SSH user. The options are as follows: ● password ● rsa ● dsa ● ecc ● password-rsa (password and RSA) ● password-dsa (password and DSA) ● password-ecc (password and ECC) ● all (password, ECC, DSA, or RSA) Run the **ssh user authentication-type** command to set this item.
User-public-key-name	Peer RSA, DSA, or ECC public key assigned to an SSH user. Run the **rsa peer-public-key**, **dsa peer-public-key**, or **ecc peer-public-key** command to set this item.

Item	Description
User-public-key-type	The public key type for an SSH user can be RSA, DSA, or ECC.
Sftp-directory	SFTP service directory of an SSH user. Run the **ssh user sftp-directory** command to set this item.
Service-type	Service type for an SSH user. The options are as follows: ● sftp ● stelnet ● all: The service types are SFTP and STelnet. Run the **ssh user service-type** command to set this item.
Authorization-cmd	Command line authentication mode configured for an SSH user. Run the **ssh user authorization-cmd aaa** command to set this item.

2.6.17 display telnet server status

Function

The **display telnet server status** command displays the status and configuration of a Telnet server.

Format

display telnet server status

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

- To check whether a device functions as a Telnet server, run the **display telnet server status** command.

- If you have set a port number for the Telnet server using the **telnet server port** *port-number* command, run **display telnet server status** command to check the port number.

Example

Display the status and configuration of the Telnet server.

```
<HUAWEI> display telnet server status
 TELNET IPv4 server                    :Enable
 TELNET IPv6 server                    :Enable
 TELNET server port                    :23
 TELNET server source address              :0.0.0.0
 ACL4 number                          :0
 ACL6 number                          :0
```

Table 2-43 Description of the **display telnet server status** command output

Item	Description
TELNET IPv4 server	IPv4 Telnet server.
TELNET IPv6 server	IPv6 Telnet server.
TELNET server port	Listening port number of the Telnet server.
TELNET Server Source address	Source address of the Telnet server
ACL4 number	ACL4 number of the Telnet server
ACL6 number	ACL6 number of the Telnet server

2.6.18 display telnet-client

Function

The **display telnet-client** command displays the source parameters when a device works as a Telnet client.

Format

display telnet-client

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

After setting source parameters of a Telnet client, you can run this command to check the setting result. If you have not run the **telnet client-source** command, the default source IP address is 0.0.0.0.

Example

Display the source parameters of the device functioning as a Telnet client.

```
<HUAWEI> display telnet-client
 The source address of telnet client is 10.1.1.1
```

Table 2-44 Description of the **display telnet-client** command output

Item	Description
The source address of telnet client is 10.1.1.1	The source IP address of the Telnet client is 10.1.1.1.

2.6.19 dsa local-key-pair create

Function

The **dsa local-key-pair create** command generates the local DSA host key pairs.

Format

dsa local-key-pair create

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Compared with RSA, Digital Signature Algorithm (DSA) has a wider application in the SSH protocol. The asymmetric encryption system generates public and private keys to implement secure key exchange, thereby ensuring secure sessions.

If a DSA key exists, when you run this command, the system prompts you to confirm whether to change the original key. If you agree, the key in the new key pair is named ***device name*_Host_DSA**, for example, **HUAWEI_Host_DSA**. The local DSA private key is saved in PKCS#8 format to the hostkey_dsa file in the system NOR FLASH.

After you enter the command, the device prompts you to enter the number of bits in the host key. The length of a host key pair can be 2048. By default, the key length is 2048.

Precautions

This command is not saved in a configuration file and can take effect immediately after being run. After the device restarts, you do not need to run the command again.

To improve security of the device, it is recommended that you use a key pair of 2048 bits.

Example

Generate DSA key pairs on the device.

```
<HUAWEI> system-view
[HUAWEI] dsa local-key-pair create
Info: The key name will be: HUAWEI_Host_DSA.
Info: The key modulus can be any one of the following : 2048.
Info: If the key modulus is greater than 512, it may take a few minutes.
Please input the modulus [default=2048]:
Info: Generating keys...
Info: Succeeded in creating the DSA host keys.
```

2.6.20 dsa local-key-pair destroy

Function

The **dsa local-key-pair destroy** command deletes local DSA host key pairs.

Format

dsa local-key-pair destroy

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

DSA applies to SSH verification. The asymmetric encryption system generates public and private keys to implement secure key exchange, thereby ensuring secure sessions. You can run the **dsa local-key-pair create** command to generate local DSA keys. When local DSA keys are unnecessary, you can run the **dsa local-key-pair destroy** command to delete these keys.

Prerequisite

The local DSA keys have been created.

Configuration Impact

After you run this command, the ****_DSA** file that stores DSA keys on the device is cleared.

Precautions

The **dsa local-key-pair destroy** command takes effect once, and therefore will not be saved in the configuration file.

Example

Delete local DSA keys.

```
<HUAWEI> system-view
[HUAWEI] dsa local-key-pair destroy
Info: The name of the key which will be destroyed is
HUAWEI_Host_DSA.
Warning: These keys will be destroyed. Continue? [Y/N]:y
Info: Succeeded in destroying the DSA host keys.
```

2.6.21 dsa peer-public-key

Function

The **dsa peer-public-key** command configures an encoding format for a DSA public key and displays the DSA public key view.

The **undo dsa peer-public-key** command deletes a DSA public key.

By default, no encoding format is configured for a DSA public key.

Format

dsa peer-public-key *key-name* **encoding-type** { **der** | **openssh** | **pem** }

undo dsa peer-public-key *key-name*

Parameters

Parameter	Description	Value
key-name	Specifies the public key name.	The value is a string of 1 to 30 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
encoding-type	Specifies an encoding format for a DSA public key.	-
der	Specifies the Distinguished Encoding Rules (DER) format for a DSA public key. DER encodes data in hexadecimal format.	-
openssh	Specifies the OpenSSH format for a DSA public key. OpenSSH encodes data in base-64 format. OpenSSH is an encoding format based on PEM.	-
pem	Specifies the Privacy Enhanced Mail (PEM) format for a DSA public key. PEM encodes data in base-64 format.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you use a DSA public key for authentication, you must specify the public key of the corresponding client for an SSH user on the server. When the client logs in to the server, the server uses the specified public key to authenticate the client. You can also save the public key generated on the server to the client. Then the client can be successfully authenticated by the server when it logs in to the server for the first time.

Huawei data communications devices support the DER, OpenSSH and PEM formats for DSA keys. If you use a DSA key in non-DER/OpenSSH/PEM format, use a third-party tool to convert the key into a key in DER, OpenSSH or PEM format.

Because a third-party tool is not released with Huawei system software, DSA usability is unsatisfactory. In addition to DER and PEM, DSA keys need to support the OpenSSH format to improve DSA usability.

Third-party software, such as PuTTY, OpenSSH, and OpenSSL, can be used to generate DSA keys in different formats. The details are as follows:

- The PuTTY generate DSA keys in PEM format.
- The OpenSSH generates DSA keys in OpenSSH format.
- The OpenSSL generates DSA keys in DER format.

OpenSSL is an open source software. You can download related documents at the OpenSSL official website.

After you configure an encoding format for a DSA public key, Huawei data communications device automatically generates a DSA public key in the configured encoding format and enters the DSA public key view. Then, you can run the **public-key-code begin** command and manually copy the DSA public key generated on the peer device to the local device.

Follow-up Procedure

After you copy the DSA public key generated on the peer device to the local device, perform the following operations to exit the DSA public key view:

1. Run the **public-key-code end** command to return to the DSA public key view.
2. Run the **peer-public-key end** command to exit the DSA public key view and return to the system view.

Precautions

When you run the **undo dsa peer-public-key** command to delete a DSA public key:

- If the public key has been assigned to an SSH client, run the **undo ssh user** *user-name* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to release the binding between the public key and the SSH client. If you do not release the binding between them, the **undo dsa peer-public-key** command will fail to delete the public key.
- If the name of the host public key of the SSH server to be connected is specified on the SSH client, you need to run the **undo ssh client** *servername* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to delete the host public key of the SSH server. Otherwise, the DSA public key cannot be deleted.

The peer public key supports only PKCS#1. Other PKCS versions are not supported.

Example

Configure an encoding format for a DSA public key and enter the DSA public key view.

```
<HUAWEI> system-view
[HUAWEI] dsa peer-public-key 23 encoding-type der
[HUAWEI-dsa-public-key]
```

2.6.22 ecc local-key-pair create

Function

The **ecc local-key-pair create** command generates a local Elliptic Curves Cryptography (ECC) host key pair.

Format

ecc local-key-pair create

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A local key pair is a prerequisite to a successful SSH login. Compared with the RSA algorithm used by the **rsa local-key-pair create** command, the ECC algorithm shortens the key length, accelerates the encryption, and improves the security. The length of the server key pair and the host key pair can be 256 bits, 384 bits and 521 bits. By default, the length of the key pair is 521 bits.

Precautions

- The generated ECC host key pair is named in the format of switch name_Host_ECC, such as HUAWEI_Host_ECC. The local DSA private key is saved in PKCS#8 format to the hostkey_ecc file in the system NOR FLASH.
- The **ecc local-key-pair create** and **ecc local-key-pair destroy** commands are not saved in the configuration file. They only need to be run once and take effect even after the switch restarts.
- Do not delete the ECC key file from the switch. If the ECC key file is deleted, the ECC key pair cannot be restored after the switch is restarted.

Example

Generate a local ECC host key pair.

```
<HUAWEI> system-view
[HUAWEI] ecc local-key-pair create
Info: The key name will be: HUAWEI_Host_ECC.
Info: The ECC host key named HUAWEI_Host_ECC already exists.
Warning: Do you want to replace it ? [Y/N]: Y
Info: The key modulus can be any one of the following : 256, 384, 521.
Info: If the key modulus is greater than 512, it may take a few minutes.
Please input the modulus [default=521]:521
Info: Generating keys...
Info: Succeeded in creating the ECC host keys.
```

Enter a key with incorrect length and re-enter the key with incorrect length for five times, which is the maximum number of retry attempts.

```
<HUAWEI> system-view
[HUAWEI] ecc local-key-pair create
Info: The key name will be: HUAWEI_Host_ECC.
Info: The ECC host key named HUAWEI_Host_ECC already exists.
Warning: Do you want to replace it ?[Y/N]: Y
Info: The key modulus can be any one of the following : 256, 384, 521.
Info: If the key modulus is greater than 512, it may take a few minutes.
Please input the modulus [default=521]:123
Error: Invalid ECC key modulus.
Please input the modulus [default=521]:1024
Error: Invalid ECC key modulus.
Please input the modulus [default=521]:512
Error: Invalid ECC key modulus.
Please input the modulus [default=521]:2048
Error: Invalid ECC key modulus.
Please input the modulus [default=521]:4096
Error: Invalid ECC key modulus.
Error: The maximum number of retries has reached, and the command has already been canceled.
```

2.6.23 ecc local-key-pair destroy

Function

The **ecc local-key-pair destroy** command deletes the local Elliptic Curves Cryptography (ECC) keys.

Format

ecc local-key-pair destroy

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If you no longer need the local ECC key pairs, run the **ecc local-key-pair destroy** command to delete them.

Configuration Impact

After the **ecc local-key-pair destroy** command is run, the ECC key files on the device are cleared. Exercise caution when running the command.

Precautions

- The **ecc local-key-pair create** and **ecc local-key-pair destroy** commands are not saved in the configuration file. They only need to be run once and take effect even after the switch restarts.
- Do not delete the ECC key file from the switch. If the ECC key file is deleted, the ECC key pair cannot be restored after the switch is restarted.

Example

Delete the local ECC host key pair and server key pair.

```
<HUAWEI> system-view
[HUAWEI] ecc local-key-pair destroy
Info: The name of the key which will be destroyed is HUAWEI_Host_ECC.
Warning: These keys will be destroyed. Continue? [Y/N]:Y
Info: Succeeded in destroying the ECC host keys.
```

2.6.24 ecc peer-public-key

Function

The **ecc peer-public-key** command creates an ECC public key and enters the Elliptic Curves Cryptography (ECC) public key view.

The **undo ecc peer-public-key** command deletes an ECC public key.

By default, no ECC public key is created.

Format

ecc peer-public-key *key-name* **encoding-type** { **der** | **pem** | **openssh** }

undo ecc peer-public-key *key-name*

Parameters

Parameter	Description	Value
key-name	Specifies an ECC public key name.	The value is a string of 1 to 30 case-sensitive characters, spaces not supported.

Parameter	Description	Value
encoding-type	Indicates the encoding type of an ECC public key.	-
der	Specifies DER as the encoding type of an ECC public key. If DER is specified, data is encoded in hexadecimal notation.	-
pem	Specifies PEM as the encoding type of an ECC public key. If PEM is specified, data is Base64 encoded.	-
openssh	Specifies OpenSSH as the encoding type of an ECC public key. If OpenSSH is specified, data is Base64 encoded. OpenSSH is derived from PEM.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When ECC public key authentication is used, a client's public key must be specified on the server for an SSH user. When the client logs in to the server, the server performs authentication on the client based on the public key of the SSH user.

After an ECC public key is created and the ECC public key view is displayed, run the **public-key-code begin** command, then you can manually copy the client's public key to the server.

The client's public key is randomly generated by the client software.

Follow-up Procedure

After copying the client's ECC public key to the server, run the following commands to quit the ECC public key view:

1. Run the **public-key-code end** command to return to the ECC public key view.
2. Run the **peer-public-key end** command to exit the ECC public key view and return to the system view.

Precautions

A maximum of 20 ECC public keys can be created.

When you run the **undo ecc peer-public-key** command to delete an ECC public key:

- If the public key has been assigned to an SSH client, run the **undo ssh user** *user-name* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to release the binding between the public key and the SSH client. If you do not release the binding between them, the **undo dsa peer-public-key** command will fail to delete the public key.
- If the name of the host public key of the SSH server to be connected is specified on the SSH client, you need to run the **undo ssh client** *servername* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to delete the host public key of the SSH server. Otherwise, the DSA public key cannot be deleted.

The peer public key supports only PKCS#1. Other PKCS versions are not supported.

Example

Create an ECC public key and enter the ECC public key view.

```
<HUAWEI> system-view
[HUAWEI] ecc peer-public-key ecc-peer-key encoding-type pem
Info: Enter "ECC public key" view, return system view with "peer-public-key end".
[HUAWEI-ecc-public-key] public-key-code begin
Info: Enter "ECC key code" view, return the last view with "public-key-code end".
[HUAWEI-ecc-key-code] ---- BEGIN SSH2 PUBLIC KEY ----
[HUAWEI-ecc-key-code]
AAAAE2VjZHNhLXNoYTItbmlzdHA1MjEAAAAIbmlzdHA1MjEAAACDBL5J4v3pqi5S
[HUAWEI-ecc-key-code] ALI9lvLw4cdvtpD2AC6sEJXg9GDCD5vGBnkXlKmnOy6d1TyrXx57ZPNnrSdqVkHC
[HUAWEI-ecc-key-code] sMBa63vSwg1XsVW2qZgx8H57+FJiTPY61b1Vfst9GUif1ymfpB7XrbdYZDownoh0
[HUAWEI-ecc-key-code] FZNadZtIf2CRc0OeiKXbCSPP25dfoT/DTcc=
[HUAWEI-ecc-key-code] ---- END SSH2 PUBLIC KEY ----
[HUAWEI-ecc-key-code] public-key-code end
[HUAWEI-ecc-public-key] peer-public-key end
```

Delete an ECC public key.

```
<HUAWEI> system-view
[HUAWEI] undo ecc peer-public-key ecc-peer-key
Warning: The public key named ecc-peer-key will be deleted. Continue? [Y/N]:Y
```

2.6.25 free http user-id

Function

The **free http user-id** command configures a device to release web users.

Format

free http user-id *user-id*

Parameters

Parameter	Description	Value
user-id	Specifies the VTY ID of a web user to be released. You can run the **display users** command to query the VTY ID.	The value is an integer that ranges from 1 to 256.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A maximum of five web users are supported at present. If one of the five web users is logged out unexpectedly, the user's client keeps connection with the FTP server before the connection expires. During this period, other users cannot log in to the FTP server. To manually release the web user, run the **free http user-id** command.

Precautions

The **free http user-id** command is used only to release web users. **user-id** of web users ranges from 89 to 93, and a maximum of five users are allowed to stay online concurrently. If you set **user-id** to a value smaller than 89 or greater than 93, the message "Error: The specified user does not exist or is not an HTTP user." is displayed.

Example

Release the web user whose VTY ID is 89.

```
<HUAWEI> system-view
[HUAWEI] free http user-id 89
```

2.6.26 http acl

Function

The **http acl** command configures an ACL/ACL6 on the HTTP or HTTPS server.

The **undo http acl** command deletes the ACL/ACL6 on the HTTP or HTTPS server.

By default, no ACL/ACL6 is configured on the HTTP or HTTPS server.

Format

HTTP or HTTPS IPv4:

http acl *acl-number*

undo http acl

HTTP or HTTPS IPv6:

http ipv6 acl *acl6-number*

undo http ipv6 acl

Parameters

Parameter	Description	Value
acl-number	Specifies the ACL number for an HTTP or HTTPS IPv4 server.	The value is an integer that ranges from 2000 to 3999.
acl6-number	Specifies the ACL6 number for an HTTP or HTTPS IPv6 server.	The value is an integer that ranges from 2000 to 3999.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To ensure the security of an HTTP or HTTPS server, you need to configure an ACL/ ACL6 for it to specify clients that can log in to the current HTTP or HTTPS server.

Precautions

- The **http acl** command takes effect only after you run the **rule** command to configure the ACL/ACL6 rule.
- After an ACL/ACL6 rule is modified, the HTTP or HTTPS server does not forcibly log out an online user who matches the ACL/ACL6 rule until the user sends the next login request.
- If the **http acl** command is configured several times, only the latest configuration takes effect.

Example

Set the ACL number to 2000 for the HTTP or HTTPS IPv4 server.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule 1 permit source 10.1.1.1 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] http acl 2000
```

Set the ACL6 number to 2000 for the HTTP or HTTPS IPv6 server.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2000
[HUAWEI-acl6-basic-2000] rule 1 permit source fc00:1::1 128
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] http ipv6 acl 2000
```

2.6.27 http secure-server enable

Function

The **http secure-server enable** command enables the HTTPS service function.

The **undo http secure-server enable** command disables the HTTPS service function.

The **http secure-server disable** command disables the HTTPS service function.

By default, the HTTPS IPv4 service function is enabled, and the HTTPS IPv6 service function is disabled.

Format

http [**ipv6**] **secure-server enable**

undo http [**ipv6**] **secure-server enable**

http [**ipv6**] **secure-server disable**

Parameters

Parameter	Description	Value
ipv6	Enables or disables the HTTPS IPv6 service function. If this parameter is not specified, the HTTPS IPv4 service function is enabled or disabled.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After an SSL policy is loaded to an HTTPS server, the HTTPS server provides HTTPS service using SSL. The client and HTTPS server establish an SSL connection to protect user information from theft.

Prerequisites

The web page file has been loaded to the device.

Precautions

- After the HTTPS service is enabled, only authenticated users can use the web browser to access the web network management system to manage devices.
- After the HTTPS service is enabled, the SSL handshake negotiation is triggered.
- After the **http secure-server enable** command is run, the HTTPS server accepts only login requests from MEth0/0/1 or VLANIF1 by default. To allow authorized users to log in to the HTTPS server from other interfaces, you should run the **http server-source** command to specify the source interface of the HTTPS server.
- After the **http ipv6 secure-server enable** command is run, the HTTPS server does not accept login requests from any IPv6 address by default, you should run the **http ipv6 server-source** command to specify the IPv6 source address for the HTTPS server.

Example

Enable the HTTPS IPv4 service.

```
<HUAWEI> system-view
[HUAWEI] http secure-server enable
```

Enable the HTTPS IPv6 service.

```
<HUAWEI> system-view
[HUAWEI] http ipv6 secure-server enable
```

2.6.28 http secure-server port

Function

The **http secure-server port** command sets a port number for an HTTPS server.

The **undo http secure-server port** command restores the default port number of an HTTPS server.

By default, the port number of an HTTPS server is 443.

Format

http [**ipv6**] **secure-server port** *port-number*

undo http [**ipv6**] **secure-server port**

Parameters

Parameter	Description	Value
ipv6	Specifies the port number for an HTTPS IPv6 server. If this parameter is not specified, the command sets the port number for an HTTPS IPv4 server.	-

Parameter	Description	Value
port-number	Specifies the port number of an HTTPS server.	The value is 443 or an integer that ranges from 1025 to 55535.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, the port number of an HTTPS server is 443. Attackers may frequently access an HTTPS server through the default port, consuming bandwidth, deteriorating server performance, and causing authorized users unable to access the server. You can run the **http secure-server port** command to specify another port number to prevent attackers from accessing the default port.

Precautions

If the **http secure-server port** command is configured several times, only the latest configuration takes effect.

Example

Set the port number of an HTTPS IPv4 server to 8080.

```
<HUAWEI> system-view
[HUAWEI] http secure-server port 8080
```

Set the port number of an HTTPS IPv6 server to 8080.

```
<HUAWEI> system-view
[HUAWEI] http ipv6 secure-server port 8080
```

2.6.29 http secure-server ssl-policy

Function

The **http secure-server ssl-policy** command configures an SSL policy for the HTTP server.

The **undo http secure-server ssl-policy** command restores the default SSL policy for the HTTP server.

A default SSL policy is available on an HTTP server.

Format

http secure-server ssl-policy *policy-name*

undo http secure-server ssl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an SSL policy.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Traditional HTTP service transmits data in plain text, which can be intercepted and tampered with. User identity cannot be authenticated, and the HTTP server cannot ensure online data security of applications such as the e-commerce and online banks. You can run the **http secure-server ssl-policy** command to configure an SSL policy for the HTTP server to encrypt data, authenticate user identity, and check message integrity to ensure data security during the web access.

Prerequisites

Before running the **http secure-server ssl-policy** command, you must first run the **ssl policy** command to create an SSL policy on the HTTP server.

Precautions

- The device provides a default SSL policy named **Default**. After the web page file is loaded to the device, the default SSL policy is loaded automatically, and you do not need to configure an SSL policy. To enhance device security, it is recommended that you obtain a new digital certificate from the CA and manually configure an SSL policy
- Only one SSL policy can be configured for the HTTP server, and the latest configured SSL policy takes effect.

Example

Configure an SSL policy for the HTTP server.

```
<HUAWEI> system-view
[HUAWEI] http secure-server ssl-policy http_server
```

2.6.30 http server enable

Function

The **http server enable** command enables the HTTP server function.

The **undo http server enable** command disables the HTTP server function.

The **http server disable** command disables the HTTP server function.

By default, the HTTP IPv4 server function is enabled, and the HTTP IPv6 server function is disabled.

Format

http [**ipv6**] **server enable**

undo http [**ipv6**] **server enable**

http [**ipv6**] **server disable**

Parameters

Parameter	Description	Value
ipv6	Enables or disables the HTTP IPv6 server function. If this parameter is not specified, the HTTP IPv4 server function is enabled or disabled.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After running the **http server enable** command to enable the HTTP server, you can use the browser to access the web NMS to manage devices.

If the web page to load does not exist, the HTTP service cannot be enabled.

Prerequisites

The HTTPS service has been enabled using the **http secure-server enable** command.

Precautions

- After the **http server enable** command is run, the HTTPS server accepts only login requests from MEth0/0/1 or VLANIF1 by default. To allow authorized users to log in to the HTTPS server from other interfaces, you should run the **http server-source** command to specify the source interface of the HTTP server.

- After the **http ipv6 server enable** command is run, the HTTP server does not accept login requests from any IPv6 address by default, you should run the **http ipv6 server-source** command to specify the IPv6 source address for the HTTP server.

Example

Enable the HTTP IPv4 server.

```
<HUAWEI> system-view
[HUAWEI] http secure-server enable
[HUAWEI] http server enable
Warning: HTTP is not a secure protocol, and it is recommended to use HTTPS.
Info: Succeeded in starting the HTTP server.
```

Enable the HTTP IPv6 server.

```
<HUAWEI> system-view
[HUAWEI] http ipv6 secure-server enable
[HUAWEI] http ipv6 server enable
Warning: HTTP is not a secure protocol, and it is recommended to use HTTPS.
Info: Succeeded in starting the HTTP IPv6 server.
```

2.6.31 http server load

Function

The **http server load** command loads a web page file.

The **undo http server load** command cancels loading of a specified web page file.

By default, the web page file in the system software has been loaded to the devices.

Format

http server load { *file-name* | **default** }

undo http server load

Parameters

Parameter	Description	Settings
file-name	Specifies the name of the web page file to load. The web page file must be stored in the root directory of the storage device.	The value is a string of 4 to 64 characters without spaces. The file name is in the *.web.7z format.

Parameter	Description	Settings
default	Specifies the web page file in the current system software that is to be loaded.	–

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If you need to manage and maintain devices on the graphical user interface (GUI), configure the Web network management function. When you need to update web page file when using the Web network management function, run this command to load web page file.

Prerequisites

Before loading the web page file using the **http server load** command, ensure that the web page file has been stored to the root directory of the storage device on the device; otherwise, file loading will fail.

Precautions

- If the system software is upgraded from V200R006 or an earlier version to V200R007 or a later version, but the target software version conflicts with the configuration file for next startup, the device will cancel the configuration of loading the web page file in the original system software after the upgrade, and loads the web page file integrated in the new system software by default.
- The web page file contains the SSL certificate, which is used to authenticate the HTTP server during login to ensure information security. When a user attempts to log in to the device through HTTP, the HTTPS login page is pushed to the user. After the user is authenticated, the system returns to the HTTP page. The SSL certificate is also used in the HTTPS login mode to ensure security of user information and data exchanged between the client and server. You can load a new digital certificate to the device.
- If the loaded web page file does not exist, the HTTP service cannot be enabled when the device restarts.
- To disable a loaded web page file, you must load another file.

Example

Load the web page file **web_1.web.7z**.

```
<HUAWEI> system-view
[HUAWEI] http server load web_1.web.7z
```

2.6.32 http server port

Function

The **http server port** command sets the listening port number of the HTTP server.

The **undo http server port** command restores the default listening port number of the HTTP server.

By default, the listening port number of the HTTP server is 80.

Format

http [**ipv6**] **server port** *port-number*

undo http [**ipv6**] **server port**

Parameters

Parameter	Description	Value
ipv6	Specifies a listening port number for an HTTP IPv6 server. If this parameter is not specified, the command configures a listening port number for an HTTP IPv4 server.	-
port-number	Specifies the listening port number of the HTTP server.	The value is 80, or an integer that ranges from 1025 to 55535. The default value is 80.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, the listening port number of the security HTTP server is 80. Attackers may frequently access the default listening port, which wastes bandwidth, deteriorates server performance, and prevents authorized users from accessing the HTTP server through the listening port. You can run the **http server port** command to specify another listening port number to prevent attackers from accessing the listening port.

Precautions

If the **http server port** command is configured several times, only the latest configuration takes effect.

Example

Set the listening port number of the HTTP IPv4 server to 1025.

```
<HUAWEI> system-view
[HUAWEI] http server port 1025
```

Set the listening port number of the HTTP IPv6 server to 1500.

```
<HUAWEI> system-view
[HUAWEI] http ipv6 server port 1500
```

2.6.33 http server-source

Function

The **http server-source** command specifies a source interface for an HTTP or HTTPS server.

The **undo http server-source** command cancels the source interface specified for an HTTP or HTTPS server.

By default, the source interface of an HTTP or HTTPS server is MEth0/0/1 or VLANIF 1. The web login is supported after the device enters the initial configuration mode. The source interface of an HTTP or HTTPS server is MEth0/0/1 or VLANIF 1..

Format

http server-source -i *interface-type interface-number*

undo http server-source

http server-source all-interface

Parameters

Parameter	Description	Value
-i *interface-type interface-number*	Specifies the source interface of an HTTP or HTTPS server.	-
all-interface	Indicates that any interface that has an IPv4 address configured can be used as the source interface of an HTTP or HTTPS server.	-

NOTE

In V200R020C00 and later versions, to allow authorized users to log in to the HTTP server through a non-management network port, run a command to specify the source interface of the HTTP server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, an HTTP or HTTPS server receives connection requests from all interfaces by default, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, an HTTP or HTTPS server accepts only login requests from MEth0/0/1 or VLANIF1 by default. To allow authorized users to log in to the HTTP or HTTPS server, run either of the following commands to specify the source interface of the HTTP or HTTPS server.

- Run the **http server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the HTTP or HTTPS server.
- Run the **http server-source all-interface** command to configure all interfaces configured with IPv4 addresses as the source interfaces of the HTTP or HTTPS server.

Prerequisites

Before you specify a logical interface as the source interface, ensure that the interface to be specified is created and has an IP address configured. Before you specify a physical interface as the source interface, ensure that the interface has an IPv4 address configured. Otherwise, the **http server-source** command cannot be successfully executed.

Configuration Impact

Users can log in to an HTTP or HTTPS server only from the specified source interface.

After you run **http server-source** command, the HTTP IPv4 user that has logged in to the server will be forcibly logged out and needs to log in again.

Precautions

After the source interface of an HTTP or HTTPS server is specified using the **http server-source** command, ensure that HTTP or HTTPS users can access the source interface at Layer 3. Otherwise, the HTTP or HTTPS users will fail to log in to the HTTP or HTTPS server.

After the **http server-source all-interface** command is run, the system allows HTTP or HTTPS users to log in to the HTTP or HTTPS server through all interfaces with IPv4 addresses configured. This increases system security risks. Therefore, you are not advised to run this command.

Example

Specify loopback 0 as the source interface of an HTTP or HTTPS server.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
[HUAWEI-LoopBack0] quit
[HUAWEI] http server-source -i loopback 0
Warning: The operation will reboot the HTTP server. Continue? [Y/N]:y
Info: Succeeded in setting the source interface of the HTTP server to
LoopBack0.
Info: Succeeded in starting the HTTP secure server.
Warning: HTTP is not a secure protocol, and it is recommended to use
HTTPS.
Info: Succeeded in starting the HTTP server.
```

2.6.34 http ipv6 server-source

Function

The **http ipv6 server-source** command specifies an IPv6 source address for an HTTP or HTTPS server.

The **undo http ipv6 server-source** command cancels the IPv6 source address specified for an HTTP or HTTPS server.

By default, the IPv6 source address of an HTTP or HTTPS server is not specified.

Format

http ipv6 server-source -a *ipv6_address* [**-vpn-instance** *vpn_name*]

undo http ipv6 server-source

http ipv6 server-source all-interface

Parameters

Parameter	Description	Value
-a *ipv6_address*	Specifies the IPv6 source address for an HTTP or HTTPS server.	The total length of an IPv6 address is 128 bits, which are divided into eight groups. Each group contains four hexadecimal digits. The value is in the format X:X:X:X:X:X:X:X.

Parameter	Description	Value
-vpn-instance *vpn_name*	Specifies the name of a VPN instance.	The value is a string of 1 to 31 case-sensitive characters. It cannot contain spaces. The VPN instance name cannot be **_public_**. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
all-interface	Indicates that any interface IPv6 address on the device can be used as the IPv6 source address of the HTTP or HTTPS server.	-

NOTE

In V200R020C00 and later versions, to allow authorized users to log in to the HTTP server through a non-management network port, run a command to specify the source interface of the HTTP server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, an HTTP or HTTPS server receives connection requests from all interfaces by default, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, an HTTP or HTTPS server does not accept login requests from any interface by default. To allow authorized users to log in to the HTTP or HTTPS server, run either of the following commands to specify the source interface of the HTTP or HTTPS server.

- Run the **http ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure the specified IPv6 address as the IPv6 source address of the HTTP or HTTPS server.
- Run the **http ipv6 server-source all-interface** command to configure all interface IPv6 addresses on the device as the IPv6 source addresses of the HTTP or HTTPS server.

Prerequisites

A VPN instance has been created before you specify it for an HTTP or HTTPS server. Otherwise, the **http ipv6 server-source** command cannot be executed.

Configuration Impact

After an IPv6 source address is specified for an HTTP or HTTPS server, HTTP or HTTPS users can log in to the HTTP or HTTPS server only using this IPv6 address. This configuration applies to the HTTP or HTTPS users who attempt to log in to the server, not to the HTTP or HTTPS users who have logged in to the server.

Precautions

After an IPv6 source address is specified for an HTTP or HTTPS server using this command, ensure that HTTP or HTTPS users can access this IPv6 address at Layer 3. Otherwise, HTTP or HTTPS users will fail to log in to the HTTP or HTTPS server.

If the specified IPv6 source address is bound to a VPN instance, the HTTP or HTTPS server is also bound to the VPN instance.

After the **http ipv6 server-source all-interface** command is run, the system allows HTTP or HTTPS users to log in to the HTTP or HTTPS server through all interfaces with IPv6 addresses configured. This increases system security risks. Therefore, running this command is not recommended.

Example

Specify the IPv6 source address 2001:DB8:: for an HTTP or HTTPS server.

```
<HUAWEI> system-view
[HUAWEI] http ipv6 server-source -a 2001:DB8::
```

2.6.35 http timeout

Function

The **http timeout** command sets the idle timeout duration of the web server.

The **undo http timeout** command restores the default idle timeout duration of the web server.

By default, the idle timeout duration of the web server is 20 minutes.

Format

http timeout *timeout*

undo http timeout

Parameters

Parameter	Description	Value
timeout	Specifies the idle timeout duration of the web server for online users.	The value is an integer that ranges from 1 to 60, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A maximum of five web users are supported at present. When the fifth web user logs in to the web server, any other user cannot log in to the web server even if any of the five users does not perform operations for a long time. The idle timeout duration is configured to release web resources in time. To occupy web channels for a long time, you must set the idle timeout duration to the maximum value.

Precautions

- After you run the **http timeout** command, the idle timeout durations are the same for all web users who log in to the web server. If the idle timeout duration expires, a user is disconnected from the web server and the web server notifies the user only after the user sends the next login request.
- If the **http timeout** command is configured several times, only the latest configuration takes effect.

Example

Set the idle timeout duration of the web server to 6 minutes.

```
<HUAWEI> system-view
[HUAWEI] http timeout 6
```

2.6.36 lock

Function

The **lock** command locks the current user interface to prevent unauthorized users from operating the interface.

By default, the system does not automatically lock the current user interface.

Format

lock

Parameters

None

Views

User view

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

Lock the current user interface using this command to prevent other users from operating the interface. The user interface can be console or VTY.

After running the **lock** command, you are prompted to enter a password twice. If you enter the correct password twice, the user interface is locked.

Precautions

- The passwords must meet the following requirements:
  - The password must be a string of 8 to 16 case-sensitive characters.
  - The password must contain at least two types of the following characters: upper-case characters, lower-case characters, digits, and special characters.

    Special characters do not include the question mark (?) and space.
- The password entered in interactive mode is not displayed on the screen.
- You can press **CTRL_C** to cancel the password-based locking operation.
- To unlock the user interface, press **Enter**, and then enter the correct password as prompted.

Example

Lock the current user interface after logging in through the console port.

```
<HUAWEI> lock
Please configure the login password (8-16)
Enter Password:
Confirm Password:
Info: The terminal is locked.
```

To log in to the system again, press **Enter**. The following information is displayed:

```
Enter Password:
```

Enter the correct password and return to the user view.

```
<HUAWEI>
```

2.6.37 matched upper-view

Function

The **matched upper-view** command allows a device to search for the **undo** command in the upper view, and returns to the upper view.

The **undo matched upper-view** command prohibits a device from searching for the **undo** command in the upper view.

By default, a device does not search for the **undo** command in the upper view.

Format

matched upper-view

undo matched upper-view

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If the **matched upper-view** command is run, when you run an **undo** command that is not registered in the current view, a device searches for the **undo** in the upper view. If the device finds the same **undo** command, it executes this command in the upper view. If the device does not find the same **undo** command in the upper view, it continues to search for this command in more upper views till the system view.

Running this command brings security risks. For example, if you run the **undo ftp server** command in the interface view, while this command is not registered in the interface view, the device automatically searches for it in the upper view, that is, the system view, and disables the FTP function.

The **matched upper-view** command is valid only for current login users who run this command.

Example

Allow a device to search for the **undo** command in the upper view.

```
<HUAWEI> system-view
[HUAWEI] matched upper-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo ftp server
Info: Succeeded in closing the FTP server.
```

Prohibit a device from searching for the **undo** command in the upper view.

```
<HUAWEI> system-view
[HUAWEI] undo matched upper-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo ftp server
                               ^
Error: Unrecognized command found at '^' position.
```

2.6.38 peer-public-key end

Function

The **peer-public-key end** command returns to the system view from the public key view and saves the configured public keys.

Format

peer-public-key end

Parameters

None

Views

Public key view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You must save the public key generated on the remote host to the local host, which ensures that the validity check on the remote end is successful. After editing a public key in the public key view, you can run this command to return to the system view.

Prerequisites

Before you run this command, the **rsa peer-public-key** command has been run to enter the RSA public key view, the **dsa peer-public-key** command has been run to enter the DSA public key view, or the **ecc peer-public-key** command has been run to enter the ECC public key view.

Example

Return to the system view from the public key view.

```
<HUAWEI> system-view
[HUAWEI] dsa peer-public-key dsakey001 encoding-type der
[HUAWEI-dsa-public-key] public-key-code begin
[HUAWEI-dsa-key-code] 308188
[HUAWEI-dsa-key-code] 028180
[HUAWEI-dsa-key-code] B21315DD 859AD7E4 A6D0D9B8 121F23F0 006BB1BB
[HUAWEI-dsa-key-code] A443130F 7CDB95D8 4A4AE2F3 D94A73D7 36FDFD5F
[HUAWEI-dsa-key-code] 411B8B73 3CDD494A 236F35AB 9BBFE19A 7336150B
[HUAWEI-dsa-key-code] 40A35DE6 2C6A82D7 5C5F2C36 67FBC275 2DF7E4C5
[HUAWEI-dsa-key-code] 1987178B 8C364D57 DD0AA24A A0C2F87F 474C7931
[HUAWEI-dsa-key-code] A9F7E8FE E0D5A1B5 092F7112 660BD153 7FB7D5B2
[HUAWEI-dsa-key-code] 171896FB 1FFC38CD
[HUAWEI-dsa-key-code] 0203
[HUAWEI-dsa-key-code] 010001
```

```
[HUAWEI-dsa-key-code] public-key-code end
[HUAWEI-dsa-public-key] peer-public-key end
[HUAWEI]
```

2.6.39 public-key-code begin

Function

The **public-key-code begin** command displays the public key editing view.

Format

public-key-code begin

Parameters

None

Views

Public key view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To ensure that the remote host passes the validity check performed by the local host, the public key generated on the remote host must be saved to the local host. To save the public key, run the **public-key-code begin** command to enter the public key editing view and then enter the key. The key characters can contain spaces. You can also press **Enter** to enter data in another line.

Prerequisite

A key name has been specified using the **rsa peer-public-key**, **dsa peer-public-key**, or **ecc peer-public-key** command.

Precautions

- The public key must be a hexadecimal character string in the public key encoding format, and generated by the client or server that supports SSH.
- The public key displayed using the **display rsa local-key-pair public**, **display dsa local-key-pair public**, or **display ecc local-key-pair public** command can be used as the key data to enter.
- The last line of the key cannot contain only spaces and dsa-key; otherwise, the spaces at the beginning of the lines that are entered will be automatically deleted, and an error will be reported after the **public-key-code end** command is run.

Example

Display the DSA public key editing view and enter the key data.

```
<HUAWEI> system-view
[HUAWEI] dsa peer-public-key dsakey001 encoding-type der
[HUAWEI-dsa-public-key] public-key-code begin
[HUAWEI-dsa-key-code] 308188
[HUAWEI-dsa-key-code] 028180
[HUAWEI-dsa-key-code] B21315DD 859AD7E4 A6D0D9B8 121F23F0 006BB1BB
[HUAWEI-dsa-key-code] A443130F 7CDB95D8 4A4AE2F3 D94A73D7 36FDFD5F
[HUAWEI-dsa-key-code] 411B8B73 3CDD494A 236F35AB 9BBFE19A 7336150B
[HUAWEI-dsa-key-code] 40A35DE6 2C6A82D7 5C5F2C36 67FBC275 2DF7E4C5
[HUAWEI-dsa-key-code] 1987178B 8C364D57 DD0AA24A A0C2F87F 474C7931
[HUAWEI-dsa-key-code] A9F7E8FE E0D5A1B5 092F7112 660BD153 7FB7D5B2
[HUAWEI-dsa-key-code] 171896FB 1FFC38CD
[HUAWEI-dsa-key-code] 0203
[HUAWEI-dsa-key-code] 010001
[HUAWEI-dsa-key-code] public-key-code end
[HUAWEI-dsa-public-key] peer-public-key end
[HUAWEI]
```

2.6.40 public-key-code end

Function

The **public-key-code end** command returns to the public key view from the public key editing view and saves the configured public key.

Format

public-key-code end

Parameters

None

Views

Public key editing view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After this command is run, editing the public key ends. Before saving the public key, the system will check the validity of the key.

- If there are illegal characters in the public key configured by the user, the system displays an error prompt. The public key is then discarded, and the configuration fails.
- If the public key configured is valid, it is saved in the public key chain table of the host.

Prerequisites

Before you run this command, the **public-key-code begin** command has been run to enter the public key edit view.

Precautions

- Generally, in the public key view, only the **public-key-code end** command can be used to exit. The **quit** command cannot be used.
- If no valid key coding is input, the key cannot be generated after the **public-key-code end** command is used. The system prompts that key generation fails.
- If the key has been deleted in another window, when you run the **public-key-code end** command, the system prompts that the key does not exist and returns to the system view.

Example

Exit the DSA public key editing view and saves the DSA key configuration.

```
<HUAWEI> system-view
[HUAWEI] dsa peer-public-key dsakey001 encoding-type der
[HUAWEI-dsa-public-key] public-key-code begin
[HUAWEI-dsa-key-code] 308188
[HUAWEI-dsa-key-code] 028180
[HUAWEI-dsa-key-code] B21315DD 859AD7E4 A6D0D9B8 121F23F0 006BB1BB
[HUAWEI-dsa-key-code] A443130F 7CDB95D8 4A4AE2F3 D94A73D7 36FDFD5F
[HUAWEI-dsa-key-code] 411B8B73 3CDD494A 236F35AB 9BBFE19A 7336150B
[HUAWEI-dsa-key-code] 40A35DE6 2C6A82D7 5C5F2C36 67FBC275 2DF7E4C5
[HUAWEI-dsa-key-code] 1987178B 8C364D57 DD0AA24A A0C2F87F 474C7931
[HUAWEI-dsa-key-code] A9F7E8FE E0D5A1B5 092F7112 660BD153 7FB7D5B2
[HUAWEI-dsa-key-code] 171896FB 1FFC38CD
[HUAWEI-dsa-key-code] 0203
[HUAWEI-dsa-key-code] 010001
[HUAWEI-dsa-key-code] public-key-code end
[HUAWEI-dsa-public-key] peer-public-key end
[HUAWEI]
```

2.6.41 rsa local-key-pair create

Function

The **rsa local-key-pair create** command generates the local RSA host and server key pairs.

By default, the local RSA host and server key pairs are not configured.

Format

rsa local-key-pair create

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To implement secure data exchange between the server and client, run the **rsa local-key-pair create** command to generate a local key pair.

Precautions

If the RSA key pair exists, the system prompts you to confirm whether to replace the original key pair. The keys in the new key pair are named **device name_Server** and **device name_Host**, for example, HUAWEI_Host and HUAWEI_Server. After being encrypted by AES256, the local RSA private key is saved to the hostkey and serverkey files in the system NOR FLASH.

After you run this command, the system prompts you to enter the number of bits in the host key. The difference between the bits in the server and host key pairs must be at least 128 bits. The length of the server or host key pair is 2048 ~ 4096 bits.

After you run this command, the generated key pair is saved in the device and will not be lost after the device restarts.

To improve security of the device, it is recommended that you use a key pair of 4096 bits.

This command is not saved in a configuration file.

Example

Generate the local RSA host and server key pairs.

```
<HUAWEI> system-view
[HUAWEI] rsa local-key-pair create
The key name will be: HUAWEI_Host
The range of public key size is (2048 ~ 4096).
NOTES: If the key modulus is greater than 512,
       it will take a few minutes.
Input the bits in the modulus[default = 2048]:
Generating keys...
......................++++++++
.......................................................++++++++
........+++++++++
.....+++++++++
```

2.6.42 rsa local-key-pair destroy

Function

The **rsa local-key-pair destroy** command deletes all local RSA host and server key pairs.

Format

rsa local-key-pair destroy

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To delete the local key pairs, run **rsa local-key-pair destroy** command. If the host key pair and server key pair of an SSH server are deleted, run the **rsa local-key-pair create** command to create a new host key pair and server key pair for the SSH server.

After you run this command, verify that all local RSA keys are deleted. This command is not saved in a configuration file.

Prerequisite

The local RSA key pairs that can be deleted exist.

Example

Delete all RSA server key pairs.

```
<HUAWEI> system-view
[HUAWEI] rsa local-key-pair destroy
% The name for the keys which will be destroyed is HUAWEI_Host.
% Confirm to destroy these keys? [y/n]:y
Destroying keys............Succeeded.
```

2.6.43 rsa peer-public-key

Function

The **rsa peer-public-key** command configures an encoding format for an RSA public key and displays the RSA public key view.

The **undo rsa peer-public-key** command deletes an RSA public key.

By default, the encoding format is distinguished encoding rules (DER) for an RSA public key.

Format

rsa peer-public-key *key-name* [**encoding-type** { **der** | **openssh** | **pem** }]

undo rsa peer-public-key *key-name*

Parameters

Parameter	Description	Value
key-name	Specifies the RSA public key name.	The value is a string of 1 to 30 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
encoding-type	Specifies the encoding format of an RSA public key.	-
der	Specifies the DER format of an RSA public key. DER encodes data in hexadecimal format.	-
openssh	Specifies the OpenSSH format of an RSA public key. OpenSSH encodes data in base-64 format. OpenSSH is an encoding format based on PEM.	-
pem	Specifies the PEM format of an RSA public key. PEM encodes data in base-64 format.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you use an RSA public key for authentication, you must specify the public key of the corresponding client for an SSH user on the server. When the client logs in to the server, the server uses the specified public key to authenticate the client. You can also save the public key generated on the server to the client. Then the client can be successfully authenticated by the server when it logs in to the server for the first time.

Huawei data communications devices support the DER, OpenSSH and PEM formats for RSA keys. If you use an RSA key in non-DER/OpenSSH/PEM format, use a third-party tool to convert the key into a key in DER, OpenSSH or PEM format.

Because a third-party tool is not released with Huawei system software, RSA usability is unsatisfactory. In addition to DER, RSA keys need to support the privacy-enhanced mail (PEM) and OpenSSH formats to improve RSA usability.

Third-party software, such as PuTTY, OpenSSH, and OpenSSL, can be used to generate RSA keys in different formats. The details are as follows:

- The PuTTY generate RSA keys in PEM format.
- The OpenSSH generates RSA keys in OpenSSH format.
- The OpenSSL generates RSA keys in DER format.

OpenSSL is an open source software. You can download related documents at the OpenSSL official website.

After you configure an encoding format for an RSA public key, Huawei data communications device automatically generates an RSA public key in the configured encoding format and enters the RSA public key view. Then you can run the **public-key-code begin** command and manually copy the RSA public key generated on the peer device to the local device.

Prerequisite

The RSA public key in hexadecimal notation on the remote host has been obtained and recorded.

Follow-up Procedure

After you copy the RSA public key generated on the peer device to the local device, perform the following operations to exit the RSA public key view:

1. Run the **public-key-code end** command to return to the RSA public key view.
2. Run the **peer-public-key end** command to exit the RSA public key view and return to the system view.

Precautions

When you run the **undo rsa peer-public-key** command to delete a public key:

- If the public key has been assigned to an SSH client, run the **undo ssh user** *user-name* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to release the binding between the public key and the SSH client. If you do not release the binding between them, the **undo dsa peer-public-key** command will fail to delete the public key.
- If the name of the host public key of the SSH server to be connected is specified on the SSH client, you need to run the **undo ssh client** *servername* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } command to delete the host public key of the SSH server. Otherwise, the DSA public key cannot be deleted.

The peer public key supports only PKCS#1. Other PKCS versions are not supported.

Example

Display the RSA public key view.

```
<HUAWEI> system-view
[HUAWEI] rsa peer-public-key rsakey001
[HUAWEI-rsa-public-key]
```

Configure an encoding format for an RSA public key and enter the RSA public key view.

```
<HUAWEI> system-view
[HUAWEI] rsa peer-public-key RsaKey001 encoding-type openssh
[HUAWEI-rsa-public-key]
```

2.6.44 run

Function

The **run** command runs a user view command in the system view.

By default, a user view command cannot be run in the system view.

Format

run *command-line*

Parameters

Parameter	Description	Value
command-line	Specifies a command to be run.	-

Views

All views except the user view

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

Some commands can be run only in the user view. To run these commands, you must return to the user view first. To facilitate command execution, the device allows you to run the **run** command to run such commands in the other views without returning to the user view.

Precautions

- The command specified in the **run** command can be run in the user view.
- When you run the **run** command, the association help function is unavailable.
- When you check the command history on the device using the **display history-command** command, only the commands that you enter are recorded. The command format is **run** *command-line*.

- When you check log information using the **SHELL/5/CMDRECORD** command, only the commands that are actually run are recorded in logs. The command format is **run** *command-line*.

Example

Run the **dir *.cfg** command to check the .cfg file in the system view.

```
<HUAWEI> system-view
[HUAWEI] run dir *.cfg
Directory of flash:/
  Idx  Attr     Size(Byte)  Date        Time       FileName
    0  -rw-         11,970  Mar 14 2012 19:11:22   31.cfg
    1  -rw-         12,033  Apr 22 2012 17:10:30   31_new.cfg
509,256 KB total (118,784 KB free)
```

2.6.45 send

Function

The **send** command configures a device to send messages to all user interfaces.

Format

send { **all** | *ui-number* | *ui-type ui-number1* }

Parameters

Parameter	Description	Value
all	Specifies that the device sends messages to all user interfaces.	-
ui-number	Specifies the absolute number of a user interface.	The minimum value is 0. The maximum value is the number of the user interfaces that the device supports minus 1.
ui-type	Specifies the type of a user interface.	-
ui-number1	Specifies the relative number of a user interface.	-

Views

User view

Default Level

1: Monitoring level

Usage Guidelines

After you run the **send** command on a device, the device prompts you to enter a message to send. After you confirm to send this message, the user who logs in to the device from a specified user interface can receive this message.

Example

Send a message to the user interface VTY 0.

```
<HUAWEI> send vty 0
Enter message, end with CTRL+Z or Enter; abort with CTRL+C:
Hello, good morning!
Warning: Send the message? [Y/N]: y
```

After you confirm to send the message, the user who logs in to the HUAWEI from VTY 0 can receive this message.

```
<HUAWEI>
Info: Receive a message from VTY2:Hello, good morning!
```

2.6.46 ssh authentication-type default password

Function

The **ssh authentication-type default password** command configures password authentication as the default authentication mode for SSH users.

The **undo ssh authentication-type default password** command cancels the default password authentication mode for SSH users.

By default, the default authentication mode of SSH users is password authentication.

Format

ssh authentication-type default password

undo ssh authentication-type default password

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When there are multiple SSH users, the default password authentication mode simplifies the configuration.

When a TACACS server is used to authenticate a user who uses SSH to log in to a device, the network administrator must specify the SSH user on the TACACS server. In most cases, the SSH server cannot obtain the user information from the TACACS server. In this situation, you can set the authentication mode to **password**. SSH users can then directly log in to the device without additional SSH user configurations on the device.

Precautions

To configure password authentication for a specific SSH user, you can also run the **ssh user** *user-name* **authentication-type password** command.

Example

Configure password authentication as the default authentication mode for SSH users.

```
<HUAWEI> system-view
[HUAWEI] ssh authentication-type default password
```

2.6.47 ssh authorization-type default aaa

Function

The **ssh authorization-type default aaa** command configures the AAA authorization function for the SSH public key authentication user.

The **undo ssh authorization-type default aaa** command cancels the AAA authorization function configured for the SSH public key authentication user.

By default, the AAA authorization function is not configured for the SSH public key authentication user.

Format

ssh authorization-type default aaa

undo ssh authorization-type default aaa

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The SSH public key authentication user is an SSH user that uses the elliptic curve cryptography (ECC), Rivest-Shamir-Adleman (RSA), or digital signature algorithm (DSA) authentication mode.

If the AAA authorization function is not configured for the SSH public key authentication user, the SSH public key authentication user uses the level of the involved VTY channel. After the AAA authorization function is configured for the SSH public key authentication user, if the authorization succeeds, the SSH public key authentication user uses the level returned by the AAA. If the authorization fails, the user still uses the level of the involved VTY channel.

Precautions

AAA authorization configuration succeeds for the SSH public key authentication user if the following conditions are met:

- A local authorization scheme is configured for the default domain of the AAA management user.
- A local user exists, and the SSH access type is configured.

Example

Configure the AAA authorization function for the SSH public key authentication user.

```
<HUAWEI> system-view
[HUAWEI] ssh authorization-type default aaa
```

2.6.48 ssh client assign

Function

The **ssh client assign** command specifies the host public key of an SSH server on an SSH client.

The **undo ssh client assign** command cancels the specified host public key of the SSH server on the SSH client.

By default, the host public key of a server is not specified on clients.

Format

ssh client *servername* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } *keyname*

undo ssh client *servername* **assign** { **rsa-key** | **dsa-key** | **ecc-key** }

Parameters

Parameter	Description	Value
servername	Specifies the host name or IP address of an SSH server.	The value is a string of 1 to 255 characters without spaces.

Parameter	Description	Value
rsa-key	Specifies the RSA public key.	-
dsa-key	Specifies the DSA public key.	-
ecc-key	Specifies the ECC public key.	-
keyname	Specifies the SSH server public key name that has been configured on an SSH client.	The value is a string of 1 to 30 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If an SSH client connects to an SSH server for the first time and first authentication is not enabled on the SSH client using the **ssh client first-time enable** command, the SSH client must determine whether the server is reliable. To do so, run the **ssh client assign** command to specify the host public key of the SSH server and the mapping between the key and SSH server on the SSH client. The client then uses the correct public key to determine whether the server is reliable based on the mapping.

Precautions

The name of the RSA, DSA, or ECC public key to be assigned to the SSH server must be the same as that configured on the SSH client. This public key must have been configured on the SSH server using the **rsa peer-public-key**, **dsa peer-public-key**, or **ecc peer-public-key** command. If either of the preceding conditions is not met, RSA, DSA, or ECC public key authentication of the SSH server fails on the SSH client.

To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.

Example

Assign the DSA public key to the SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh client 10.164.39.120 assign dsa-key sshdsakey01
```

Delete the DSA public key of the SSH server.

```
<HUAWEI> system-view
[HUAWEI] undo ssh client 10.164.39.120 assign dsa-key
```

2.6.49 ssh client cipher

Function

The **ssh client cipher** command configures an encryption algorithm list for an SSH client.

By default, the WEAKEA plug-in is not installed; the SSH client supports only the **aes128_ctr** and **aes256_ctr** algorithms; the **undo ssh client cipher** command cannot be used. After the WEAKEA plug-in is installed, the **aes256_cbc**, **aes128_cbc**, **3des_cbc**, and **des_cbc** algorithms are supported, and the **undo ssh client cipher** command can be used.

Format

ssh client cipher { **aes128_ctr** | **aes256_ctr** } *

Parameters

Parameter	Description	Value
aes128_ctr	Specifies the CTR AES128 encryption algorithm.	-
aes256_ctr	Specifies the CTR AES256 encryption algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate an encryption algorithm for the packets exchanged between them. You can run the **ssh client cipher** command to configure an encryption algorithm list for the SSH client. After the SSH server receives a packet from the client, the server matches the encryption algorithm list of the client against its local list and selects the first matched encryption algorithm. If no encryption algorithm matches, the negotiation fails.

Precautions

The following encryption algorithms are listed in descending order of security level: **aes256_ctr** and **aes128_ctr**.

The system software does not support the **aes256_cbc**, **aes128_cbc**, **3des_cbc,** and **des_cbc** parameters. To use these parameters, you need to install the

WEAKEA plug-in. To ensure high security, you are advised to configure the **aes256_ctr** or **aes128_ctr** parameter. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

In V200R019C00 and later versions, when the device starts with the default configurations, it automatically performs the following configurations and saves the configurations to the configuration file:

- Run the **ssh server dh-exchange min-len 2048** command to set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.
- Run the **ssh server cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH server.
- Run the **ssh server hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH server.
- Run the **ssh client cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH client.
- Run the **ssh client hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH client.

Example

Configure CTR encryption algorithms for an SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client cipher aes128_ctr aes256_ctr
```

2.6.50 ssh client first-time enable

Function

The **ssh client first-time enable** command enables the first authentication function on an SSH client.

The **undo ssh client first-time enable** command disables the first authentication function on the SSH client.

By default, the first authentication function is disabled on the SSH client.

Format

ssh client first-time enable

undo ssh client first-time enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an SSH client accesses an SSH server for the first time and the public host key of the SSH server is not configured on the SSH client, run the **ssh client first-time enable** command to enable the first authentication function. The SSH client then can access the SSH server and save the public host key on the SSH client. When the SSH client accesses the SSH server next time, the saved public host key is used to authenticate the SSH server.

Precautions

To log in to the SSH server successfully at the first time, you can also run the **ssh client assign** command to pre-assign a public host key to the SSH server. When you use STelnet or SFTP to connect to the server, you need to specify the public key authentication algorithm for server authentication as the ECC, RSA, or DSA key algorithm.

Example

Enable the first authentication function on the SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client first-time enable
```

2.6.51 ssh client hmac

Function

The **ssh client hmac** command configures an HMAC algorithm list for an SSH client.

By default, the WEAKEA plug-in is not installed, an SSH client supports only the **sha2_256** algorithm, and the **undo ssh client hmac** command is unavailable. When the WEAKEA plug-in is installed, an SSH client also supports the **sha2_256_96**, **sha1**, **sha1_96**, **md5** and **md5_96** algorithms, and the **undo ssh client hmac** command is available.

Format

ssh client hmac { **sha2_256** }

Parameters

Parameter	Description	Value
sha2_256	Specifies the SHA2_256 algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate an HMAC algorithm for the packets exchanged between them. You can run the **ssh client hmac** command to configure an HMAC algorithm list for the SSH client. After the SSH server receives a packet from the client, the server matches the list of the client against its local list and selects the first matched HMAC algorithm. If no matched HMAC algorithms, the negotiation fails.

Precautions

The system software does not support the **sha2_256_96**, **sha1**, **sha1_96**, **md5**, and **md5_96** parameters. To use these parameters, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the **sha2_256** parameter. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

In V200R019C00 and later versions, when the device starts with the default configurations, it automatically performs the following configurations and saves the configurations to the configuration file:

- Run the **ssh server dh-exchange min-len 2048** command to set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.
- Run the **ssh server cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH server.
- Run the **ssh server hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH server.
- Run the **ssh client cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH client.
- Run the **ssh client hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH client.

Example

Configure the **SHA2_256** algorithm for an SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client hmac sha2_256
```

2.6.52 ssh client key-exchange

Function

The **ssh client key-exchange** command configures a key exchange algorithm list for an SSH client.

By default, the WEAKEA plug-in is not installed, an SSH client supports only the **dh_group14_sha256**, **dh_group15_sha512**, **dh_group16_sha512**, **dh_group_exchange_sha256**, **ecdh_sha2_nistp256**, **ecdh_sha2_nistp384**, and **ecdh_sha2_nistp521** algorithm, and the **undo ssh client key-exchange** command is unavailable. When the WEAKEA plug-in is installed, an SSH client also supports the **dh_group14_sha1**, **dh_group1_sha1**, and **dh_group_exchange_sha1** algorithms, and the **undo ssh client key-exchange** command is available.

Format

ssh client key-exchange { **dh_group14_sha256** | **dh_group15_sha512** | **dh_group16_sha512** | **dh_group_exchange_sha256** | **ecdh_sha2_nistp256**| **ecdh_sha2_nistp384**| **ecdh_sha2_nistp521** }*

Parameters

Parameter	Description	Value
dh_group14_sha256	Adds the diffie-hellman-group14_sha256 algorithm to the key exchange algorithm list of an SSH client.	-
dh_group15_sha512	Adds the diffie-hellman-group15_sha512 algorithm to the key exchange algorithm list of an SSH client.	-
dh_group16_sha512	Adds the diffie-hellman-group16_sha512 algorithm to the key exchange algorithm list of an SSH client.	-
dh_group_exchange_sha256	Adds the diffie-hellman-group_exchange_sha256 algorithm to the key exchange algorithm list of an SSH client.	-
ecdh_sha2_nistp256	Adds the ecdh_sha2_nistp256 algorithm to the key exchange algorithm list of an SSH client.	-
ecdh_sha2_nistp384	Adds the ecdh_sha2_nistp384 algorithm to the key exchange algorithm list of an SSH client.	-

Parameter	Description	Value
ecdh_sha2_nistp521	Adds the ecdh_sha2_nistp521 algorithm to the key exchange algorithm list of an SSH client.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate a key exchange algorithm for the packets exchanged between them. You can run the **ssh client key-exchange** command to configure a key exchange algorithm list for the SSH client. The server compares the key exchange algorithm list sent by the client with its own key exchange algorithm list, and selects the first key exchange algorithm on the client's list that matches a key exchange algorithm on its own list as the key exchange algorithm for packet transmission. If no algorithm on the client's list matches an algorithm on the server's list, the negotiation fails.

Precautions

The following key exchange algorithms are listed in descending order of security level: **dh_group_exchange_sha256**, **ecdh_sha2_nistp521**, **ecdh_sha2_nistp384**, **ecdh_sha2_nistp256**, **dh_group16_sha512**, **dh_group15_sha512**, and **dh_group14_sha256**.

The system software does not contain the **dh_group_exchange_sha1**, **dh_group14_sha1**, and **dh_group1_sha1** parameters. To use these parameters, you need to install the WEAKEA plug-in. However, the algorithms specified by these parameters are less secure. For higher security purposes, you are advised to use other parameters. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

NOTICE

The higher the security level of a key exchange algorithm, the longer the time required by the device to calculate the key.

Example

Add two key exchange algorithms **dh_group_exchange_sha256** and **dh_group14_sha256** to the key exchange algorithm list of the SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client key-exchange dh_group_exchange_sha256 dh_group14_sha256
```

2.6.53 ssh client rekey

Function

The **ssh client rekey** command configures key renegotiation parameters for an SSH client.

The **undo ssh client rekey** command restores the default key renegotiation parameter settings of the SSH client.

By default, the interval at which an SSH client triggers key renegotiation is 60 minutes, the maximum size of data sent and received by an SSH client during key renegotiation is 1000 MB, and a maximum of 268435456 (2^28) packets can be sent and received by an SSH client during key renegotiation.

Format

ssh client rekey { **time** *rekey-time* | **data-limit** *data-limit* | **max-packet** *max-packet* } *

undo ssh client rekey { **time** | **data-limit** | **max-packet** } *

Parameters

Parameter	Description	Value
time *rekey-time*	Specifies an interval at which key renegotiation is triggered.	The value is an integer ranging from 30 to 1440, in minutes.
data-limit *data-limit*	Specifies the maximum size of data sent and received during key renegotiation.	The value is an integer ranging from 100 to 10000, in MB.
max-packet *max-packet*	Specifies the maximum number of packets sent and received during key renegotiation.	The value is an integer ranging from 268435456 to 2147483648.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the SSH session duration reaches the specified interval at which key renegotiation is triggered, the system renegotiates a key and uses the new key to establish SSH session connections, improving system security.

If the **time** parameter is configured for an SSH client, the client sends a key renegotiation packet to the server to renegotiate an encryption key when the SSH session duration reaches the specified interval.

If the **data-limit** parameter is configured for an SSH client, the client sends a key renegotiation packet to the server to renegotiate an encryption key when the size of sent and received data exceeds the maximum value.

If the **max-packet** parameter is configured for an SSH client, the client sends a key renegotiation packet to the server to renegotiate an encryption key when the number of sent and received packets exceeds the maximum value.

Precautions

A key renegotiation request is initiated when either an SSH client or server meets the key renegotiation criteria. After one party initiates such a request, the other party responds.

Example

Set the maximum size of data sent and received by the SSH client during key renegotiation to 2000 MB.

```
<HUAWEI> system-view
[HUAWEI] ssh client rekey data-limit 2000
```

2.6.54 ssh server acl

Function

The **ssh server acl** command configures an ACL that the SSH server uses to control the access permission of SSH clients.

The **undo ssh server acl** command cancels the configured ACL of the SSH server.

By default, no ACL is configured for SSH servers.

Format

ssh [**ipv6**] **server acl** *acl-number*

undo ssh [**ipv6**] **server acl**

Parameters

Parameter	Description	Value
acl-number	Specifies an ACL number.	The value is an integer that ranges from 2000 to 3999.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Configure the ACL for the following servers for access control:

- STelnet server: controls which clients can log in to this server through STelnet.
- SFTP server: controls which clients can log in to this server through SFTP.
- SCP server: controls which clients can log in to this server through SCP.

Prerequisites

An ACL has been configured using the **acl (system view)** command in the system view, and an ACL rule has been configured using the **rule (basic ACL view)** or **rule (advanced ACL view)** command.

Precautions

A basic ACL can be configured to restrict source addresses. An advanced ACL can be configured to restrict source and destination addresses.

Example

Configure ACL 2000 on an SSH server.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule permit source 10.10.10.10 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] ssh server acl 2000
```

2.6.55 ssh server authentication-retries

Function

The **ssh server authentication-retries** command sets the maximum number of authentication retries for an SSH connection.

The **undo ssh server authentication-retries** command restores the default maximum number of authentication retries for an SSH connection.

The default maximum number of authentication retries for an SSH connection is 3.

Format

ssh server authentication-retries *times*

undo ssh server authentication-retries

Parameters

Parameter	Description	Value
times	Specifies the maximum number of authentication retries for an SSH connection.	The value is an integer that ranges from 1 to 5.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure the maximum number of authentication retries for an SSH connection, run the **ssh server authentication-retries** command. This prevents server overload due to numerous malicious access requests.

Precautions

The configured number of retries takes effect upon the next login.

Example

Set the maximum number of authentication retries to 4.

```
<HUAWEI> system-view
[HUAWEI] ssh server authentication-retries 4
```

2.6.56 ssh server authentication-type keyboard-interactive enable

Function

The **ssh server authentication-type keyboard-interactive enable** command enables keyboard interactive authentication on an SSH server.

The **undo ssh server authentication-type keyboard-interactive enable** command disables keyboard interactive authentication on an SSH server.

By default, keyboard interactive authentication is enabled on SSH servers.

Format

ssh server authentication-type keyboard-interactive enable

undo ssh server authentication-type keyboard-interactive enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To log in to the SSH server in keyboard interactive authentication mode, run the **ssh server authentication-type keyboard-interactive enable** command.

To log in to the SSH server in password authentication mode, run the **undo ssh server authentication-type keyboard-interactive enable** command to disable keyboard interactive authentication.

Example

Enable keyboard interactive authentication on an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server authentication-type keyboard-interactive enable
```

2.6.57 ssh server cipher

Function

The **ssh server cipher** command configures an encryption algorithm list for an SSH server.

By default, the WEAKEA plug-in is not installed; the SSH server supports only the **aes128_ctr** and **aes256_ctr** algorithms; the **undo ssh server cipher** command cannot be used. After the WEAKEA plug-in is installed, the **aes256_cbc**, **aes128_cbc**, **3des_cbc**, and **des_cbc** algorithms are supported, and the **undo ssh server cipher** command can be used.

Format

ssh server cipher { **aes128_ctr** | **aes256_ctr** } *

Parameters

Parameter	Description	Value
aes128_ctr	Specifies the CTR AES128 encryption algorithm.	-
aes256_ctr	Specifies the CTR AES256 encryption algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate an encryption algorithm for the packets exchanged between them. You can run the **ssh server cipher** command to configure an encryption algorithm list for the SSH server. After the SSH server receives a packet from the client, the server matches the encryption algorithm list of the client against its local list and selects the first matched encryption algorithm. If no encryption algorithm matches, the negotiation fails.

Precautions

The following encryption algorithms are listed in descending order of security level: **aes256_ctr** and **aes128_ctr**.

The system software does not support the **aes256_cbc**, **aes128_cbc**, **3des_cbc,** and **des_cbc** parameters. To use these parameters, you need to install the WEAKEA plug-in. To ensure high security, you are advised to configure the **aes256_ctr** or **aes128_ctr** parameter. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

In V200R019C00 and later versions, when the device starts with the default configurations, it automatically performs the following configurations and saves the configurations to the configuration file:

- Run the **ssh server dh-exchange min-len 2048** command to set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.
- Run the **ssh server cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH server.
- Run the **ssh server hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH server.
- Run the **ssh client cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH client.

- Run the **ssh client hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH client.

Example

Configure CTR encryption algorithms for an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server cipher aes256_ctr aes128_ctr
```

2.6.58 ssh server dh-exchange min-len

Function

The **ssh server dh-exchange min-len** command configures the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client.

The **undo ssh server dh-exchange min-len** command restores the default minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client.

By default, the minimum key length supported is 1024 bytes.

Format

ssh server dh-exchange min-len *min-len*

undo ssh server dh-exchange min-len

Parameters

Parameter	Description	Value
min-len	Specifies the minimum Diffie-hellman-group-exchange key length supported on the SSH server.	The value can be either 1024, 2048 or 3072, in bytes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The Diffie-hellman-group-exchange key of 1024 bytes poses security risks. If the SSH client supports the Diffie-hellman-group-exchange key of more than 1024 bytes, run the **ssh server dh-exchange min-len** command to set the minimum key length to 2048 bytes to improve security.

Precautions

Security risks exist if the minimum Diffie-hellman-group-exchange key length is less than 2048 bytes. You are advised to set the minimum key length to 2048 bytes.

In V200R019C00 and later versions, when the device starts with the default configurations, it automatically performs the following configurations and saves the configurations to the configuration file:

- Run the **ssh server dh-exchange min-len 2048** command to set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.
- Run the **ssh server cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH server.
- Run the **ssh server hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH server.
- Run the **ssh client cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH client.
- Run the **ssh client hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH client.

Example

Set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.

```
<HUAWEI> system-view
[HUAWEI] ssh server dh-exchange min-len 2048
```

2.6.59 ssh server hmac

Function

The **ssh server hmac** command configures an HMAC algorithm list for an SSH server.

By default, the WEAKEA plug-in is not installed, an SSH server supports only the **sha2_256** algorithm, and the **undo ssh server hmac** command is unavailable. When the WEAKEA plug-in is installed, an SSH server also supports the **sha2_256_96**, **sha1**, **sha1_96**, **md5** and **md5_96** algorithms, and the **undo ssh server hmac** command is available.

Format

ssh server hmac {**sha2_256** }

Parameters

Parameter	Description	Value
sha2_256	Specifies the SHA2_256 algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate an HMAC algorithm for the packets exchanged between them. You can run the **ssh server hmac** command to configure an HMAC algorithm list for the SSH server. After the server receives a packet from the client, the server matches the list of the client against its local list and selects the first matched HMAC algorithm. If no matched HMAC algorithms, the negotiation fails.

Precautions

The system software does not support the **sha2_256_96**, **sha1**, **sha1_96**, **md5**, and **md5_96** parameters. To use these parameters, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the **sha2_256** parameter. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

In V200R019C00 and later versions, when the device starts with the default configurations, it automatically performs the following configurations and saves the configurations to the configuration file:

- Run the **ssh server dh-exchange min-len 2048** command to set the minimum key length supported during Diffie-hellman-group-exchange key exchange between the SSH server and client to 2048 bytes.
- Run the **ssh server cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH server.
- Run the **ssh server hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH server.
- Run the **ssh client cipher aes256_ctr aes128_ctr** command to configure CTR encryption algorithms for an SSH client.
- Run the **ssh client hmac sha2_256** command to configure the HMAC SHA2_256 algorithm for an SSH client.

Example

Configure the **SHA2_256** algorithm for an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server hmac sha2_256
```

2.6.60 ssh server key-exchange

Function

The **ssh server key-exchange** command configures a key exchange algorithm list for an SSH server.

By default, the WEAKEA plug-in is not installed, an SSH server supports only the **dh_group14_sha256**, **dh_group15_sha512**, **dh_group16_sha512**, **dh_group_exchange_sha256**, **ecdh_sha2_nistp256**, **ecdh_sha2_nistp384**, and **ecdh_sha2_nistp521** algorithm, and the **undo ssh server key-exchange** command is unavailable. When the WEAKEA plug-in is installed, an SSH server also supports the **dh_group14_sha1**, **dh_group1_sha1**, and **dh_group_exchange_sha1** algorithms, and the **undo ssh server key-exchange** command is available.

Format

ssh server key-exchange { **dh_group14_sha256** | **dh_group15_sha512** | **dh_group16_sha512** | **dh_group_exchange_sha256** | **ecdh_sha2_nistp256**| **ecdh_sha2_nistp384**| **ecdh_sha2_nistp521** }*

Parameters

Parameter	Description	Value
dh_group14_sha256	Adds the diffie-hellman-group14_sha256 algorithm to the key exchange algorithm list of an SSH server.	-
dh_group15_sha512	Adds the diffie-hellman-group15_sha512 algorithm to the key exchange algorithm list of an SSH server.	-
dh_group16_sha512	Adds the diffie-hellman-group16_sha512 algorithm to the key exchange algorithm list of an SSH server.	-
dh_group_exchange_sha256	Adds the diffie-hellman-group_exchange_sha256 algorithm to the key exchange algorithm list of an SSH server.	-
ecdh_sha2_nistp256	Adds the ecdh_sha2_nistp256 algorithm to the key exchange algorithm list of an SSH server.	-
ecdh_sha2_nistp384	Adds the ecdh_sha2_nistp384 algorithm to the key exchange algorithm list of an SSH server.	-

Parameter	Description	Value
ecdh_sha2_nistp521	Adds the ecdh_sha2_nistp521 algorithm to the key exchange algorithm list of an SSH server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SSH server and a client need to negotiate a key exchange algorithm for the packets exchanged between them. You can run the **ssh server key-exchange** command to configure a key exchange algorithm list for the SSH server. The server compares the key exchange algorithm list sent by the client with its own key exchange algorithm list, and selects the first key exchange algorithm on the client's list that matches a key exchange algorithm on its own list as the key exchange algorithm for packet transmission. If no algorithm on the client's list matches an algorithm on the server's list, the negotiation fails.

Precautions

The following key exchange algorithms are listed in descending order of security level: **dh_group_exchange_sha256**, **ecdh_sha2_nistp521**, **ecdh_sha2_nistp384**, **ecdh_sha2_nistp256**, **dh_group16_sha512**, **dh_group15_sha512**, and **dh_group14_sha256**.

The system software does not contain the **dh_group_exchange_sha1**, **dh_group14_sha1**, and **dh_group1_sha1** parameters. To use these parameters, you need to install the WEAKEA plug-in. However, the algorithms specified by these parameters are less secure. For higher security purposes, you are advised to use other parameters. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Add the **dh_group14_sha256** algorithm to the key exchange algorithm list of the SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server key-exchange dh_group14_sha256
```

2.6.61 ssh server port

Function

The **ssh server port** command configures a listening port number for an SSH server.

The **undo ssh server port** command restores the default listening port number of an SSH server.

The default listening port number of the SSH server is 22.

Format

ssh [**ipv4** | **ipv6**] **server port** *port-number*

undo ssh [**ipv4** | **ipv6**] **server port**

Parameters

Parameter	Description	Value
port-number	Specifies the listening port number of the SSH server.	The value is 22 or an integer ranging from 1025 to 55535.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To prevent attackers from attacking the standard SSH listening port number, run the **ssh server port** command to configure a new listening port. This improves security.

Precautions

If the server is listening on port 22, the SSH client can log in successfully with no port specified. If the server is listening on another port, the port number must be specified.

Before changing the current port number, disconnect all devices from the port. After the port number is changed, the server starts to listen on the new port.

After the **ssh server port** *port-number* command is run, the numbers of IPv4 port and IPv6 port are both changed. To change the number of IPv4 port or IPv6 port separately, run the **ssh** { **ipv4** | **ipv6** } **server port** *port-number* command.

Example

Set the listening port number of the SSH server to 1025.

```
<HUAWEI> system-view
[HUAWEI] ssh server port 1025
```

Set the IPv4 port number of the SSH server to 1025.

```
<HUAWEI> system-view
[HUAWEI] ssh ipv4 server port 1025
```

2.6.62 ssh server publickey

Function

The **ssh server publickey** command specifies a public key algorithm for an SSH server.

The **undo ssh server publickey** command restores all the public key algorithms of an SSH server to default settings.

By default, the DSA, ECC, RSA, RSA_SHA2_256, and RSA_SHA2_512 algorithms are enabled.

Format

ssh server publickey { **dsa** | **ecc** | **rsa** | **rsa_sha2_256** | **rsa_sha2_512** } *

undo ssh server publickey

Parameters

Parameter	Description	Value
dsa	Specifies the DSA algorithm for an SSH server.	-
ecc	Specifies the ECC algorithm for an SSH server.	-
rsa	Specifies the RSA algorithm for an SSH server.	-
rsa_sha2_256	Specifies the RSA_SHA2_256 algorithm for an SSH server.	-
rsa_sha2_512	Specifies the RSA_SHA2_512 algorithm for an SSH server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run this command to specify a public key algorithm for an SSH server. In this case, the SSH server cannot use other public key algorithms, improving device security. The ECC public key algorithm is recommended.

If a public key algorithm is specified in the **ssh server publickey** command, the SSH server can use the specified public key algorithm and cannot use other public key algorithms. For example, if the **ssh server publickey dsa** command is run, the SSH server can use the DSA algorithm and cannot use the ECC and RSA algorithms.

Precautions

A client can log in to an SSH server using a public key algorithm only if the server also uses this public key algorithm.

For security purposes, you are not advised to use the RSA algorithm with the key of less than 2048 bits to authenticate SSH users. Instead, you are advised to use the more secure ECC, RSA_SHA2_256, or RSA_SHA2_512 authentication algorithm.

If this command has been run for multiple times, the latest configuration takes effect.

Example

Configure an SSH server to use the ECC algorithm.

```
<HUAWEI> system-view
[HUAWEI] ssh server publickey ecc
```

2.6.63 ssh server rekey

Function

The **ssh server rekey** command sets key renegotiation parameters for an SSH server.

The **undo ssh server rekey** command restores the default key renegotiation parameter settings of the SSH server.

By default, the interval at which an SSH server triggers key renegotiation is 60 minutes, the maximum size of data sent and received by an SSH server during key renegotiation is 1000 MB, and a maximum of 268435456 (2^28) packets can be sent and received by an SSH server during key renegotiation.

Format

ssh server rekey { **time** *rekey-time* | **data-limit** *data-limit* | **max-packet** *max-packet* } *

undo ssh server rekey { **time** | **data-limit** | **max-packet** } *

Parameters

Parameter	Description	Value
time *rekey-time*	Specifies an interval at which key renegotiation is triggered.	The value is an integer ranging from 30 to 1440, in minutes.
data-limit *data-limit*	Specifies the maximum size of data sent and received during key renegotiation.	The value is an integer ranging from 100 to 10000, in MB.
max-packet *max-packet*	Specifies the maximum number of packets sent and received during key renegotiation.	The value is an integer ranging from 268435456 to 2147483648.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the SSH session duration reaches the specified interval at which key renegotiation is triggered, the system renegotiates a key and uses the new key to establish SSH session connections, improving system security.

After the **time** parameter is configured for an SSH server, the SSH server checks each SSH session. If the session duration reaches the interval, the SSH server sends a key renegotiation packet to the client to renegotiate an encryption key.

After the **data-limit** parameter is configured for an SSH server, the SSH server checks each SSH session. If the size of data sent and received by the SSH server through a session exceeds the maximum value, the SSH server sends a key renegotiation packet to the client to renegotiate an encryption key.

After the **max-packet** parameter is configured for an SSH server, the SSH server checks each SSH session. If the number of packets sent and received by the SSH server through a session exceeds the maximum value, the SSH server sends a key renegotiation packet to the client to renegotiate an encryption key.

Precautions

A key renegotiation request is initiated when either an SSH client or server meets the key renegotiation criteria. After one party initiates such a request, the other party responds.

Example

Set the maximum size of data sent and received by the SSH server during key renegotiation to 2000 MB.

```
<HUAWEI> system-view
[HUAWEI] ssh server rekey data-limit 2000
```

2.6.64 ssh server rekey-interval

Function

The **ssh server rekey-interval** command sets the interval for updating the SSH server key pair.

The **undo ssh server rekey-interval** command restores the default interval for updating the SSH server key pair.

The default interval for updating the SSH server key pair is 0, indicating that the key pair is never updated.

Format

ssh server rekey-interval *hours*

undo ssh server rekey-interval

Parameters

Parameter	Description	Value
hours	Specifies the interval for updating the server key pair.	The value is an integer that ranges from 0 to 24, in hours.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the server key pair is not updated for a long time, the key is easy to decrypt, and the server is insecure. After the interval for updating the SSH server key pair is set using the **ssh server rekey-interval** command, the device will automatically update the key pair at the specified interval.

Precautions

If the client is connected to the server, the server public key on the client is not updated immediately. This key is updated only when the client is reconnected to the server.

This command takes effect only for SSH1.X. However, SSH1.X provides poor security and is therefore not recommended.

Example

Set the interval for updating the SSH server key pair to 2 hours.

```
<HUAWEI> system-view
[HUAWEI] ssh server rekey-interval 2
```

2.6.65 ssh server timeout

Function

The **ssh server timeout** command sets the timeout period for SSH connection authentication.

The **undo ssh server timeout** restores the default timeout period for SSH connection authentication.

The default timeout period for SSH connection authentication is 60 seconds.

Format

ssh server timeout *seconds*

undo ssh server timeout

Parameters

Parameter	Description	Value
seconds	Specifies the timeout period for SSH connection authentication.	The value is an integer ranging from 1 to 120, in seconds.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a user has not logged in successfully before the timeout period for SSH connection authentication expires, the current connection is terminated to ensure security. To query the current timeout period, run the **display ssh server** command.

Precautions

The timeout period setting takes effect upon next login.

NOTE

If a very short timeout period is configured for SSH connection authentication, user login may fail due to a connection timeout. Using the default timeout period is recommended.

Example

Set the timeout period for SSH connection authentication to 90 seconds.

```
<HUAWEI> system-view
[HUAWEI] ssh server timeout 90
```

2.6.66 ssh server-source

Function

The **ssh server-source** command specifies a source interface for an SSH server.

The **undo ssh server-source** command restores the default setting.

By default, no source interface is specified for an SSH server.

Format

ssh server-source -i *interface-type interface-number*

undo ssh server-source

ssh server-source all-interface

Parameters

Parameter	Description	Value
-i *interface-type interface-number*	Specifies the source interface for an SSH server.	-
all-interface	Specifies any interface that has an IPv4 address configured as the source interface of an SSH server.	-

NOTE

In V200R020C00 and later versions, an SSH server does not accept login connection requests from any interface by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, an SSH server accepts login connection requests from all interfaces by default, leading to low system security. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, an SSH server does not accept login connection requests from any interface by default. To authorize users to log in to the server, run either of the following commands to specify the source interface of the SSH server:

- Run the **ssh server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the SSH server.
- Run the **ssh server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the SSH server.

Prerequisites

Before specifying a logical interface as the source interface, ensure that the source interface has been created and has an IPv4 address configured. Otherwise, this command cannot be executed successfully.

Precautions

After this command is run, the new configuration takes effect upon the next login.

After the source interface is specified, the system allows users to log in to the SSH server only using the specified source interface. This configuration applies to the SSH users who attempt to log in to the SSH server, but not to the SSH users who have logged in to the server.

After the source interface of an SSH server is specified using this command, ensure that authorized SSH users can access the source interface at Layer 3. Otherwise, the SSH users will fail to log in to the SSH server.

If the source address or source interface is not specified, there are security risks.

When the **ssh server-source -i** command is run, if a VLANIF interface is specified as the source interface and has a secondary address configured, SSH login using the secondary address is not supported.

After the **ssh server-source all-interface** command is run, the system allows SSH users to log in to the SSH server through all interfaces with IPv4 addresses configured. This increases system security risks. Therefore, you are not advised to run this command.

Example

Specify Loopback0 as the source interface of an SSH server.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
[HUAWEI-LoopBack0] ip address 10.1.1.1 24
[HUAWEI-LoopBack0] quit
[HUAWEI] ssh server-source -i loopback 0
```

2.6.67 ssh ipv6 server-source

Function

The **ssh ipv6 server-source** command specifies an IPv6 source address for an SSH server.

The **undo ssh ipv6 server-source** command cancels the IPv6 source address specified for an SSH server.

By default, the IPv6 source address of an SSH server is not specified.

Format

ssh ipv6 server-source -a *ipv6_address* [**-vpn-instance** *vpn_name*]

undo ssh ipv6 server-source

ssh ipv6 server-source all-interface

Parameters

Parameter	Description	Value
-a *ipv6_address*	Specifies the IPv6 source address for an SSH server.	The total length of an IPv6 address is 128 bits, which are divided into eight groups. Each group contains four hexadecimal digits. The value is in the format X:X:X:X:X:X:X:X.
-vpn-instance *vpn_name*	Specifies the name of a VPN instance.	The value is a string of 1 to 31 case-sensitive characters. It cannot contain spaces. The VPN instance name cannot be **_public_**. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
all-interface	Indicates that any interface IPv6 address on the device can be used as the IPv6 source address of the SSH server.	-

NOTE

In V200R020C00 and later versions, an SSH server does not accept login connection requests from any interface by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, an SSH server accepts connection requests from all IPv6 addresses by default, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, an SSH server does not accept login requests from any IPv6 address by default. To allow authorized users to log in to the SSH server, run either of the following commands to specify an IPv6 source address for the SSH server.

- Run the **ssh ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure the specified IPv6 address as the IPv6 source address of the SSH server.
- Run the **ssh ipv6 server-source all-interface** command to configure all interface IPv6 addresses on the device as the IPv6 source addresses of the SSH server.

Prerequisites

A VPN instance has been created before you specify it for an SSH server. Otherwise, the **ssh ipv6 server-source** command cannot be executed.

Configuration Impact

After an IPv6 source address is specified for an SSH server, SSH users can log in to the SSH server only using this IPv6 address. This configuration applies to the SSH users who attempt to log in to the SSH server, not to the SSH users who have logged in to the server.

Precautions

After this command is run, the new configuration takes effect upon the next login.

After an IPv6 source address is specified for an SSH server using this command, ensure that SFTP or SSH users can access this IPv6 address at Layer 3. Otherwise, SFTP or SSH users will fail to log in to the SSH server.

If the specified IPv6 source address is bound to a VPN instance, the SSH server is also bound to the VPN instance.

After the **ssh ipv6 server-source all-interface** command is run, the system allows SSH users to log in to the SSH server through all interfaces with IPv6 addresses configured. This increases system security risks. Therefore, running this command is not recommended.

Example

Specify the IPv6 source address 2001:DB8:: for an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh ipv6 server-source -a 2001:DB8::
```

2.6.68 ssh user

Function

The **ssh user** command creates an SSH user.

The **undo ssh user** command deletes an SSH user.

By default, no SSH user is created.

Format

ssh user *user-name*

undo ssh user [*user-name*]

Parameters

Parameter	Description	Value
user-name	Specifies the SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").

Views

System view

Default Level

3: Management level

Usage Guidelines

You can create an SSH user in either of the following ways:

- Run the **ssh user** command.
- Run the **ssh user authentication-type**, **ssh user service-type**, or **ssh user sftp-directory** command with the user name you want to create. If the device

cannot find the user with the name you specified, it automatically creates the user.

Example

Create an SSH user named **testuser**.

```
<HUAWEI> system-view
[HUAWEI] ssh user testuser
```

2.6.69 ssh user assign

Function

The **ssh user assign** command assigns an existing public key to a user.

The **undo ssh user assign** command deletes the mapping between the user and public key.

By default, no public key is assigned to a user.

Format

ssh user *user-name* **assign** { **rsa-key** | **dsa-key** | **ecc-key** } *key-name*

undo ssh user *user-name* **assign** { **rsa-key** | **dsa-key** | **ecc-key** }

Parameters

Parameter	Description	Value
user-name	Specifies the SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
rsa-key	Specifies an RSA public key.	-
dsa-key	Specifies a DSA public key.	-
ecc-key	Specifies an ECC public key.	-
key-name	Specifies the client public key name.	The value is a string of 1 to 30 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an SSH client needs to log in to the SSH server in RSA, DSA, or ECC mode, run the **ssh user assign** command to assign a public key to the client. If the client has been assigned keys, the latest assigned key takes effect.

Precautions

The newly configured public key takes effect upon next login.

If the user named *user-name* to whom a public key is assigned does not exist, the device automatically creates an SSH user named *user-name* and performs the configured authentication for the SSH user.

To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.

Example

Assign key1 to the user named John.

```
<HUAWEI> system-view
[HUAWEI] ssh user john assign rsa-key key1
```

2.6.70 ssh user authorization-cmd aaa

Function

The **ssh user authorization-cmd aaa** command enables command line authorization for an SSH user.

The **undo ssh user authorization-cmd aaa** command restores the default authorization mode.

By default, command line authorization is disabled for an SSH user.

Format

ssh user *user-name* **authorization-cmd aaa**

undo ssh user *user-name* **authorization-cmd aaa**

Parameters

Parameter	Description	Value
user-name	Specifies the name of a valid SSH user defined by the AAA.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

The new setting for command line authorization takes effect upon next login.

This command is valid only for SSH users. The AAA configuration determines whether to configure an authorization mode for the users who log in using passwords.

Example

Enable command line authorization for the user named John.

```
<HUAWEI> system-view
[HUAWEI] ssh user john authorization-cmd aaa
Info: Please make sure that the command line authorization method has been set for the user.
```

2.6.71 ssh user authentication-type

Function

The **ssh user authentication-type** command configures an authentication mode for an SSH user.

The **undo ssh user authentication-type** command restores the default authentication mode for an SSH user.

By default, no authentication mode is configured for an SSH user.

Format

ssh user *user-name* **authentication-type** { **password** | **rsa** | **password-rsa** | **dsa** | **password-dsa** | **ecc** | **password-ecc** | **all** }

undo ssh user *user-name* **authentication-type**

Parameters

Parameter	Description	Value
user-name	Specifies an SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
password	Specifies the password authentication mode.	-
rsa	Specifies the RSA authentication mode.	-
password-rsa	Specifies the password and RSA authentication modes.	-
dsa	Specifies the DSA authentication mode.	-
password-dsa	Specifies the password and DSA authentication modes.	-
ecc	Specifies the ECC authentication mode.	-
password-ecc	Specifies the password and ECC authentication modes.	-

Parameter	Description	Value
all	Specifies the password, ECC, DSA, or RSA authentication mode. **NOTE** In all authentication mode, the user priority depends on the authentication mode that the user selected. - If password authentication is selected, the user priority is the same as that specified on the AAA module. - If RSA/DSA/ECC authentication is selected, the user priority depends on the priority of the VTY interface used during user access. If all authentication is selected and an AAA user with the same name as the SSH user exists, user priorities may be different in password authentication and RSA, DSA, or ECC authentication modes. Set relevant parameters as needed.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you configure an authentication mode for an SSH user, if the user does not exist, a device automatically creates an SSH user named *user-name*.

Table 2-45 describes the usage scenarios for different authentication modes.

Table 2-45 Usage scenarios for authentication modes

Authentication Mode	Usage Scenario
RSA	It is a public key encryption architecture and an asymmetric encryption algorithm. RSA is mainly used to transmit the keys of the symmetric encryption algorithm, which improves encryption efficiency and simplify key management. The server checks whether the SSH user, public key, and digital user signature are valid. If all of them are valid, the user is permitted to access the server. If any of them is invalid, the authentication fails, and the user is denied to access the server.
DSA	It is same as RSA authentication in implementation. The server checks whether the SSH user, public key, and digital user signature are valid. If all of them are valid, the user is permitted to access the server. If any of them is invalid, the authentication fails, and the user is denied to access the server. Compared with RSA authentication, DSA authentication uses the digital signature algorithm for encryption and has a wider application scope. ● Many SSH tools only support DSA authentication for servers and clients. ● Based on the latest RFC recommendation for SSH, DSA authentication takes precedence over RSA authentication.

Authentication Mode	Usage Scenario
ECC	Like RSA authentication, the server first checks the validity of the SSH user and whether the public key and the numeric signature are valid. If all of them are consistent with those configured on the server, user authentication succeeds. If any of the three cannot pass authentication, the user access is denied. Compared with the RSA algorithm, the ECC authentication has the following advantages: ● Provides the same security with shorter key length. ● Features a shorter computing process and higher processing speed. ● Requires less storage space. ● Requires lower bandwidth.
password	On the server, the AAA module assigns each authorized user a password for login. The server has the mapping between user names and passwords. When a user requests to access the server, the server authenticates the user name and password. If either of them fails to be authenticated, the access request of the user is denied. The account information of users who are configured with the password authentication mode can be configured on devices or remote authentication servers (for example, RADIUS servers).
password-rsa, password-dsa, and password-ecc	The SSH server authenticates a client by checking both the public key and password. The client can be authenticated only when both the public key and password meet the requirement.
all	The SSH server authenticates a client by checking the public key or password. The client can be authenticated when either the public key or password meets the requirement.

Precautions

A new SSH user cannot log in to the SSH server unless being configured with an authentication mode. The newly configured authentication mode takes effect upon next login.

To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.

Example

Configure password authentication for the SSH user John.

```
<HUAWEI> system-view
[HUAWEI] ssh user john authentication-type password
```

2.6.72 ssh user service-type

Function

The **ssh user service-type** command configures a service type for an SSH user.

The **undo ssh user service-type** command restores the default service type for an SSH user.

By default, no service type is configured for an SSH user.

Format

ssh user *user-name* **service-type** { **sftp** | **stelnet** | **all** }

undo ssh user *user-name* **service-type**

Parameters

Parameter	Description	Value
user-name	Specifies the SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
sftp	Specifies the SFTP service type.	-
stelnet	Specifies the STelnet service type.	-
all	Specifies the SFTP and STelnet service types.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure a service type for an SSH user, run the **ssh user service-type** command on a device. If the specified user does not exist, the device creates an SSH user who has the same name as the specified user and uses the configured service type for the SSH user.

Precautions

If the SFTP service type is configured for an SSH user, you need to run the **ssh user sftp-directory** command to set an authorized directory for the user. By default, the SFTP service authorized directory is flash: for the SSH user.

Example

Configure the **all** service type for an SSH user John.

```
<HUAWEI> system-view
[HUAWEI] ssh user john service-type all
```

2.6.73 stelnet

Function

The **stelnet** command enables a user to use the STelnet protocol to log in to another device from the current device.

Format

IPv4 address

stelnet [**-a** *source-address* | **-i** *interface-type interface-number*] *host-ip* [*port-number*] [[**-vpn-instance** *vpn-instance-name*] | [**identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** }] | [**user-identity-key** { **rsa** | **dsa** | **ecc** }] | [**prefer_kex** *prefer_key-exchange*] | [**prefer_ctos_cipher** *prefer_ctos_cipher*] | [**prefer_stoc_cipher** *prefer_stoc_cipher*] | [**prefer_ctos_hmac** *prefer_ctos_hmac*] | [**prefer_stoc_hmac** *prefer_stoc_hmac*] | [**-ki** *aliveinterval*] | [**-kc** *alivecountmax*]] *

IPv6 address

stelnet ipv6 [**-a** *source-address*] *host-ipv6* [**-oi** *interface-type interface-number*] [*port-number*] [[**identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** }] | [**user-identity-key** { **rsa** | **dsa** | **ecc** }] | [**prefer_kex** *prefer_key-exchange*] | [**prefer_ctos_cipher** *prefer_ctos_cipher*] | [**prefer_stoc_cipher** *prefer_stoc_cipher*] | [**prefer_ctos_hmac** *prefer_ctos_hmac*]

| [**prefer_stoc_hmac** *prefer_stoc_hmac*] | [**-ki** *aliveinterval*] | [**-kc** *alivecountmax*]] *

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **-a** *source-address* and **-i** *interface-type interface-number* parameter in the command.

Parameters

Parameter	Description	Value
-a *source-address*	Specifies the STelnet source IP address.	-
-i *interface-type interface-number*	Specifies the STelnet source interface. If the source interface is specified using **-i** *interface-type interface-number*, the **-vpn-instance** *vpn-instance-name* parameter is not supported.	-
host-ip	Specifies the IP address or host name of the remote IPv4 STelnet server.	The value is a string of 1 to 255 case-insensitive characters without spaces.
host-ipv6	Specifies the IPv6 address or host name of the remote IPv6 STelnet server.	The value is a string of 1 to 255 case-insensitive characters without spaces.
-oi *interface-type interface-number*	Specifies the outbound interface on the local device.	If the IPv6 address of the remote host is linked to a local address, the outbound interface must be specified.
port-number	Specifies the port number that the SSH server is listening on.	The value is an integer that ranges from 1 to 65535. The default value 22 is the standard port number.

Parameter	Description	Value
identity-key	Specifies the public key for server authentication.	The public key algorithm includes dsa, rsa, rsa_sha2_256, rsa_sha2_512 and ecc. By default, the server authentication uses the ECC public key. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.
user-identity-key	Specifies the public key algorithm for the client authentication.	The public key algorithm includes dsa, rsa, and ecc. By default, the client authentication uses the RSA public key. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.
prefer_kex *prefer_key-exchange*	Indicates the preferred key exchange algorithm.	Specifies the preferred key exchange algorithm. The **dh_exchange_group**, **dh_exchange_group_sha256**, **dh_group14_sha1**, **dh_group14_sha256**, **dh_group15_sha512**, and **dh_group16_sha512** algorithms are supported currently. The default key exchange algorithm is dh_group14_sha1.

Parameter	Description	Value
prefer_ctos_cipher *prefer_ctos_cipher*	Specifies the preferred encryption algorithm from the client to the server. The 3des, aes128, aes256, aes128_ctr, and aes256_ctr algorithms are supported currently.	The default algorithm is aes256_ctr. To improve security, it is recommended that you use aes128_ctr and aes256_ctr algorithms. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.
prefer_stoc_cipher *prefer_stoc_cipher*	Specifies the preferred encryption algorithm from the server to the client. The 3des, aes128, aes256, aes128_ctr, and aes256_ctr algorithms are supported currently.	The default algorithm is aes256_ctr. To improve security, it is recommended that you use aes128_ctr and aes256_ctr algorithms. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.

Parameter	Description	Value
prefer_ctos_hmac *prefer_ctos_hmac*	Specifies the preferred HMAC algorithm from the client to the server. The sha1, sha1_96, md5, md5_96, sha2_256, and sha2_256_96 algorithms are supported currently.	The default algorithm is sha2_256. To improve security, it is recommended that you use sha2_256 algorithms.
prefer_stoc_hmac *prefer_stoc_hmac*	Specifies the preferred HMAC algorithm from the server to the client. The sha1, sha1_96, md5, md5_96, sha2_256, and sha2_256_96 algorithms are supported currently.	The default algorithm is sha2_256. To improve security, it is recommended that you use sha2_256 algorithms.
-vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance to which the server belongs.	The value must be an existing VPN instance name.
-ki *aliveinterval*	Specifies the interval for sending keepalive packets when no packet is received.	The value is an integer that ranges from 1 to 3600, in seconds.
-kc *alivecountmax*	Specifies the number of times for no reply of keepalive packets.	The value is an integer that ranges from 3 to 10. The default value is 5.

Usage Guidelines

Usage Scenario

Logins through Telnet bring security risks because Telnet does not provide any authentication mechanism and data is transmitted using TCP in plain text. Compared with Telnet, SSH guarantees secure file transfer on a traditional insecure network by authenticating clients and encrypting data in bidirectional mode. The SSH protocol supports STelnet. You can run this command to use STelnet to log in to another device from the current device.

STelnet is a secure Telnet service. SSH users can use the STelnet service in the same way as the Telnet service.

When a fault occurs in the connection between the client and server, the client needs to detect the fault in real time and proactively release the connection. You need to set the interval for sending keepalive packets and the maximum number of times on the client that logs in to the server through STelnet.

- Interval for sending keepalive packets: If a client does not receive any packet within the specified interval, the client sends a keepalive packet to the server.
- Maximum number of times the server has no response: If the number of times that the server does not respond exceeds the specified value, the client proactively releases the connection.

Precautions

- Before connecting the SSH server using the **STelnet** command, run the **stelnet server enable** command to enable the STelnet service on the SSH server.
- If the server is listening on port 22, the SSH client can log in to the SSH server with no port specified. If the server is listening on another port, the port number must be specified upon login.

Example

Set keepalive parameters when a client logs in to a server through STelnet.

```
<HUAWEI> system-view
[HUAWEI] stelnet 10.164.39.209 -ki 10 -kc 4
```

Remotely connect to the STelnet server that uses an IPv6 address.

```
<HUAWEI> system-view
[HUAWEI] stelnet ipv6 fc00:2001:db8::1 prefer_ctos_cipher aes128
```

2.6.74 stelnet server enable

Function

The **stelnet server enable** command enables the STelnet service on an SSH server.

The **undo stelnet server enable** command disables the STelnet service on an SSH server.

By default, the STelnet service is disabled on SSH servers.

Format

stelnet [**ipv4** | **ipv6**] **server enable**

undo stelnet [**ipv4** | **ipv6**] **server enable**

Parameters

Parameter	Description	Value
ipv4	Configures a device as the STelnet IPv4 server.	-
ipv6	Configure a device as the STelnet IPv6 server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To connect a client to an SSH server through STelnet, you must enable the STelnet service on the SSH server.

Prerequisites

Before enabling the STelnet service, run either of the following commands as required:

- Run the **ssh server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the SSH server or run the **ssh server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the SSH server.
- Run the **ssh ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure a specified IPv6 address as the IPv6 source address of the SSH server or run the **ssh ipv6 server-source all-interface** command to specify any interface IPv6 address on the device as the IPv6 source address of the SSH server.

Precautions

After you disable the STelnet service on the SSH server, all clients that have logged in through STelnet are disconnected.

After the **stelnet server enable** command is run, the numbers of IPv4 port and IPv6 port are both changed. To change the IPv4 or IPv6 port number separately, run the **stelnet** { **ipv4** | **ipv6** } **server enable** command.

Example

Enable the STelnet service.

```
<HUAWEI> system-view
[HUAWEI] stelnet server enable
```

Enable the STelnet IPv4 service.

```
<HUAWEI> system-view
[HUAWEI] stelnet ipv4 server enable
```

2.6.75 super

Function

The **super** command changes the user's current privilege level.

User privilege level indicates the type of the login user. There are 16 user privilege levels. Different from the use of command privilege level, a login user can only use the commands with the levels no higher than the user privilege level.

Format

super [*level*]

Parameters

Parameter	Description	Value
level	Specifies the user privilege level.	The value is an integer ranging from 0 to 15. By default, the level is 3.

Views

User view

Default Level

0: Visit level

Usage Guidelines

User privilege level indicates the type of the login user. There are 16 user privilege levels. Different from the use of command privilege level, a login user can only use the commands with the privilege levels no higher than the user privilege level.

In order to prevent unauthorized users from illegal intrusion, user ID authentication is performed when users at a lower level switch to users at a higher level. In other word, the password of the higher level is needed. You can run the **super password** command to set the password for changing the user from a lower level to a higher level.

For the sake of confidentiality, the password the user inputs is not shown on the screen. The user can switch to the higher level only when inputting the correct password within three times. Otherwise, the original user privilege level remains unchanged.

The passwords must meet the following requirements:

- The password is a string of 8 to 16 case-sensitive characters.
- The password must contain at least two of the following characters: upper-case character, lower-case character, digit, and special character. Special character except the question mark (?) and space.

NOTICE

Huawei switches use the combination of user name, password, and level to control users' operation rights. If you use the super command to switch user privilege levels, this right control method will become invalid. Moreover, any user can use the super password of a higher level to obtain high-level operation rights. Therefore, you are not advised to use the super command to switch user privilege levels.

Example

Enable the user to switch to level 3.

```
<HUAWEI> super 3
Password:
Now user privilege is 3 level, and only those commands whose level is equal to or less than this level can
be used.
Privilege note: 0-VISIT, 1-MONITOR, 2-SYSTEM, 3-MANAGE
```

2.6.76 super password

Function

The **super password** command sets the password for switching a user from a lower level to a higher level.

The **undo super password** command deletes the password for switching a user from a lower level to a higher level.

By default, no password is configured for switching a user from a lower level to a higher level. A password must be configured for switching a user from a lower level to a higher level. Otherwise, the switching fails.

Format

super password [**level** *user-level*] [**cipher** *password*]

undo super password [**level** *user-level*]

Parameters

Parameter	Description	Value
level *user-level*	Specifies the user privilege level that needs to be changed.	The value is an integer that ranges from 1 to 15. By default, the system sets a password for a user that switches to level 3.

Parameter	Description	Value
cipher *password*	Specifies the password for changing a level.	- When **cipher** is not entered, password input is in man-machine interaction mode, and the system does not display the entered password. The password is a string of 8 to 16 case-sensitive characters. The password must contain at least two of the following characters: upper-case character, lower-case character, digit, and special character. Question mark (?) and space characters are not supported. - When **cipher** is entered, the password is displayed in either simple or ciphertext mode during input. – When being input in simple mode, the password requirements are the same as those when **cipher** is not entered. – When being input in ciphertext, the password must be a string of 56 consecutive characters. **NOTE** If the source version supports a ciphertext password which is a string of 24 or 32 characters, the target version also supports this type of password. When setting the password for switching the user privilege level, if the current user privilege level is higher than the specified user privilege level and the password exists, the old password does not need to be verified. If the current user privilege level is lower than the specified user privilege level, enter the correct old password; otherwise, the configuration will fail. The password is displayed in ciphertext in the configuration file regardless of whether it is input in simple or ciphertext mode.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If users' rights are redefined, users need to run the **super** command to change their levels from low to high. For safety, users need to be authenticated when they change their levels. Users can run the **super password** command to set the password of changing their levels from low to high for authentication.

Precautions

- The password entered by a user is saved in ciphertext, irrespective of whether **cipher** is specified. Therefore, if the password is lost, you cannot get it back.
- Users can press **Ctrl+C** to cancel the operation when they run the **super password**.
- When a user with a level lower than the level configured using this command queries the password configured using the **display this** or **display current-configuration** command, the password is displayed as asterisks (******).

Example

Set the password **Abcd@123** for switching a user from a lower level to level 3, with **cipher** configured for the password.

```
<HUAWEI> system-view
[HUAWEI] super password level 3 cipher Abcd@123
Info: The password will be changed, please verify the old password.
Please enter old password:
Info: The password is changed successfully.
```

Set the password **Abcd@123** for switching a user from a lower level to level 3, with **cipher** not configured for the password.

```
<HUAWEI> system-view
[HUAWEI] super password level 3
Please configure the login password (8-16)
Enter Password:
Confirm Password:
Info: The password will be changed, please verify the old password.
Please enter old password:
Info: The password is changed successfully.
```

2.6.77 super password complexity-check disable

Function

The **super password complexity-check disable** command disables password complexity check when a low-level user is switched to a high-level user.

The **undo super password complexity-check disable** command enables password complexity check when a low-level user is switched to a high-level user.

By default, password complexity check is enabled when a low-level user is switched to a high-level user.

Format

super password complexity-check disable

undo super password complexity-check disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The device has the following requirements for the password for switching a low-level user to a high-level user:

- By default, the minimum password length is eight characters. If the password length set by the **set password min-length** command exceeds eight characters, the value set by this command is the minimum password length.
- A password must contain two or more types of characters, such as upper-case letters, lower-case letters, digits, and special characters.

  The special characters exclude question marks (?) and spaces.

To ensure security of the password for switching a low-level user to a high-level user, run the **undo super password complexity-check disable** command to enable password complexity check. In this case, if a specified password fails the password complexity check, the configuration does not take effect. In a scenario where high security is not required, run the **super password complexity-check disable** command to disable password complexity check.

Precautions

If password complexity check is disabled when a low-level user is switched to a high-level user, a simple password will bring security risks.

Example

Disable password complexity check when a low-level user is switched to a high-level user.

```
<HUAWEI> system-view
[HUAWEI] super password complexity-check disable
```

2.6.78 telnet

Function

The **telnet** command enables a user to use the Telnet protocol to log in to another device from the current device.

Format

Log in to another device through Telnet based on IPv4.

telnet [**vpn-instance** *vpn-instance-name*] [**-a** *source-ip-address* | **-i** *interface-type interface-number*] *host-ip* [*port-number*]

Log in to another device through Telnet based on IPv6.

telnet ipv6 [**-a** *source-ip-address*] [**vpn6-instance** *vpn6-instance-name*] *host-ipv6* [**-oi** *interface-type interface-number*] [*port-number*]

(Only S5720I-SI, S5720-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vpn6-instance** *vpn6-instance-name*.)

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the VPN4 instance name of the device to log in through Telnet.	The value must be an existing VPN instance name.
-a *source-ip-address*	Specifies a source IP address through which a server communicates with the device. This improves security. If no source address is specified, a device will use the IP address of the local outbound interface to initiate a Telnet connection.	-
-i *interface-type interface-number*	Specifies the source interface type and number on the local device.	-
vpn6-instance *vpn6-instance-name*	Specifies the name of the VPN6 instance to which the login device belongs.	The value must be an existing VPN instance name.
host-ip	Specifies the IPv4 address or host name of the remote device.	The value is a string of 1 to 255 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").

Parameter	Description	Value
host-ipv6	Specifies the IPv6 address or host name of the remote device.	The value is a string of 1 to 255 case-insensitive characters without spaces. **NOTE** The string can contain spaces if it is enclosed with double quotation marks (").
-oi *interface-type interface-number*	Specifies the outbound interface on the local device.	If the IPv6 address of the remote host is linked to a local address, the outbound interface must be specified.
port-number	Specifies the number of the TCP port that is used by the remote device to provide the Telnet service.	The value is an integer that ranges from 1 to 65535. The default value is 23.

User view

Default Level

0: Visit level

Usage Guidelines

Usage Scenario

If multiple devices on a network need to be configured and managed, run the **telnet** command to log in to these devices from your terminal for remote device configuration, facilitating device management.

You can press **Ctrl+K** to terminate an active connection between the local and remote devices.

Precautions

- Before you run the **telnet** command to connect to the Telnet server, the Telnet client and server must be able to communicate at Layer 3 and the Telnet service must be enabled on the Telnet server.
- Logins through Telnet bring security risks because Telnet does not provide any authentication mechanism and data is transmitted using TCP in plain text. The STelnet mode is recommended for networks that have high security requirements.

Example

Connect to a remote device through Telnet.

```
<HUAWEI> telnet 192.168.1.6
```

Use the IPv6 address to connect to a remote device through Telnet.

```
<HUAWEI> telnet ipv6 fc00:0:0:11::158
```

2.6.79 telnet client-source

Function

The **telnet client-source** command specifies a source IP address or source interface for a Telnet client.

The **undo telnet client-source** command restores the default settings.

The default source IP address of a Telnet client is 0.0.0.0, and there is no default source interface.

Format

telnet client-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo telnet client-source

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the IPv4 address of the local switch.	-
-i *interface-type interface-number*	Specifies the source interface of the local switch.	-

Usage Guidelines

Usage Scenario

If the source IP address is not specified in the **telnet** command, the source IP address specified using the **telnet client-source** is used. If a source IP address is specified in the **telnet** command, the specified setting is used. Check the current Telnet connection on the server. The IP address displayed is the specified source IP address or the primary IP address of the specified interface.

Prerequisites

The source interface specified using the command must exist and have an IP address configured.

Example

Set the source IP address of the Telnet client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] telnet client-source -a 10.1.1.1
```

2.6.80 telnet server acl

Function

The **telnet server acl** command configures an ACL to control the access of clients to the Telnet server.

The **undo telnet server acl** command cancels the configuration of the ACL.

By default, no ACL is configured for Telnet servers.

Format

telnet [**ipv6**] **server acl** *acl-number*

undo telnet [**ipv6**] **server acl**

Parameters

Parameter	Description	Value
ipv6	Specifies a Telnet IPv6 server.	-
acl-number	Specifies an ACL number.	The value is an integer that ranges from 2000 to 3999.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a device functions as a Telnet server, configure an ACL on the device to control the login of the clients to the device.

Prerequisites

An ACL has been configured using the **acl (system view)** command in the system view, and an ACL rule has been configured using the **rule (basic ACL view)** or **rule (advanced ACL view)** command.

Precautions

None.

Example

Configure ACL 2000 on a Telnet server.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule permit source 10.1.1.1 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] telnet server acl 2000
```

2.6.81 telnet server-source

Function

The **telnet server-source** command specifies a source interface for a Telnet server.

The **undo telnet server-source** command restores the default setting.

By default, the source interface of a Telnet server is not specified.

Format

telnet server-source -i *interface-type interface-number*

undo telnet server-source

telnet server-source all-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the source interface of the local device.	-
all-interface	Indicates that any interface that has an IPv4 address configured can be used as the source interface of a Telnet server.	-

NOTE

In V200R020C00 and later versions, a Telnet server does not accept login connection requests from any interface by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, a Telnet server receives connection requests from all interfaces by default, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, a Telnet server does not accept login requests from any interface by default. To allow authorized users to log in to the Telnet server, run either of the following commands to specify the source interface of the Telnet server.

- Run the **telnet server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the Telnet server.
- Run the **telnet server-source all-interface** command to configure all interfaces configured with IPv4 addresses as the source interfaces of the Telnet server.

Prerequisites

Before you specify a logical interface as the source interface, ensure that the interface to be specified is created and has an IP address configured. Before you specify a physical interface as the source interface, ensure that the interface has an IPv4 address configured. Otherwise, the **telnet server-source** command cannot be successfully executed.

Precautions

By default, no source interface is specified for an SSH server.

After the source interface is specified, a device allows Telnet users to log in to the Telnet server only through this source interface, and Telnet users logging in through other interfaces are denied. Note that setting this parameter only affects Telnet users who attempt to log in to the Telnet server, and it does not affect Telnet users who have logged in to the server.

After the source interface of a Telnet server is specified using this command, ensure that Telnet users can access the source interface at Layer 3. Otherwise, the Telnet users will fail to log in to the Telnet server.

No source address or source interface is specified, so security risks exist.

After the **telnet server-source all-interface** command is run, the system allows Telnet users to log in to the Telnet server through all interfaces with IPv4 addresses configured. This increases system security risks. Therefore, you are not advised to run this command.

Example

Specify loopback0 as the source interface of the Telnet server.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
```

```
[HUAWEI-LoopBack0] ip address 10.1.1.1 24
[HUAWEI-LoopBack0] quit
[HUAWEI] telnet server-source -i loopback 0
```

2.6.82 telnet ipv6 server-source

Function

The **telnet ipv6 server-source** command specifies an IPv6 source address for a Telnet server.

The **undo telnet ipv6 server-source** command cancels the IPv6 source address specified for a Telnet server.

By default, the IPv6 source address of a Telnet server is not specified.

Format

telnet ipv6 server-source -a *ipv6_address* [**vpn-instance** *vpn_name*]

undo telnet ipv6 server-source

telnet ipv6 server-source all-interface

Parameters

Parameter	Description	Value
-a *ipv6_address*	Specifies the IPv6 source address for a Telnet server.	The total length of an IPv6 address is 128 bits, which are divided into eight groups. Each group contains four hexadecimal digits. The value is in the format X:X:X:X:X:X:X:X.
vpn-instance *vpn_name*	Specifies the name of a VPN instance.	The value is a string of 1 to 31 case-sensitive characters. It cannot contain spaces. The VPN instance name cannot be **_public_**. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
all-interface	Indicates that any interface IPv6 address on the device can be used as the IPv6 source address of the Telnet server.	-

NOTE

In V200R020C00 and later versions, a Telnet server does not accept login connection requests from any IPv6 address by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, a Telnet server accepts connection requests from all IPv6 addresses by default, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, a Telnet server does not accept login requests from any IPv6 address by default. To allow authorized users to log in to the Telnet server, run either of the following commands to specify an IPv6 source address for the Telnet server.

- Run the **telnet ipv6 server-source -a** *ipv6_address* [**vpn-instance** *vpn_name*] command to configure the specified IPv6 address as the IPv6 source address of the Telnet server.
- Run the **telnet ipv6 server-source all-interface** command to configure all interface IPv6 addresses on the device as the IPv6 source addresses of the Telnet server.

Prerequisites

A VPN instance has been created before you specify it for a Telnet server. Otherwise, the **telnet ipv6 server-source** command cannot be executed.

Configuration Impact

After an IPv6 source address is specified for a Telnet server, Telnet users can log in to the Telnet server only using this IPv6 address. This configuration applies to the Telnet users who attempt to log in to the server, not to the Telnet users who have logged in to the server.

Precautions

After this command is run, the new configuration takes effect upon the next login.

After an IPv6 source address is specified for a Telnet server using this command, ensure that Telnet users can access this IPv6 address at Layer 3. Otherwise, Telnet users will fail to log in to the Telnet server.

If the specified IPv6 source address is bound to a VPN instance, the Telnet server is also bound to the VPN instance.

After the **telnet ipv6 server-source all-interface** command is run, the system allows Telnet users to log in to the Telnet server through all interfaces with IPv6 addresses configured. This increases system security risks. Therefore, running this command is not recommended.

Example

Specify the IPv6 source address 2001:DB8:: for a Telnet server.

```
<HUAWEI> system-view
[HUAWEI] telnet ipv6 server-source -a 2001:DB8::
```

2.6.83 telnet server enable

Function

The **telnet server enable** command enables the Telnet service.

The **undo telnet server enable** command disables the Telnet service.

The **telnet server disable** command disables the Telnet service.

By default, the Telnet service is disabled.

Format

telnet [**ipv6**] **server enable**

undo telnet [**ipv6**] **server enable**

telnet [**ipv6**] **server disable**

Parameters

Parameter	Description	Value
ipv6	Specifies a Telnet IPv6 server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **telnet server enable** command to enable the Telnet service. A Telnet server can be connected only when it is enabled.

Prerequisites

Before enabling the Telnet service, run either of the following commands as required:

- Run the **telnet server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the Telnet server or run the **telnet server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the Telnet server.
- Run the **telnet ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure a specified IPv6 address as the IPv6 source address of the Telnet server or run the **telnet ipv6 server-source all-interface** command to specify any interface IPv6 address on the device as the IPv6 source address of the Telnet server.

Precautions

If the user who logged in to the server through Telnet is online, the **undo telnet** [**ipv6**] **server enable** command fails to be run on the server.

When a Telnet server is disabled, you can log in to the device only through the console port or SSH.

NOTICE

The Telnet protocol poses a security risk, and therefore using STelnet V2 is recommended.

Example

Enable the Telnet service.

```
<HUAWEI> system-view
[HUAWEI] telnet server enable
```

Disable the Telnet service.

```
<HUAWEI> system-view
[HUAWEI] undo telnet server enable
```

Enable the IPv6 Telnet service.

```
<HUAWEI> system-view
[HUAWEI] telnet ipv6 server enable
```

2.6.84 telnet server port

Function

The **telnet server port** command configures a listening port number for a Telnet server.

The **undo telnet server port** command restores the default listening port of a Telnet server.

The default listening port of a Telnet server is 23.

Format

telnet server port *port-number*

undo telnet server port

Parameters

Parameter	Description	Value
port-number	Specifies the listening port number of a Telnet server.	The value is an integer that is 23 or ranges from 1025 to 55535. The default value 23 is the standard Telnet server port number.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To prevent attackers from attacking the standard Telnet listening port number, run the **telnet server port** command to configure a new listening port. This improves security.

Precautions

If the server is listening on port 23, the Telnet client can log in successfully with no port specified. If the server is listening on another port, the port number must be specified.

Before changing the current port number, disconnect all devices from the port. After the port number is changed, the server starts to listen on the new port.

Example

Set the listening port number to 1026.

```
<HUAWEI> system-view
[HUAWEI] telnet server port 1026
```

Restore the listening port number to the default value.

```
<HUAWEI> system-view
[HUAWEI] undo telnet server port
```

2.7 File Management Commands

2.7.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.7.2 ascii

Function

The **ascii** command sets the file transfer mode to ASCII on an FTP client.

The default file transfer mode is ASCII.

Format

ascii

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Files can be transferred in ASCII or binary mode.

ASCII mode is used to transfer plain text files, and binary mode is used to transfer application files, such as system software, images, video files, compressed files, and database files.

Example

Set the file transfer mode to ASCII.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] ascii
200 Type set to A.
```

2.7.3 binary

Function

The **binary** command sets the file transfer mode to binary on an FTP client.

The default file transfer mode is ASCII.

Format

binary

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Files can be transferred in ASCII or binary mode.

ASCII mode is used to transfer plain text files, and binary mode is used to transfer application files, such as system software, images, video files, compressed files, and database files.

Example

Set the file transfer mode to binary.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.
[ftp] binary
200 Type set to I
```

2.7.4 binding cipher-suite-customization

Function

The **binding cipher-suite-customization** command binds a customized SSL cipher suite policy to an SSL policy.

The **undo binding cipher-suite-customization** command unbinds the customized SSL cipher suite policy from an SSL policy.

By default, no customized cipher suite policy is bound to an SSL policy. Each SSL policy uses a default cipher suite.

Format

binding cipher-suite-customization *customization-policy-name*

undo binding cipher-suite-customization

Parameters

Parameter	Description	Value
customization-policy-name	Specifies the name of a customized SSL cipher suite policy.	The value is a string of 1 to 32 case-insensitive characters, spaces not supported.

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To bind a customized SSL cipher suite policy to an SSL policy, run the **binding cipher-suite-customization** command. After a customized SSL cipher suite policy is bound to an SSL policy, the device uses an algorithm in the specified cipher suite to perform SSL negotiation.

After a customized cipher suite policy is unbound from an SSL policy, the SSL policy uses one of the following cipher suites supported by default:

- tls1_ck_rsa_with_aes_256_sha
- tls1_ck_rsa_with_aes_128_sha
- tls1_ck_dhe_rsa_with_aes_256_sha
- tls1_ck_dhe_dss_with_aes_256_sha
- tls1_ck_dhe_rsa_with_aes_128_sha
- tls1_ck_dhe_dss_with_aes_128_sha
- tls12_ck_rsa_aes_256_cbc_sha256

Prerequisites

The customized cipher suite policy to be bound to an SSL policy contains cipher suites.

Precautions

If the cipher suite in the customized cipher suite policy bound to an SSL policy contains only one type of algorithm (RSA or DSS), the corresponding certificate must be loaded for the SSL policy to ensure successful SSL negotiation.

Example

Bind customized SSL cipher suite policy named **cipher1** to an SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] binding cipher-suite-customization cipher1
```

2.7.5 bye

Function

The **bye** command terminates the connection with the remote FTP server and enters the user view.

Format

bye

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

This command is equivalent to the **quit** command.

You can use the **close** and **disconnect** commands to terminate the connection with the remote FTP server and retain the FTP client view.

Example

Terminate the connection with the remote FTP server and enter the user view.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] bye
```

```
221 server closing.
<HUAWEI>
```

2.7.6 cd (FTP client view)

Function

The **cd** command changes the working directory of the FTP server.

Format

cd *remote-directory*

Parameters

Parameter	Description	Value
remote-directory	Specifies the name of a working directory on the FTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

The FTP server authorizes users to access files in certain directories and their subdirectories.

Example

Change the working directory to **d:/temp**.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] cd d:/temp
250 "D:/temp" is current directory.
```

2.7.7 cd (SFTP client view)

Function

The **cd** command changes the working directory of the SFTP server.

Format

cd [*remote-directory*]

Parameters

Parameter	Description	Value
remote-directory	Specifies the name of a directory on the SFTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

- The SFTP server authorizes users to access files in certain directories and their subdirectories.
- The specified working directory must exist on the SFTP server. If the *remote-directory* parameter is not included in the **cd** command, only the current working directory of an SSH user is displayed as the command output.

Example

Change the current working directory of the SFTP server to /bill.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> cd bill
Current directory is:
/bill
```

2.7.8 cd (user view)

Function

The **cd** command changes the current working directory of a user.

By default, the current working directory is flash:.

Format

cd *directory*

Parameters

Parameter	Description	Value
directory	Specifies the current working directory of a user.	The value is a string of 1 to 64 case-insensitive characters without spaces in the **[drive] path** format. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' " For example, a directory name is flash:/selftest/test/.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.

- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

For example, if you change the current working directory flash:/selftest/ to the logfile directory in flash, the absolute path is flash:/logfile/, and the relative path is /logfile/. The logfile directory is not **logfile/** because it is not in the current working directory **selftest**.

Precautions

- The directory specified in the **cd** command must exist; otherwise, the error messages will be displayed:

  You can perform the following operations to rectify faults:

  a. Run the **pwd** command to view the current working directory.
  b. Run the **dir** command to view the current working directory and verify that the directory specified in the **cd** command exists.

Example

Change the current working directory from flash:/temp to flash:.

```
<HUAWEI> pwd
flash:/temp
<HUAWEI> cd flash:
<HUAWEI> pwd
flash:
```

Change the current working directory from flash: to flash:/t1/t2.

```
<HUAWEI> pwd
flash:
<HUAWEI> cd flash:/t1/t2
<HUAWEI> pwd
flash:/t1/t2
```

Change the current working directory from flash:/selftest to flash:/logfile.

```
<HUAWEI> pwd
flash:/selftest
<HUAWEI> cd /logfile/
<HUAWEI> pwd
flash:/logfile
```

Change the current working directory from flash:/selftest to flash:/selftest/test.

```
<HUAWEI> pwd
flash:/selftest
<HUAWEI> cd test/
<HUAWEI> pwd
flash:/selftest/test
```

2.7.9 cdup (SFTP client view)

Function

The **cdup** command changes the current working directory of an SSH user to its parent directory.

Format

cdup

Parameters

None

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **cdup** command to change the current working directory to its parent directory.

Precautions

If the current working directory is the SFTP authorization directory, the command cannot change the current working directory.

Example

Change the current working directory to its parent directory.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> cd dhcp
Current directory is:
/dhcp
sftp-client> cdup
Current directory is:
/
sftp-client> cdup
Error: Failed to change the current directory.
sftp-client>
```

2.7.10 cdup (FTP client view)

Function

The **cdup** command enables you to return to the upper-level directory.

Format

cdup

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To exit from the current directory and return to the upper-level directory, run the **cdup** command.

Precautions

The directories accessible to an FTP user are restricted by the authorized directories configured for the user.

Example

Exit from the current directory and return to the upper-level directory.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] cd security
250 CWD command successfully.
[ftp] cdup
200 CDUP command successfully.
```

2.7.11 certificate load

Function

The **certificate load** command loads a digital certificate for a Secure Sockets Layer (SSL) policy.

The **undo certificate load** command unloads a digital certificate for the SSL policy.

By default, no digital certificate is loaded for an SSL policy.

Format

Load a PEM digital certificate for an SSL policy.

certificate load pem-cert *cert-filename* **key-pair** { **dsa** | **rsa** } **key-file** *key-filename* **auth-code cipher** *auth-code*

Load an ASN1 digital certificate for an SSL policy.

certificate load asn1-cert *cert-filename* **key-pair** { **dsa** | **rsa** } **key-file** *key-filename*

Load a PFX digital certificate for an SSL policy.

certificate load pfx-cert *cert-filename* **key-pair** { **dsa** | **rsa** } { **mac cipher** *mac-code* | **key-file** *key-filename* } **auth-code cipher** *auth-code*

Load a PEM certificate chain for an SSL policy.

certificate load pem-chain *cert-filename* **key-pair** { **dsa** | **rsa** } **key-file** *key-filename* **auth-code cipher** *auth-code*

Unload a digital certificate for an SSL policy.

undo certificate load

Parameters

Parameter	Description	Value
pem-cert	Loads a PEM digital certificate for the SSL policy. A PEM digital certificate has a file name extension .pem. A PEM digital certificate transfers text data between systems.	-
cert-filename	Specifies the name of a certificate file. The file is in the subdirectory of the system directory **security**. If the **security** directory does not exist in the system, create this directory.	The value is a string of 1 to 64 characters. The file name is the same as that of the uploaded file.
key-pair	Specifies the key pair type.	-
dsa	Sets the key pair type to DSA.	-
rsa	Sets the key pair type to RSA.	-

Parameter	Description	Value
key-file *key-filename*	Specifies the key pair file. The file is in the subdirectory of the system directory **security**. If the **security** directory does not exist in the system, create this directory.	The value is a string of 1 to 64 characters. The file name is the same as that of the uploaded file.
auth-code cipher *auth-code*	Specifies the authentication code of the key pair file. The authentication code verifies user identity to ensure that only authorized clients access the server.	The value is a string of case-sensitive characters without spaces. If the value begins and ends with double quotation marks (" "), the string of characters can contain spaces. When the value is displayed in plaintext, its length ranges from 1 to 31. When the value is displayed in ciphertext, its length is 48 or 68. A ciphertext password with the length of 32 or 56 characters is also supported.
asn1-cert	Loads an ASN1 digital certificate for the SSL policy. An ASN1 digital certificate has a file name extension .der. By default, most browsers support the ASN1 digital certificate.	-
pfx-cert	Loads a PFX digital certificate for the SSL policy. A PFX digital certificate has a file name extension .pfx. A digital certificate can be converted from the PFX format to another format.	-

Parameter	Description	Value
mac cipher *mac-code*	Specifies a message authentication code. The message authentication code ensures the packet data reliability and security.	The value is a string of case-sensitive characters without spaces. If the value begins and ends with double quotation marks (" "), the string of characters can contain spaces. When the value is displayed in plaintext, its length ranges from 1 to 31. When the value is displayed in ciphertext, its length is 48 or 68. A ciphertext password with the length of 32 or 56 characters is also supported.
pem-chain	Specifies a PEM certificate chain.	-

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

SSL security mechanism includes:

- Data transmission security: Uses the symmetric key algorithm to encrypt data.
- Message integrity: uses the multiplexed analog component (MAC) algorithm to ensure message integrity.
- Identity authentication mechanism: authenticates users based on the digital signatures and certificates.

The Certificate Authority (CA) issues PEM, ASN1, and PFX digital certificates that provide user identity information. Based on digital certificates, users establish trust relationships with partners who require high security.

A digital certificate data includes the applicant information such as the applicant's name, applicant's public key, digital signature of the CA that issues the certificate, and the certificate validity period. The CA can issue a certificate chain along with the digital certificate. After receiving a certificate chain, the receiver owns all the certificates on the chain.

Prerequisites

The **ssl policy** command has been run in the system view to create an SSL policy.

Precautions

You can load a certificate or certificate chain for only one SSL policy. Before loading a certificate or certificate chain, you must unload the existing certificate or certificate chain.

To ensure security, the device automatically saves the key file in the system and deletes the file from the storage medium after a certificate is successfully loaded. It is recommended that you do not delete a certificate or certificate chain that has been successfully loaded; otherwise, services using the SSL policy will be affected.

For device that supports the NOR flash, after the certificate is loaded, the key pair file is stored in the NOR flash, and the file in the **security** directory is deleted. After the SSL policy is deleted, the file in the NOR flash is deleted. To re-load the certificate, upload the key file again.

Example

Load an ASN1 digital certificate for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] certificate load asn1-cert servercert.der key-pair dsa key-file
serverkey.der
```

Load a PEM digital certificate for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] certificate load pem-cert servercert.pem key-pair dsa key-file
serverkey.pem auth-code cipher YsHsjx_202206
```

Load a PFX digital certificate for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy http_server
[HUAWEI-ssl-policy-http_server] certificate load pfx-cert servercert.pfx key-pair dsa key-file
serverkey.pfx auth-code cipher YsHsjx_202206
```

Load a PEM certificate chain for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy http_server
[HUAWEI-ssl-policy-http_server] certificate load pem-chain chain-servercert.pem key-pair dsa key-file
chain-servercertkey.pem auth-code cipher YsHsjx_202206
```

2.7.12 close

Function

The **close** command terminates the connection with the remote FTP server and retains the FTP client view.

Format

close

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command is equivalent to the **disconnect** command.

You can run the **bye** and **quit** commands to terminate the connection with the remote FTP server and enter the user view.

Precautions

To enter the user view from the FTP client view, you can run the **bye** or **quit** command.

Example

Terminate the connection with the remote FTP server and enter the FTP client view.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] close
221 Server closing.

[ftp]
```

2.7.13 copy

Function

The **copy** command copies a file.

The **copy** command allows downloading files from an HTTP/HTTPS server or uploading files to an HTTP/HTTPS server.

NOTE

HTTPS is recommended because it is more secure than HTTP.

Format

copy *source-filename destination-filename* [**all**]

copy { *source-http-urlname destination-filename* | *source-filename destination-http-urlname* } [**username** *user-name* **password** *password*]
(V200R013C00SPC500 or later)

copy { *source-https-urlname destination-filename* | *source-filename destination-https-urlname* } [**username** *user-name* **password** *password*] **ssl-policy** *ssl-policy*
(V200R013C00SPC500 or later)

Parameters

Parameter	Description	Value
source-filename	Specifies the path and name of a source file.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Value
destination-filename	Specifies the path and name of a destination file.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "
all	Copies a file to all member devices. **NOTE** This parameter is available only in a stack system.	-
username *user-name*	Specifies the user name used to log in to a server.	The value is a string of 1 to 64 characters.
password *password*	Specifies the password used to log in to a server.	The value is a string of 1 to 64 characters.
source-http-urlname	Specifies the URL of an HTTP server from which a file is downloaded.	The value is a string of 1 to 230 case-insensitive characters without spaces.
destination-http-urlname	Specifies the URL of an HTTP server to which a file is uploaded.	The value is a string of 1 to 230 case-insensitive characters without spaces.

Parameter	Description	Value
source-https-urlname	Specifies the URL of an HTTPS server from which a file is downloaded.	The value is a string of 1 to 230 case-insensitive characters without spaces.
destination-https-urlname	Specifies the URL of an HTTPS server to which a file is uploaded.	The value is a string of 1 to 230 case-insensitive characters without spaces.
ssl-policy *ssl-policy*	Specifies the name of an SSL policy.	The value is a string of 1 to 23 case-insensitive characters without spaces.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- If the destination file name is not specified, the designation file and the source file have the same name. If the source file and the destination file are in the same directory, you must specify the destination file name. If the destination file name is not specified, you cannot copy the source file.

- If the destination file name is the same as that of an existing file, the system prompts you whether to overwrite the existing file. The system prompt is displayed only when **file prompt** is set to **alert**.

Example

Copy the file **config.cfg** from the root directory of the flash card to flash:/temp. The destination file name is **temp.cfg**.

```
<HUAWEI> copy flash:/config.cfg flash:/temp/temp.cfg
Copy flash:/config.cfg to flash:/temp/temp.cfg?[Y/N]:y
100%  complete.
Info: Copied file flash:/config.cfg to flash:/temp/temp.cfg...Done.
```

If the current directory is the root directory of the flash card, you can perform the preceding configuration using the relative path.

```
<HUAWEI> pwd
flash:
<HUAWEI> dir
Directory of flash:/

  Idx  Attr     Size(Byte)  Date        Time       FileName
    0   -rw-      6,721,804  Mar 19 2012 12:31:58   devicesoft.cc
    1   -rw-            910  Mar 19 2012 12:32:58   config.cfg
    2   drw-              -  Mar 05 2012 09:54:34   temp
...
65,233 KB total (7,289 KB free)
<HUAWEI> copy config.cfg temp/temp.cfg
Copy flash:/config.cfg to flash:/temp/temp.cfg?[Y/N]:y
100%  complete.
Info: Copied file flash:/config.cfg to flash:/temp/temp.cfg...Done.
```

Copy the file **config.cfg** from the root directory of the flash card to flash:/temp. The destination file name is **config.cfg**.

```
<HUAWEI> pwd
flash:
<HUAWEI> dir
Directory of flash:/

  Idx  Attr     Size(Byte)  Date        Time       FileName
    0   -rw-      6,721,804  Mar 19 2012 12:31:58   devicesoft.cc
    1   -rw-            910  Mar 19 2012 12:32:58   config.cfg
    2   drw-              -  Mar 05 2012 09:54:34   temp
...
65,233 KB total (7,289 KB free)
<HUAWEI> copy config.cfg temp
Copy flash:/config.cfg to flash:/temp/config.cfg?[Y/N]:y
100%  complete.
Info: Copied file flash:/config.cfg to flash:/temp/config.cfg...Done.
```

Copy the file **backup.zip** to **backup1.zip** in the test directory from the current working directory flash:/test/.

```
<HUAWEI> pwd
flash:/test
<HUAWEI> copy backup.zip backup1.zip
Copy flash:/test/backup.zip to flash:/test/backup1.zip?[Y/N]:y
100%  complete.
Info: Copied file flash:/test/backup.zip to flash:/test/backup1.zip...Done.
```

2.7.14 crl load

Function

The **crl load** command loads the CRL for the SSL policy.

The **undo crl load** command unloads the SSL policy CRL.

By default, the SSL policy CRL is not loaded.

Format

crl load { **pem-crl** | **asn1-crl** } *crl-filename*

undo crl load { **pem-crl** | **asn1-crl** } *crl-filename*

Parameters

Parameter	Description	Value
pem-crl	Loads the CRL in the PEM format for the SSL policy.	-
asn1-crl	Loads the CRL in the ASN1 format for the SSL policy.	-
crl-filename	Specifies the name of a CRL. The file is in the subdirectory of the system directory **security**. If the **security** directory does not exist in the system, create this directory.	The value is a string of 1 to 64 case-insensitive characters without spaces. The file name is the same as that of the uploaded file.

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The CA can shorten the validity period of a certificate using a CRL. The CA releases the CRL that specifies a set of invalid certificates. If the CA revokes a certificate in the CRL, the declaration about authorized key pair is revoked before the certificate expires. When the certificate expires, data related to the certificate is cleared from the CRL.

If the certificate key is disclosed or if you need to revoke a certificate due to other reasons, use a third-party tool to revoke released certificates and mark them as invalid, generating a CRL.

Prerequisites

Before running the **crl load** command, you have run the **ssl policy** command to create the SSL policy in the system view.

Precautions

- When you load the CRL on the FTPS client and access the FTPS server on the FTPS client, the FTPS server checks whether the certificate is declared in the CRL. If the certificate has been declared, the FTPS client and server disconnects.
- A maximum of two CRL files can be loaded in an SSL policy. For the sake of security, deleting the installed CRL file is not recommended; otherwise, services using the SSL policy will be affected.

Example

Load the CRL in the PEM format for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] crl load pem-crl server.pem
```

Load the CRL in the ASN1 format for the SSL policy.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] crl load asn1-crl server.der
```

2.7.15 delete (FTP client view)

Function

The **delete** command deletes a file from the FTP server.

Format

delete *remote-filename*

Parameters

Parameter	Description	Value
remote-filename	Specifies the name of a file to be deleted.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

A file deleted in the FTP client view cannot be restored.

Example

Delete the file **temp.c**.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] delete temp.c
Warning: File temp.c will be deleted. Continue? [Y/N]: y
250 DELE command successfully.
```

2.7.16 delete (user view)

Function

The **delete** command deletes a specified file in the storage device.

Format

delete [**/unreserved**] [**/quiet**] { *filename* | *devicename* } [**all**]

Parameters

Parameter	Description	Value
/unreserved	Deletes a specified file. The deleted file cannot be restored.	-
/quiet	Deletes a file directly without any confirmation.	-

Parameter	Description	Value
filename	Specifies the name of a file to be deleted.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "
devicename	Deletes all the files in the storage device.	-
all	Deletes files in the specified directory in a batch from all storage devices. **NOTE** This parameter is available only in a stack system.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Like *devicename*, **drive** specifies the storage device name.

Precautions

- The wildcard (*) character can be used in the **delete** command.
- If the parameter **/unreserved** is not included, the file is stored in the recycle bin. To display all files including deleted files that are displayed in square brackets ([ ]), run the **dir /all** command. To restore these files that are displayed in square brackets ([ ]), run the **undelete** command. To clear these files from the recycle bin, run the **reset recycle-bin** command.

NOTICE

If you delete a file using the **/unreserved** parameter, the file cannot be restored.

- If you delete a specified storage device, all files are deleted from the root directory of the storage device.
- If you delete two files with the same name from different directories, the last file deleted is kept in the recycle bin.
- If you attempt to delete a protected file, such as a configuration file, log file, or patch file, a system prompt is displayed.
- If you need to delete protected log files, you can run the **info-center max-logfile-number** command to modify the maximum number of protected log files. When the number of log files exceeds the maximum value, the system will delete the older log files to ensure that the number of log files is less than or equal to the configured value.
- You cannot delete a directory by running the **delete** command. To delete a directory, run the **rmdir (user view)** command.

Example

Delete the file **test.txt** from the **flash:/test/** directory.

```
<HUAWEI> delete flash:/test/test.txt
Delete flash:/test/test.txt?[Y/N]:y
```

Delete the file **test.txt** from the current working directory **flash:/selftest**.

```
<HUAWEI> delete test.txt
Delete flash:/selftest/test.txt?[Y/N]:y
```

2.7.17 dir (user view)

Function

The **dir** command displays information about files and directories in the storage medium.

NOTE

The **dir** command cannot display information about files and directories in a USB flash drive.

Format

dir [**/all**] [*filename* | *directory* | **/all-filesystems**]

Parameters

Parameter	Description	Value
/all	Displays information about all files and directories in the current directory, including files and directories moved to the recycle bin from the current directory.	-

Parameter	Description	Value
filename	Specifies the file name.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "
directory	Specifies the file directory.	The value is a string of 1 to 64 case-insensitive characters without spaces in the **[drive] path** format. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Value
/all-filesystems	Display information about files and directories in the root directories of all the storage media on the device.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

The wildcard character (*) can be used in this command. If no parameter is specified, this command displays information about files and directories in the current directory.

The following describes the drive name:

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

You can run the **dir /all** command to view information about all files and directories of the storage medium, including those moved to the recycle bin. The name of a file in the recycle bin is placed in square brackets ([]), for example, [test.txt].

Example

Display information about all files and directories in the current directory.

```
<HUAWEI> dir /all
Directory of flash:/

65,233 KB total (13,632 KB free)
```

Display information about all .txt files in the current directory.

```
<HUAWEI> dir *.txt
Directory of flash:/

  Idx  Attr     Size(Byte)  Date        Time       FileName
    0  -rw-            889  Feb 25 2012 10:00:58   private-data.txt

65,233 KB total (13,632 KB free)
```

Table 2-46 Description of the **dir** command output

Item	Description
d	Directory. If this item is not displayed, the corresponding **FileName** field displays a file. For example, **devicesoft.cc** is a file and **security** is a directory.
r	The file or directory is readable.
w	The file or directory is writable.
[ ]	A file moved to the recycle bin.
FileName	● private-data.txt: The file saves service initialization data. Initialization data of some tasks is irrelevant to the configuration and is not recorded in the configuration file. The **private-data.txt** file records initialization data of these tasks, for example, the number of times the device restarts. ● vrpcfg.cfg: configuration file. The file name extension of the configuration file must be .cfg or .zip. ● basicsoft.cc: system software. The file name extension of the system software must be .cc. ● logfile: log file. Some software sub-systems store necessary data in other files in the file system when the device is running properly.

2.7.18 dir/ls (FTP client view)

Function

The **dir** and **ls** commands display all files or specified files that are stored on the FTP server, and save them to a local disk.

Format

dir [*remote-filename* [*local-filename*]]

ls [*remote-filename* [*local-filename*]]

Parameters

Parameter	Description	Value
remote-filename	Specifies the name and directory of a file stored on the FTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.
local-filename	Specifies the name of the local file that saves the FTP server file information.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes differences between the **dir** and **ls** commands.

- When you run the **dir** command, detailed file information is displayed, including the file size, date when the file was created, whether the file is a directory, and whether the file can be modified. When you run the **ls** command, only the file name is displayed.
- The **dir** command is used to save detailed file information, while the **ls** command is used to save only the file name even if the file is specified and saved in a local directory.

Precautions

A wildcard character (*) can be used in commands **dir** and **ls**.

Example

Display the name or detailed information about a file that is saved in the test directory.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.

```

Table 2-47 Description of the dir/ls command output

Item	Description
d	Indicates a directory. If this parameter is not present, the command output indicates a file.
r	Indicates that the file or directory can be read.

Item	Description
w	Indicates that the file or directory can be modified.

2.7.19 dir/ls (SFTP client view)

Function

The **dir** and **ls** commands display a list of specified files that are stored on the SFTP server.

Format

dir [**-l** | **-a**] [*remote-directory*]

ls [**-l** | **-a**] [*remote-directory*]

Parameters

Parameter	Description	Value
-l	Displays detailed information about all files and directories in a specified directory.	-
-a	Displays names of all files and directories in a specified directory.	-
remote-directory	Specifies the name of a directory on the SFTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

The **dir** and **ls** commands are equivalent.

- If **-l** and **-a** parameters are not specified, detailed information about all files and directories in a specified directory is displayed when you run the **dir** or **ls** command. The effect is the same as the **dir -l** command output.
- By default, if the *remote-directory* parameter is not specified, the list of current directory files is displayed when you run the **dir** or **ls** command.

Example

Display a list of files in the **test** directory of the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...

backup1.txt
```

2.7.20 disconnect

Function

The **disconnect** command terminates the connection with the remote FTP server and displays the FTP client view.

Format

disconnect

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

This command is equivalent to the **close** command.

You can run the **bye** and **quit** commands to terminate the connection with the remote FTP server and enter the user view.

To enter the user view from the FTP client view, you can run the **bye** or **quit** command.

Example

Terminate the connection with the remote FTP server and enter the FTP client view.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] disconnect

221 Server closing.

[ftp]
```

2.7.21 display ftp-client

Function

The **display ftp-client** command displays the source IP address configured for the FTP client.

Format

display ftp-client

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

The default source IP address 0.0.0.0 is used if **ftp client-source** is not configured.

Example

Display the source IP address of the FTP client.

```
<HUAWEI> display ftp-client
The source address of FTP client is 10.1.1.1.
```

Table 2-48 Description of the display ftp-client command output

Item	Description
The source IP address of FTP client is 10.1.1.1.	10.1.1.1 is the source IP address of the FTP client. You can run the **ftp client-source** command to configure the source IP address. If a source IP address has been configured by using the **ftp client-source** command, the message "The source interface of FTP client is LoopBack0" is displayed.

2.7.22 display ftp-server

Function

The **display ftp-server** command displays FTP server parameter settings.

Format

display [**ipv6**] **ftp-server**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to display FTP server parameter settings.

Example

Display FTP server parameter settings.

```
<HUAWEI> display ftp-server
  FTP server is running
  Max user number              5
  User count                   1
  Timeout value(in minute)       30
  Listening port               21
  Acl number                   2010
  FTP server's source address     10.1.1.1
  FTP SSL policy
  FTP Secure-server is stopped
```

Display FTP server parameter settings when the secure FTP server function is enabled.

```
<HUAWEI> display ftp-server
  FTP server is stopped
  Max user number              5
  User count                   0
  Timeout value(in minute)       1
  Listening port               21
  Acl number                   0
  FTP server's source interface   LoopBack0
  FTP SSL policy
  FTP Secure-server is running
```

Table 2-49 Description of the display ftp-server command output

Item	Description
FTP server is running	The FTP server starts. You can run the **ftp** [**ipv6**] **server enable** command to start the FTP server.
Max user number	Maximum number of users who can access the FTP server.
User count	Number of users who are accessing the FTP server.
Timeout value(in minute)	Idle timeout duration of FTP users. You can run the **ftp** [**ipv6**] **timeout** command to set the idle timeout duration of FTP users.
Listening port	Number of the listening port on the FTP server. The default value is 21. If the value is not 21, you can run the **ftp** [**ipv6**] **server port** command to configure the listening port number.
Acl number	Number of the ACL of the FTP server. The default value is 0. You can run the **ftp** [**ipv6**] **acl** command to change the ACL number.

Item	Description
FTP server's source address	Source IP address for the FTP server to send packets. The default value is 0.0.0.0. You can run the **ftp server-source** command to configure the source IP address for the FTP server. Here, the source IP address 10.1.1.1 is displayed. If a source interface is configured, this field displays "FTP server's source interface." **NOTE** If you run the **display ipv6 ftp-server** command, the **FTP server's source address** is not displayed.
FTP SSL policy	SSL policy that the secure FTP server function uses. Before enabling the FTP function, you must run the **ftp secure-server ssl-policy** *policy-name* command to configure the SSL policy.
FTP Secure-server is stopped	Whether to enable the secure FTP server function. To enable the secure FTP server function, disable the common FTP function and run the **ftp secure-server enable** command.

2.7.23 display ftp-users

Function

The **display ftp-users** command displays FTP user parameters on the FTP server.

Format

display ftp-users

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can check FTP user parameters on the FTP server, such as the FTP user name, IP address of the client host, port number, idle duration, and the authorized directories.

Example

Display FTP user parameters.

```
<HUAWEI> display ftp-users
 username  host                                  port  idle  topdir
 user      10.138.77.41                          4028  0     flash:/test
 huawei    10.137.217.159                           51156 0     flash:
```

The preceding information indicates that two users are connected to the FTP server.

Table 2-50 Description of the display ftp-users command output

Item	Description
username	FTP user name.
host	IP address of the client host.
port	Port number of the client host.
idle	Idle duration.
topdir	Authorized directory of a user. You can run the **local-user ftp-directory** command to configure the authorized directory.

2.7.24 display scp-client

Function

The **display scp-client** command displays source parameters of the current SCP client.

Format

display scp-client

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display scp-client** command to check source parameters of the SCP client.

If **scp client-source** { **-a** *source-ip-address* | **-i** *interface-type interface-number* } is not configured, source parameters are not displayed.

Example

Display source parameters of the SCP client.

```
<HUAWEI> display scp-client
 The source of SCP ipv4 client: 10.1.1.1
```

2.7.25 display sftp-client

Function

The **display sftp-client** command displays the source IP address configured for the SFTP client.

Format

display sftp-client

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display sftp client** command to display the source IP address of the SFTP client. The default source IP address 0.0.0.0 is used if **sftp client-source** is not configured.

Example

Display the source IP address configured for the SFTP client.

```
<HUAWEI> display sftp-client
The source address of SFTP client is 10.1.1.1.
```

Table 2-51 Description of the display sftp-client command output

Item	Description
The source address of SFTP client is 10.1.1.1.	10.1.1.1 is the source IP address of the SFTP client. You can run the **sftp client-source** command to configure the source IP address for the SFTP client. If an IP address has been configured for the source port, the message "The source interface of SFTP client is LoopBack0" is displayed.

2.7.26 display ssl policy

Function

The **display ssl policy** command displays information about an SSL policy.

Format

display ssl policy [*policy-name*]

Parameters

Parameter	Description	Value
policy-name	Displays the configuration of a specific SSL policy. If the SSL policy name is not specified, configurations of all SSL policies are displayed.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ssl policy** command to display the SSL policy configuration when the device functions as a server or client.

After an SSL policy and its certificates are loaded and configured, you can run this command to obtain information such as the SSL policy name, service applications supported by the SSL policy, certificate name, and certificate type so that you can determine whether the existing SSL policy and certificates are available.

Example

Display the configuration of SSL policy **ftp_server**.

```
<HUAWEI> display ssl policy ftp_server
       SSL Policy Name: ftp_server
     Policy Applicants:
         Key-pair Type: DSA
 Certificate File Type: ASN1
      Certificate Type: certificate
  Certificate Filename: servercert.der
     Key-file Filename: serverkey.der
             Auth-code:
                   MAC:
              CRL File:
       Trusted-CA File:
           Issuer Name:
   Validity Not Before:
    Validity Not After:
```

Display the configuration of SSL policy **ftp_client**.

```
<HUAWEI> display ssl policy ftp_client

       SSL Policy Name: ftp_client
     Policy Applicants:
         Key-pair Type: RSA
 Certificate File Type: ASN1
      Certificate Type: certificate
  Certificate Filename: servercert.der
     Key-file Filename: serverkey.der
             Auth-code:
                   MAC:
              CRL File:
       Trusted-CA File:
           Issuer Name:
   Validity Not Before:
    Validity Not After:
```

Table 2-52 Description of the display ssl policy command output

Item	Description
SSL Policy Name	SSL policy name. You can run the **ssl policy** command to configure the SSL policy name.
Policy Applicants	Service using SSL policies. Currently, SSL policies are supported in HTTP, FTP and Syslog services.

Item	Description
Key-pair Type	Type of a key pair. - RSA - DSA - ECC You can run the **certificate load** command to configure the type of a key pair.
Certificate File Type	Certificate format. This parameter is mandatory when the device functions as a server. - PEM - ASN1 - PFX You can run the **certificate load** command to configure the certificate format.
Certificate Type	Certificate type. This parameter is mandatory when the device functions as a server. - certificate - certificate-chain You can run the **certificate load** command to configure the certificate type.
Certificate Filename	Certificate name. This parameter is mandatory when the device functions as a server. You can run the **certificate load** command to configure the certificate name.
Key-file Filename	Key pair file name. This parameter is mandatory when the device functions as a server. You can run the **certificate load** command to configure the key pair file name.
Auth-code	Authentication code of a key file. You can run the **certificate load** command to configure the authentication code of a key file. If an ASN1 certificate is loaded, the authentication code is unavailable.

Item	Description
MAC	Message authentication code. The message authentication code is required only when you load PFX digital certificates. You can run the **certificate load** command to configure the message authentication code.
CRL File	CRL file. You are advised to configure the CRL file for a client. You can run the **crl load** command to configure the CRL file.
Trusted-CA File	File of a trusted CA. This parameter is mandatory when the device functions as a client. ● **Format**: file format. ● **Auth-code**: authentication code of a PFX file. This field is displayed only when a PFX file has been loaded to the device. ● **Filename**: file name. You can run the **trusted-ca load** command to configure the file of a trusted CA.
Issuer Name	Issuer name.
Validity Not Before	Time when validity starts.
Validity Not After	Time when validity ends.

2.7.27 display tftp-client

Function

The **display tftp-client** command displays the source IP address configured for the TFTP client.

Format

display tftp-client

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display tftp client** command to query source IP address of the TFTP client. The default source IP address is 0.0.0.0 if **tftp client-source** is not configured.

Example

Display the source IP address configured for the TFTP client.

```
<HUAWEI> display tftp-client
The source address of TFTP client is 10.1.1.1.
```

Table 2-53 Description of the display tftp-client command output

Parameter	Description
The source address of TFTP client is 10.1.1.1.	10.1.1.1 is the source IP address of the TFTP client. You can run the **tftp client-source** command to configure the source IP address for the TFTP client. If the IP address is configured for the source port, the message "The source interface of TFTP client is LoopBack0" is displayed.

2.7.28 execute

Function

The **execute** command executes a specified batch file.

Format

execute *batch-filename*

Parameters

Parameter	Description	Value
batch-filename	Specifies the name of a batch file. *batch-filename* supports file name association. The disk and directory where the file resides can be automatically associated. ● Full help: All the disks of the device can be associated and displayed. ● Partial help: The related disk, directory, and file can be associated and displayed after you enter a specified character string.	The value is a string of 5 to 160 case-sensitive characters. It cannot contain spaces. The file name extension is .bat.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a series of commands are frequently executed, write these commands in a batch file, and store this file in system. In this way, you can only execute this command to run multiple commands which were manually entered before. This command improves maintenance and management efficiency.

NOTE

- The batch file is edited in .txt format. When editing the file, ensure that one command occupies one line. After editing the file, save the file and change the file name extension to .bat.
- Transfer the batch file in file transmission mode to the device.

Prerequisites

Before running the **execute** command, ensure that the batch file to be processed is in the current directory; otherwise, the system cannot find the batch file.

Precautions

- The commands in a batch file are run one by one. A batch file cannot contain invisible characters (control characters or escape characters, such as \r, \n, and \b). If any invisible character is detected, the execute command exits from the current process and no rollback is performed.
- The **execute** command does not ensure that all commands can be run. If the system runs a wrong or immature command, it displays the error and goes to

next command. The **execute** command does not perform the hot backup operation, and the command format or content is not restricted.

- In case of interactive commands, batch file execution waits the device to interact with users before continuing.

NOTE

When processing files in batches, add the **echo off** field in the first line to mask command line prompts. After the **echo off** field is added, the command line prompts and command lines are not displayed when command lines are processed in batches. Comply with the following rules:

- The **echo off** field can be added only to the first line of the files to be processed in batches.
- The **echo off** field is case-insensitive.
- The line where the **echo off** field resides cannot contain any special characters, spaces excluded.

In the batch file, you can enter **wait(*time*)** between commands to set a command execution delay. The value of *time* ranges from 1 to 1800, in seconds. For example, **wait(10)** indicates that the next command is executed 10 seconds later. The value of **wait(*time*)** is case-insensitive. In the line where **wait(*time*)** resides, spaces cannot be placed before or after **wait(*time*)**, or before or after *time*. Other characters are also not allowed.

Example

Execute the **test.bat** file in the directory flash:/. The **test.bat** file contains the following commands: **system-view**, **local-user huawei password irreversible-cipher Helloworld@6789**, and **aaa**.

```
<HUAWEI> system-view
[HUAWEI] execute test.bat
[HUAWEI]
        ^
Error: Unrecognized command found at '^' position.
[HUAWEI]
[HUAWEI-aaa]
 Info: Add a new user
[HUAWEI-aaa]
```

When the system runs the first command **system-view** in the current system view, it displays an error and continues to run the following commands.

The system displays the execution of a batch file in AAA view.

```
[HUAWEI-aaa] display this
 local-user huawei password irreversible-cipher $1a$HW=5%Mr;:2)/RX$FnU1HLO%-TBMp4wn%;~\#
%iAut}_~O%0L$
```

2.7.29 feat

Function

The **feat** command displays extended commands that the FTP server supports.

Format

feat

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

You can run the **feat** command to display extended functions that the FTP server supports, such as:

- Authentication transport layer security (AUTH TLS)
- Data channel protection level (PROT)
- Protection buffer size (PBSZ)

Precautions

If no extended command is supported, the message "211 no features" is displayed.

Example

Display extended commands that the FTP server supports.

```
[ftp] feat
211-Extension Supported
AUTH TLS
PROT
PBSZ
211 End
```

Table 2-54 Description of the feat command output

Parameter	Description
211	Value of the FTP relay code. The value is returned in the help information or system status query result.
AUTH TLS	AUTH TLS commands supported.
PROT	PROT commands supported.s
PBSZ	PBSZ commands supported.

2.7.30 file prompt

Function

The **file prompt** command changes the prompt mode when you perform operations on files.

The **undo file prompt** command restores the default prompt mode.

The default prompt mode is alert.

Format

file prompt { **alert** | **quiet** }

undo file prompt quiet

Parameters

Parameter	Description	Value
alert	Display a prompt message before users perform an operation.	-
quiet	Do not display a prompt message before users perform an operation.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

NOTICE

If the prompt mode is set to quiet, the system does not provide prompt messages when operations leading to data loss are executed, such as deleting or overwriting files. Therefore, this prompt mode should be used with caution.

Example

Set the prompt mode to quiet. When you rename a copied file **test.txt** using an existing file name **test1.txt**, no prompt message is displayed.

```
<HUAWEI> system-view
[HUAWEI] file prompt quiet
[HUAWEI] quit
<HUAWEI> copy test.txt test1.txt
```

```
100%  complete
Info: Copied file flash:/test.txt to flash:/test1.txt...Done.
```

Set the prompt mode to alert.

```
<HUAWEI> system-view
[HUAWEI] file prompt alert
[HUAWEI] quit
<HUAWEI> copy test.txt test1.txt
Copy flash:/test.txt to flash:/test1.txt?[Y/N]:y
The file flash:/test1.txt exists. Overwrite it?[Y/N]:y
100%  complete
Info: Copied file flash:/test.txt to flash:/test1.txt...Done.
```

2.7.31 fixdisk

Function

The **fixdisk** command restores a storage device in which the file system fails to run properly.

Format

fixdisk *drive*

Parameters

Parameter	Description	Value
drive	Specifies the name of the storage device to restore.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the storage device name.

- **drive** is the storage device and is named as flash:.
- In a stack system, *devicename* can be set as follows:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

If the file system does not run properly, the system prompts you to restore it. You can run the **fixdisk** command to attempt to restore the file system. You can run the **fixdisk** command to release the space whose usage status is unknown from the storage device.

You can run the **dir** command to display information about a specified file or directory on the storage device. If the command output contains **unknown**, for example, 30,000 KB total (672 KB free, 25,560 KB used, 3,616 KB unknown), you can run the **fixdisk** command to release the space whose usage status is unknown.

Precautions

- The **fixdisk** command is not recommended when the system works properly. This command cannot rectify device-level faults.
- If you are still prompted to restore the storage device after running the **fixdisk** command, the physical medium may have been damaged.
- Running the **fixdisk** command to restore a flash memory requires high CPU usage. Therefore, do not run this command when the CPU usage in the system is high.

Example

Restore the flash memory when an error message indicating that the flash memory is faulty is displayed.

```
Lost chains in flash detected, please use fixdisk to recover them!
<HUAWEI> fixdisk flash:
Fix disk flash: will take long time if needed...
% Fix disk flash: completed.
```

2.7.32 format

Function

The **format** command formats a storage device.

NOTE

In V200R013C00SPC500 and later versions, this command can be run only if you log in to the device through the serial port.

The following models do not support this command:

S300, S500, S2730S-S, S5735-L1, S5735S-L1, S5731-S (S5731-S24P4X, S5731-S24T4X, S5731-S24T4X-A, S5731-S24T4X-D, S5731-S48P4X, S5731-S48T4X, S5731-S48T4X-A), S5731S-S (S5731S-S24P4X-A, S5731S-S24T4X-A, S5731S-S24T4X-A1, S5731S-S48P4X-A, S5731S-S48T4X-A, S5731S-S48T4X-A1), S5731-H, S5731S-H, S5732-H (S5732-H24S6Q, S5732-H24UM2CC, S5732-H48S6Q, S5732-H48UM2CC), S6730-S, S6730S-S, S6730-H (S6730-H24X6C, S6730-H48X6C), S6730S-H

Format

format *drive*

Parameters

Parameter	Description	Value
drive	Specifies the name of the storage device to format.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the storage device name.

- **drive** is the storage device and is named as flash:.
- In a stack system, *devicename* can be set as follows:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

When the file system fault cannot be rectified or the data on the storage device is unnecessary, the storage device can be formatted. When you run the **format** command, all files and directories are cleared from the storage device.

Configuration Impact

When the storage device has the configuration file and system software package required for the next start, do not format the storage device because data on it will be deleted after the format. If the configuration file required for the next start is deleted, the configuration is lost after the switch restarts. If the system software package is deleted, the switch will fail to start.

After the storage is formatted, you can upload the system software through the Enter ethernet submenu option in the Bootload menu. The Modify startup configuration option modifies the startup configuration information and restarts the device.

Precautions

NOTICE

After the **format** command is run, files and directories are cleared from the specified storage device and cannot be restored. Therefore, this command should be used with caution.

If the storage device is still unavailable after the **format** command is run, a physical exception may have occurred.

Example

Format the storage device.

```
<HUAWEI> format flash:
All data(include configuration and system startup file) on flash: will be lost, proceed with format ? [Y/N]:y
%Format flash: completed.
```

2.7.33 format ssd

Function

The **format ssd** command formats the SSD card.

Format

format ssd [**slot** *slot-id*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, and S5731S-S support this command.

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID.	The value depends on the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

Application Scenario

When the file system fault cannot be rectified or all data on the SSD card is unnecessary, the SSD card can be formatted. When this command is run, all files and directories are cleared from the SSD card.

Configuration Impact

If the SSD card contains the configuration file and software package required for the next startup, do not format the card because formatting the SSD card will cause all data on the card to be cleared. As a result, the configuration file for the next startup is deleted, and configurations are lost after the device is restarted; the software package for the next startup is deleted, and the device cannot be started.

Precautions

NOTICE

After this command is run, all files and directories are cleared from the SSD card and cannot be restored. Therefore, exercise caution when running this command.

If the SSD card is still unavailable after this command is run, a physical exception may have occurred.

Example

Format the SSD card.

```
<HUAWEI> format ssd
Warning: The format requires a long time. All data on SSD will be lost, proceed
with format, Continue? [Y/N]:y
Info: Operating, please wait for a moment......................................
....
Info: Succeed in formating the SSD.
```

2.7.34 ftp

Function

The **ftp** command connects the FTP client to the FTP server and enters the FTP client view.

Format

Connect the FTP client to the FTP server based on the IPv4 address.

ftp [[**ssl-policy** *policy-name*] [**-a** *source-ip-address* | **-i** *interface-type interface-number*] *host-ip* [*port-number*] [**public-net** | **vpn-instance** *vpn-instance-name*]]

Connect the FTP client to the FTP server based on the IPv6 address.

ftp [**ssl-policy** *policy-name*] **ipv6** *host-ipv6* [*port-number*]

ftp [**ssl-policy** *policy-name*] **ipv6** *ipv6-linklocal-address* **-oi** { *interface-name* | *interface-type interface-number* } [*port-number*]

Parameters

Parameter	Description	Value
ssl-policy *policy-name*	Specifies the name of the SSL policy that provides the secure FTP function.	The value is a string of 1 to 23 case-insensitive characters without spaces.

Parameter	Description	Value
-a *source-ip-address*	Specifies the source IP address for connecting to the FTP client. You are advised to use the loopback interface IP address.	The value is in dotted decimal notation.
-i *interface-type interface-number*	Specifies the source interface type and ID. You are advised to use the loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the FTP connection cannot be set up.	-
host-ip	Specifies the IP address or host name of the remote IPv4 FTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
port-number	Specifies the port number of the FTP server.	The value is an integer that ranges from 1 to 65535. The default value is the standard port number 21.
public-net	Specifies the FTP server on the public network. You must set the **public-net** parameter when the FTP server IP address is a public network IP address.	-
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance where the FTP server is located.	The value must be an existing VPN instance name.

Parameter	Description	Value
host-ipv6	Specifies the IP address or host name of the remote IPv6 FTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
ipv6-linklocal-address	Specifies the local link address that is automatically generated by the remote IPv6 FTP server.	-
-oi	Specifies the outbound interface for the local IPv6 link address.	-
interface-name	Specifies the name of the outbound interface for the local IPv6 link address.	-
interface-typeinterface-number	Specifies the number of the outbound interface for the local IPv6 link address.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before accessing the FTP server on the FTP client, you must first run the **ftp** command to connect the FTP client to the FTP server. If an SSL-based secure FTP connection is set up between the device and remote FTP server, you must specify **ssl-policy**. If the connection is a common FTP connection, you do not need to specify this parameter.

Precautions

- Before running the **ftp** command to set up a secure FTP connection, you must perform the following steps on the FTP client:

  a. In the system view, run the **ssl policy** command to create an SSL policy and enter the SSL policy view.
  b. In the SSL policy view, run the **trusted-ca load** command to load a trusted CA.
  c. In the SSL policy view, run the **crl load** command to load a CRL. This step is optional but recommended.
- You can set the source IP address to the source or destination IP address in the ACL rule when the **-a** or **-i** parameter is specified on the IPv4 network. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.
- You can run the **set net-manager vpn-instance** command to configure the NMS management VPN instance before running the **open** command to connect the FTP client and server.
  - If **public-net** or **vpn-instance** is not specified, the FTP client accesses the FTP server in the VPN instance managed by the NMS.
  - If **public-net** is specified, the FTP client accesses the FTP server on the public network.
  - If **vpn-instance** *vpn-instance-name* is specified, the FTP client accesses the FTP server in a specified VPN instance.
- If no parameter is set in the **ftp** command, only the FTP client view is displayed, and no connection is set up between the FTP server and client.
- If the port number that the FTP server uses is non-standard, you must specify a standard port number; otherwise, the FTP server and client cannot be connected.
- When you run the **ftp** command, the system prompts you to enter the user name and password for logging in to the FTP server. You can log in to the FTP server if the user name and password are correct.
- If the number of login users exceeds the maximum value that the FTP server allows (that is, 5), other authorized users cannot log in to the FTP server. To allow news authorized users to log in to the FTP server, users who have performed FTP services must disconnect their clients from the FTP server. You can run the **bye** or **quit** command to disconnect the FTP client from the FTP server and return to the user view, or run the **close** or **disconnect** command to disconnect the FTP client from the FTP server and retain in the FTP client view.

Example

Connect to the FTP server whose IP address is 10.137.217.201.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp]
```

Connect to the remote IPv6 FTP server whose address is fc00:2001:db8::1.

```
<HUAWEI> ftp ipv6 fc00:2001:db8::1
Trying fc00:2001:db8::1
Press CTRL+K to abort
Connected to ftp fc00:2001:db8::1
220 FTP service ready.
User(fc00:2001:db8::1:(none)):huawei
331 Password required for huawei
Enter Password:
230 User logged in.

[ftp]
```

Connect to the FTPS server whose IP address is 10.1.1.2.

```
<HUAWEI> ftp ssl-policy ftp_server 10.1.1.2
Trying 10.1.1.2 ...
Press CTRL+K to abort
Connected to 10.1.1.2.
220 FTP service ready.
234 AUTH command successfully, Security mechanism accepted.
200 PBSZ is ok.
200 Data channel security level is changed to private.
User(10.1.1.2:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp]
```

2.7.35 ftp acl

Function

The **ftp acl** command specifies an ACL number for the current FTP server so that the FTP client with the same ACL number can access the FTP server.

The **undo ftp acl** command deletes an ACL number of the current FTP server.

By default, no ACL is configured for FTP server.

Format

ftp [**ipv6**] **acl** *acl-number*

undo ftp [**ipv6**] **acl**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-
acl-number	Specifies the number of the ACL.	The value is an integer that ranges from 2000 to 3999.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the device functions as an FTP server, you can configure an access control list (ACL) on the device to control the source IP address, destination IP address, source port, destination port, VPN instance, and packets whose protocol type is TCP, allows specific clients to log in to the device through FTP.

Precautions

The **ftp server acl** command takes effect only after you run the **rule** command to configure the ACL rule.

Example

Allow the client whose ACL number is 2000 to log in to the FTP server.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule permit source 10.10.10.1 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] ftp acl 2000
```

2.7.36 ftp client-source

Function

The **ftp client-source** command specifies the source IP address for the FTP client to send packets.

The **undo ftp client-source** command restores the default source IP address for the FTP client to send packets.

The default source IP address for the FTP client to send packets is 0.0.0.0.

Format

ftp client-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo ftp client-source

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the IPv4 address of the source interface on the local device.	The value is in dotted decimal notation.

Parameter	Description	Value
-i *interface-type interface-number*	Specifies the source interface of the local device. The IP address configured for the source interface is the source IP address for sending packets. If no IP address is configured for the source interface, the FTP connection cannot be set up.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If no source IP address is specified, the client uses the source IP address that the router specifies to send packets. The source IP address must be configured for an interface with stable performance. The loopback interface is recommended. Using the loopback interface as the source interface simplifies the ACL rule and security policy configuration. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.

Prerequisites

Before you specify a logical interface as the source interface, ensure that the interface to be specified is created and has an IP address configured. Before you specify a physical interface as the source interface, ensure that the interface has an IPv4 address configured. Otherwise, the **ftp server-source** command cannot be successfully executed.

Precautions

- You can also run the **ftp** command to configure the source IP address whose priority is higher than that of the source IP address specified by the **ftp client-source** command. If you specify the source IP addresses by running the **ftp client-source** and **ftp** commands, the source IP address specified by the **ftp** command is used for data communication and is available only for the current FTP connection, while the source IP address specified by the **ftp client-source** command is available for all FTP connections.
- The IP address that a user displays on the FTP server is the specified source IP address or source interface IP address.
- No source address or source interface is specified, so security risks exist.

Example

Set the source IP address of the FTP client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] ftp client-source -a 10.1.1.1
Info: Succeeded in setting the source address of the FTP client to 10.1.1.1.
```

2.7.37 ftp secure-server enable

Function

The **ftp secure-server enable** command enables the secure FTP server function for FTP users.

The **undo ftp secure-server** command disables the secure FTP server function.

By default, the secure FTP server function is disabled.

Format

ftp [**ipv6**] **secure-server enable**

undo ftp [**ipv6**] **secure-server**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After SSL policies are configured on an FTP server, the secure FTP server function is provided based on SSL policies. To use the secure FTP server function, you must run the **ftp secure-server enable** command to enable the secure FTP server function. You can log in to the FTP server with secure FTP function configured from a client, and manage files between the FTP server and client.

Prerequisites

To enable the secure FTP server function, you must disable the common FTP server function.

Precautions

- If the FTP server function is disabled, no user can log in to the FTP server, and users who have logged in to the FTP server cannot perform any operation except logout.
- After the **ftp secure-server enable** command is run, the FTP server does not accept login requests from any interface by default, you should run the **ftp server-source** command to specify the source interface of the FTP server.
- After the **ftp ipv6 secure-server enable** command is run, the FTP server does not accept login requests from any IPv6 address by default, you should run the **ftp ipv6 server-source** command to specify the IPv6 source address for the FTP server.

Example

Enable the secure FTP server function.

```
<HUAWEI> system-view
[HUAWEI] ftp secure-server enable
```

2.7.38 ftp secure-server ssl-policy

Function

The **ftp secure-server ssl-policy** command configures an SSL policy for the FTP server.

The **undo ftp secure-server ssl-policy** command deletes an SSL policy from the FTP server.

By default, no SSL policy is configured for the FTP server.

Format

ftp secure-server ssl-policy *policy-name*

undo ftp secure-server ssl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an SSL policy.	The value is a string of 1 to 23 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The traditional FTP function transmits data in plain text, which can be intercepted and tampered with. You can run the **ftp secure-server ssl-policy** command to configure an SSL policy for the FTP server to ensure data security so that the FTP server implements session negotiation, sets up connections, and transmits data based on the SSL policy. You can log in to the FTP server from a client and manage files between the FTP server and client.

Prerequisites

Before running the **ftp secure-server ssl-policy** command to configure the SSL policy, you must first run the **ssl policy** command to create an SSL policy for the FTP server.

Precautions

- You must apply for a digital certificate for the FTP client from a trusted CA to authenticate the validity of the FTP server digital certificate.
- Only one SSL policy can be configured for the FTP server, and the latest configured SSL policy takes effect.

Example

Configure an SSL policy for the FTP server.

```
<HUAWEI> system-view
[HUAWEI] ftp secure-server ssl-policy ftp_server
```

2.7.39 ftp server enable

Function

The **ftp server enable** command enables the FTP server function to allow FTP users to log in to the FTP server.

The **undo ftp server** command disables the FTP server function so that FTP users cannot log in to the FTP server.

By default, the FTP function is disabled.

Format

ftp [**ipv6**] **server enable**

undo ftp [**ipv6**] **server**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To manage FTP server files on a client, you must run the **ftp server enable** command to enable the FTP server function to allow FTP users to log in to the FTP server.

Prerequisites

Before enabling the FTP service, run either of the following commands as required:

- Run the **ftp server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the FTP server or run the **ftp server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the FTP server.
- Run the **ftp ipv6 server-source -a** *ipv6_address* [**vpn-instance** *vpn_name*] command to configure a specified IPv6 address as the IPv6 source address of the FTP server or run the **ftp ipv6 server-source all-interface** command to specify any interface IPv6 address on the device as the IPv6 source address of the FTP server.

Precautions

If the FTP server function is disabled, no user can log in to the FTP server, and users who have logged in to the FTP server cannot perform any operation except logout.

NOTICE

The FTP protocol compromises device security. SFTP V2 or FTPS mode is recommended.

Example

Enable the FTP server function.

```
<HUAWEI> system-view
[HUAWEI] ftp server enable
Warning: FTP is not a secure protocol, and it is recommended to use SFTP.
Info: Succeeded in starting the FTP server.
```

2.7.40 ftp server max-sessions

Function

The **ftp server max-sessions** command sets the maximum number of sessions supported by the FTP server.

The **undo ftp server max-sessions** command restores the maximum number of sessions supported by the FTP server to the default value.

By default, the FTP server supports a maximum of five sessions.

Format

ftp [**ipv6**] **server max-sessions** *max-sessions-number*

undo ftp [**ipv6**] **server max-sessions**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-
max-sessions *max-sessions-number*	Specifies the maximum number of sessions supported by the FTP server.	The value is an integer ranging from 0 to 5.

Views

System view

Default Level

3: Management level

Usage Guidelines

You can run this command to set the maximum number of sessions supported by the FTP server. When the number of online users is equal to the maximum number of sessions supported by the FTP server, other users cannot log in to the FTP server.

Example

Set the maximum number of sessions supported by the FTP server to 3.

```
<HUAWEI> system-view
[HUAWEI] ftp server max-sessions 3
```

2.7.41 ftp server port

Function

The **ftp server port** command specifies the listening port number of the FTP server.

The **undo ftp server port** command restores the default value of the listening port number.

The default value is 21.

Format

ftp [**ipv6**] **server port** *port-number*

undo ftp [**ipv6**] **server port**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-
port *port-number*	Specifies the listening port number of the FTP server.	The value is 21 or an integer that ranges from 1025 to 55535.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, the listening port number of the FTP server is 21. Attackers may frequently access the default listening port, which wastes bandwidth, deteriorates server performance, and prevents authorized users from accessing the FTP server through the listening port. You can run the **ftp server port** command to specify another listening port number to prevent attackers from accessing the listening port.

Prerequisites

Before running the **ftp server port** command to specify the listening port number, you must first run the **undo ftp server** command to disable FTP services.

Precautions

- After the **ftp server port** command is executed, the FTP server disconnects all FTP connections and uses the new listening port.

- If the current listening port number is 21, FTP client users do not need to specify the port number for logging in to the FTP server. If the current listening port number is not 21, FTP client users must use the FTP server's listening port number to log in to the FTP server.
- After the listening port number is changed, you must run the **ftp server enable** command to enable FTP services to make the configuration take effect.

Example

Change the port number of the FTP server to 1028.

```
<HUAWEI> system-view
[HUAWEI] undo ftp server
[HUAWEI] ftp server port 1028
```

2.7.42 ftp server-source

Function

The **ftp server-source** command specifies the source IP address for an FTP server to send packets.

The **undo ftp server-source** command restores the default source IP address for an FTP server to send packets.

By default, the source IP address of an FTP server is not specified.

Format

ftp server-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo ftp server-source

ftp server-source all-interface

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the IPv4 address of the source interface on the local device.	The value is in dotted decimal notation.
-i *interface-type interface-number*	Specifies the source interface of the local device. The primary IP address of the source interface is the source IP address for sending packets. If no IP address is configured for the source IP address, the FTP connection cannot be set up.	-

Parameter	Description	Value
all-interface	Indicates that any interface that has an IPv4 address configured can be used as the source interface of an FTP server.	-

NOTE

In V200R020C00 and later versions, the source address for the FTP server to send packets is not specified by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, the default source IP address for the FTP server to send packets is 0.0.0.0, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, the default source IP address for the FTP server to send packets is not specified. To allow authorized users to log in to the FTP server, run either of the following commands to specify the source IP address of the FTP server.

- Run the **ftp server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the FTP server.
- Run the **ftp server-source all-interface** command to configure all interfaces configured with IPv4 addresses as the source interfaces of the FTP server.

Prerequisites

Before you specify a logical interface as the source interface, ensure that the interface to be specified is created and has an IP address configured. Before you specify a physical interface as the source interface, ensure that the interface has an IPv4 address configured. Otherwise, the **ftp server-source** command cannot be successfully executed.

Precautions

- After the source IP address is specified for the FTP server, you must use the specified IP address to log in to the FTP server.
- If the FTP service has been enabled, the FTP service restarts after the **ftp server-source** command is executed.

- After the **ftp server-source all-interface** command is run, the system allows FTP users to log in to the FTP server through all interfaces with IPv4 addresses configured. This increases system security risks. Therefore, you are not advised to run this command.

Example

Set the source IP address of the FTP server to **LoopBack0**.

```
<HUAWEI> system-view
[HUAWEI] ftp server-source -i loopback 0
Warning: To make the server source configuration take effect, the FTP server will be restarted. Continue? [Y/
N]: y
Info: Succeeded in setting the source interface of the FTP server to LoopBack0.
Info: Succeeded in starting the FTP server.
```

2.7.43 ftp ipv6 server-source

Function

The **ftp ipv6 server-source** command specifies an IPv6 source address for an FTP server.

The **undo ftp ipv6 server-source** command cancels the IPv6 source address specified for an FTP server.

By default, the IPv6 source address of an FTP server is not specified.

Format

ftp ipv6 server-source -a *ipv6_address* [**vpn-instance** *vpn_name*]

undo ftp ipv6 server-source

ftp ipv6 server-source all-interface

Parameters

Parameter	Description	Value
-a *ipv6_address*	Specifies an IPv6 source address for an FTP server.	The total length of an IPv6 source address is 128 bits, which are divided into eight groups. Each group contains four hexadecimal digits. The value is in the format X:X:X:X:X:X:X:X.
vpn-instance *vpn_name*	Specifies the name of a VPN instance.	The value is a string of 1 to 31 case-sensitive characters. It cannot contain spaces. The VPN instance name cannot be **_public_**. If the string is enclosed in double quotation marks (" "), the string can contain spaces.

Parameter	Description	Value
all-interface	Indicates that any interface IPv6 address on the device can be used as the IPv6 source address of the FTP server.	-

NOTE

In V200R020C00 and later versions, the source address for the FTP server to send packets is not specified by default. To allow authorized users to log in to the server, run a command to specify the source interface or source address of the server. For details about the command, see "Usage Scenario" in "Usage Guidelines" in this section.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In versions earlier than V200R020C00, the default source IP address for the FTP server to send packets is ::, incurring security risks. For details, see the product documentation of the corresponding version.

In V200R020C00 and later versions, the default source IP address for the FTP server to send packets is not specified. To allow authorized users to log in to the FTP server, run either of the following commands to specify the source IP address of the FTP server.

- Run the **ftp ipv6 server-source -a** *ipv6_address* [**vpn-instance** *vpn_name*] command to specify the specified IPv6 address as the IPv6 source address of the FTP server.
- Run the **ftp ipv6 server-source all-interface** command to specify all interface IPv6 addresses on the device as the IPv6 source addresses of the FTP server.

Prerequisites

A VPN instance has been created before you specify it for an FTP server. Otherwise, the **ftp ipv6 server-source** command cannot be executed.

Configuration Impact

After an IPv6 source address is specified for an FTP server, FTP users can log in to the FTP server only using this IPv6 address. This configuration applies to the FTP users who attempt to log in to the FTP server, not to the FTP users who have logged in to the server.

Precautions

After an IPv6 source address is specified for an FTP server using this command, ensure that FTP users can access this IPv6 address at Layer 3. Otherwise, FTP users will fail to log in to the FTP server.

If the specified IPv6 source address is bound to a VPN instance, the FTP server is also bound to the VPN instance.

After the **ftp ipv6 server-source all-interface** command is run, the system allows FTP users to log in to the FTP server through all interfaces with IPv6 addresses configured. This increases system security risks. Therefore, running this command is not recommended.

Example

Specify the IPv6 source address 2001:DB8:: for an FTP server.

```
<HUAWEI> system-view
[HUAWEI] ftp ipv6 server-source -a 2001:DB8::
```

2.7.44 ftp timeout

Function

The **ftp timeout** command configures the idle timeout duration of the FTP server.

The **undo ftp timeout** command restores the default idle timeout duration.

By default, the idle timeout duration of the FTP server is 10 minutes.

Format

ftp [**ipv6**] **timeout** *minutes*

undo ftp [**ipv6**] **timeout**

Parameters

Parameter	Description	Value
ipv6	Specifies the IPv6 FTP server.	-
minutes	Specifies idle timeout duration.	The value is an integer that ranges from 1 to 35791, in minutes. By default, the idle timeout duration is 10 minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

After a user logs in to the FTP server, a connection is set up between the FTP server and the user's client. The idle timeout duration is configured to release the connection when the connection is interrupted or when the user performs no operation for a specified time.

NOTICE

When you use the **get** command in the FTP view to overwrite a file, the operation may fail due to timeout of the FTP connection. To prevent this problem, set a long timeout period for the FTP connection.

Example

Set the idle timeout duration to 36 minutes.

```
<HUAWEI> system-view
[HUAWEI] ftp timeout 36
```

2.7.45 get (SFTP client view)

Function

The **get** command downloads a file from the SFTP server and saves the file to the local device.

Format

get *remote-filename* [*local-filename*]

Parameters

Parameter	Description	Value
remote-filename	Specifies the name of the file to be downloaded from the SFTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.
local-filename	Specifies the name of a downloaded file to be saved to the local device.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **get** command to download files from the FTP server to upgrade devices.

Precautions

- If *local-filename* is not specified on the local device, the original file name is used.
- If the name of the downloaded file is the same as that of an existing local file, the system prompts you whether to overwrite the existing file.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Download a file from the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> get test.txt
Remote file: / test.txt --->  Local file: test.txt
Info: Downloading file successfully ended.
```

2.7.46 get (FTP client view)

Function

The **get** command downloads a file from the FTP server and saves the file to the local device.

Format

get *remote-filename* [*local-filename*]

Parameters

Parameter	Description	Value
remote-filename	Specifies the name of the file to be downloaded from the FTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.
local-filename	Specifies the name of a downloaded file to be saved to the local device.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **get** command to download system software, backup configuration files, and patch files from the FTP server to upgrade devices.

Precautions

- If the downloaded file name is not specified on the local device, the original file name is used.
- If the name of the downloaded file is the same as that of an existing local file, the system prompts you whether to overwrite the existing file.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Download the system software **devicesoft.cc** from the FTP server.

```
<HUAWEI>ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] get devicesoft.cc
200 Port command successful. 150 Opening BINARY mode data connection for file transfer. 226 Transfer
complete  FTP: 6482944 byte(s) received in 54.500 second(s) 1117.40Kbyte(s)/sec.
```

2.7.47 help (SFTP client view)

Function

The **help** command displays the help information in the SFTP client view.

Format

help [**all** | *command-name*]

Parameters

Parameter	Description	Value
all	Displays all commands in the SFTP client view.	-
command-name	Displays the format and parameters of a specified command in the SFTP client view.	-

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In the SFTP view, you can only enter the question mark (?) to obtain all commands in the SFTP client view. If you enter a command keyword and the question mark (?) to query command parameters, an error message is displayed, as shown in the following:

```
sftp-client> dir ?
Error: Failed to list files.
```

You can run the **help** command to obtain the help information and display all commands or a command format in the SFTP client view.

Precautions

If you specify no parameter when running the **help** command, all commands in the SFTP client view are displayed. This has the same effect as the **help all** command or directly entering the question mark (?) in the SFTP client view.

Example

Display the format of the command **get**.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> help get
get Remote file name STRING<1-64>   [Local file name STRING<1-64>]  Download file
Default local file name is the same with remote file.
```

Display all commands in the SFTP client view.

```
sftp-client> help all
cd
cdup
dir
get
```

```
help
ls
mkdir
put
pwd
quit
rename
remove
rmdir
```

2.7.48 lcd

Function

The **lcd** command displays and changes the local working directory of the FTP client in the FTP client view.

Format

lcd [*local-directory*]

Parameters

Parameter	Description	Value
local-directory	Specifies the local working directory of the FTP client.	The value is a string of 1 to 128 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **lcd** command to display the local working directory of the FTP client when uploading or downloading files, and set the upload or download path to the path of the local working directory.

Precautions

The **lcd** command displays the local working directory of the FTP client, while the **pwd** command displays the working directory of the FTP server. If you specify the parameter *local-directory* in the **lcd** command, you can directly change the local working directory in the FTP client view.

Example

Change the local working directory to **flash:/test**.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] lcd
The current local directory is flash:.
[ftp] lcd flash:/test
The current local directory is flash:/test.
```

2.7.49 mget

Function

The **mget** command downloads multiple files from the remote FTP server to the local device.

Format

mget *remote-filenames*

Parameters

Parameter	Description	Value
remote-filenames	Specifies multiple files to download to the local device. File names are separated using spaces, and the wildcard (*) is supported.	The value is a string of 1 to 255 characters.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **mget** command to download multiple files at the same time.

Precautions

- The command cannot download all files in a directory or subdirectory.
- If the name of the downloaded file is the same as that of an existing local file, the system prompts you whether to overwrite the existing file.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Download files **1.txt**, **2.txt**, and **vrp221.cfg** from the remote FTP server.

```
<HUAWEI> ftp 10.10.10.1
Trying 10.10.10.1 ...
Press CTRL+K to abort
Connected to 10.10.10.1.
220 FTP service ready.
User(10.10.10.1:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] mget 1.txt 2.txt vrp221.cfg
200 Port command okay.
150 Opening ASCII mode data connection for 1.txt.

226 Transfer complete.
FTP: 3885 byte(s) received in 0.174 second(s) 22.32Kbyte(s)/sec.

200 Port command okay.
150 Opening ASCII mode data connection for 2.txt.

226 Transfer complete.
FTP: 8721 byte(s) received in 0.179 second(s) 48.72Kbyte(s)/sec.

200 Port command okay.
150 Opening ASCII mode data connection for vrp221.cfg.

226 Transfer complete.
FTP: 6700 byte(s) received in 0.151 second(s) 44.37Kbyte(s)/sec.

[ftp]
```

2.7.50 mkdir (FTP client view)

Function

The **mkdir** command creates a directory on the remote FTP server.

Format

mkdir *remote-directory*

Parameters

Parameter	Description	Value
remote-directory	Specifies the directory to be created.	The value is a string of case-insensitive characters without spaces. The absolute path length ranges from 1 to 64, while the directory name length ranges from 1 to 15.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

- You can run the **mkdir** command to create a subdirectory in a specified directory, and the subdirectory name must be unique.
- If no path is specified when you create a subdirectory, the subdirectory is created in the current directory.
- The created directory is stored on the FTP server.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Create a directory **test** on the remote FTP server.

```
<HUAWEI> ftp 172.16.104.110
Trying 172.16.104.110 ...
Press CTRL+K to abort
Connected to 172.16.104.110.
220 FTP service ready.
User(172.16.104.110:(none)):huawei
331 Password required for huawei
Enter password:
230 User logged in.

[ftp] mkdir test
257 "test" new directory created.
```

2.7.51 mkdir (SFTP client view)

Function

The **mkdir** command creates a directory on the remote SFTP server.

Format

mkdir *remote-directory*

Parameters

Parameter	Description	Value
remote-directory	Specifies the directory to be created.	The value is a string of case-insensitive characters without spaces. The absolute path length ranges from 1 to 64, while the directory name length ranges from 1 to 15.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

- You can run the **mkdir** command to create a subdirectory in a specified directory, and the subdirectory name must be unique.
- If no path is specified when you create a subdirectory, the subdirectory is created in the current directory.
- The created directory is stored on the SFTP server.
- After a directory is created, you can run the **dir/ls (SFTP client view)** command to view the directory.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Create a directory on the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> mkdir ssh
Info: Succeeded in creating a directory.
```

2.7.52 mkdir (User view)

Function

The **mkdir** command creates a directory in the current storage device.

Format

mkdir *directory*

Parameters

Parameter	Description	Settings
directory	Specifies a directory or directory and its path.	The value is a string of case-insensitive characters in the **[drive] [path] directory** format. The absolute path length ranges from 1 to 64, while the directory name length ranges from 1 to 15. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

If you only the subdirectory name is specified, a subdirectory is created in the current working directory. You can run the **pwd** command to query the current working directory. If the subdirectory name and directory path are specified, the subdirectory is created in the specified directory.

Precautions

- The subdirectory name must be unique in a directory; otherwise, the message "Error: Directory already exists." is displayed.
- A maximum of four directory levels are supported when you create a directory.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Create the subdirectory **new** in the flash card.

```
<HUAWEI> mkdir flash:/new
Info: Create directory flash:/new......Done.
```

2.7.53 more

Function

The **more** command displays the content of a specified file.

Format

more *filename* [*offset*] [**all**]

Parameters

Parameter	Description	Value
filename	Specifies the file name.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "
offset	Specifies the file offset.	The value is an integer that ranges from 0 to 2147483647, in bytes.
all	Displays all the file content on one screen.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **more** command to display the file content directly on a device.

- The following describes the drive name.
  - **drive** is the storage device and is named as **flash:**.
  - If devices are stacked, **drive** can be named as:
    - flash: root directory of the flash memory of the master switch in the stack.
    - chassis ID#flash: root directory of the flash memory on a device in the stack.

    For example, **slot2#flash:** indicates the flash memory in slot 2.
- The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working

directory. A relative path beginning with a slash (/) is a path relative to the root directory.

  - **flash:/my/test/** is an absolute path.
  - **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
  - **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- You are not advised to use this command to display non-text files; otherwise, the terminal is shut down or displays garbled characters, which is harmless to the system.
- Files are displayed in text format.
- You can display the file content flexibly by specifying parameters before running the **more** command:
  - You can run the **more** *filename* command to view a specified text file. The content of the specified text file is displayed on multiple screens. You can press the spacebar consecutively on the current session GUI to display all content of the file.

    To display the file content on multiple screens, you must ensure that:

    - The number of lines that can be displayed on a terminal screen is greater than 0. (The number of lines that can be displayed on a terminal screen is set by running the **screen-length** command.)
    - The total number of file lines is greater than the number of lines that can be displayed on a terminal screen. (The number of lines that can be displayed on a terminal screen is set by running the **screen-length** command.)
  - You can run the **more** *filename offset* command to view a specified file. The content of the specified text file starting from *offset* is displayed on multiple screens. You can press the spacebar consecutively on the current session GUI to display all content of the file.

    To display the file content on multiple screens, you must ensure that:

    - The number of lines that can be displayed on a terminal screen is greater than 0. (The number of lines that can be displayed on a terminal screen is set by running the **screen-length** command.)
    - The number of lines starting from *offset* in the file is greater than the number of lines that can be displayed on a terminal screen. (The number of lines that can be displayed on a terminal screen is set by running the **screen-length** command.)
  - You can run the **more** *file-name* **all** command to view a specified file. The file content is displayed on one screen.

Example

Display the content of the file **test.bat**.

```
<HUAWEI> more test.bat
rsa local-key-pair create
```

```
user-interface vty 12 14
authentication-mode aaa
protocol inbound ssh
user privilege level 5
quit
ssh user sftpuser authentication-type password
ssh user sftpuser service-type all
sftp server enable
```

Display the content of the file **log.txt** and set the offset to 100.

```
<HUAWEI> more log.txt 100

2.7.54 move

Function

The **move** command moves the source file from a specified directory to a destination directory.

Format

move *source-filename destination-filename*

Parameters

Parameter	Description	Settings
source-filename	Specifies the directory and name of a source file.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Settings
destination-filename	Specifies the directory and name of a destination file.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- If the destination file has the same name as an existing file, the system prompts you whether to overwrite the existing file. The system prompt is displayed only when **file prompt** is set to **alert**. If **file prompt** is set to **quiet**, no prompt is displayed.
- The **move** and **copy** commands have different effects:
  - The **move** command moves the source file to the destination directory.
  - The **copy** command copies the source file to the destination directory.

Example

Move a file from **flash:/test/sample.txt** to **flash:/sample.txt**.

```
<HUAWEI> move flash:/test/sample.txt flash:/sample.txt
Move flash:/test/sample.txt to flash:/sample.txt ?[Y/N]: y
%Moved file flash:/test/sample.txt to flash:/sample.txt.
```

2.7.55 mput

Function

The **mput** command uploads multiple files from the local device to the remote FTP server.

Format

mput *local-filenames*

Parameters

Parameter	Description	Value
local-filenames	Specifies files to be uploaded. File names are separated using spaces, and the wildcard (*) is supported.	The value is a string of 1 to 255 characters.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **mput** command to upload multiple files to the remote FTP server at the same time, especially in the upgrade scenario.

Precautions

If the name of the uploaded file is the same as that of an existing file on the FTP server, the system overwrites the existing file.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Upload two local files **111.text** and **vrp222.cfg** to the remote FTP server.

```
<HUAWEI> ftp 10.10.10.1
Trying 10.10.10.1 ...
Press CTRL+K to abort
Connected to 10.10.10.1.
220 FTP service ready.

FTP: 4198 byte(s) sent in 0.171 second(s) 24.54Kbyte(s)/sec.

[ftp]
```

2.7.56 open

Function

The **open** command connects the FTP client and server.

Format

Connect the FTP client to the FTP server based on the IPv4 address.

open [**ssl-policy** *policy-name*] [**-a** *source-ip-address* | **-i** *interface-type interface-number*] *host-ip* [*port-number*] [**public-net** | **vpn-instance** *vpn-instance-name*]

Connect the FTP client to the FTP server based on the IPv6 address.

open [**ssl-policy** *policy-name*] **ipv6** *host-ipv6* [*port-number*]

If the connection address is the IPv6 link-local address generated automatically by the interface of the remote IPv6 FTP server, the command format is as follows:

open [**ssl-policy** *policy-name*] **ipv6** *ipv6-linklocal-address* **-oi** *interface-type interface-number* [*port-number*]

Parameters

Parameter	Description	Value
ssl-policy *policy-name*	Specifies the name of the SSL policy that provides the secure FTP function.	The value is a string of 1 to 23 case-insensitive characters without spaces.
-a *source-ip-address*	Specifies the source IP address for connecting to the FTP client. You are advised to use the loopback interface IP address.	-
-i *interface-type interface-number*	Specifies the source interface type and ID. You are advised to use the loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the FTP connection cannot be set up.	-
host-ip	Specifies the IP address or host name of the remote IPv4 FTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
port-number	Specifies the port number of the FTP server.	The value is an integer that ranges from 1 to 65535. The default value is the standard port number 21.

Parameter	Description	Value
public-net	Specifies the FTP server on the public network. You must set the **public-net** parameter when the FTP server IP address is a public network IP address.	-
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance where the FTP server is located.	The value must be an existing VPN instance name.
host-ipv6	Specifies the IP address or host name of the remote IPv6 FTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
ipv6-linklocal-address	Specifies the IPv6 link-local address generated automatically by the interface of the remote IPv6 FTP server.	-
-oi	Indicates the outbound interface of the IPv6 link-local address.	-
interface-typeinterface-number	Specifies the outbound interface type and number of the IPv6 link-local address.	-

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **open** command in the FTP client view to connect the FTP client to the server to transmit files and manage files and directories of the FTP server.

Precautions

- You can run the **ftp** command in the user view to connect the FTP client and server and enter the FTP client view.
- Before enabling the FTP or FTPS function and specifying the **ssl-policy** *policy-name* parameter, you must first configure an SSL policy.
- You can set the source IP address to the source or destination IP address in the ACL rule when the **-a** or **-i** parameter is specified on the IPv4 network. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.
- You can run the **set net-manager vpn-instance** command to configure the NMS management VPN instance before running the **open** command to connect the FTP client and server.
  - If **public-net** or **vpn-instance** is not specified, the FTP client accesses the FTP server in the VPN instance managed by the NMS.
  - If **public-net** is specified, the FTP client accesses the FTP server on the public network.
  - If **vpn-instance** *vpn-instance-name* is specified, the FTP client accesses the FTP server in a specified VPN instance.
- If the port number that the FTP server uses is non-standard, you must specify a standard port number; otherwise, the FTP server and client cannot be connected.
- When you run the **open** command, the system prompts you to enter the user name and password for logging in to the FTP server. You can log in to the FTP client and enter the FTP client view if the user name and password are correct.

Example

Connect the FTP client with the FTP server whose IP address is 10.137.217.204.

```
<HUAWEI> ftp
[ftp] open 10.137.217.204
Trying 10.137.217.204 ...
Press CTRL+K to abort
Connected to 10.137.217.204.
220 FTP service ready.
User(10.137.217.204:(none)):huawei

2.7.57 passive

Function

The **passive** command sets the data transmission mode to passive.

The **undo passive** command sets the data transmission mode to active.

By default, the data transmission mode is active.

Format

passive

undo passive

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

The device supports the active and passive data transmission modes. In active mode, the server initiates a connection request, and the client and server need to enable and monitor a port to establish a connection. In passive mode, the client initiates a connection request, and only the server needs to monitor the corresponding port. This command is used together with the firewall function. When the client is configured with the firewall function, FTP connections are restricted between internal clients and external FTP servers if the FTP transmission mode is active. If the FTP transmission mode is passive, FTP connections between internal clients and external FTP servers are not restricted.

Example

Set the data transmission mode to passive.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] passive
Info: Succeeded in switching passive on.
```

2.7.58 prompt

Function

The **prompt** command enables the prompt function when files are transmitted between the FTP client and server.

The **undo prompt** command disables the prompt function.

By default, the prompt function is disabled.

Format

prompt

undo prompt

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can enable the prompt function as required when transmitting files between the FTP client and server.

Precautions

- The **prompt** command can be used when you run the **put**, **mput**, **get**, and **mget** commands.
- The prompt function can be enabled only for confirming service upload and download.
  - When you run the **put** or **mput** command, the system always overwrites the existing file if the name of the uploaded file is the same as that of an existing file on the FTP server.
  - When you run the **get** or **mget** command, the system always prompts you whether to overwrite the existing file if the name of the uploaded file is the same as an existing file name in the specified directory.

Example

Enable the FTP message prompt function.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
```

```
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] prompt
Info: Succeeded in switching prompt on.
```

Disable the FTP message prompt function.

```
[ftp] undo prompt
Info: Succeeded in switching prompt off.
```

2.7.59 put (FTP client view)

Function

The **put** command uploads a local file to the remote FTP server.

Format

put *local-filename* [*remote-filename*]

Parameters

Parameter	Description	Value
local-filename	Specifies the local file name of the FTP client.	The value is a string of 1 to 64 case-insensitive characters without spaces.
remote-filename	Specifies the name of the file to be uploaded to the remote FTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **put** command to upload a local file to the remote FTP server for further check and backup. For example, you can upload the local log file to the FTP server for other users to check, and upload the configuration file to the FTP server as a backup before upgrading the device.

Precautions

- If the file name is not specified on the remote FTP server, the local file name is used.
- If the name of the uploaded file is the same as that of an existing file on the FTP server, the system overwrites the existing file.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Upload the configuration file **vrpcfg.zip** to the remote FTP server as a backup, and save it as **backup.zip**.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] put vrpcfg.zip backup.zip
200 Port command successful.
150 Opening BINARY mode data connection for file transfer.
226 Transfer complete
FTP: 1098 byte(s) sent in 0.131 second(s) 8.38Kbyte(s)/sec.
```

2.7.60 put (SFTP client view)

Function

The **put** command uploads a local file to a remote SFTP server.

Format

put *local-filename* [*remote-filename*]

Parameters

Parameter	Description	Value
local-filename	Specifies a local file name on the SFTP client.	The value is a case-insensitive character string without spaces. The file name (including the absolute path) contains 1 to 64 characters.
remote-filename	Specifies the name of the file uploaded to the remote SFTP server.	The value is a case-insensitive character string without spaces. The file name (including the absolute path) contains 1 to 64 characters.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command enables you to upload files from the local device to a remote SFTP server to view the file contents or back up the files. For example, you can upload log files of a device to an SFTP server and view the logs in the server. During an upgrade, you can upload the configuration file of the device to the SFTP server for backup.

Precautions

- If *remote-filename* is not specified, the uploaded file is saved on the remote SFTP server with the original file name.
- If the specified *remote-filename* is the same as an existing file name on the SFTP server, the uploaded file overwrites the existing file on the server.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Upload a file to the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> put wm.cfg
local file: wm.cfg --->  Remote file: /wm.cfg
Info: Uploading file successfully ended.
```

2.7.61 pwd (FTP client view)

Function

The **pwd** command displays the FTP client's working directory on the remote FTP server.

Format

pwd

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

After logging in to the FTP server, you can run the **pwd** command to display the FTP client's working directory on the remote FTP server.

If the displayed working directory is incorrect, you can run the **cd** command to change the FTP client's working directory on the remote FTP server.

Example

Display the FTP client's working directory on the remote FTP server.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] pwd
257 "/" is current directory.
```

2.7.62 pwd (SFTP client view)

Function

The **pwd** command displays the SFTP client's working directory on the remote FTP server.

Format

pwd

Parameters

None

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

After logging in to the SFTP server, you can run the **pwd** command to display the SFTP client's working directory on the remote SFTP server.

If the displayed working directory is incorrect, you can run the **cd** command to change the SFTP client's working directory on the remote SFTP server.

Example

Display the SFTP client's working directory on the remote SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> pwd
/
sftp-client> cd test
Current directory is:
/test
sftp-client> pwd
/test
```

2.7.63 pwd (user view)

Function

The **pwd** command displays the current working directory.

Format

pwd

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can run the **pwd** command in any directory to display the current working directory. To change the current working directory, you can run the **cd** command.

Example

Display the current working directory.

```
<HUAWEI> pwd
flash:/test
```

2.7.64 remotehelp

Function

The **remotehelp** command displays the help information about an FTP command when the FTP client and server are connected.

Format

remotehelp [*command*]

Parameters

Parameter	Description	Value
command	Specifies the FTP command.	The value is a string of 1 to 16 characters.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

You can run the **remotehelp** command to display help information about an FTP command.

- The help information is provided by the remote server. Different remote servers may provide different help information for an FTP command.
- The help information can be displayed for FTP commands **user**, **pass**, **cwd**, **cdup**, **quit**, **port**, **pasv**, **type**, **retr**, **stor**, **dele**, **rmd**, **mkd**, **pwd**, **list**, **nlst**, **syst**, **help**, **xcup**, **xcwd**, **xmkd**, **xpwd**, **xrmd**, **eprt**, **epsv**, and **feat**.

Example

Display the syntax of the **cdup** command.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

```

2.7.65 remove (SFTP client view)

Function

The **remove** command deletes specified files from the remote SFTP server.

Format

remove *remote-filename* &<1-10>

Parameters

Parameter	Description	Value
remote-filename	Specifies the name of the file to be deleted from the remote SFTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

- You can configure a maximum of 10 file names in the command and separate them using spaces and delete them at one time.
- If the file to be deleted is not in the current directory, you must specify the file path.

Example

Delete the file **3.txt** from the server and **backup1.txt** from the **test** directory.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> remove 3.txt test/backup1.txt
Warning: Make sure to remove these files? [Y/N]:y
Info: Succeeded in removing the file /3.txt.
Info: Succeeded in removing the file /test/backup1.txt.
```

2.7.66 rename (SFTP client view)

Function

The **rename** command renames a file or directory stored on the SFTP server.

Format

rename *old-name new-name*

Parameters

Parameter	Description	Value
old-name	Specifies the name of a file or directory.	The value is a string of 1 to 64 case-insensitive characters without spaces.
new-name	Specifies the new name of the file or directory.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

You can run the **rename** command to rename a file or directory.

Example

Rename the directory **yourtest** on the SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> rename test/yourtest test/test
Warning: Rename /test/yourtest to /test/test? [Y/N]:y
Info: Succeeded in renaming file.
sftp-client> cd test
Current directory is:
/test
sftp-client> dir
drwxrwxrwx   1 noone    nogroup         0 Mar 29 2012 .
drwxrwxrwx   1 noone    nogroup         0 Mar 29 2012 ..
drwxrwxrwx   1 noone    nogroup         0 Mar 24 2012 test
-rwxrwxrwx   1 noone    nogroup      5736 Mar 24 2012 backup.txt
```

2.7.67 rename (user view)

Function

The **rename** command renames a file or folder.

Format

rename *old-name new-name*

Parameters

Parameter	Description	Settings
old-name	Specifies the name of a file or folder.	The value is a string of 1 to 64 case-insensitive characters without spaces in the **[drive] [path] filename** format. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Settings
new-name	Specifies the new name of the file or directory.	The value is a string of 1 to 64 case-insensitive characters without spaces in the **[drive] [path] filename** format. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name:

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.

- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- You must rename a file or directory in its source directory.
- If the renamed file or directory has the same name as an existing file or directory, an error message is displayed.
- If you specify *old-name* or *new-name* without specifying the file path, the file must be saved in your current working directory.

Example

Rename the directory **mytest** to **yourtest** in the directory **flash:/test/**.

```
<HUAWEI> pwd
flash:/test
<HUAWEI> rename mytest yourtest
Rename flash:/test/mytest to flash:/test/yourtest ?[Y/N]:y
Info: Rename file flash:/test/mytest to flash:/test/yourtest ......Done.
```

Rename the file **sample.txt** to **sample.bak**.

```
<HUAWEI> rename sample.txt sample.bak
Rename flash:/sample.txt to flash:/sample.bak ?[Y/N] :y
Info: Rename file flash:/sample.txt to flash:/sample.bak .......Done.
```

2.7.68 reset recycle-bin

Function

The **reset recycle-bin** command permanently deletes files from the recycle bin.

Format

reset recycle-bin [*filename* | *devicename*]

Parameters

Parameter	Description	Value
filename	Specifies the name of a file to be deleted.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' " The wildcard (*) character is supported.
devicename	Specifies the storage device name.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If you run the **delete** command without specifying the **/unreserved** parameter, the file is moved to the recycle bin and still occupies the memory. To free up the space, you can run the **reset recycle-bin** command to permanently delete the file from the recycle bin.

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Like *devicename*, **drive** specifies the storage device name.

Precautions

- You can run the **dir /all** command to display all files that are moved to the recycle bin from the current directory, and file names are displayed in square brackets ([ ]).
- If you delete a specified storage device, all files in the root directory of the storage device are deleted.
- If you run the **reset recycle-bin** command directly, all files that are moved to the recycle bin from the current directory are permanently deleted.

Example

Delete the file **test.txt** that is moved to the recycle bin from the directory **test**.

```
<HUAWEI> reset recycle-bin flash:/test/test.txt
Squeeze flash:/test/test.txt?[Y/N]:y
%Cleared file flash:/test/test.txt.
```

Delete files that are moved to the recycle bin from the current directory.

```
<HUAWEI> pwd
flash:/test
<HUAWEI> reset recycle-bin
Squeeze flash:/test/backup.zip?[Y/N]:y
%Cleared file flash:/test/backup.zip.
Squeeze flash:/test/backup1.zip?[Y/N]:y
%Cleared file flash:/test/backup1.zip.
```

2.7.69 rmdir (FTP client view)

Function

The **rmdir** command deletes a specified directory from the remote FTP server.

Format

rmdir *remote-directory*

Parameters

Parameter	Description	Value
remote-directory	Specifies a directory or path on the FTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **rmdir** command to delete a specified directory from the remote FTP server.

Precautions

- Before running the **rmdir** command to delete a directory, you must delete all files and subdirectories from the directory.
- If no path is specified when you delete a subdirectory, the subdirectory is deleted from the current directory.
- The directory is deleted from the FTP server rather than the FTP client.

Example

Delete the directory **d:/temp1** from the remote FTP server.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] ascii
200 Type set to A.
[ftp] rmdir d:/temp1
250 'D:\temp1': directory removed.
```

2.7.70 rmdir (user view)

Function

The **rmdir** command deletes a specified directory from the storage device.

Format

rmdir *directory*

Parameters

Parameter	Description	Value
directory	Specifies a directory or directory and its path.	The value is a string of case-insensitive characters in the **[drive] [path] directory** format. The absolute path length ranges from 1 to 64, while the directory name length ranges from 1 to 15. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- Before running the **rmdir** command to delete a directory, you must delete all files and subdirectories from the directory.
- A deleted directory and its files cannot be restored from the recycle bin.

Example

Delete the directory **test** from the current directory.

```
<HUAWEI> rmdir test
Remove directory flash:/test?[Y/N]:y
%Removing directory flash:/test...Done!%Removing directory flash:/test....Done!
```

2.7.71 rmdir (SFTP client view)

Function

The **rmdir** command deletes a specified directory from the remote SFTP server.

Format

rmdir *remote-directory* &<1-10>

Parameters

Parameter	Description	Value
remote-directory	Specifies the name of a file on the SFTP server.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

SFTP client view

Default Level

3: Management level

Usage Guidelines

- You can configure a maximum of 10 file names in the command and separate them using spaces and delete them at one time.
- Before running the **rmdir** command to delete a directory, you must delete all files and subdirectories from the directory.
- If the directory to be deleted is not in the current directory, you must specify the file path.

Example

Delete the directory **1** from the current directory, and the directory **2** from the **test** directory.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.137.217.201
```

```
Please input the username:admin
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201 ...
Enter password:
sftp-client> rmdir 1 test/2
Warning: Make sure to remove these directories? [Y/N]:y
Info: Succeeded in removing the directory /test/1.
Info: Succeeded in removing the directory /test/test/2.
```

2.7.72 scp

Function

The **scp** command uploads a local file to the remote SCP server or downloads a file from the remote SCP server to a local directory.

Format

Transfer a file between the local client and the remote SCP server based on IPv4.

scp [**-port** *port-number* | { **public-net** | **vpn-instance** *vpn-instance-name* } | **identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** } | **user-identity-key** { **rsa** | **dsa** | **ecc** } | { **-a** *source-address* | **-i** *interface-type interface-number* } | **-r** | **-cipher** *-cipher* | **-c**] * *sourcefile destinationfile*

Transfer a file between the local client and the remote SCP server based on IPv6.

scp ipv6 [**-port** *port-number* | { **public-net** | **vpn-instance** *vpn-instance-name* } | **identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** } | **user-identity-key** { **rsa** | **dsa** | **ecc** } | **-a** *source-address* | **-r** | **-cipher** *-cipher* | **-c**] * *sourcefile destinationfile* [**-oi** *interface-type interface-number*]

Parameters

Parameter	Description	Value
-port *port-number*	Specifies the port number of the SCP server.	The value is an integer that ranges from 1 to 65535. The default value is 22.
public-net	Indicates that the SCP server is connected to the public network.	-
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance where the SCP server is located.	The value must be an existing VPN instance name.

Parameter	Description	Value
identity-key	Specifies the public key algorithm for server authentication.	Public key algorithms include DSA, RSA, RSA_SHA2_256, RSA_SHA2_512 and ECC. By default, ECC is used for server authentication. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.
user-identity-key	Specifies the public key algorithm for client authentication.	Public key algorithms include DSA, RSA, and ECC. By default, RSA is used for client authentication. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.
-a *source-address*	Specifies the source IP address for connecting to the SCP client. You are advised to use the loopback interface IP address.	-
-i *interface-type interface-number*	Specifies the source interface used by the SCP client to set up connections. It consists of the interface type and number. It is recommended that you specify a loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the SCP connection cannot be set up.	-

Parameter	Description	Value
-oi *interface-type interface-number*	Specifies an outbound interface on the local device. If the remote host uses an IPv6 address, you must specify the outbound interface on the local device.	-
-r	Uploads or downloads files in batches.	-
-cipher *-cipher*	Specifies the encryption algorithms for uploading or downloading files.	Encryption algorithms **des**, **3des**, **aes256**, **aes128_ctr**, **aes256_ctr**, and **aes128** are supported. The default encryption algorithm is **aes256_ctr**. You are advised to use aes128_ctr and aes256_ctr encryption algorithms to ensure high security. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.
-c	Compress files when uploading or downloading them.	-
sourcefile	Specifies a source file to be uploaded or downloaded.	The source file format is *username*@*hostname*:[*path*][*filename*].

Parameter	Description	Value
destinationfile	Specifies a destination file to be uploaded or downloaded.	The destination file format is *username*@*hostname*:[*path*][*filename*].

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

SCP is an SSH2.0-based secure file transfer protocol. Compared with the SFTP file transfer mode, the SCP file transfer mode allows you to upload or download files when the connection is set up between the SCP client and server.

- You are advised to set the source IP address to the loopback address, or set the outbound interface to the loopback interface using **-a** and **-i**, to improve security.
- When **-r** is specified, you can use the wildcard (*) to upload or download files in batches, for example, *.txt and huawei.*.
- When **-c** is specified, files are compressed before being transmitted. File compression takes a long time and affects file transfer speed; therefore, you are not advised to compress files before transferring them.

Precautions

- The format of uploaded and downloaded files of the SCP server is *username*@*hostname*:[*path*][*filename*]. In the preceding file format, *username* indicates the user name for logging in to the SCP server, *hostname* indicates the SCP server name or IP address, and *path* indicates user's working directory specified on the SCP server, and *filename* indicates the file name. The following describes the preceding parameters when you upload a file to the SCP server:
  - If *filename* and *path* are not specified, the file is transferred to the root directory of the user's working directory.
  - If only *path* is specified, the file is transferred to the specified directory.
  - If only *filename* is specified, the file is named as *filename*, and transferred to the SCP server.
  - To set *hostname* to the IPv6 address, you must add the IPv6 address with square brackets ([ ]), for example, zhangsan@[FC00::/7]:.
- If the destination file name is the same as the name of an existing directory, the file is moved to this directory with the source file name. If the destination

file has the same name as an existing file, the system prompts you whether to overwrite the existing file.

- If an SCP user on the client authenticates the server using an RSA, a DSA, or an ECC public key, the SCP user is prompted to select the key pair for authentication.
- You can run the **set net-manager vpn-instance** command to configure the NMS management VPN instance before running the **open** command to connect the FTP client and server.
  - If **public-net** or **vpn-instance** is not specified, the FTP client accesses the FTP server in the VPN instance managed by the NMS.
  - If **public-net** is specified, the FTP client accesses the FTP server on the public network.
  - If **vpn-instance** *vpn-instance-name* is specified, the FTP client accesses the FTP server in a specified VPN instance.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Log in through ECC authentication and copy the **xxxx.txt** file to the flash memory of remote SCP server at 10.10.0.114.

```
<HUAWEI> system-view
[HUAWEI] scp identity-key ecc flash:/xxxx.txt root@10.10.0.114:flash:/xxxx.txt
Trying 10.10.0.114 ...
Press CTRL+K to abort
Connected to 10.10.0.114 ...
The server's public key does not match the one catched before.
The server is not authenticated. Continue to access it? [Y/N]:y
Update the server's public key now? [Y/N]: y

Enter password:
flash:/xxxx.txt              100%          12Bytes           1KByte(s)/sec
```

2.7.73 scp client-source

Function

The **scp client-source** command specifies the source IP address for the SCP client to send packets.

The **undo scp client-source** command cancels the source IP address for the SCP client to send packets.

By default, no source IP address is configured on the SCP client.

Format

scp client-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo scp client-source

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the source IP address of the SCP client. You are advised to use the loopback interface IP address.	-
-i *interface-type interface-number*	Source interface type and ID. You are advised to use the loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the SCP connection cannot be set up.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If no source IP address is specified, the client uses the source IP address that the router specifies to send packets. The source IP address must be configured for an interface with stable performance. The loopback interface is recommended. Using the loopback interface as the source interface simplifies the ACL rule and security policy configuration. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.

Prerequisites

The source interface specified using the command must exist and have an IP address configured.

Precautions

The **scp** command also configures the source IP address whose priority is higher than that of the source IP address specified in the **scp client-source** command. If you specify source addresses in the **scp client-source** and **scp** commands, the source IP address specified in the **scp** command is used for data communication. The source address specified in the **scp client-source** command applies to all SCP connections. The source address specified in the **scp** command applies only to the current SCP connection.

Example

Set the source IP address of the SCP client to the loopback interface IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] scp client-source -a 10.1.1.1
```

2.7.74 scp server enable

Function

The **scp server enable** command enables the SCP service on the SSH server.

The **undo scp server enable** command disables the SCP service on the SSH server.

By default, the SCP function is disabled.

Format

scp [**ipv4** | **ipv6**] **server enable**

undo scp [**ipv4** | **ipv6**] **server enable**

Parameters

Parameter	Description	Value
ipv4	Indicates that the SCP IPv4 service is enabled on the SSH server.	-
ipv6	Indicates that the SCP IPv6 service is enabled on the SSH server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To use SCP for file transfer, you need to first enable the SCP service on the SSH server. The client can establish an SCP connection with the SSH server only after SCP service has been enabled on the SSH server.

Prerequisites

Before enabling the SCP service, run either of the following commands as required:

- Run the **ssh server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the SSH server or run the **ssh server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the SSH server.

- Run the **ssh ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure a specified IPv6 address as the IPv6 source address of the SSH server or run the **ssh ipv6 server-source all-interface** command to specify any interface IPv6 address on the device as the IPv6 source address of the SSH server.

Precautions

After the **scp server enable** command is run, the numbers of IPv4 port and IPv6 port are both changed. To change the number of IPv4 port or IPv6 port separately, run the **scp** [**ipv4** | **ipv6**] **server enable** command.

Example

Enable the SCP service.

```
<HUAWEI> system-view
[HUAWEI] scp server enable
```

Enable the SCP IPv4 service.

```
<HUAWEI> system-view
[HUAWEI] scp ipv4 server enable
```

2.7.75 set cipher-suite

Function

The **set cipher-suite** command configures cipher suites for a customized SSL cipher suite policy.

The **undo set cipher-suite** command deletes cipher suites in a customized SSL cipher suite policy.

By default, no cipher suite is configured for a customized SSL cipher suite policy.

Format

set cipher-suite { **tls12_ck_dss_aes_128_gcm_sha256** | **tls12_ck_dss_aes_256_gcm_sha384** | **tls12_ck_rsa_aes_128_gcm_sha256** | **tls12_ck_rsa_aes_256_gcm_sha384** }

undo set cipher-suite { **tls12_ck_dss_aes_128_gcm_sha256** | **tls12_ck_dss_aes_256_gcm_sha384** | **tls12_ck_rsa_aes_128_gcm_sha256** | **tls12_ck_rsa_aes_256_gcm_sha384** }

Parameters

Parameter	Description	Value
tls12_ck_dss_aes_128_gcm_sha256	Configures the TLS12_CK_DSS_AES_128_GCM_SHA256 cipher suite.	-

Parameter	Description	Value
tls12_ck_dss_aes_256_gcm_sha384	Configures the TLS12_CK_DSS_AES_256_GCM_SHA384 cipher suite.	-
tls12_ck_rsa_aes_128_gcm_sha256	Configures the TLS12_CK_RSA_AES_128_GCM_SHA256 cipher suite.	-
tls12_ck_rsa_aes_256_gcm_sha384	Configures the TLS12_CK_RSA_AES_256_GCM_SHA384 cipher suite.	-

Views

Customized SSL cipher suite policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure cipher suites for a customized SSL cipher suite policy, run the **set cipher-suite** command.

Precautions

- If a customized SSL cipher suite policy is being referenced by an SSL policy, the cipher suites in the customized cipher suite policy can be added, modified, or partially deleted. Deleting all of the cipher suites is not allowed.
- The system software does not support the **tls12_ck_rsa_aes_256_cbc_sha256**, **tls1_ck_dhe_dss_with_aes_128_sha**, **tls1_ck_dhe_dss_with_aes_256_sha**, **tls1_ck_dhe_rsa_with_aes_128_sha**, **tls1_ck_dhe_rsa_with_aes_256_sha**, **tls1_ck_rsa_with_aes_128_sha**, and **tls1_ck_rsa_with_aes_256_sha** parameters. To use the **tls12_ck_rsa_aes_256_cbc_sha256**, **tls1_ck_dhe_dss_with_aes_128_sha**, **tls1_ck_dhe_dss_with_aes_256_sha**, **tls1_ck_dhe_rsa_with_aes_128_sha**, **tls1_ck_dhe_rsa_with_aes_256_sha**, **tls1_ck_rsa_with_aes_128_sha**, or **tls1_ck_rsa_with_aes_256_sha** parameter, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to use other parameters. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Configure the **tls12_ck_dss_aes_128_gcm_sha256** cipher suite for the customized SSL cipher suite policy named **cipher1**.

```
<HUAWEI> system-view
[HUAWEI] ssl cipher-suite-list cipher1
[HUAWEI-ssl-cipher-suite-cipher1] set cipher-suite tls12_ck_dss_aes_128_gcm_sha256
```

2.7.76 set default ftp-directory

Function

The **set default ftp-directory** command configures the default FTP working directory.

The **undo set default ftp-directory** command disables the default FTP working directory.

By default, no default FTP working directory is configured.

Format

set default ftp-directory *directory*

undo set default ftp-directory

Parameters

Parameter	Description	Value
directory	Specify the default FTP working directory.	The value is a string of 1 to 160 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **set default ftp-directory** command to configure a default FTP working directory for all FTP users at one time.

Precautions

- The **set default ftp-directory** command takes effect only when the device functions as an FTP server and the user function as an FTP client.
- You can run the **local-user ftp-directory** command to configure an authorized working directory for a local user.
- If you have configured the FTP working directory by running the **local-user ftp-directory** command, you must use this FTP working directory.
- You can run the **lcd** command to view the working directory of FTP users.

- If no FTP working directory is specified on the device, FTP users cannot log in to the device, and are prompted that the working directory is unauthorized.

Example

Set the default FTP working directory to **flash:/**.

```
<HUAWEI> system-view
[HUAWEI] set default ftp-directory flash:/
```

2.7.77 set device auto-delete-file disable

Function

The **set device auto-delete-file disable** command disables the automatic file deletion function.

The **undo set device auto-delete-file disable** command enables the automatic file deletion function.

By default, the device is enabled to automatically delete files.

Format

set device auto-delete-file disable

undo set device auto-delete-file disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The device periodically checks the storage space. When the space usage exceeds 85%, the device automatically releases the space using the following methods in sequence: empty the recycle bin, delete the system software package, delete patches, and delete logs. If you need to manually delete the files, run this command to disable the automatic file deletion function.

If no command output is displayed, run the **display current-configuration** command to check the parameters that have taken effect on the device and determine whether the automatic file deletion function is enabled.

Example

Disable the automatic file deletion function.

```
<HUAWEI> system-view
[HUAWEI] set device auto-delete-file disable
```

2.7.78 set net-manager vpn-instance

Function

The **set net-manager vpn-instance** command configures the default VPN instance that the NMS uses on the device.

The **undo set net-manager vpn-instance** command deletes the default VPN instance from the device.

By default, no VPN instance is configured on the device.

Format

set net-manager vpn-instance *vpn-instance-name*

undo set net-manager vpn-instance

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of the default VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the NMS manages devices on the VPN network, you need to send the device information to the NMS using the VPN instance.

You can run the **set net-manager vpn-instance** command to configure the default VPN instance for the NMS to manage the device so that the device can use this VPN instance to communicate with the NMS.

Precautions

- Before running the **set net-manager vpn-instance** command, you must create VPN instances.
- After running this command, you can successfully run file transfer commands that you have configured based on the FTP, TFTP, SCP, and SFTP commands only in the default VPN instance.
- If the host has been configured as a log host, the NMS can receive device logs from the default VPN instance.
- After you configure a VPN instance using the **set net-manager vpn-instance** command, the FTP, SFTP, SCP, and TFTP clients as well as the Information Center (IC), SNMP, and TACACS modules will use this instance by default.

  If the preceding clients or modules need to use a public network server or a specified VPN server, run the following commands to set parameters. If **public-net** is specified, the device accesses the server on the public network. If **vpn-instance***vpn-instance-name* is specified, the device accesses the server in the specified VPN instance.
  - FTP client: **ftp**
  - SFTP client: **sftp**
  - SCP client: **scp**
  - TFTP client: **tftp**
  - IC module: **info-center loghost**
  - SNMP module: **snmp-agent target-host trap**
  - TACACS module: **hwtacacs-server accounting**, **hwtacacs-server authentication**, **hwtacacs-server authorization**

Example

Set the default VPN instance to v1.

```
<HUAWEI> system-view
[HUAWEI] set net-manager vpn-instance v1
```

2.7.79 sftp

Function

The **sftp** command connects the device to the SSH server so that you can manage files that are stored on the SFTP server.

Format

Connect the SFTP client to the SFTP server based on IPv4.

sftp [**-a** *source-address* | **-i** *interface-type interface-number*] *host-ip* [*port*] [[**public-net** | **-vpn-instance** *vpn-instance-name*] | **identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** } | **user-identity-key** { **rsa** | **dsa** | **ecc** } | **prefer_kex** *prefer_key-exchange* | **prefer_ctos_cipher** *prefer_ctos_cipher* | **prefer_stoc_cipher** *prefer_stoc_cipher* | **prefer_ctos_hmac** *prefer_ctos_hmac* | **prefer_stoc_hmac** *prefer_stoc_hmac*| **-ki** *aliveinterval*] | [**-kc** *alivecountmax*] *

Connect the SFTP client to the SFTP server based on IPv6.

sftp ipv6 [**-a** *source-address*] *host-ipv6* [**-oi** *interface-type interface-number*] [*port*] [**identity-key** { **dsa** | **rsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** } | **user-identity-key** { **rsa** | **dsa** | **ecc** } | **-vpn-instance** *vpn-instance-name* | **prefer_kex** *prefer_key-exchange* | **prefer_ctos_cipher** *prefer_ctos_cipher* | **prefer_stoc_cipher** *prefer_stoc_cipher* | **prefer_ctos_hmac** *prefer_ctos_hmac* | **prefer_stoc_hmac** *prefer_stoc_hmac* | **-ki** *aliveinterval* | **-kc** *alivecountmax*] *

Parameters

Parameter	Description	Value
-a *source-address*	Specifies the source IP address for connecting to the SFTP client. You are advised to use the loopback interface IP address.	-
-i *interface-type interface-number*	Specifies the source interface type and ID. You are advised to use the loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the SFTP connection cannot be set up.	-
host-ip	Specifies the IP address or host name of the remote IPv4 SFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.
host-ipv6	Specifies the IPv6 address or host name of the remote IPv6 SFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
-oi *interface-type interface-number*	Specifies an outbound interface on the local device. If the remote host uses an IPv6 address, you must specify the outbound interface on the local device.	-
port	Specifies the port number of the SSH server.	The value is an integer that ranges from 1 to 65535. The default port number is 22.
public-net	Specifies the SFTP server on the public network. You must set the **public-net** parameter when the SFTP server IP address is a public network IP address.	-
-vpn-instance *vpn-instance-name*	Name of the VPN instance where the SFTP server is located.	The value must be an existing VPN instance name.
prefer_kex *prefer_key-exchange*	Indicates the preferred key exchange algorithm.	The **dh_exchange_group**, **dh_exchange_group_sha256**, **dh_group14_sha1**, **dh_group14_sha256**, **dh_group15_sha512**, and **dh_group16_sha512** algorithms are supported currently. The default key exchange algorithm is dh_group14_sha1.

Parameter	Description	Value
prefer_ctos_cipher *prefer_ctos_cipher*	Specify an encryption algorithm for transmitting data from the client to the server.	Encryption algorithms 3des, aes128, aes128_ctr, aes256_ctr, and aes256 are supported. The default encryption algorithm is aes256_ctr. You are advised to use aes128_ctr and aes256_ctr encryption algorithms to ensure high security. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.

Parameter	Description	Value
prefer_stoc_cipher *prefer_stoc_cipher*	Specify an encryption algorithm for transmitting data from the server to the client	Encryption algorithms 3des, aes128, aes128_ctr, aes256_ctr, and aes256 are supported. The default encryption algorithm is aes256_ctr. You are advised to use aes128_ctr and aes256_ctr encryption algorithms to ensure high security. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.
prefer_ctos_hmac *prefer_ctos_hmac*	Specify an HMAC algorithm for transmitting data from the client to the server.	HMAC algorithms sha1, sha1_96, md5, sha2_256, sha2_256_96, and md5_96 are supported. The default HMAC algorithm is sha2_256. **NOTE** To enhance security, you are not advised to use the md5 or md5_96 algorithm.
prefer_stoc_hmac *prefer_stoc_hmac*	Specify an HMAC algorithm for transmitting data from the server to the client.	HMAC algorithms sha1, sha1_96, md5, sha2_256, sha2_256_96, and md5_96 are supported. The default HMAC algorithm is sha2_256. **NOTE** To enhance security, you are not advised to use the md5 or md5_96 algorithm.

Parameter	Description	Value
-ki *aliveinterval*	Specifies the interval for sending keepalive packets when no packet is received in reply.	The value is an integer that ranges from 1 to 3600, in seconds.
-kc *alivecountmax*	Specifies the times for sending keepalive packets when no packet is received in reply.	The value is an integer that ranges from 3 to 10. The default value is 5.
identity-key	Specifies the public key for server authentication.	Public key algorithms include dsa, rsa, rsa_sha2_256, rsa_sha2_512 and ecc. By default, the server authentication uses the ECC public key. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.
user-identity-key	Specifies the public key algorithm for the client authentication.	Public key algorithms include dsa, rsa, and ecc. By default, the client authentication uses the RSA public key. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.

Usage Guidelines

Usage Scenario

SFTP is short for SSH FTP that is a secure FTP protocol. SFTP is on the basis of SSH. It ensures that users can log in to a remote device securely for file management and transmission, and enhances the security in data transmission. In addition, you can log in to a remote SSH server from the device that functions as an SFTP client.

When the connection between the SFTP server and client fails, the SFTP client must detect the fault in time and disconnect from the SFTP server. To ensure this, before being connected to the server in SFTP mode, the client must be configured with the interval and times for sending the keepalive packet when no packet is received in reply. If the client receives no packet in reply within the specified interval, the client sends the keepalive packet to the server again. If the maximum number of times that the client sends keepalive packets exceeds the specified value, the client releases the connection. By default, when no packet is received, the function for sending keepalive packets is not enabled.

Precautions

- You can set the source IP address to the source or destination IP address in the ACL rule when the **-a** or **-i** parameter is specified. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.
- The SSH client can log in to the SSH server with no port number specified only when the port number of the SSH server is 22. If the SSH server uses another port, the port number must be specified when SSH clients log in to the SSH server.
- You can run the **set net-manager vpn-instance** command to configure the NMS management VPN instance before running the **open** command to connect the FTP client and server.
  - If **public-net** or **vpn-instance** is not specified, the FTP client accesses the FTP server in the VPN instance managed by the NMS.
  - If **public-net** is specified, the FTP client accesses the FTP server on the public network.
  - If **vpn-instance** *vpn-instance-name* is specified, the FTP client accesses the FTP server in a specified VPN instance.
- If you cannot run the **sftp** command successfully when you configured the ACL on the SFTP client, or when the TCP connection fails, an error message is displayed indicating that the SFTP client cannot be connected to the server.

Example

Set keepalive parameters when the client is connected to the server in SFTP mode.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.164.39.223 -ki 10 -kc 4
Please input the username: client001
Trying 10.164.39.223 ...
Press CTRL+K to abort
Connected to 10.164.39.223 ...
Enter password:
sftp-client>
```

Connect the client to the server using the DSA authentication in SFTP mode.

```
<HUAWEI> system-view
[HUAWEI] sftp 10.164.39.223 identity-key dsa
Please input the username:root
Trying 10.164.39.223 ...
Press CTRL+K to abort
Connected to 10.164.39.223 ...
Enter password:
```

```
sftp-client> quit
Bye
```

2.7.80 sftp client-source

Function

The **sftp client-source** command specifies the source IP address for the SFTP client to send packets.

The **undo sftp client-source** command restores the default source IP address for the SFTP client to send packets.

The default source IP address for the SFTP client to send packets is 0.0.0.0.

Format

sftp client-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo sftp client-source

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the source IP address. Set the value to the IP address of a loopback interface.	The value is in dotted decimal notation.
-i *interface-type interface-number*	Specifies the loopback interface as the source interface. The IP address configured for the source interface is the source IP address for sending packets. If no IP address is configured for the source interface, the FTP connection cannot be set up.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If no source IP address is specified, the client uses the source IP address that the router specifies to send packets. The source IP address must be configured for an interface with stable performance. The loopback interface is recommended. Using the loopback interface as the source interface simplifies the ACL rule and security policy configuration. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.

Prerequisites

The loopback source interface specified using the command must exist and have an IP address configured.

Precautions

- The source interface must be set to the loopback interface. You can query the source IP address or primary IP address of the source interface for the SFTP connection on the SFTP server.
- The **sftp** command also configures the source IP address whose priority is higher than that of the source IP address specified in the **sftp client-source** command. If you specify source addresses in the **sftp client-source** and **sftp** commands, the source IP address specified in the **sftp** command is used for data communication. The source address specified in the **sftp client-source** command applies to all SFTP connections. The source address specified in the **sftp** command applies only to the current SFTP connection.

Example

Set the source IP address of the SFTP client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] sftp client-source -a 10.1.1.1
Info: Succeeded in setting the source address of the SFTP client to 10.1.1.1.
```

2.7.81 sftp client-transfile

Function

The **sftp client-transfile** command uploads files to or downloads files from the SFTP server.

Format

Establish an SFTP connection on an IPv4 network.

sftp client-transfile { **get** | **put** } [**-a** *source-address* | **-i** *interface-type interface-number*] **host-ip** *host-ipv4* [*port*] [[**public-net** | **-vpn-instance** *vpn-instance-name*] | **prefer_kex** *prefer_key-exchange* | **identity-key** { **rsa** | **dsa** | **ecc** | **rsa_sha2_256** | **rsa_sha2_512** } | **prefer_ctos_cipher** *prefer_ctos_cipher* | **prefer_stoc_cipher** *prefer_stoc_cipher* | **prefer_ctos_hmac** *prefer_ctos_hmac* | **prefer_stoc_hmac** *prefer_stoc_hmac* | **-ki** *aliveinterval* | **-kc** *alivecountmax*] * **username** *user-name* **password** *password* **sourcefile** *source-file* [**destination** *destination*]

Establish an SFTP connection on an IPv6 network.

sftp client-transfile { **get** | **put** } **ipv6** [**-a** *source-address*] **host-ip** *host-ipv6* [**-oi** *interface-type interface-number*] [*port*] [**-vpn-instance** *vpn-instance-name* | **prefer_kex** *prefer_key-exchange* | **identity-key** { **rsa** | **dsa** | **ecc** | **rsa_sha2_256** |

rsa_sha2_512 } | **prefer_ctos_cipher** *prefer_ctos_cipher* | **prefer_stoc_cipher** *prefer_stoc_cipher* | **prefer_ctos_hmac** *prefer_ctos_hmac* | **prefer_stoc_hmac** *prefer_stoc_hmac* | **-ki** *aliveinterval* | **-kc** *alivecountmax*] * **username** *user-name* **password** *password* **sourcefile** *source-file* [**destination** *destination*]

Parameters

Parameter	Description	Value
get	Downloads files from the SFTP server.	-
put	Uploads files to the SFTP server.	-
-a *source-address*	Specifies the source address of an SFTP client.	-
-i *interface-type interface-number*	Specifies the source interface of an SFTP client.	-
host-ip *host-ipv4*	Specifies the IPv4 address or host name of an SFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.
port	Specifies the current monitoring port number on the SFTP server. Only when the monitoring port number on the SFTP server is 22, the SFTP client can log in without a port number being specified. If the monitoring port number on the SFTP server is not 22, you must specify a port number for the SFTP client to log in.	The value is an integer ranging from 1 to 65535. The default value is 22.
public-net	Establishes the SFTP connection on a public network.	-

Parameter	Description	Value
-vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance. The SFTP connection is established on a private network.	The value must be an existing VPN instance name.
prefer_kex *prefer_key-exchange*	Specifies a preferred algorithm for key exchange.	● dh_exchange_group ● dh_exchange_group_sha256 ● dh_group14_sha1 ● dh_group14_sha256 ● dh_group15_sha512 ● dh_group16_sha512 The default algorithm is dh_exchange_group. **NOTE** The **dh_exchange_group** algorithm is recommended.
identity-key	Specifies a public key algorithm for the server authentication.	● dsa ● rsa ● ecc ● rsa_sha2_256 ● rsa_sha2_512 The default algorithm is rsa. **NOTE** To improve security, it is not recommended that you use RSA or DSA as the authentication algorithm.

Parameter	Description	Value
prefer_ctos_cipher *prefer_ctos_cipher*	Specifies the preferred encryption algorithm for packets from the client to the server	● 3des ● aes128 ● aes256 ● aes128_ctr(Advanced Encryption Standard 128_ctr) ● aes256_ctr(Advanced Encryption Standard 256_ctr) The default algorithm is aes256_ctr. To improve security, it is recommended that you use aes128_ctr, and aes256_ctr algorithms. **NOTE** ● If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. ● If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.

Parameter	Description	Value
prefer_stoc_cipher *prefer_stoc_cipher*	Specifies the preferred encryption algorithm for packets from the server to the client.	- 3des - aes128 - aes256 - aes128_ctr - aes256_ctr The default algorithm is aes256_ctr. To improve security, it is recommended that you use aes128_ctr, and aes256_ctr algorithms. **NOTE** - If an encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select an encryption algorithm from the list. - If no encryption algorithm list has been configured using the **ssh client cipher** command for the SSH client, select one from **3des**, **aes128**, **aes256**, **aes128_ctr**, and **aes256_ctr**.
prefer_ctos_hmac *prefer_ctos_hmac*	Specifies the preferred HMAC algorithm for packets from the client to the server.	- sha1 - sha1_96 - md5 - md5_96 - sha2_256 - sha2_256_96 The default algorithm is sha2_256.
prefer_stoc_hmac *prefer_stoc_hmac*	Specifies the preferred HMAC algorithm for packets from the server to the client.	- sha1 - sha1_96 - md5 - md5_96 - sha2_256 - sha2_256_96 The default algorithm is sha2_256.

Parameter	Description	Value
-ki *aliveinterval*	Specifies the interval at which the client sends a Keepalive packet to the server. When the connection between the server and the client fails, the client must detect the fault in time and removes the connection proactively. Therefore, when logging in to the server using SFTP, the client must be configured with an interval at which the client sends keepalive packets to the server and the maximum number of times that the server provides no response. If a client does not receive any packet within a specified period, the client sends a Keepalive packet to the server. If the maximum number of times that the server does not respond exceeds the specified value, the client proactively removes the connection. By default, the function of sending Keepalive packets to the server in the case of no data transmission is not configured.	The value is an integer ranging from 1 to 3600, in seconds. The default value is 60 seconds.
-kc *alivecountmax*	Specifies the maximum number of times that the server does not respond.	The value is an integer ranging from 3 to 10. The default value is 5.
username *user-name*	Specifies the user name for an SFTP connection.	The value is a string of 1 to 255 case-sensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
password *password*	Specifies the password for an SFTP connection.	The value is a string of 1 to 128 case-sensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.
sourcefile *source-file*	Specifies the source file to be uploaded to or downloaded from the server.	The absolute path of the file ranges from 1 to 160 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.
destination *destination*	Specifies the destination file to be uploaded to or downloaded from the server. If **destination** *destination* is not specified, the name of the file to be downloaded from or uploaded to the server is the same as that on the SFTP server.	The absolute path of the file ranges from 1 to 160 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.
ipv6	Specifies an IPv6 SFTP server.	-
-oi *interface-type interface-number*	Specifies the source IPv6 interface of an SFTP client. If *host-ipv6* is a link-local IPv6 address, you must specify the interface name corresponding to the link-local address. If *host-ipv6* is not a link-local IPv6 address, no interface name is required.	-

Parameter	Description	Value
host-ip *host-ipv6*	Specifies the IPv6 address or host name of an SFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces. When quotation marks are used around the string, spaces are allowed in the string.

3: Management level

Usage Guidelines

Usage Scenario

To upload files to or download files from an SFTP server, run the **sftp client-transfile** command.

Prerequisites

The SFTP function on the SFTP server has been enabled using the **sftp client-transfile** command.

Configuration Impact

After a connection is established between an SFTP client and an SFTP server, they start to intercommunicate.

Precautions

If command execution fails due to ACLs on the SFTP client or the TCP connection fails, the system prompts an error message indicating that the connection to the server fails.

If the **sftp client-transfile** command is run for the device to connect to the SFTP server, only password authentication is supported.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Configure the current monitoring port number 1025 on the SSH server on a private network (SFTP client on the public network), and download the **sample.txt** file to the SFTP client.

```
<HUAWEI> system-view
[HUAWEI] sftp client-transfile get host-ip 10.137.144.231 1025 -vpn-instance ssh username root
password YsHsjx_202206 sourcefile sample.txt
```

Specify Keepalive parameters for the client that attempts to log in to the server using SFTP and download the **sample.txt** file to the SFTP client.

```
<HUAWEI> system-view
[HUAWEI] sftp client-transfile get host-ip 10.164.39.209 -ki 10 -kc 4 username root password
YsHsjx_202206 sourcefile sample.txt
```

Configure the client to pass DSA authentication before logging in to the server using SFTP and download the **sample.txt** file to the SFTP client.

```
<HUAWEI> system-view
[HUAWEI] sftp client-transfile get host-ip 10.100.0.114 identity-key dsa username root password
YsHsjx_202206 sourcefile sample.txt
```

Upload the **sample.txt** file to the IPv6 SFTP server.

```
<HUAWEI> system-view
[HUAWEI] sftp client-transfile put host-ip 10.100.0.114 identity-key dsa username root password
YsHsjx_202206 sourcefile sample.txt
```

2.7.82 sftp server enable

Function

The **sftp server enable** command enables the SFTP service on the SSH server.

The **undo sftp server enable** command disables the SFTP service on the SSH server.

By default, the SFTP service is disabled.

Format

sftp [**ipv4** | **ipv6**] **server enable**

undo sftp [**ipv4** | **ipv6**] **server enable**

Parameters

Parameter	Description	Value
ipv4	Indicates that the SFTP IPv4 service is enabled on the SSH server.	-
ipv6	Indicates that the SFTP IPv6 service is enabled on the SSH server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To connect the client to the SSH server to transfer files in SFTP mode, you must first enable the SFTP server on the SSH server.

Prerequisites

Before enabling the SFTP service, run either of the following commands as required:

- Run the **ssh server-source -i** *interface-type interface-number* command to configure a specified interface as the source interface of the SSH server or run the **ssh server-source all-interface** command to specify any interface with an IPv4 address configured on the device as the source interface of the SSH server.
- Run the **ssh ipv6 server-source -a** *ipv6_address* [**-vpn-instance** *vpn_name*] command to configure a specified IPv6 address as the IPv6 source address of the SSH server or run the **ssh ipv6 server-source all-interface** command to specify any interface IPv6 address on the device as the IPv6 source address of the SSH server.

Precautions

After the **sftp server enable** command is run, the numbers of IPv4 port and IPv6 port are both changed. To change the number of IPv4 port or IPv6 port separately, run the **sftp** [**ipv4** | **ipv6**] **server enable** command.

Example

Enable the SFTP service.

```
<HUAWEI> system-view
[HUAWEI] sftp server enable
Info: Succeeded in starting the SFTP server.
```

Disable the SFTP service.

```
<HUAWEI> system-view
[HUAWEI] undo sftp server enable
Info: Succeeded in closing the SFTP server.
```

Enable the SFTP IPv4 service.

```
<HUAWEI> system-view
[HUAWEI] sftp ipv4 server enable
```

2.7.83 ssh user sftp-directory

Function

The **ssh user sftp-directory** command configures the SFTP service authorized directory for an SSH user.

The **undo ssh user sftp-directory** command cancels the SFTP service authorized directory for an SSH user.

The default SFTP service authorized directory is flash: for an SSH user.

Format

ssh user *username* **sftp-directory** *directoryname*

undo ssh user *username* **sftp-directory**

Parameters

Parameter	Description	Value
username	Specifies the SSH user name.	The value is a string of 1 to 64 case-insensitive characters without spaces.
directoryname	Specifies the directory name on the SFTP server.	The value is a string of 1 to 160 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If there is the default authorized directory for an SFTP user on the device, you can run this command to change the directory.

Precautions

Users can only access the specified directory on the SFTP server. If the *username* user does not exist, the system creates an SSH user named *username* and uses the SFTP service authorized directory configured for the user. If the configured directory does not exist, the SFTP client fails to connect to the SSH server using this SSH user. After a master/backup switchover or device restart is performed, the SFTP client fails to connect to the SSH server if the configured directory does not exist. In this case, check whether the configured directory is valid. If the configured directory is invalid, re-configure it.

Example

Configure the SFTP service authorized directory flash:/ssh for the SSH user **admin**.

```
<HUAWEI> system-view
[HUAWEI] ssh user admin sftp-directory flash:/ssh
```

2.7.84 ssl cipher-suite-list

Function

The **ssl cipher-suite-list** command customizes an SSL cipher suite policy and displays the view of the cipher suite policy. If the SSL cipher suite policy to be customized already exists, the command directly displays the view of this cipher suite policy.

The **undo ssl cipher-suite-list** command deletes a customized SSL cipher suite policy.

By default, no customized SSL cipher suite policy is configured.

Format

ssl cipher-suite-list *customization-policy-name*

undo ssl cipher-suite-list *customization-policy-name*

Parameters

Parameter	Description	Value
customization-policy-name	Sets a name for a customized SSL cipher suite policy.	The value is a string of 1 to 32 case-insensitive characters, spaces not supported.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To improve system security, the device supports only secure algorithms by default. However, to improve compatibility, the device also allows you to customize cipher suite policies. To customize a cipher suite policy, run the **ssl cipher-suite-list** command.

Example

Customize an SSL cipher suite policy named **cipher1** and enter the view of the cipher suite policy.

```
<HUAWEI> system-view
[HUAWEI] ssl cipher-suite-list cipher1
[HUAWEI-ssl-cipher-suite-cipher1]
```

2.7.85 ssl minimum version

Function

The **ssl minimum version** command configures a minimum SSL version for an SSL policy.

The **undo ssl minimum version** command restores the default version.

By default, the minimum SSL version used by an SSL policy is TLS1.2.

NOTE

When the minimum SSL version used for an SSL policy is set to TLS1.2, an SSL certificate is required, which is provided by a third-party authoritative certificate authority.

Format

ssl minimum version { **tls1.1** | **tls1.2** }

undo ssl minimum version

Parameters

Parameter	Description	Value
tls1.1	Sets the minimum SSL version to TLS1.1 for an SSL policy.	-
tls1.2	Sets the minimum SSL version to TLS1.2 for an SSL policy.	-

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure a minimum SSL version for an SSL policy, run the **ssl minimum version** command so that service modules can flexibly adopt the SSL policy.

The SSL versions supported by SSL policies include TLS1.1, TLS1.2 in ascending order of security.

Precautions

The system software does not support the tls1.0 parameter. To use the tls1.0 parameter, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the tls1.2 parameter. For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Configure the minimum SSL version for the SSL policy **ftp_server** to be TLS1.2.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] ssl minimum version tls1.2
```

2.7.86 ssl policy

Function

The **ssl policy** command creates an SSL policy and displays the SSL policy view. If the SSL policy has been created before you run this command, the command directly displays the SSL policy view.

The **undo ssl policy** command deletes an SSL policy.

By default, no SSL policy is created.

Format

ssl policy *policy-name*

undo ssl policy *policy-name*

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an SSL policy.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Traditional FTP and HTTP protocols does not have the security mechanism. Data that is transmitted in plain text can be modified. User identity cannot be authenticated and data security cannot be ensured. The SSL security policy uses the data encryption, user identity authentication, and message integrity check mechanisms to ensure the security of the TCP-based application layer.

Follow-up Procedure

After you have run the **ssl policy** command to display the SSL policy view, perform either of the following operations:

- When the device functions as a server, run the **certificate load** to load the certificate or certificate chain.
- When the device functions as a client, run the **trusted-ca load** and **crl load** commands to load the trusted CA and CRL so that the server validity can be authenticated.

Precautions

- You can run the **ssl policy** command to create an SSL policy for the secure FTP and HTTP servers.
- A maximum of four SSL policies can be created.

Example

Create SSL policy **https_der** and display the SSL policy view.

```
<HUAWEI> system-view
[HUAWEI] ssl policy https_der
[HUAWEI-ssl-policy-https_der]
```

2.7.87 tftp

Function

The **tftp** command uploads a file to the TFTP server or downloads a file to the local device.

Format

Upload a file to the TFTP server or download a file to the local device based on the IPv4 address

tftp [**-a** *source-ip-address* | **-i** *interface-type interface-number*] *tftp-server* [**public-net** | **vpn-instance** *vpn-instance-name*] { **get** | **put** } *source-filename* [*destination-filename*]

Upload a file to the TFTP server or download a file to the local device based on the IPv6 address

tftp ipv6 [**-a** *source-ip-address*] *tftp-server-ipv6* [**-oi** *interface-type interface-number*] { **get** | **put** } *source-filename* [*destination-filename*]

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the source IP address for connecting to the TFTP client. You are advised to use the loopback interface IP address.	-

Parameter	Description	Value
-i *interface-type interface-number*	Specifies the source interface used by the TFTP client to set up connections. It consists of the interface type and number. It is recommended that you specify a loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the TFTP connection cannot be set up.	-
-oi *interface-type interface-number*	Specifies an outbound interface on the local device.	If the remote host uses an IPv6 address, you must specify the outbound interface on the local device.
tftp-server	Specifies the IPv4 address or host name for the TFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces.
tftp-server-ipv6	Specifies the IPv6 address of the IPv6 TFTP server.	The value is a string of 1 to 255 case-insensitive characters without spaces.
public-net	Specifies the TFTP server on the public network.	-
vpn-instance *vpn-instance-name*	Name of the VPN instance where the TFTP server is located.	The value must be an existing VPN instance name.
get	Download a file.	-
put	Upload a file.	-
source-filename	Specifies the source file name.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Parameter	Description	Value
destination-filename	Specifies the destination file name.	The value is a string of 1 to 64 case-insensitive characters without spaces. By default, source and destination file names are the same.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When upgrading the system, you can run the **tftp** command to upload an important file to the TFTP server or download a system software to the local device.

Precautions

- When you run the **tftp** command to upload a file to the TFTP server in TFTP mode, files are transferred in binary mode by default. The tftp does not support the ASCII mode for file transfer.
- After specifying a source IP address, you can use this IP address to communicate with the server and implement packet filtering to ensure data security.
- You can run the **set net-manager vpn-instance** command to configure the NMS management VPN instance before running the **open** command to connect the FTP client and server.
  - If **public-net** or **vpn-instance** is not specified, the FTP client accesses the FTP server in the VPN instance managed by the NMS.
  - If **public-net** is specified, the FTP client accesses the FTP server on the public network.
  - If **vpn-instance** *vpn-instance-name* is specified, the FTP client accesses the FTP server in a specified VPN instance.

NOTE

The file system has a restriction on the number of files in the root directory. Therefore, if more than 50 files exist in the root directory, creating new files in this directory may fail.

Example

Download file **vrpcfg.txt** from the root directory of the TFTP server to the local device. The IP address of the TFTP server is 10.1.1.1. Save the downloaded file to the local device as file **vrpcfg.bak**.

```
<HUAWEI> tftp 10.1.1.1 get vrpcfg.txt flash:/vrpcfg.bak
```

Upload file **vrpcfg.txt** from the root directory of the storage device to the default directory of the TFTP server. The IP address of the TFTP server is 10.1.1.1. Save file **vrpcfg.txt** on the TFTP server as file **vrpcfg.bak**.

```
<HUAWEI> tftp 10.1.1.1 put flash:/vrpcfg.txt vrpcfg.bak
```

Obtain the link local IP address and interface name from the TFTP server.

```
<HUAWEI> tftp ipv6 FC00::/7 -oi gigabitethernet 0/0/1 get file1 file2
Info: Transfer file in binary mode.
Downloading the file from the remote TFTP server. Please wait...
100%

249704 byte(s) received in 10 second(s).
```

2.7.88 tftp client-source

Function

The **tftp client-source** command specifies the source IP address for the TFTP client to send packets.

The **undo tftp client-source** command restores the default source IP address for the TFTP client to send packets.

By default, the TFTP client source address is the IP address of the outbound interface connecting to the TFTP server, and it is displayed as 0.0.0.0.

Format

tftp client-source { **-a** *source-ip-address* | **-i** *interface-type interface-number* }

undo tftp client-source

Parameters

Parameter	Description	Value
-a *source-ip-address*	Specifies the source IP address of the TFTP client. You are advised to use the loopback interface IP address.	The value is in dotted decimal notation.

Parameter	Description	Value
-i *interface-type interface-number*	Source interface type and ID. You are advised to use the loopback interface. The IP address configured for this interface is the source IP address for sending packets. If no IP address is configured for the source interface, the TFTP connection cannot be set up.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If no source IP address is specified, the client uses the source IP address that the router specifies to send packets. The source IP address must be configured for an interface with stable performance. The loopback interface is recommended. Using the loopback interface as the source interface simplifies the ACL rule and security policy configuration. This shields the IP address differences and interface status impact, filters incoming and outgoing packets, and implements security authentication.

Prerequisites

The source interface specified using the command must exist and have an IP address configured.

Precautions

- The **tftp** command also configures the source IP address whose priority is higher than that of the source IP address specified in the **tftp client-source** command. If you specify source addresses in the **tftp client-source** and **tftp** commands, the source IP address specified in the **tftp** command is used for data communication. The source address specified in the **tftp client-source** command applies to all TFTP connections. The source address specified in the **tftp** command applies only to the current TFTP connection.
- You can query the source IP address or source interface IP address specified in the TFTP connection on the TFTP server.

Example

Set the source IP address of the TFTP client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] tftp client-source -a 10.1.1.1
Info: Succeeded in setting the source address of the TFTP client to 10.1.1.1.
```

2.7.89 tftp-server acl

Function

The **tftp-server acl** command specifies the ACL number for the local device so that the device can access TFTP servers with the same ACL number.

The **undo tftp-server acl** command deletes the ACL number from the local device.

By default, no ACL number is specified on the local client.

Format

tftp-server [**ipv6**] **acl** *acl-number*

undo tftp-server [**ipv6**] **acl**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the basic ACL.	The value is an integer that ranges from 2000 to 2999.
ipv6	Specifies the IPv6 address of a specific server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To ensure the security of the local device, you need to run the **tftp-server acl** command to specify an ACL to specify TFTP servers that the local device can access.

Precautions

- The **tftp-server acl** command takes effect only after you run the **rule** command to configure the ACL rule. If no ACL rule is configured, the local device can access a specified TFTP server in TFTP mode.
- The TFTP supports only the basic ACL whose number ranges from 2000 to 2999.

Example

Allow the local device to the access the TFTP server whose ACL number is 2000.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule permit source 10.10.10.1 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] tftp-server acl 2000
```

2.7.90 trusted-ca load

Function

The **trusted-ca load** command loads the trusted CA file for the SSL policy for the FTP client.

The **undo trusted-ca load** command unloads the trusted CA file of the SSL policy.

By default, no trusted CA file is loaded for the SSL policy.

Format

Load the trusted CA file for the SSL policy in ASN1 format.

trusted-ca load asn1-ca *ca-filename*

Load the trusted CA file for the SSL policy in PEM format.

trusted-ca load pem-ca *ca-filename*

Load the trusted CA file for the SSL policy in PFX format.

trusted-ca load pfx-ca *ca-filename* **auth-code cipher** *auth-code*

Unload the trusted CA file for the SSL policy.

undo trusted-ca load { **asn1-ca** | **pem-ca** | **pfx-ca** } *ca-filename*

Parameters

Parameter	Description	Value
asn1-ca	Load the trusted CA file for the SSL policy in ASN1 format.	-
pem-ca	Load the trusted CA file for the SSL policy in PEM format.	-
pfx-ca	Load the trusted CA file for the SSL policy in PFX format.	-

Parameter	Description	Value
ca-filename	Specifies the name of the trusted CA file. The file is in the subdirectory of the system directory **security**. If the **security** directory does not exist in the system, create this directory.	The value is a string of 1 to 64 characters. The file name is the same as that of the uploaded file.
auth-code cipher *auth-code*	Specifies the verification code for the trusted CA file in PFX format. The authentication code verifies user identity to ensure that only authorized users can log in to the server.	The value is a string of case-sensitive characters without spaces. If the value begins and ends with double quotation marks (" "), the string of characters can contain spaces. When the value is displayed in plaintext, its length ranges from 1 to 31. When the value is displayed in ciphertext, its length is 48 or 68. A ciphertext password with the length of 32 or 56 characters is also supported.

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

CAs that are widely trusted in the world are called root CAs. Root CAs can authorize other lower-level CAs. The identity information about a CA is provided in the file of a trusted CA. To ensure the communication security and verify the server validity, you must run the **trusted-ca load** command to load the trusted CA file.

Prerequisites

Before running the **trusted-ca load** command, you have run the **ssl policy** command to create the SSL policy in the system view.

Precautions

A maximum of four trusted CA files can be loaded for an SSL policy. For the sake of security, deleting the installed trusted CA file is not recommended; otherwise, services using the SSL policy will be affected.

Example

Load the trusted CA file for the SSL policy in ASN1 format.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] trusted-ca load asn1-ca servercert.der
```

Load the trusted CA file for the SSL policy in PEM format.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] trusted-ca load pem-ca servercert.pem
```

Load the trusted CA file for the SSL policy in PFX format.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] trusted-ca load pfx-ca servercert.pfx auth-code cipher YsHsjx_202206
```

2.7.91 undelete

Function

The **undelete** command restores a file that has been temporally deleted from or moved to the recycle bin.

Format

undelete { *filename* | *devicename* }

Parameters

Parameter	Description	Value
filename	Specifies the name of a file to be restored.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Value
devicename	Specifies the storage device name.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **undelete** command to restore a file that has been temporally deleted and moved to the recycle bin. However, files that are permanently deleted by running the **delete** or **reset recycle-bin** command with the **/unreserved** parameter cannot be restored.

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Like *devicename*, **drive** specifies the storage device name.

Precautions

- To display information about a temporally deleted file, run the **dir /all** command. The file name is displayed in square brackets ([ ]).
- If the name of a file is the same as an existing directory, the file cannot be restored. If the destination file has the same name as an existing file, the system prompts you whether to overwrite the existing file. The system prompt is displayed only when **file prompt** is set to **alert**.

Example

Restore file **sample.bak** from the recycle bin.

```
<HUAWEI> undelete sample.bak
Undelete flash:/sample.bak ?[Y/N]:y
%Undeleted file flash:/sample.bak.
```

Restore a file that has been moved from the root directory to the recycle bin.

```
<HUAWEI> undelete flash:
Undelete flash:/test.txt?[Y/N]:y
%Undeleted file flash:/test.txt.
Undelete flash:/rr.bak?[Y/N]:y
%Undeleted file flash:/rr.bak.
```

2.7.92 unzip

Function

The **unzip** command decompresses a file.

Format

unzip *source-filename destination-filename*

Parameters

Parameter	Description	Value
source-filename	Specifies the name of a source file to be decompressed.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Parameter	Description	Value
destination-filename	Specifies the name of a destination file that is decompressed.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can decompress files, especially log files that are stored on the storage device and run the **more** command to query the file.

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.
  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- If the destination file path is specified while the file name is not specified, the designation file name is the same as the source file name.
- The source file persists after being decompressed.
- The compressed file must be a .zip file. If a file to be decompressed is not a zip file, the system displays an error message during decompression.
- The source file must be a single file. If you attempt to decompress a directory or multiple files, the decompression cannot succeed.

Example

Decompress log file **logfile-2012-02-27-17-47-50.zip** that is stored in the **logfile** directory and save it to the root directory as file **log.txt**.

```
<HUAWEI> pwd
flash:/logfile
<HUAWEI> unzip logfile-2012-02-27-17-47-50.zip flash:/log.txt
Extract flash:/logfile/logfile-2012-02-27-17-47-50.zip to flash:/log.txt?[Y/N]:y
100%  complete
%Decompressed file flash:/logfile/logfile-2012-02-27-17-47-50.zip to flash
:/log.txt.
```

2.7.93 user

Function

The **user** command changes the current FTP user when the local device is connected to the FTP server.

Format

user *user-name* [*password*]

Parameters

Parameter	Description	Value
user-name	Specifies the name of a login user.	The value is a string of 1 to 255 case-insensitive characters without space.
password	Specifies the login password.	The value is a string of 1 to 255 case-sensitive characters without space, single quotation mark, or question mark.

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the device accesses the remote FTP server, to switch from the current user to another user, you only need to run the **user** command to log in to the FTP server by using another user name without disconnecting the FTP connection.

Precautions

After you run the **user** command to change the current user, a new FTP connection is set up, which is the same as that you specify using the **ftp** command.

Example

Log in to the FTP server using the user name **tom**.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] user tom
331 Password required for tom.
Enter password:
230 User logged in.
```

2.7.94 verbose

Function

The **verbose** command enables the verbose function on the FTP client.

The **undo verbose** command disables the verbose function.

By default, the verbose function is enabled.

Format

verbose

undo verbose

Parameters

None

Views

FTP client view

Default Level

3: Management level

Usage Guidelines

After the verbose function is enabled, all FTP responses are displayed on the FTP client, including FTP protocol information and details about the responses.

Example

Enable the verbose function.

```
<HUAWEI> ftp 10.137.217.201
Trying 10.137.217.201 ...
Press CTRL+K to abort
Connected to 10.137.217.201.
220 FTP service ready.
User(10.137.217.201:(none)):huawei
331 Password required for huawei.
Enter password:
230 User logged in.

[ftp] verbose
Info: Succeeded in switching verbose on.
[ftp] get h1.txt
200 Port command okay.
150 Opening ASCII mode data connection for h1.txt.

226 Transfer complete.
FTP: 69 byte(s) received in 0.160 second(s) 431.25byte(s)/sec.
```

Disable the verbose function.

```
[ftp] undo verbose
Info: Succeeded in switching verbose off.
[ftp] get h1.txt

FTP: 69 byte(s) received in 0.150 second(s) 460.00byte(s)/sec.
```

2.7.95 zip

Function

The **zip** command compresses a file.

Format

zip *source-filename destination-filename*

Parameters

Parameter	Description	Value
source-filename	Specifies the name of a source file to be compressed.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "
destination-filename	Specifies the name of a destination file that is compressed.	The value is a string of 1 to 160 case-insensitive characters without spaces in the format [drive] [path] filename. If the string is enclosed in double quotation marks (" "), the string can contain spaces. If the value is a file name, the value is a string of 1 to 64 characters. In the preceding parameter, **drive** specifies the storage device name, and **path** specifies the directory and subdirectory. You are advised to add : and / between the storage device name and directory. The directory name cannot contain the following characters: ~ * / \ : ' "

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The following describes the drive name.

- **drive** is the storage device and is named as **flash:**.
- If devices are stacked, **drive** can be named as:
  - flash: root directory of the flash memory of the master switch in the stack.

  - chassis ID#flash: root directory of the flash memory on a device in the stack.

  For example, **slot2#flash:** indicates the flash memory in slot 2.

The path can be an absolute path or relative path. A relative path can be designated relative to either the root directory or the current working directory. A relative path beginning with a slash (/) is a path relative to the root directory.

- **flash:/my/test/** is an absolute path.
- **/selftest/** is a path relative to the root directory and indicates the selftest directory in the root directory.
- **selftest/** is a path relative to the current working directory and indicates the selftest directory in the current working directory.

Precautions

- If the destination file path is specified while the file name is not specified, the designation file name is the same as the source file name.
- The source file persists after being compressed.
- Directories cannot be compressed.

Example

Compress file **log.txt** that is stored in the root directory and save it to the **test** directory as file **log.zip**.

```
<HUAWEI> dir
Directory of flash:/

  Idx  Attr     Size(Byte)  Date        Time       FileName

2.8 Configuring System Startup Commands

2.8.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.8.2 check file-integrity

Function

The **check file-integrity** command checks whether a file is consistent with the corresponding signature file.

Format

check file-integrity *filename signature-filename*

Parameters

Parameter	Description	Value
filename	Specifies the name of a file to be checked. The file must exist.	The value is a string of 4 to 64 case-insensitive characters without spaces. The file name extension can be .cc, .pat, .zip, .mod, or .7z.
signature-filename	Specifies the name of the signature file corresponding to the file to be checked. The signature file must exist.	The value is a string of 5 to 64 case-insensitive characters without spaces. The file name extension must be .asc or .p7s.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run this command to check whether a file is consistent with the corresponding signature file. If the check fails, the file cannot be used as the system software, patch file, web page file, or mod file.

NOTE

Signature files are released with each version. Each valid system software, patch file, web page file, or mod file has a corresponding signature file. You need to upload the signature file to the switch before using this command.

Example

Check whether the system software is consistent with the corresponding signature file.

```
<HUAWEI> system-view
[HUAWEI] check file-integrity S5700-V200R023C00.cc S5700-V200R023C00.cc.asc
```

2.8.3 clear configuration interface

Function

Using the **clear configuration interface** command, you can perform one-touch configuration clearance on an interface.

Format

clear configuration interface { *interface-type-start interface-number-start* [**to** *interface-type-end interface-number-end*] } &<1-10>

Parameters

Parameter	Description	Value
interface-type-start interface-number-start [**to** *interface-type-end interface-number-end*]	Indicates the type and number of the interface where one-touch configuration clearance is performed. • *interface-type-start* specifies the type of the first interface. • *interface-number-start* specifies the number of the first interface. • *interface-type-end* specifies the type of the last interface. • *interface-number-end* specifies the number of the last interface.	At present, the tunnel and stack-port interfaces are not supported.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure an interface on a device for other use, original configurations on the interface need to be deleted one by one. If the interface has a large number of configurations, deleting these configurations one-by-one takes a long time and increases the maintenance workload. To reduce the maintenance workload and simplify the deletion operation, you can use this command to perform one-touch configuration clearance on an interface.

You can also run the **clear configuration this** command in the system view to delete configurations on a specified interface.

NOTE

The one-touch configuration clearance function cannot delete the **combo-port** command on an interface.

Configuration Impact

After this command is run, all configurations on an interface will be cleared. The status of the interface is **shutdown**.

Precautions

The execution of this command takes a long time. To terminate the running command, press **Ctrl**+**C**.

In general, after the **clear configuration this** command is run on an interface to clear the configuration, the default configuration is restored. If special configurations exist on the interface on which the **clear configuration this** command is run, the configuration may be displayed in the **undo** command format.

Example

Perform one-touch configuration clearance on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] display this
#
interface GigabitEthernet0/0/1
 port link-type hybrid
 port hybrid pvid vlan 50
#
return
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] clear configuration interface gigabitethernet 0/0/1
Warning: All configurations of the interface will be cleared, and its state will
 be shutdown. Continue? [Y/N] :y...
Info: Total execute 2 command(s), 2 successful, 0 failed.
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] display this
#
interface GigabitEthernet0/0/1
 shutdown
#
return
```

2.8.4 clear configuration this

Function

The **clear configuration this** command deletes configurations on an interface at a time to restore the default configurations.

Format

clear configuration this

Parameters

None

Views

Interface view (excluding tunnel interface view, stack-port interface view, and port group view)

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure an interface on a device for other use, original configurations on the interface need to be deleted one by one. If the interface has a large number of configurations, deleting these configurations one-by-one takes a long time and increases the maintenance workload. To reduce the maintenance workload and simplify the deletion operation, you can use this command to perform one-touch configuration clearance on an interface.

You can also run the **clear configuration interface** *interface-type interface-num* command in the system view to delete configurations on a specified interface.

Configuration Impact

After you run the **clear configuration this** command, the system displays a message, asking you whether to delete the configurations on the specified interface. If you enter **Y**, all configurations on the specified interface are deleted and the interface status becomes shutdown.

Running the **clear configuration this** command on an interface is similar to running undo commands on the interface in batches.

Precautions

The execution of this command takes a long time. To terminate the running command, press **Ctrl**+**C**.

In general, after the **clear configuration this** command is run on an interface to clear the configuration, the default configuration is restored. If special configurations exist on the interface on which the **clear configuration this** command is run, the configuration may be displayed in the **undo** command format.

As some commands correlate to each other, if you run the **undo** command to delete the configurations of a command, the configurations of the correlated command are also deleted. After the **clear configuration this** command is run on an interface, the statistics in the command output may be inconsistent with actual clearance results. Refer to the actual clearance results in real-world applications.

Example

Perform one-touch configuration clearance on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] display this
#
interface GigabitEthernet0/0/1
 description abc
 port link-type access
#
return
[HUAWEI-GigabitEthernet0/0/1] clear configuration this
Warning: All configurations of the interface will be cleared, and its state will be shutdown. Continue? [Y/
N] :y
Info: Total 2 command(s) executed, 2 successful, 0 failed.
[HUAWEI-GigabitEthernet0/0/1] display this
#
interface GigabitEthernet0/0/1
 shutdown
#
return
```

2.8.5 clear inactive-configuration all

Function

The **clear inactive-configuration all** command clears inactive configurations on the switch.

NOTE

This command can only clear inactive configurations on interfaces.

Format

clear inactive-configuration all

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If a card is removed, the original configurations on the card are saved on the switch. If the standby/slave switch leaves a stack, the configurations on the switch are saved on the master switch. These invalid configurations are called inactive or offline configurations. To view inactive configurations on the switch, run the **display current-configuration inactive** command.

You can run the **clear inactive-configuration all** command to clear all the inactive configurations on the switch to increase available space.

This command can be run by only one user at a time to clear inactive configurations on all interfaces on the device.

NOTICE

Configurations cannot be recovered after clearing. Therefore, exercise caution when deciding to run this command. You are advised to run this command under the guidance of technical support personnel.

Example

Clear inactive configurations on the switch.

```
<HUAWEI> system-view
[HUAWEI] clear inactive-configuration all
Warning: All inactive configurations will be deleted and cannot be restored.
Are you sure you want to continue?[Y/N]y
The command will take a few minutes. Please wait.
Info: There is no inactive configuration.
```

2.8.6 configuration backup local disable

Function

The **configuration backup local disable** command disables the device from backing up the running configurations locally.

The **undo configuration backup local disable** command enables the device to back up the running configurations locally.

By default, the device is enabled to back up the running configurations locally.

Format

configuration backup local disable

undo configuration backup local disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To automatically back up the current running configurations to the local storage after the device configurations are modified, run the **undo configuration backup local disable** command to enable automatic backup of the current running configurations. This function helps check historical records of configuration changes and facilitate fault location.

Precautions

- When the device is enabled to back up the current running configurations, the current running configurations are backed up 2 hours after the device configurations are modified. If saving or automatic saving operation is performed, conflicts may occur. The configuration backup will be triggered every 30 minutes until the backup succeeds.
- If the CPU usage exceeds 60% during the configuration backup, the configuration backup will be triggered every 30 minutes until the backup succeeds.
- Delivering a configuration command fails during the configuration backup.
- If the current configurations are consistent with the configurations saved last time, the device does not repeatedly back up the current configurations to the local storage.

Rules for backup file management:

- The local storage path is **$_backup/running_config/**.
- The format of the backup file name is **yyyymmddhhmmss.sysname.zip**, where **yyyymmdd** indicates the year, month, and day, **hhmmss** indicates the hour, minute, and second, and **sysname** indicates the host name of the device.
- Backup files are aged based on the aging rules each time when the number of backup files exceeds 30, when the total space used by backup files exceeds 10 MB, or when the remaining storage space is less than 30 MB.
- The backup file aging stops when the number of backup files is 5 or less.

Rules for backup file aging:

- A number and an aging priority are specified for a backup file based on the file generation time.

NOTE

File number: The latest file generated is numbered 1, the file generated before the latest file is numbered 2, and so on. A larger number indicates an earlier generation time.

File aging priority: The file with a smaller file number has a higher priority. Files with a lower priority are aged first. Note that files with priority 0 are not aged. If a file has multiple priorities, refer to the highest priority.

  - Priority 0: files numbered from 1 to 5
  - Priority 1: files numbered from 6 to 10
  - Priority 2: the last generated files on each day in the past week
  - Priority 3: the last generated files in each month in the past 5 months
  - Priority 4: other backup files
- Note for backup file aging:
  - The backup files are aged in time sequence based on the priority. A backup file generated earlier is aged first.

Example

Disable the device from backing up the running configurations locally.

```
<HUAWEI> system-view
[HUAWEI] configuration backup local disable
```

2.8.7 configuration copy file to running

Function

The **configuration copy file to running** command executes commands in a specified configuration file.

Format

configuration copy file *file-name* **to running**

Parameters

Parameter	Description	Value
file-name	Specifies the name of a configuration file to be executed.	The value is a string of 4 to 160 characters in the [*drive*] [*path*] *file-name* format. The file name extension must be .cfg or .zip.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To execute an existing configuration file, run the **configuration copy file to running** command. All the commands in the specified configuration file are executed at one time.

Precautions

- Only one user can execute the **configuration copy file to running** command at one time.
- Running this command does not clear the existing configuration.
- If configuration restoration occurs or a batch backup operation is performed, the **configuration copy file to running** command ends.
- If a command fails during the execution of the **configuration copy file to running** command, the system skips it and executes the next command.
- If the configuration file to be executed contains a restart command, the device will restart when the restart command is executed. Therefore, exercise caution when executing the configuration file.
- Do not change the configuration file manually and execute the configuration file. Otherwise, the device may not start normally.

Example

Execute the commands in the **huawei.cfg** file.

```
<HUAWEI> configuration copy file huawei.cfg to running
Warning: This operation may take a long time, press CTRL+C to break. Continue?[Y/N]:y
```

2.8.8 configuration copy startup to file

Function

The **configuration copy startup to file** command backs up the startup configuration file to a specified file.

Format

configuration copy startup to file *file-name*

Parameters

Parameter	Description	Value
file-name	Specifies the name of a destination file.	The value is a string of 4 to 160 characters in the [*drive*] [*path*] *file-name* format. The file name extension must be .cfg or .zip. The extension of the destination file and the backup file must be the same.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To back up the startup configuration file, run the **configuration copy startup to file** command.

Precautions

If a file with the same name already exists, the system asks whether to replace the previous file. Press **Y** to replace the file or **N** not to do so.

Example

Back up the startup configuration file to the **huawei.cfg** file.

```
<HUAWEI> configuration copy startup to file huawei.cfg
```

2.8.9 compare configuration

Function

The **compare configuration** compares whether the current configurations (including offline configurations) are identical with the next startup configuration file.

Format

compare configuration [*configuration-file*] [*current-line-number save-line-number*]

Parameters

Parameter	Description	Value
configuration-file	Specifies the name of the configuration file to be compared with the current configurations.	The value is a string of 5 to 48 case-insensitive characters without spaces.
current-line-number	Specifies the line number for comparison in the current configuration.	The value is an integer that ranges from 0 to 65535.

Parameter	Description	Value
save-line-number	Specifies the line number for comparison in the saved configuration.	The value is an integer that ranges from 0 to 65535.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If *current-line-number* and *save-line-number* are not specified, the configuration files are compared from the first lines. The two parameters can be specified to skip the differences that are found and continue the comparison.

The **compare configuration** command outputs display the current configuration file (including offline configurations) and the saved configuration file from the line that contains differences respectively. By default, the output difference information is restricted to 120 characters.

- If the characters from differences to the end of the configuration file are less than 120, the system displays the output difference information till the end of the configuration file.
- If the characters from differences to the end of the configuration file are more than 120, the system only displays 120 characters.

Precautions

- The execution of this command takes a long time. To terminate the running command, press **Ctrl+C**.
- The configuration file name extension must be .cfg or .zip.
- If *configuration-file* is not specified, the system compares whether the current configurations (including offline configurations) are identical with the next startup configuration file.
- If *configuration-file* is specified, the system compares whether the current configurations (including offline configurations) are identical with the specified startup configuration file.

Example

Compare whether the current configurations (including offline configurations) are identical with the next startup configuration file.

```
<HUAWEI> compare configuration
Info: The system is now comparing the configuration, please wait....
Warning: The current configuration is not the same as the next startup
configuration file. There may be several differences, and the following are some
```

```
configurations beginning from the first:
====== Current configuration line 6 ======
 vlan batch 1 to 2 10 to 11 15 70 to 71 91 to 92 100 111 230 240 901
 vlan batch 911 1111
#
 l2protocol-tunnel vtp group-mac xxxx-xxxx-xxxx

 ====== Configuration file line 6 ======
 vlan batch 1 to 2 10 to 11 15 70 91 to 92 100 111 230 240 901
 vlan batch 911 1111
#
 l2protocol-tunnel vtp group-mac xxxx-xxxx-xxxx
```

2.8.10 display changed-configuration time

Function

The **display changed-configuration time** command displays the time of the last configuration change.

Format

display changed-configuration time

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After changing the configuration of the device, you can run the **display changed-configuration time** command to view the time of the last configuration change.

Example

Display the time of the last configuration change.

```
<HUAWEI> display changed-configuration time
```

2.8.11 display configuration recover-result

Function

The **display configuration recover-result** command displays the configuration recovery result.

Format

display configuration recover-result

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can use the **display configuration recover-result** command to view the information about the configuration recovery result and records of configuration recovery failures. The records include the command that fails the configuration recovery, the view in which the command resides, the line number of the command in the current startup configuration file, the reason why the command fails, and the execution time of the configuration recovery.

This command displays a maximum of 256 records in time sequence. The latest record is displayed in the last. If the number of commands for configuration recovery exceeds 256, the device no longer records commands that fail the configuration recovery.

Prerequisites

The device has restarted and the configuration recovery is successful.

Example

Display the configuration result.

```
<HUAWEI> display configuration recover-result
The current startup saved-configuration file is flash:/vrpcfg.zip.
The number of failed commands is 2.
-----------------------------------------------------------------------

Command : ip address 10.85.1.1 255.255.255.0
View    : Vlanif85
Line    : 414
Reason  : Failed to parse the command.
Time    : 10:00:06  2012-07-25 UTC+08:00 DST

Command : ip address 10.86.1.1 255.255.255.0
View    : Vlanif86
Line    : 417
Reason  : Failed to parse the command.
Time    : 10:00:06  2012-07-25 UTC+08:00 DST

-----------------------------------------------------------------------
```

Table 2-55 Description of the display configuration recover-result command output

Item	Description
Command	Command that fails the configuration recovery
View	View in which the command resides
Line	Line number of the command in the current startup configuration file
Reason	Reason why the command fails
Time	Execution time of the configuration recovery

2.8.12 display current-configuration

Function

The **display current-configuration** command displays the currently running configuration.

This command does not display parameters that use default settings.

Format

display current-configuration [**configuration** [*configuration-type* [*configuration-instance*]] | **interface** [*interface-type* [*interface-number*]]] [**feature** *feature-name*] [**filter** *filter-expression*]

display current-configuration [**all** | **inactive**]

display current-configuration configuration vpn-instance [*vpn-instance-name*] **related**

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **display current-configuration configuration vpn-instance** [*vpn-instance-name*] **related** command.

Parameters

Parameter	Description	Value
configuration	Displays all configuration information, except for the configuration on interfaces.	-

Parameter	Description	Value
configuration-type	Specifies information about the configuration that is a specified type, except for the configuration on interfaces. The configuration type depends on the existing configuration. For example: ● system: system configuration ● user-interface: user interface configuration ● aaa: AAA configuration	-
configuration-instance	Specifies information about the specified configuration instance, except for the configuration on interfaces. The configuration instance depends on the existing configuration.	The value is a string of 1 to 180 case-insensitive characters without spaces.
interface [*interface-type* [*interface-number*]]	Specifies an interface type. The information on the interface depends on the existing configuration. ● *interface-type*: specifies the type of an interface ● *interface-number*: specifies the number of an interface	-
feature *feature-name*	Specifies the configuration information about the specified feature. The configuration information about the feature depends on the existing configuration.	-

Parameter	Description	Value
filter *filter-expression*	Displays the configuration information that matches a regular expression.	The value is a string of 1 to 255 case-insensitive characters, spaces not supported. The matching starts from the first character of the command. For example, if snmp-agent is specified for *filter-expression*, only commands beginning with snmp-agent are filtered.
all	Displays all the configuration information.	-
inactive	Displays configurations about the cards that are not installed. When a card is not inserted, its configuration information is in the inactive status. The front of these configurations in the inactive state is marked with an asterisk (*).	-
vpn-instance [*vpn-instance-name*]	Displays configurations of a VPN instance with a specified name.	The value must be an existing VPN instance name.
related	Displays configurations of a specified module.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

To check whether the configured parameters take effect, run the **display current-configuration** command. The parameters that do not take effect are not displayed.

The command output is relevant to user configuration.

You can use a regular expression to filter the command output. For the regular expression rules, see Filtering Output Information Based on the Regular Expression in "CLI Overview" in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Basic Configuration*.

If the configuration is in the offline state, the offline configuration is marked with * in the **display current-configuration all** and **display current-configuration inactive** command output.

Example

Display all configurations that include **vlan**.

```
<HUAWEI> display current-configuration | include vlan
vlan batch 10 77 88
 port trunk allow-pass vlan 10
```

Display the FTP feature configuration.

```
<HUAWEI> display current-configuration feature ftp
#
FTP server enable
#
------------ END ------------
```

2.8.13 display factory-configuration information

Function

The **display factory-configuration information** command displays whether the function of restoring the factory configuration by holding down the Reset button is enabled and the mode of restoring the factory configuration.

NOTE

Only the SS1720GW-E, S1720GWR-E, and S1720GFR-P support this command.

Format

display factory-configuration information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before restoring the factory configuration by holding down the Reset button, you can run this command to check whether the function of restoring the factory configuration by holding down the Reset button is enabled and whether the mode of restoring the factory configuration is deleted or reserved.

Example

Display whether the function of restoring the factory configuration by holding down the Reset button is enabled and the mode of restoring the factory configuration.

```
<HUAWEI> display factory-configuration information
Reset function status: enable
Operate mode: deleted
```

Table 2-56 Description of the **display factory-configuration information** command output

Item	Description
Reset function status	Whether the function of restoring the factory configuration after you hold down the Reset button is enabled. ● enable: When you hold down the Reset button on a device, the device restarts with the factory configuration. ● disable: When you hold down the Reset button on a device, the device restarts without the factory configuration.
Operate mode	Mode of restoring the factory configuration. ● deleted: The system deletes the previous configuration when restoring the factory configuration. ● reserved: The system reserves the previous configuration when restoring the factory configuration.

2.8.14 display factory-configuration reset-result

Function

The **display factory-configuration reset-result** command displays the latest factory configuration restoration result of a switch.

Format

display factory-configuration reset-result

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the factory configuration of a switch is restored using the **reset factory-configuration** command, you can run the **display factory-configuration reset-result** command to check the factory configuration restoration result.

Example

Display the latest factory configuration restoration result.

```
<HUAWEI> display factory-configuration reset-result
Slot   Time                         Type                              Result
--------------------------------------------------------------------------------------
0      2017/10/11 15:55:11 [DST]    Startup saved-configuration file     Succeeded
                                    Configuration in flash               Succeeded
                                    Netconf db-configuration             Succeeded
                                    Data file                            Succeeded
```

Table 2-57 Description of the **display factory-configuration reset-result** command output

Item	Description
Slot	Stack ID.
Time	Time for restoring the factory configuration.

Item	Description
Type	Type of the configuration file that needs to be restored to the factory configuration. - Startup saved-configuration file: configurations in the configuration file - Configuration in flash: configurations in the flash, such as the stack configuration - Netconf db-configuration: database files of the NETCONF and NETCONF - Data file: data files in the file system
Result	Result of restoring the factory configuration of the configuration file. - Succeeded: Factory configuration restoration succeeds. - Failed: Factory configuration restoration fails.

2.8.15 display pnp-button mode

Function

The **display pnp-button mode** command displays the device behavior after the PNP button is pressed and held.

Format

display pnp-button mode

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **pnp-button mode reset-system** command to configure the device behavior after the PNP button is pressed and held, you can run the **display pnp-button mode** command to view the command configuration.

Example

Display the device behavior after the PNP button is pressed and held.

```
<HUAWEI> display pnp-button mode
Pnp configuration mode: reset single switch.
Pnp button enable: enable.
```

Table 2-58 Description of the **display pnp-button mode** command output

Item	Description
Pnp configuration mode	PnP configuration mode: ● reset system: The default settings of the stack will be restored and the stack will automatically restart. ● reset single switch: The default settings of a specific stack member will be restored and the stack member will automatically restart.
Pnp button enable	Whether the PNP button is available: ● enable: The PNP button is available. ● disable: The PNP button is unavailable.

2.8.16 display reboot-info

Function

The **display reboot-info** command displays the device reset information.

Format

display reboot-info [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	- Specifies the slot ID if stacking is not configured. - Specifies the stack ID if stacking is configured.	The value is an integer. The value is 0 if stacking is not configured, and varies according to the stacking configuration if stacking is configured.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the type and time of a reset.

This command displays reset information collected by the device, including the reset type and time. The following reset types may be displayed:

- MANUAL: The device was restarted manually using the **reboot** command or the NMS.
- POWER: The device restarted after being powered off (usually because users switch off the power supply).
- SCHEDU: The device restarted at a scheduled time.
- FSP: The device restarted due to a stack split or merge or an incorrect Mod-ID.
- EXCEPTION: The device restarted due to an exception or a dead loop.
- VRP: The device restarted due to an active/standby switchover or a fault on the VRP platform.
- SOFTWARE: The device restarted due to a software fault which is traceable.
- OS: The kernel was abnormal and initiated a reset.
- WATCHDOG: The device restarted due to the hardware watchdog.
- OTHER: Other causes.
  - A hardware component, such as the CPU, flash, or memory, has failed.
  - The device has overheated.
  - The switch was power recycled instantly, for example, when the power cable is in bad contact or when transient overvoltage and loss of voltage occurs. In this case, check whether the power cable is correctly connected to the switch.
  - The reboot was caused by other reasons that cannot be categorized into the preceding types. For example, the switch rebooted after joining a stack.

Example

Display the device reset information.

```
<HUAWEI> display reboot-info
Slot ID   Times         Reboot Type         Reboot Time(DST)
==========================================================================
0           1         POWER              2013/07/18 19:19:56
0           2         SCHEDU             2013/07/18 18:51:04
0           3         SOFTWARE             2013/07/18 18:41:22
0           4         EXCEPTION           2013/07/18 17:38:26
0           5         MANUAL              2013/07/18 17:31:14
0           6         MANUAL              2013/07/18 17:26:01
0           7         EXCEPTION           2013/07/18 17:03:28
==========================================================================
Total   7
```

Table 2-59 Description of the display reboot-info command output

Item	Description
Slot ID	Stack ID if the stacking function is enabled or the slot ID if the stacking function is not enabled.
Times	Number of board resets.
Reboot Type	Types of reset, including MANUAL, POWER, SCHEDU, FSP, EXCEPTION, VRP, SOFTWARE, OS, WATCHDOG, and OTHER.
Reboot Time(DST)	Time when a board was reset. On devices that do not support RTC, the device synchronizes the system clock on the network after the NTP function is configured. During the synchronization, the system time when the device is delivered is displayed. If synchronization fails, the system time when the device is delivered is displayed.

2.8.17 display saved-configuration

Function

The **display saved-configuration** command displays the configuration file to be used for the next startup.

Format

display saved-configuration [**last** | **time** | **configuration**]

Parameters

Parameter	Description	Value
last	Displays the system configurations saved last time.	-

Parameter	Description	Value
time	Displays the recent time when the configurations are saved manually or automatically.	-
configuration	Displays the parameters of the automatic save function.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

If the device has been started and is not working properly, run the **display saved-configuration** command to check the device startup configuration in the file specified by running the **startup saved-configuration** command.

Run the **display saved-configuration last** command to check the system configurations saved last time in the configuration file loaded during the current startup.

Run the **display saved-configuration time** command to check the last time when the system configurations are saved.

Run the **display saved-configuration configuration** command to check the automatic save function parameters including the automatic save interval and CPU usage.

The command output is relevant to user configuration.

Example

Display the configuration file for the next startup.

```
<HUAWEI> display saved-configuration
#
 sysname Switch
...
#
 vlan batch 10 20
#
interface Vlanif10
 ip address 192.168.1.3 255.255.255.0
#
interface Vlanif20
 ip address 192.168.4.3 255.255.255.0
...
#
interface GigabitEthernet0/0/1
 port link-type trunk
 port trunk allow-pass vlan 10
#
interface GigabitEthernet0/0/2
 port link-type trunk
 port trunk allow-pass vlan 20
...
```

```
#
user-interface maximum-vty 15
user-interface con 0
user-interface vty 0 14
 idle-timeout 0 0
#
return
```

2.8.18 display schedule reboot

Function

The **display schedule reboot** command displays the configuration of the scheduled restart of the device.

Format

display schedule reboot

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

After using the **schedule reboot** command to configure a scheduled restart, you can use this command to view the configuration of the scheduled restart.

Example

Display the configuration of the scheduled restart of the device.

```
<HUAWEI> display schedule reboot
Info:System will reboot at 22:00:00 2013/09/17 (in 1 hours and 43 minutes).
```

Table 2-60 Description of the display schedule reboot command output

Item	Description
System will reboot at	Specific restart time.
in hours and minutes	Time span between the restart time and the current time.

2.8.19 display startup

Function

The **display startup** command displays the system software and configuration files for the current and next startup.

Format

display startup [**slot** *slot-id*]

NOTE

Devices that do not support the stack function or do not have the stack function enabled do not support the **slot** *slot-id* parameters.

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a member device in a stack.	The value is an integer. The range of the integer is dependent on the specific device.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before upgrading or degrading a device, run this command to check whether the files for next startup have been loaded. If the files have been loaded, the device can be upgraded or degraded successfully after it is restarted. You can also run the command to view the system software and files for current startup.

The **display cli command-tree** command output shows that the **chassis** parameter is registered on the device. Fixed devices do not support this parameter.

Example

Display the names of system software for current and next startup.

```
<HUAWEI> display startup
MainBoard:
  Configured startup system software:        flash:/basicsoftware.cc
  Startup system software:                   flash:/basicsoftware.cc
  Next startup system software:              flash:/basicsoftware.cc
  Startup saved-configuration file:          flash:/vrpcfg.zip
  Next startup saved-configuration file:     flash:/vrpcfg.zip
  Startup paf file:                          NULL
  Next startup paf file:                     NULL
```

```
Startup license file:                NULL
Next startup license file:           NULL
Startup patch package:               NULL
Next startup patch package:          NULL
```

Table 2-61 Description of the display startup command output

Item	Description
Configured startup system software	System software that is configured for the current startup by running the **startup system-software** command before the system starts.
Startup system software	System software that is used in the current startup.
Next startup system software	System software that is configured for the next startup by running the **startup system-software** command. If no system software for the next startup is configured, the system software used in the current startup is displayed.
Startup saved-configuration file	Configuration file that is used in the current startup.
Next startup saved-configuration file	Configuration file that is configured for the next startup by running the **startup saved-configuration** command. If no configuration file for the next startup is configured, the configuration file used in the current startup is displayed.
Startup paf file	PAF file that is used in the current startup. **default** indicates that no PAF file is specified or the PAF file does not take effect. **NULL** indicates that no PAF file exists on the device.
Next startup paf file	PAF file that is configured for the next startup. If no PAF file is configured, **default** is displayed. **NULL** indicates that no PAF file exists on the device.

Item	Description
Startup license file	License file that is used in the current startup. **default** indicates that no license file is specified or the license file does not take effect. **NULL** indicates that no license file exists on the device.
Next startup license file	License file that is configured for the next startup. If no license file is configured, **default** is displayed. **NULL** indicates that no license file exists on the device.
Startup patch package	Patch package file that is used in the current startup. **NULL** indicates that no patch package file is specified or the patch package file does not take effect.
Next startup patch package	Patch package file that is configured for the next startup by running the **startup patch** command. If no patch package file is configured, **NULL** is displayed.

2.8.20 factory-configuration prohibit

Function

The **factory-configuration prohibit** command disables the function of restoring the factory settings of a device by holding down **reset**.

The **undo factory-configuration prohibit** command enables the function of restoring the factory settings of a device by holding down **reset**.

By default, you can hold down **reset** to restore the factory configuration.

NOTE

Only SS1720GW-E, S1720GWR-E, and support this command.

Format

factory-configuration prohibit

undo factory-configuration prohibit

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

If you hold down **reset** on a device for more than 5 seconds, the device restarts with the factory settings and all user-defined configurations are lost after the restart. To retain user-defined configurations after you hold down **reset**, run the **factory-configuration prohibit** command to disable this function.

If you want to restore the factory settings of a device by holding down **reset**, run the **undo factory-configuration prohibit** command to enable this function.

Example

Disable the function of restoring the factory configuration of a device by holding down **reset**.

```
<HUAWEI> system-view
[HUAWEI] factory-configuration prohibit
```

2.8.21 pnp-button mode reset-system

Function

The **pnp-button mode reset-system** command configures all member switches in a stack to restore to the default settings and restart after the PNP button is pressed and held.

The **undo pnp-button mode reset-system** command restores the default settings.

By default, a switch in a stack restores to the default settings and automatically restarts after the PNP button is pressed and held on the switch.

Format

pnp-button mode reset-system

undo pnp-button mode reset-system

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To clear all service configurations and data files, press and hold the PNP button for more than 6 seconds to restore the default settings and automatically restart the device. By default, holding the PNP button on any device in a stack will restore the device to the default settings and automatically restart the device. To clear the service configurations and data files of the stack, run the **pnp-button mode reset-system** command to configure the device behavior after the PNP button is pressed and held.

Example

Configure all member switches in a stack to restore to the default settings and automatically restart after the PNP button is pressed and held.

```
<HUAWEI> system-view
[HUAWEI] pnp-button mode reset-system
```

2.8.22 pnp-button disable

Function

The **pnp-button disable** command disables the PNP button function of a device.

The **undo pnp-button disable** command enables the PNP button function of a device.

By default, the PNP button function is enabled on a device.

Format

pnp-button disable

undo pnp-button disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If you do not want anyone to use the PNP button to reset the device configuration or restart the device, run the **pnp-button disable** command to disable the PNP button function of the device.

Example

Disable the PNP button function of the device.

```
<HUAWEI> system-view
[HUAWEI] pnp-button disable
```

2.8.23 reboot

Function

The **reboot** command restarts the device.

Format

reboot [**fast** | **save diagnostic-information**]

Parameters

Parameter	Description	Value
fast	Fast restarts the device. In fast restart mode, the configuration file is not saved.	-
save diagnostic-information	Saves the diagnostic information before the restart.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command functions in the same way as a power recycle operation (power off and then restart the device). The command enables you to restart the device remotely.

- If the configuration file for next startup (new configuration file) is the same as the configuration file saved on the device after the **reboot** command is run, the system will not ask you whether to save the configuration before the restart. If the configuration file for next startup (new configuration file) differs from the configuration file saved on the device, the system asks you whether to save the configuration before the restart, and unsaved configuration information will be lost after the restart.

- When the **reboot fast** command is run, the system restart quickly without displaying any message and the configuration is lost.
- After the **reboot save diagnostic-information** command is run, the system will save the diagnostic information to root directory of the storage device before restarting.

Precautions

- If you do not respond to the displayed message within the timeout period after running this command, the system will return to the user view and the device will not be restarted.
- To avoid loss of diagnostic information after a restart, configure the device to save the diagnostic information before restarting.
- This command interrupts services on the entire device. Therefore, do not use this command when the device is running properly.
- Before restarting the device, ensure that the configuration file has been saved.
- If you upgrade the system software to V200R009C00 or a later version and the configuration file contains WLAN configurations, the system displays a message indicating that the configuration file conflicts with the system software for next startup when the device restarts. The system software upgrade fails. If a conflict occurs, you need to use the eDesk tool to convert configurations in the configuration file, and specify the converted configuration file as the configuration file for next startup. If the configuration file is not converted, the configurations will be lost after the system is restarted and upgraded.
- If multiple users run the **reboot save diagnostic-information** command at the same time, a message indicating that the command is locked by another user is displayed.
- If a user runs the **display diagnostic-information** command when another user is running the **reboot save diagnostic-information** command, a message indicating that the command is locked by another user is displayed.
- The S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, and S5735S-S support the stacking function since V200R019C10. S5735-L-I supports the stacking function since V200R021C00. If multiple switches set up a stack and the system software package for the next startup is earlier than V200R019C10, the stack will split after the **reboot** command is executed to restart any stack member. If the stacking function is enabled on a single switch, the system software package for the next startup is earlier than V200R019C10, and the **stack slot renumber** command is executed to change the stack ID of the switch to a non-zero value, then the stack configuration of the switch will be cleared and the slot-ID-related configuration cannot be restored after the **reboot** command is executed to restart the switch.
- Due to the component upgrade of some device models, some devices cannot be downgraded. If the message "Error: The hardware version VER.B of slot %u does not support the configured system software package." (%u indicates the actual slot number) is displayed after the command is run, you can solve this problem by installing the patch that matches the version. For details about

the first supported version of the device and matching patch version, see the device overview in the "Hardware Description"..

NOTE

After converting configurations in the configuration file using the **eDesk pro** tool, restart the switch without saving the configurations. If the configurations are saved, the converted configuration file is invalid.

Example

Restart the device.

```
<HUAWEI> reboot
Info: The system is now comparing the configuration, please wait........
Warning: The configuration has been modified, and it will be saved to the next s
tartup saved-configuration file flash:/204.cfg. Continue? [Y/N]:y
Info: If want to reboot with saving diagnostic information, input 'N' and then e
xecute 'reboot save diagnostic-information'.
System will reboot! Continue?[Y/N]:y
```

Restart the device quickly.

```
<HUAWEI> reboot fast
Info: If want to reboot with saving diagnostic information, input 'N' and then execute 'reboot save
diagnostic-information'.
System will reboot! Continue?[Y/N]:y
```

2.8.24 reset factory-configuration

Function

The **reset factory-configuration** command restores the factory settings of the device.

Format

reset factory-configuration

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To clear all service configurations and data files, run the **reset factory-configuration** command to restore the factory settings.

Precautions

After you run the **reset factory-configuration** command, the system asks you whether to restart the device. After you enter **y**, the device restarts and clears the service configurations and data files on the device. The configurations and files to be cleared include:

- Configurations in the configuration file
- Configurations in the flash memory, such as the stackconfigurations.
- Database files in NETCONF
- Data files in the file system

NOTE

- The next-startup system software package, patch, module, and license file will not be deleted.
- This command will not delete the protected directory and the $_default.cfg file in the protected directory.

NOTICE

Exercise caution and use this command under the supervision of technical support personnel.

Example

Restore the device to factory settings.

```
Warning: The command will delete all the configurations and files (except the startup, patch, module, and
license files) from the de
vice. Continue? [Y/N]:y
Warning: The system will reboot after configurations and files are deleted. Continue? [Y/
N]:y
```

2.8.25 reset saved-configuration

Function

The **reset saved-configuration** command clears the next startup configuration file and cancels the configuration file used for next startup.

Format

reset saved-configuration

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

- If the configuration file on the device is incompatible with the upgraded software, run the **reset saved-configuration** command to clear the configuration file and run the **startup saved-configuration** command to specify a new configuration file.
- If the device in use is applied to another scenario and the original configuration file of the device does not meet requirements in the scenario, run the **reset saved-configuration** command to clear the existing configuration file and restart the device to restore its factory configurations.

Precautions

- After you run the **reset saved-configuration** command, the next startup configuration file is cleared and the file is not used for next startup. If the current startup configuration file is the same as the next startup configuration file, the current startup configuration file is also cleared.
- If you do not use the **startup saved-configuration** command to specify a new configuration file or do not save the configuration file after the file is not used for next startup, the device uses default factory configurations for startup.
- If the current configuration file is empty, and the configuration file for the next startup is not empty, running the **reset saved-configuration** command clears the settings for the configuration file for the next startup.
- If the configuration file for the next startup is empty, and the current configuration file is not empty, after the **reset saved-configuration** command is run, the system prompts an error and no settings are cleared.
- Exercise caution when you run the **reset saved-configuration** command.
- Running the **reset saved-configuration** command will clear the content in the configuration file used for the next device startup but not clear the database information on the device. In NETCONF mode, run the **reset netconf db-configuration** command to clear the configuration and database file to prevent the configuration delivery failures caused by residual database files.
- After the **reset netconf db-configuration** or **reset saved-configuration** command is run, the **assign trunk** command configuration is cleared, that is, the default configuration is restored.

Example

Clear the next startup configuration file in the storage device and cancel the configuration file used for next startup.

```
<HUAWEI> reset saved-configuration
Warning: The action will delete the saved configuration in the device.
The configuration will be erased to reconfigure. Continue? [Y/N]:y
Warning: Now clearing the configuration in the device.
Info: Succeeded in clearing the configuration in the device.
```

2.8.26 reset reboot-info

Function

The **reset reboot-info** command resets the device reset information.

Format

reset reboot-info [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	- Specifies the slot ID if stacking is not configured. - Specifies the stack ID if stacking is configured.	The value is 0 if stacking is not configured; the value ranges from 0 to 8 if stacking is configured.

Views

User view

Default Level

3: Management level

Usage Guidelines

The device records information about every restart, including the number of restart events, restart type, and restart time. Run the **display reboot-info** command to view restart information. You can run the **reset reboot-info** command to clear restart information.

Example

Reset the device reset information.

```
<HUAWEI> reset reboot-info
```

2.8.27 save

Function

The **save** command saves the configurations to the default directory.

Format

save [**all**] [**force**] [*configuration-file*]

Parameters

Parameter	Description	Value
all	Saves all configurations to the next startup configuration file of the system. **NOTE** All configurations are saved, including those of the boards that are not running, no matter whether **all** is specified.	-
force	Forcibly saves configurations.	-
configuration-file	Specifies the name of a configuration file.	The value is a string of case-insensitive characters. The absolute path length ranges from 5 to 64 characters. The value cannot contain spaces and the following characters: < > \ ? , : `. Left and right square brackets cannot be used in pairs. The forward slash (/) and period (.) cannot be used together.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run commands to modify the current configuration of the device, but the modified configuration will be lost after the device restarts. To enable the new configuration to take effect after a restart, save the current configuration in the configuration file before restarting the device.

When a series of configurations are complete and take effect, you must save the current configuration file to the storage device.

- If the *configuration-file* parameter is not specified, the **save** [**all**] command saves the current configuration to the next startup configuration file in the storage device. The "Next startup saved-configuration file:" field displayed in the **display startup** command output indicates the next startup configuration file.

- The **save** [**all**] *configuration-file* command saves the current configuration to the specified directory of the storage device. Generally, the command does not affect the current startup configuration file. Only if the *configuration-file* parameter is the same as the directory and name of the configuration file for the next startup, this command can be used as the same as the **save** command without the *configuration-file* parameter.
- The **save** [**all**] **force** *configuration-file* command saves the current configurations to a file specified by the *configuration-file* parameter on a storage device without user confirmation.

All configurations are saved, no matter whether **all** is specified.

If you do not specify *configuration-file* when saving the configuration file for the first time, the system asks you whether to save the configuration file as **vrpcfg.zip**. The **vrpcfg.zip** file is the default system configuration file with empty configurations in initial state.

Precautions

- If the configuration file to be saved using this command has the same name with the existing configuration file, the existing configuration file is rewritten.
- The configuration file name extension must be .zip or .cfg.
  - .cfg: The file is saved in plain text mode. After the file is specified as the configuration file, all commands in the file are recovered one by one during startup.
  - .zip: The .cfg file is compressed to a .zip file that occupies less space. After being specified as the configuration file, the .zip file is decompressed to the .cfg file and all commands in the .cfg file are recovered one by one during startup.
- When the system is saving configuration files, other users are not allowed to perform configuration. When the current user is performing configuration, other users are not allowed to save configuration files.
- When the controller delivers configurations, the configuration cannot be saved on the device side.
- If you run the **authentication-mode none** command to change the authentication mode of the console port to none authentication, security risks exist. When you save the configuration file, the system displays a message indicating security risks.
- If you run the **undo authentication-mode** command to change the authentication mode of the console port to none authentication, security risks exist. When you save the configuration file, the system displays a message indicating security risks.

Example

Save the current configuration to the default directory when the next startup configuration file is not specified.

```
<HUAWEI> save
The current configuration will be written to the device.
Are you sure to continue?[Y/N]y
Now saving the current configuration to the slot 0.
Save the configuration successfully.
```

Save the current configuration to the next startup configuration file specified.

```
<HUAWEI> save
The current configuration will be written to flash:/vrpcfg.zip.
Are you sure to continue?[Y/N]y
Now saving the current configuration to the slot 0.
Info: Save the configuration successfully.
```

2.8.28 schedule reboot

Function

The **schedule reboot** command configures the scheduled restart of a device and sets the specific time when the device restarts or the delay time before the device restarts.

The **undo schedule reboot** command disables the scheduled restart function.

By default, the scheduled restart is disabled.

Format

schedule reboot { **at** *time* | **delay** *interval* [**force**] }

undo schedule reboot

Parameters

Parameter	Description	Value
at *time*	Specifies the device restart time.	The format of *time* is *hh:mm YYYY/MM/DD*. The restart time must be later than the current device time by less than 720 hours. *YYYY/MM/DD* indicates year, month, and date and is optional. • *hh* indicates hour and the value ranges from 0 to 23. • *mm* indicates minute and the value ranges from 0 to 59. • *YYYY* indicates year and the value ranges from 2000 to 2099. • *MM* indicates month and the value ranges from 1 to 12. • *DD* indicates date and the value ranges from 1 to 31.

Parameter	Description	Value
delay *interval*	Specifies the delay time before the device restarts.	The format of *interval* is *hh:mm* or *mm*. The delay time must be no more than 720 hours. ● In *hh:mm*, *hh* indicates hour and the value ranges from 0 to 720 and *mm* indicates minute and the value ranges from 0 to 59. ● *mm* indicates minute and the value ranges from 0 to 43200.
force	Specifies forcible scheduled restart.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When upgrading or restarting the device, you can configure the device to restart at time when few services are running to minimize the impact on services.

Precautions

- If the **schedule reboot at** command is used to set a specific date (*YYYY/MM/DD*) and the date is a future date, the device restarts at the specified time. If no date is set, two situations occur: If the specified time is later than the current time, the device restarts at the specified time of the day. If the specified time is earlier than the current time, the device restarts at the set time next day.
- Note that the gap between the specified date and current date must be shorter than or equal to 720 hours. If the scheduled restart has been configured, the latest configuration overrides the previous one.
- Run the **schedule reboot delay** *interval* command to set the delay time before the device restarts. If the **force** parameter is not specified, the system compares the configuration file with the current configuration. If the current configuration is different from the configuration file, the system asks you whether to save the current configuration. After you complete the selection, the system prompts you to confirm the configured restart time. Enter **Y** or **y** to make the configured restart time take effect. If the **force** parameter is specified, the system does not display any message, and the restart time takes effect directly. The current configuration is not compared or saved.
- The scheduled restart function becomes invalid when you use the **clock datetime** command to set the system time to over 10 minutes later than the

restart time set by the **schedule reboot** command. If the time difference is equal to or less than ten minutes, the device immediately restarts and does not save the configuration.

- This command restarts the device at the specified time, interrupting all services on the device. Therefore, do not use this command when the device is running properly.
- Before restarting the device, ensure that the configuration file has been saved.

Example

Configure the device to restart at 22:00.

```
<HUAWEI> schedule reboot at 22:00
Info: The system is now comparing the configuration, please wait.
Warning: The configuration has been modified, and it will be saved to the next startup saved-configuration
file flash:/vrpcfg.zip. C
ontinue? [Y/N]:y
Now saving the current configuration to the slot 0...
Save the configuration successfully.
Info: Reboot system at 22:00:00 2012/06/12 UTC-05:13(in 2 hours and 0 minutes)
confirm?[Y/N]:y
```

2.8.29 set factory-configuration operate-mode

Function

The **set factory-configuration operate-mode** command determines whether to reserve or delete the existing configuration when restoring the factory configuration.

The **undo set factory-configuration operate-mode** command enables the device to reserve the existing configuration when you restore the factory configuration.

By default, the system reserves the previous configuration when restoring the factory configuration.

NOTE

Only SS1720GW-E, and S1720GWR-E support this command.

Format

set factory-configuration operate-mode { **reserve-configuration** | **delete-configuration** }

undo set factory-configuration operate-mode

Parameters

Parameter	Description	Value
reserve-configuration	Reserves current configuration file after factory settings are restored.	-

Parameter	Description	Value
delete-configuration	Deletes current configuration file after factory settings are restored.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Run the **set factory-configuration operate-mode delete-configuration** command to specify the operation as **delete-configuration** for restoring factory settings. This prevents user information leak when the device is lost.

Example

Set the mode of restoring the factory configuration to **delete**.

```
<HUAWEI> system-view
[HUAWEI] set factory-configuration operate-mode delete-configuration
Warning: It may delete your configuration file when executing factory configuration, continue?[Y/N]:y
```

2.8.30 set save-configuration

Function

The **set save-configuration** command enables the function of saving system configurations periodically.

The **undo set save-configuration** command disables the function of saving system configurations periodically.

By default, the system does not periodically save configurations.

Format

set save-configuration [**interval** *interval* | **cpu-limit** *cpu-usage* | **delay** *delay-interval*] *

undo set save-configuration [**interval** | **cpu-limit** | **delay**] *

undo set save-configuration [**interval** *interval* | **cpu-limit** *cpu-usage* | **delay** *delay-interval*] *

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for saving configurations.	The value is an integer that ranges from 30 to 43200, in minutes. The default value is 30.
cpu-limit *cpu-usage*	Specifies the threshold of the CPU usage during the periodic save operation.	The value is an integer that ranges from 1 to 60. The default value is 50.
delay *delay-interval*	Specifies the delay in automatic backup after the configuration changes. **NOTE** If a configuration change occurs within the configured delay time, the device restarts the timer.	The value is an integer that ranges from 1 to 60, in minutes. The default value is five minutes. The value of *delay-interval* must be less than the value of *interval*.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After this command enables the function of saving system configurations periodically, the configuration file will not be lost if the device is powered off or restarts.

If the **set save-configuration** command is not executed, the system does not enable the function of saving system configurations periodically.

If the **set save-configuration** command is executed, the system compares the configuration files before saving configurations. If the configurations do not change, the system does not save the configurations.

- You can specify **interval** *interval* to set the interval for periodically saving configurations. The system saves the current configurations only when the configurations have been changed and are not saved. The default interval is 0 seconds, indicating that the system does not save the configurations. After the automatic save function is enabled, the default interval is 30 minutes if *interval* is not specified.
- If **cpu-limit** *cpu-usage* is specified, the automatic save function does not affect system performance. After the automatic save timer is triggered, the system cancels the current automatic save operation if the system CPU usage

  is detected to be higher than the upper limit. The default upper limit of the CPU usage is 50% for the automatic save function.
- After **delay** *delay-interval* is specified, the system saves the changed configurations after the specified delay. The default value is 5 minutes.

The **undo set save-configuration** command disables the automatic save function. The **undo set save-configuration** command with a parameter specified restores the default value of the parameter and the automatic save function still takes effect.

Follow-up Procedure

Run the **display saved-configuration configuration** command to check the configurations about the periodic save function.

Precautions

Before saving configurations, the system compares the configurations with those in the configuration file. Automatic saving of configurations is triggered in the following scenarios:

- The configurations are inconsistent with those saved last time.
- The configurations are the same as those saved last time, but changes have been made. For example, if a command is run and then its configurations are deleted, automatic saving of configurations will still be triggered although configurations are the same as those saved last time.

After the automatic save function is enabled, the configurations are saved in the configuration file for the next startup. The content in the configuration file changes when the configuration changes. The system cancels the automatic save operation when:

- Content is being written into the configuration file.
- The configurations are being recovered.
- The CPU usage is excessively high.

Example

Set the automatic save interval to 60 minutes.

```
<HUAWEI> system-view
[HUAWEI] set save-configuration interval 60
```

Configure the system to save the new configuration 3 minutes after the configuration changes at an interval of 10 hours when the upper limit of the CPU usage is 60%.

```
<HUAWEI> system-view
[HUAWEI] set save-configuration interval 600 delay 3 cpu-limit 60
```

2.8.31 set save-configuration backup-to-server server

Function

The **set save-configuration backup-to-server server** command specifies the server where the system periodically saves the configuration file.

The **undo set save-configuration backup-to-server server** command cancels the server where the system periodically saves the configuration file.

By default, the system does not periodically save configurations to the server.

Format

set save-configuration backup-to-server server *server-ip* [**vpn-instance** *vpn-instance-name*] **transport-type** { **ftp** | **sftp** } [**port** *port-number*] **user** *user-name* **password** *password* [**path** *path*]

set save-configuration backup-to-server server *server-ip* [**vpn-instance** *vpn-instance-name*] **transport-type tftp** [**path** *path*]

undo set save-configuration backup-to-server server [*server-ip* [**vpn-instance** *vpn-instance-name*]]

Parameters

Parameter	Description	Value
server *server-ip*	Specifies the IP address of the server where the system periodically saves the configuration file.	-
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance.	The value must be an existing VPN instance name.
port *port-number*	Specifies the port number of a server.	The value is an integer ranging from 1 to 65535. By default, the port number of the FTP server is 21, and that of the SFTP server is 22.
transport-type	Specifies the mode in which the configuration file is transmitted to the server.	The value can be **ftp**, **sftp**, or **tftp**. To ensure file transfer security, use the SFTP method.
user *user-name*	Specifies the name of the user who saves the configuration file on the server.	The value is a string of 1 to 64 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
password *password*	Specifies the password of the user who saves the configuration file on the server.	The value is a case-sensitive string without spaces. The value of a simple text password is a string of 1 to 16 characters. The value of a ciphertext password is a string of 24, 32 or 48 characters. When double quotation marks are used around the string, spaces are allowed in the string.
path *path*	Specifies the relative save path on the server. If this parameter is not specified, the FTP, SFTP, or TFTP root path is enabled by default.	The value is a string of 1 to 64 case-sensitive characters without spaces. The path should use forward slashes. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Run this command to periodically save the configuration file to the server.

Before periodically saving configurations, the system compares the configuration files. If the configurations do not change, the system does not periodically save them.

Precautions

If the specified path on the server does not exist, configuration files cannot be sent to the server. The system then sends an alarm message indicating the transmission failure to the NMS, and the transmission failure is recorded as a log message on the device.

The user name and password must be the same as those used in FTP or SFTP login mode.

NOTE

- When you run this command to save configuration files to a server, the system supports only the binary transmission mode. Therefore, the server must support the binary transmission mode.
- Before running this command, run the **set save-configuration** command to start the periodic configuration saving function. Otherwise, configuration files are not saved to the server.
- FTP or TFTP is insecure. Therefore, configuring SFTP is recommended.
- A server IP address can be bound to multiple VPN instances. To delete the configurations of a specified VPN instance, you must set *vpn-instance-name*. Otherwise, configurations irrelevant to the VPN instance will be deleted.
- The configuration file saved by running this command is named in the format of yyyy-mm-dd.hh-mm-ss.sysname.zip, where yyyy indicates the year, the first mm indicates the month, dd indicates the day, hh indicates the hour, the second mm indicates the minute, ss indicates the second, and sysname indicates the host name, for example, **2022-07-02.17-23-17.HUAWEI.zip**.

Example

Specify the server to which the system periodically sends the configuration file, and set the transmission mode to SFTP.

```
<HUAWEI> system-view
[HUAWEI] set save-configuration backup-to-server server 10.1.1.1 transport-type sftp user admin1234
password Helloworld@6789
```

Specify the server to which the system periodically sends the configuration file, and set the transmission mode to SFTP, port number to 88, and save path to **d:/sftp**.

```
<HUAWEI> system-view
[HUAWEI] set save-configuration backup-to-server server 10.1.1.1 transport-type sftp port 88 user
admin1234 password Helloworld@6789 path d:/sftp
```

2.8.32 startup saved-configuration

Function

The **startup saved-configuration** command specifies the system configuration file for next startup.

The **undo startup saved-configuration** command deletes the system configuration for next startup.

Format

startup saved-configuration *configuration-file* [**slot** *slot-id*]

undo startup saved-configuration

NOTE

Devices that do not support the stack function or do not have the stack function enabled do not support the **slot** *slot-id* parameters.

Parameters

Parameter	Description	Value
configuration-file	Specifies the name of a configuration file. Make sure that the file exists.	The value is a string of 5 to 64 case-insensitive characters without spaces. The file name extension can be .zip or .cfg. The file name must not contain %.
slot *slot-id*	Specifies a member device in a stack.	The value is an integer. The range of the integer is dependent on the specific device.

Views

startup saved-configuration: User view

undo startup saved-configuration: System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the original configuration file cannot be used due to the software upgrade, run the **startup saved-configuration** command to specify another configuration file for next startup. The startup configuration file must be saved in the root directory of the storage device.

Follow-up Procedure

Run the **reboot** or the **schedule reboot** command to restart the device.

Precautions

- The configuration file specified for the next startup must exist.
- The configuration file name extension must be .zip or .cfg.
  - A configuration file with the file name extension .cfg is a text file, and you can view the file content in the text file. After the file is specified as the configuration file for next startup, the system restores all commands in the file one by one during a startup.
  - A .cfg file is compressed to a .zip file that occupies less space. After being specified as the configuration file, the .zip file is decompressed to the .cfg file and the system restores all commands in the .cfg file one by one during startup.
- If the EasyDeploy function is configured, run the **undo startup saved-configuration** command to clear the configuration file for next startup and delete all the configuration files in the storage device. When the device

restarts, it finds no configuration file available and downloads a configuration file from the file server.

If the EasyDeploy function is not configured, run the **undo startup saved-configuration** command to clear the configuration file for next startup. After the command is run, the device uses empty configuration in next startup.

- The **display cli command-tree** command output shows that the **chassis** parameter is registered on the device. Fixed devices do not support this parameter.
- Do not change the configuration file manually and specify the configuration file for next startup. Otherwise, the device may not start normally.
- Users at level 3 or higher can change the configuration file used for the next startup.
- If the configuration file used for the next startup contains the **authentication-mode none** command that changes the authentication mode of the console port to none authentication, security risks exist. When you configure the configuration file used for the next startup, the system displays a message indicating security risks.
- If the configuration file used for the next startup contains the **undo authentication-mode** command that changes the authentication mode of the console port to none authentication, security risks exist. When you configure the configuration file used for the next startup, the system displays a message indicating security risks.

Example

Cancel the specified configuration file for next startup in the system view.

```
<HUAWEI> system-view
[HUAWEI] undo startup saved-configuration
```

Specify the system configuration file for the next startup.

```
<HUAWEI> startup saved-configuration vrpcfg.cfg
Info: Succeeded in setting the configuration for booting system.
```

2.8.33 startup system-software

Function

The **startup system-software** command specifies the system software for next startup.

Format

startup system-software *system-file* [**all** | **slave-board** | **slot** *slot-id*]

NOTE

Devices that do not support the stack function or do not have the stack function enabled do not support the **all**, **slave-board**, or **slot** *slot-id* parameters.

Parameters

Parameter	Description	Value
system-file	Specifies the name of the system software file.	The value is a string of 4 to 64 case-sensitive characters without spaces and %. It is in the format of [*drive-name*] [*file-name*]. If *drive-name* is not specified, the name of the default storage device is used.
all	Specifies all member devices in a stack.	-
slave-board	Specifies the system software for next startup on the slave switch.	-
slot *slot-id*	Specifies a member device in a stack.	The value is an integer. The range of the integer is dependent on the specific device.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In system software upgrade or downgrade, run this command to specify the system software for next startup.

Follow-up Procedure

Run the **reboot** or the **schedule reboot** command to restart the device.

Precautions

- When the **startup system-software** command is run, the system displays a prompt and the current password is cleared only after the user confirms the operation.
- The system software package must use .cc as the file name extension and be saved to the root directory of the storage device.
- When the system software for next startup is configured using the **startup system-software** command, the system checks the system software integrity. If the digital signature of the system software is invalid, the configuration fails. Therefore, ensure the system software validity.

- If the upgrade or downgrade cannot be performed between versions, the system displays a message, prompting you to perform operations as prompted.
- The **display cli command-tree** command output shows that the **chassis** parameter is registered on the device. Fixed devices do not support this parameter.
- During system software upgrade of fixed PoE switches, powered devices (PDs) will be powered off.
- During the downgrade to an earlier version, the system checks whether the software package of the earlier version contains a complete signature file. If the software package does not contain a complete signature file, the system prompts you whether to continue the downgrade. After confirming that the software package is correct, the downgrade does not affect functions. However, you are advised to upgrade to a more secure version.

NOTE

The system file is authenticated when you configure the file name of the system software used in the next startup. Wait for a while.

Table 2-62 lists the possible causes and troubleshooting methods for failures to load the system software package to the device.

Table 2-62 Possible causes and troubleshooting methods for failures to load the system software package

Failure Cause		Troubleshooting Method
CRC check fails.	The system software package is damaged. Please upload again.	Upload the system software package again.
Version check fails.	The %s only supports the system software package of %s and later versions.	Upload the system software package of the version supported by the device.
Signature verification fails.	Software package verification failed. Please upload again.	Upload the system software package again.
The system software package is corrupted.	The system software package is damaged. Please upload again.	Upload the system software package again.
The system software package is not supported on the device.	The system software package does not match the device.	Upload the system software package that matches the device.
The name of the system software package is incorrect.	The system software package does not exist.	Change the name of the system software package and upload the package again.

Failure Cause		**Troubleshooting Method**
The name of the system software package is too long.	The file name is too long.	Change the name of the system software package and upload the package again.
Stacking is not supported.	The target version does not support CSS card stacking. Disable this stacking function and try later.	Disable the stacking function and upload the system software package again.
The system software package does not match the MPU.	The system software package does not include the MPU software package.	Upload the system software package that matches the MPU.
Failed to set the system software package.	Failed in setting the software for booting system.	Check whether the system software package matches the device type.
The directory where the system software package is uploaded is incorrect.	The file flash:/%.cc doesn't exist in the main board. (Default directory is flash:/)	Upload the system software package to the root directory of the flash memory.
The flash version does not support the system software package to be uploaded.	The flash chip version xxx does not support the new startup system software package. This file cannot be specified as the startup system software package.	Upload the system software package of the version supported by the flash.
The PHY version does not support the system software package to be uploaded.	The PHY chip version xxx does not support the new startup system software package. This file cannot be specified as the startup system software package.	Upload the system software package of the version supported by the PHY.
The LSW version does not support the system software package to be uploaded.	The LSW chip version xxx does not support the new startup system software package. This file cannot be specified as the startup system software package.	Upload the system software package of the version supported by the LSW.

Failure Cause		Troubleshooting Method
The hardware version VER.B does not support the new system software package.	The hardware VER.B does not support the startup software package. You need to configure the matching patch first.	Configure the matching patch first. For details, see the reference document or upgrade guide.

Example

Specify the system software to be loaded for next startup.

```
<HUAWEI> startup system-software basicsoft.cc
```

2.8.34 startup patch

Function

The **startup patch** command specifies the patch file for next startup.

Format

startup patch *patch-name* [**slave-board** | **slot** *slot-id*]

NOTE

Devices that do not support the stack function or do not have the stack function enabled do not support the **slave-board** parameters.

Parameters

Parameter	Description	Value
patch-name	Specifies the name of the patch file for next startup.	The value is a string of 5 to 64 case-insensitive characters without spaces. It is in the format of [*drive-name*] [*path*] [*file-name*]. If *drive-name* is not specified, the name of the default storage device is used.
slave-board	Specifies the patch file for next startup on slave switch.	-
slot *slot-id*	Specifies a member device in a stack.	The value is an integer. The range of the integer is dependent on the specific device.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To make the patch file take effect after the device restarts, run this command to specify the patch file for next startup.

Follow-up Procedure

Run the **reboot** or the **schedule reboot** command to restart the device.

Precautions

- A patch file uses .pat as the file name extension and must be saved in the root directory.
- If you use this command to specify another patch for next startup, the previous patch will be overridden.
- After the patch file is specified for next startup, run the **display patch-information** command to view the patch file.
  - If the patch file for next startup is not empty, the device load the patch automatically after next startup.
  - If the patch file for next startup is empty, the device cannot load the patch after next startup.
- After the device restarts, the system loads and runs the patch. If you do not want the system to load the patch file after startup, use either of the following methods to delete the patch file:
  - Run the **patch delete all** command to delete the current patch.
  - Run the **reset patch-configure** [**next-startup**] command to delete the patch file already loaded on the system after startup.
- The **display cli command-tree** command output shows that the **chassis** parameter is registered on the device. Fixed devices do not support this parameter.

Example

Specify the patch file for next startup.

```
<HUAWEI> startup patch patch.pat.........................................
................................
Info: Succeeded in setting main board resource file for system.
```

2.9 Smart Upgrade Commands

2.9.1 Command Support

All models of S300, S500, S2700, S5700, and S6700 series switches (except the S5731-L and S5731S-L) support Smart Upgrade.

Only the following switch models support Smart AP Upgrade:

S5731-H, S5731S-H, S5732-H, S6730-H, S6730S-H

2.9.2 display smart-upgrade information

Function

The **display smart-upgrade information** command displays details about smart upgrade.

Format

display smart-upgrade information

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After smart upgrade is enabled, you can run the **display smart-upgrade information** command to check network connectivity with the HOUP and check whether a new version of software or patch is available for upgrade.

Precautions

This command triggers information exchange between the switch and HOUP. If this command is used frequently, smart upgrade may be affected.

Example

Display details about smart switch or AP upgrade.

```
<HUAWEI> display smart-upgrade information
Info: Loading the information, please wait .

Table 2-63 Description of the **display smart-upgrade information** command output

Item	Description
Configuration	Configuration information.
URL	Configured proxy server.
HTTPS port	HTTPS port number of the proxy server. The default port number is 443.
Bind SSL policy	Name of the bound SSL policy.
Verify HTTPS server	Whether to verify the HTTPS server. ● true: The HTTPS server is verified. ● false: The HTTPS server is not verified.
Version information	Version information.
Refresh time	Time when version information is obtained. Each time the command is run, the time is updated.
Check version result	Version check result. ● needUpdate: An upgrade is required. ● netError: The network is unavailable. ● versionOptimal: The version is optimal.
Recommended software version	Recommended software package version.
Recommended patch version	Recommended patch version.
Upgrade description	Upgrade description.

Item	Description
Firmware and Patch Description in English	Hardware and patch description in English.
Software package name	Software package name.
Software package size(B)	Software package size.
Patch package name	Patch package name.
Patch package size(B)	Patch package size.
Upgrade information	Upgrade information.
Upgrade Time	Upgrade time.
Upgrade status	Upgrade status: ● success: The upgrade succeeds. ● running: The upgrade is ongoing. ● netError: Network error. ● serverSpecUpLimit: The server specification reached the upper limit of the connection. ● CertOutDate: The certificate has expired. ● writeFlashFailed: The system file fails to be saved in the flash memory. ● fileCheckFailed: The file verification fails. ● upgradeCancelled: The upgrade is canceled. ● abnormalReset: The switch is restarted or an active/standby switchover is performed during an upgrade. ● fileNotMatch: The file does not match. ● systemError: System error. ● other: Other status.
Cancellation status	Upgrade cancellation status: ● Initial: The initialization is generally performed when the loading starts. ● Cancelling: The upgrade is being canceled. ● Successful: The upgrade is successfully canceled. ● Failed: The upgrade fails to be canceled.

Item	Description
Software download time	Time when the software package is downloaded to a device.
Software download progress(%)	Software package download progress, in percentage.
Software download speed(KB/s)	Software package download rate.
Patch download time	Time when a patch is downloaded to a device.
Patch download progress(%)	Patch download progress, in percentage.
Patch download speed(KB/s)	Patch download rate.
Last upgrade time	Last upgrade time.
Last upgrade result	Last upgrade result.
Local information	Local device information.
Device name	Device name.
ESN	Device ESN.
Software version	Software version.
Patch version	Patch version.
AP information	AP information.
Device Type	AP type.
Schedule Upgrade Information	Scheduled upgrade information.
Download time	Scheduled time when system files will be downloaded.
Download triggered	Whether system file download is triggered: ● yes: System file download is triggered. ● no: System file download is not triggered.
Download pre-check result	Result of the device status pre-check before system files are downloaded: ● failed: The check fails. ● succeeded: The check is successful.
Reboot time	Scheduled time for a reboot following an upgrade.

Item	Description
Reboot triggered	Check whether the reboot following an upgrade is triggered. ● yes: The reboot following an upgrade is triggered. ● no: The reboot following an upgrade is not triggered.
Reboot triggered result	Result of the device status pre-check before a restart is performed: ● failed: The check fails. ● succeeded: The check is successful.

2.9.3 smart-upgrade { url | https-port }

Function

The **smart-upgrade** { **url** | **https-port** } command configures the URL and HTTPS port number of a proxy server.

The **undo smart-upgrade** { **url** | **https-port** } command cancels the configured URL and HTTPS port number of a proxy server.

By default, the URL and HTTPS port number of a proxy server for connecting to a device are s.houp.huawei.com and 443, respectively.

Format

smart-upgrade { **url** *host* | **https-port** *https-port* }

undo smart-upgrade { **url** | **https-port** }

Parameters

Parameter	Description	Value
host	Specifies the URL or IP address of a proxy server.	The value is a string of 1 to 127 characters.
https-port	Specifies the HTTPS port number of a proxy server.	The value is an integer ranging from 1 to 65535.

Views

System view

Default Level

3: Management level

Usage Guidelines

When a device resides on an intranet, it cannot directly access the HOUP (s.houp.huawei.com). You can run this command to configure the URL and HTTPS port number of a proxy server, so that the device can access public networks through the proxy server.

When the device resides on a public network, it cannot directly access the HOUP (s.houp.huawei.com). You can run this command to configure s.houp.huawei.cn as the URL for connecting to the public network.

Example

Configure the URL and HTTPS port number of a proxy server.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade url 10.10.10.20
[HUAWEI] smart-upgrade https-port 10020
```

2.9.4 smart-upgrade download

Function

The **smart-upgrade download** command configures a smart upgrade-enabled switch to download the system file from the HOUP.

Format

smart-upgrade download

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the smart upgrade status of the switch or AP is displayed as **needUpdate**, you can run the **smart-upgrade download** command to configure the switch or AP to download the system file first and then run the **smart-upgrade right-now** command at the right time to implement smart upgrade.

Precautions

Resumable download is supported during system file download for smart upgrade. If the system file fails to be downloaded due to a network exception, run the **smart-upgrade download** command to enable the switch to start downloading the system file from the breakpoint.

During the smart upgrade of an AP, if the upgrade file version of the AP does not match the software version of the switch, the system displays an error message.

Example

Configure a smart upgrade-enabled switch to download the system file from the HOUP.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade download
Info: Getting version information from houp, please wait ...
Info: If you want to stop the download, please press CTRL + C.
Info: Downloading file basic-soft.cc ...
Info: Current percent is 100%.
Info: 83148260 byte(s) received in 160.618 second(s) 505.54 Kbyte(s)/sec.
Info: Downloading file basic-soft.cc.asc ...
Info: The file already exists, check whether it can be resumed from the breakpoint.
Info: The file content is inconsistent with houp, delete and re-download...
Info: Current percent is 100%.
Info: 490 byte(s) received in 0.228 second(s) 2.10 Kbyte(s)/sec.
Info: Start verifying signature ...
Info: Signature verification passed.
Info: Start set next startup file, please wait...
Info: Set next startup file basic-soft.cc successfully.
```

2.9.5 smart-upgrade enable

Function

The **smart-upgrade enable** command enables smart upgrade.

The **undo smart-upgrade enable** command disables smart upgrade.

By default, smart upgrade is disabled on a switch.

Format

smart-upgrade enable

undo smart-upgrade enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

After the **smart-upgrade enable** command is run on a switch, the switch queries the latest version information from the HOUP every 24 hours.

Prerequisites

An SSL policy has been bound to smart upgrade using the **smart-upgrade ssl-policy** command.

Follow-up Task

After smart upgrade is enabled, perform the following operations according to the actual situation:

- Run the **display smart-upgrade information** command to check details about smart upgrade.
- Run the **smart-upgrade download** command to configure the switch to download the system file from the HOUP.
- Run the **smart-upgrade right-now** command to perform a smart upgrade immediately.

Example

Enable smart upgrade.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade enable
```

2.9.6 smart-upgrade ap enable

Function

The **smart-upgrade ap enable** command enables smart upgrade for APs.

The **undo smart-upgrade ap enable** command disables smart upgrade for APs.

By default, smart upgrade is disabled for APs.

NOTE

This command is supported only on the following models:

S5731-H, S5731S-H, S5732-H, S6730-H, S6730S-H

Format

smart-upgrade ap enable

undo smart-upgrade ap enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To upgrade APs to the latest version more conveniently, you can deploy the smart upgrade function to implement one-click upgrade. After the **smart-upgrade ap enable** command is run to enable smart upgrade for APs, the switch queries the latest version information from the HOUP every 24 hours.

Prerequisites

Smart upgrade has been enabled using the **smart-upgrade enable** command.

Follow-up Task

After the smart upgrade function is enabled for APs, perform the following operations as required:

- Run the **smart-upgrade download** command to download system files.
- Run the **smart-upgrade right-now** command to perform a smart upgrade immediately.
- Run the **display smart-upgrade information** command to check details about smart upgrade.

Example

Enable smart upgrade for APs.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade ap enable
```

2.9.7 smart-upgrade right-now

Function

The **smart-upgrade right-now** command performs smart upgrade on a switch immediately.

Format

smart-upgrade right-now

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the smart upgrade status of a switch is displayed as **needUpdate**, you can run the **smart-upgrade right-now** to implement loading of and upgrade to a new software version in one-click mode.

Before this command is run, you can also run the **smart-upgrade download** command to configure the switch to download the system file from the HOUP first and then run the **smart-upgrade right-now** command at the right time to implement smart upgrade. The wait time in this method is shorter than that when the **smart-upgrade right-now** command is run.

Precautions

Switches cannot be added to or removed from a stack during smart upgrade.

Resumable download is supported during system file download for smart upgrade. If the download is interrupted due to a network exception, run the **smart-upgrade right-now** command to enable the switch to continue the download from the breakpoint.

During the smart upgrade of an AP, if the upgrade file version of the AP does not match the software version of the switch, the system displays an error message.

Example

Perform smart upgrade on a switch immediately.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade right-now
Info: Getting version information from houp, please wait ...
Info: If you want to stop the upgrade, please press CTRL + C.
Info: Downloading file basic-soft.cc ...
Info: The file already exists, check whether it can be resumed from the breakpoint.
Info: Resume from the 15728640 bytes breakpoint.
Info: Current percent is 100%.
Info: 104372996 byte(s) received in 197.329 second(s) 516.53 Kbyte(s)/sec.

2.9.8 smart-upgrade ssl-policy

Function

The **smart-upgrade ssl-policy** command binds an SSL policy to smart upgrade.

The **undo smart-upgrade ssl-policy** command unbinds an SSL policy from smart upgrade.

By default, no SSL policy is bound to smart upgrade.

Format

smart-upgrade ssl-policy *policy-name*

undo smart-upgrade ssl-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an SSL policy.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).

Views

System view

Default Level

3: Management level

Usage Guidelines

Because a switch where smart upgrade is to be enabled is connected to the HOUP using HTTPS, an SSL policy must be bound to smart upgrade for the switch to establish HTTPS connection with the HOUP before smart upgrade is enabled on the switch.

Example

Bind an SSL policy named **houp** to smart upgrade.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade ssl-policy houp
```

2.9.9 smart-upgrade schedule

Function

The **smart-upgrade schedule** command configures the scheduled smart upgrade function on a switch.

The **undo smart-upgrade schedule** command disables the scheduled smart upgrade function on a switch.

By default, the scheduled smart upgrade function is disabled on a switch.

Format

smart-upgrade schedule download at *download-time* [**reboot at** *reboot-time*]

undo smart-upgrade schedule

Parameters

Parameter	Description	Value
download at *download-time*	Specifies the time when a switch downloads system files.	The format is YYYY-MM-DD HH:MM:SS. ● YYYY indicates the year. The value is an integer in the range from 2000 to 2099. ● MM indicates the month. The value is an integer in the range from 1 to 12. ● DD indicates the day. The value is an integer in the range from 1 to 31. ● HH specifies the hour. The value is an integer in the range from 0 to 23. ● MM indicates the minute. The value is an integer in the range from 0 to 59. ● SS indicates the second. The value is an integer in the range from 0 to 59. **NOTE** The time when a switch downloads system files must be later than the current time of the switch.

Parameter	Description	Value
reboot at *reboot-time*	Specifies the time when a switch restarts after an upgrade.	The format is YYYY-MM-DD HH:MM:SS. ● YYYY indicates the year. The value is an integer in the range from 2000 to 2099. ● MM indicates the month. The value is an integer in the range from 1 to 12. ● DD indicates the day. The value is an integer in the range from 1 to 31. ● HH specifies the hour. The value is an integer in the range from 0 to 23. ● MM indicates the minute. The value is an integer in the range from 0 to 59. ● SS indicates the second. The value is an integer in the range from 0 to 59. **NOTE** ● The time when a switch restarts after an upgrade must be later than the time when the switch downloads system files. ● If you do not specify the time when a switch restarts after an upgrade, the switch only downloads system files. In this case, you need to manually restart the switch to complete the upgrade.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a switch requires a smart upgrade, you can run the **smart-upgrade schedule** command on the switch to configure it to perform a smart upgrade at an off-peak time. This configuration will prevent the upgrade from affecting services running on the switch.

Precautions

- This command takes effect only for smart upgrade of switches instead of APs.
- During a scheduled smart upgrade, if the switch fails to download system files at the scheduled time due to network problems, the switch attempts to download system files again when the scheduled restart time arrives. If the upgrade still fails, the scheduled smart upgrade fails.
- The following operations will disable the scheduled smart upgrade function:

  - Resets a switch.
  - Run the **undo smart-upgrade enable** command to disable smart upgrade.
  - Run the **smart-upgrade download** command to download system files.
  - Run the **smart-upgrade right-now** command to perform a smart upgrade immediately.
  - Download system files immediately through the web system.
  - Perform a smart upgrade immediately through the web system.

Example

Configure the scheduled smart upgrade function.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade schedule download at 2020-12-01 00:00:00
```

2.9.10 smart-upgrade verify-server disable

Function

The **smart-upgrade verify-server disable** command disables the server certificate verification function before a switch is connected to a proxy server for smart upgrade.

The **undo smart-upgrade verify-server disable** command enables the server certificate verification function before a switch is connected to a proxy server for smart upgrade.

By default, the server certificate verification function is enabled before a switch is connected to a proxy server for smart upgrade.

Format

smart-upgrade verify-server disable

undo smart-upgrade verify-server disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

When the certificate for smart upgrade is invalid or no certificate for smart upgrade is available, you can run the **smart-upgrade verify-server disable** command to temporarily disable the certificate verification function.

Although the certificate verification function is manually disabled, an SSL policy still needs to be bound to smart upgrade. Therefore, after the certificate verification function is disabled, run the **ssl policy** *policy-name* command to create an empty SSL policy and run the **smart-upgrade ssl-policy** command to bind the SSL policy to smart upgrade.

Example

Disable the function of verifying the HTTPS certificate of the server.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade verify-server disable
```

2.9.11 smart-upgrade web-prompt disable

Function

The **smart-upgrade web-prompt disable** command disables web prompt for smart upgrade.

The **undo smart-upgrade web-prompt disable** command enables web prompt for smart upgrade.

By default, web prompt for smart upgrade is enabled.

Format

smart-upgrade web-prompt disable

undo smart-upgrade web-prompt disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

By default, when smart upgrade is disabled on a switch, the web system prompts the user that this function is disabled. After smart upgrade is enabled on the switch and a new software version is available, the web system prompts the user to upgrade the switch to the new version. If such information is not required, you can run this command to disable web prompt for smart upgrade.

Example

Disable web prompt for smart upgrade.

```
<HUAWEI> system-view
[HUAWEI] smart-upgrade web-prompt disable
```

2.10 Upgrade Commands

2.10.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

2.10.2 check startup

Function

The **check startup** command checks the correctness of various resource files, including the PAF file, the patch package, the startup software, and the configuration file.

Format

check startup [**crc**] [**next**]

Parameters

Parameter	Description	Value
crc	Performs a CRC check on various resource files.	-
next	Checks various resource files used for next startup.	-

Views

User view

Default Level

1: Monitoring level

Usage Guidelines

After configuring the resource files for next startup, you can run this command to check whether the resource files are complete and whether the formats and versions of the resource files are correct.

Example

Check the correctness of the resource files.

```
<HUAWEI> check startup
Main board:
Check startup software.......ok
Check configuration file.....ok
Check PAF....................ok
Check Patch..................ok
PAF is fitted with startup software
Info: Slave board is not existing.
```

Performs a CRC check on various resource files.

```
<HUAWEI> check startup crc
Warning: This operation will take several minutes! Continue?[Y/N]:y
Check startup software CRC..................................................
ok
Info: Slave board is not existing.
```

2.10.3 display device group-speed license-usage

Function

The **display device group-speed license-usage** command displays the usage of license control items.

NOTE

This command takes effect only on the following devices that have license control items loaded:

S5732-H24UM2CC, S5732-H48UM2CC, and S5736-S24UM4XC

Format

display device group-speed license-usage

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the usage of license control items, run the **display device group-speed license-usage** command.

For details about license control items, see **License Control Items**.

Example

Display the usage of license control items.

```
<HUAWEI> display device group-speed license-usage
Slot LicenseItem      ResourceCount ResourceUsed
-----------------------------------------------
 0   1G->2.5G         4             0
     1G->5G           4             0
     1G->10G          4             3
     2.5G->5G         1             0
     2.5G->10G        1             0
     5G->10G          1             0
```

Table 2-64 Description of the **display device group-speed license-usage** command output

Item	Description
Slot	Slot ID.
LicenseItem	Control item name.
ResourceCount	Number of control Items.
ResourceUsed	Number of used control items.

2.10.4 display last startup information

Function

The **display last startup information** command displays the version of the system software used for the last startup.

Format

display last startup information slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the version of the system software used for the last startup in the MPU slot.	The value must be set according to the device configuration.

Views

All view

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display last startup information** command to check the version of the system software used for the last startup.

Precautions

- If the device is upgraded from V200R020C10SPC100 or an earlier version to V200R020C10SPC500 or a later version, because the source version does not support this command, the system displays a message "Info: The file that records information about the last startup system software is empty." after this command is executed.
- If the device version is V200R020C10SPC500 or later and the system software remains unchanged, the system displays a message "Info: The file that records information about the last startup system software is empty." after this command is executed.

Example

Display the version of the system software used for the last startup.

```
<HUAWEI> system-view
[HUAWEI] display last startup information slot 0
Startup system software : flash:/basicsoft.cc
Software version        : V200R021C01SPC100B236
Software compile time   : Oct 30 2021, 19:32:02
```

2.10.5 display license

Function

The **display license** command displays information about the license file in the system.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license [*file-name* | **verbose**]

Parameters

Parameter	Description	Value
file-name	Displays summary information about the license file with a specified file name. *file-name* supports file name association. The disk where the file resides can be automatically associated. ● Full help: All the disks of the device can be associated and displayed. ● Partial help: The related disk and file can be associated and displayed after you enter a specified character string.	The value is a string of 5 to 64 case-insensitive characters without spaces.
verbose	Displays detailed information about the current active license file.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A license file dynamically controls the availability of some features. Only one license file is active in the system. Run this command to view detailed information about the active license in the system, including license file name, version, validity period, and control item. Based on the information, you can determine whether to upgrade the system version to support more features.

Precautions

The license of an N1 software package is activated on iMaster NCE-Campus. Therefore, you cannot view the license control items of the N1 software package by running this command on the device.

On the S5732-H24UM2CC, S5732-H48UM2CC, and S5736-S24UM4XC, if these devices set up a stack and the master and non-master devices have inconsistent license control items, run the **display device group-speed license-usage** command to check the usage of license control items in the stack.

Example

Display information about the active license file of the device.

```
<HUAWEI> display license
 Active license     : flash:/LICORTF163673-554BEF51E8.dat
```

```
License state     : Trial
Revoke ticket     : No ticket

RD of Huawei Technologies Co., Ltd.

Product name      : S5700
Product version   : V200R0012

 Master board license state: Trial. The trial days remains 60 days. Apply for authentic license before the
current license expires.
```

Table 2-65 Description of the **display license** command output

Item	Description
Active license	Name and path of the active license file.

Item	Description
License state	Status of a license file: - Normal This state value indicates that a license file is working properly. If the status of the license file on the live network is not **Normal**, check the license file. - Trial – A license file enters the Trial state if the ESN does not match the device. A license file in Trial state can be used only for 60 days. To continue to use a license file after the Trial state, apply for a new license file using the correct ESN. – A temporary license file expires and enters the Trial state. To continue to use a license file after the Trial state, apply for a new license file and activate it. – A license file is revoked and enters the Trial state. To continue to use a license file after the Trial state, apply for a new license file based on the revocation code and activate it. - Demo When you activate a temporary license file, it enters the Demo state. The Demo state exists only for a demo license file used for test and deployment. A license file in Demo state allows you to use normal functions within a specified period. Before the expiration of the license file in Demo state, replace it with a commercial license file. - Emergency In emergency conditions like earthquakes, volcano explosions, and tsunamis, run the **license emergency** command to trigger a license file to enter the emergency

Item	Description
	state. The emergency state stays for seven days, and a license file can enter the emergency state three times. - Default: No license file is activated or a license file expires. If a license file enters the Default state, services will be interrupted. If you want to use services after a license file expires or becomes invalid, apply for a new license file and activate it.
Revoke ticket	License revocation code. **no ticket** indicates that the license is permanently valid.
Product name	Name of the product that runs the license.
Product version	Product version.
License Serial No	Serial number of the license file.
Creator	Creator of the file.
Created Time	Time when the file was created.
Sns End Data	SnS end date in the N1 business model. Only the following models support this field: - S5700 series: S300, S500, S5720-LI, S5720-SI, S5720-HI, S5720-EI, S5720I-SI, S5730-SI, S5730-HI, S5731-S, S5731-H, , S5732-H, S5735-L, S5735-L-I, S5735-L1, S5735-S, S5735-S-I, S5736-S - S6700 series: S6720-LI, S6720-SI, S6735-S, S6720-EI, S6720-HI, S6730-S, S6730-H,
Feature name	Feature name.
Authorize type	Authorization type. - demo: trial authorization. - comm: commercial authorization.

Item	Description
Expired date	License expiration date. **PERMANENT** indicates that the license is permanently valid. A license file enters the trial period after it expires. This does not affect services. When the trial period expires, a license file will be invalid. The services and functions under its control revert to the default values. **NOTE** You need to apply for a new license file and activate it during the trial period. After activation, the new license file replaces the one in the trial period automatically.
Trial days	Trial period of an expired license. - For a license file in the trail state, the trial period is 60 days. The value of this field is displayed as 60. - For a license file that is not in the trail state, this field is meaningless, and its value is displayed as **--**.
Item name	Name of a control item.
Item type	Type of a control item. - Function: function items controlled by a license file - Resource: resource items controlled by a license file
Value	Value of a control item. - When **Item type** displays **Function**, **Value** displays **Yes**, indicating that this function is enabled. - When **Item type** displays **Resource**, **Value** displays a specified value, indicating the maximum number of this resource item. **NOTE** This parameter is displayed in the **display license** command output.
Control value	Values supported by a control item. **NOTE** This parameter is displayed in the **display license verbose** command output.

Item	Description
Used value	Actual used value. **NOTE** This parameter is displayed in the **display license verbose** command output.
Description	Description of a control item.

2.10.6 display license esn

Function

The **display license esn** command displays the equipment serial number (ESN) used for applying a license.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license esn

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you need to use licensed resource items or function items, apply for a license file. When applying for a license, you need to provide the device ESN.

ESN is the only identifier of device components, run the **display license esn** command to display the ESN of the current device, and then use the ESN to apply a license file for the device.

The ESN of the chassis must be the same as the ESN in the license to be activated. If they are different, the license file cannot be activated.

Example

Display the ESN used for applying a license.

```
<HUAWEI> display license esn
```

```
ESN: 2102113090P0xxxxxxxx
```

Table 2-66 Description of the **display license esn** command output

Item	Description
ESN	ESN of the device.

2.10.7 display license information

Function

The **display license information** command displays license information about the master, standby, and slave switches in a stack system.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

- If the control items of the license files on the standby/slave and master switches are the same, the standby/slave switch uses its own license file and does not synchronize the license file of the master switch. You can run the **display license** command to check the license control items. An active/standby switchover has no impact on the license files loaded on the master, standby, and slave switches.
- If the control items of the license files on the standby/slave and master switches are different, the standby/slave switch synchronizes the license file of the master switch. The ESN in the synchronized license file will differ from the standby/slave switch's ESN. If so, the license changes to the Trial state and enters the trial period. After an active/standby switchover, the license on the new master switch enters the trial period. You can run the **display license**

information command on the master switch to check whether the switch's ESN is the same as the ESN in the license file.

Precautions

The **display license** command displays license information about the master switch only, whereas the **display license information** command displays license information about the master, standby, and slave switches in the stack system.

If a switch is not in a stack system, the **display license information** command displays license information about the switch only. If a stack system contains the master, standby, and slave switches, the **display license information** command displays license information about the master, standby, and slave switches.

Follow-up Procedure

If the ESN of the standby/slave switch differs from the ESN in the synchronized license file, the license enters the trial period. Apply for a new license file before the trial period expires according to the following process.

1. Run the **license revoke** command on the master switch to obtain the revocation code of the license file on the switch.
2. Run the **display esn** command on the master switch to collect ESNs of the master, standby, and slave switches.
3. Log in to license application website, and use the revocation code and ESNs of the master, standby, and slave switches to apply for a new license file for the stack system.
4. Run the **license active** *license-name* command on the master switch to activate the new license file.

Example

Display license information about the master, standby, and slave switches in a stack system.

```
<HUAWEI> display license information

Slot 0:
Current license file          : flash:/s5720-hi_slot0_full.datSynchronize from master board  : NO
Current license file esn       : 210235859810xxxxxxxx
Current slot esn              : 210235859810xxxxxxxx
License esn match with device  : YES

Slot 1:
Current license file          : flash:/s5720-hi_slot2_full.dat
Synchronize from master board  : YES
Current license file esn       : 210235859810xxxxxxxx
Current slot esn              : 210235859810xxxxxxxx
License esn match with device  : NO

Slot 2:
Current license file          : flash:/s5720-hi_slot2_full.dat
Synchronize from master board  : YES
Current license file esn       : 210235859810xxxxxxxx
Current slot esn              : 210235859810xxxxxxxx
License esn match with device  : YES
```

Table 2-67 Description of the **display license information** command output

Item	Description
Slot	Slot ID.
Current license file	Current license file.
Synchronize from master board	Whether the license file is synchronized from the master switch. For the master switch, the value is YES.
Current license file esn	ESN in the current license file.
Current slot esn	ESN of the switch.
License esn match with device	Whether the ESN in the license file matches the switch's ESN.

2.10.8 display license resource usage

Function

The **display license resource usage** command displays the usage of the resource items defined in a license file.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license resource usage

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display license resource usage** command to check the usage of the resource items defined in the license file, including the number of remaining licenses and the resource usage.

Resource usage refers to the percentage of resources used out of resources defined by the license file. For details about license control items, see **License Control Items**.

Example

Display the usage of licensed resources.

```
<HUAWEI> display license resource usage
Info: Active License on master board: flash:/LICORTF163673-554BEF51E8.dat
 FeatureName     | ConfigureItemName       | ResourceUsage

 ES5FEA1          ES5SF4512K00             0/2
 ES5FEA1          ES5SF4128K00             0/6
 ES5FEA1          ES5SWL16AP00              0/64
 ES5FEA1          ES5SWL64AP00              0/16
 ES5FEA1          ES5SWL128AP0              0/8
 ES5FEA1          ES5SWL512AP0              0/2
```

Table 2-68 Description of the display license resource usage command output

Item	Description
Active License on master board	File name and path of an active license name.
FeatureName	Name of the feature controlled by the license.
ConfigureItemName	Name of a control item.
ResourceUsage	Percentage of used resources.

2.10.9 display license revoke-ticket

Function

The **display license revoke-ticket** command displays the revocation code of the current license file of the device.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license revoke-ticket

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display license revoke-ticket** command enables you to check the revocation code of a license file that has become invalid on the device. This code proves that the current license file is invalid and is used to apply for a new license.

Precautions

This command displays information only when the license file in current device system is invalid. Otherwise, no command output is displayed.

Example

Display the revocation code of the current invalid license file.

```
<HUAWEI> display license revoke-ticket
 Info: The revoke ticket is: LIC20091103006100:27C1B773ED11D9F877855CDAEE74ABFE60E07126.
```

2.10.10 display license state

Function

The **display license state** command displays the license status on the device.

NOTE

This command takes effect only on the device that loads the license control item.

Format

display license state

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check the status of the running license, run this command. The command displays the current status of the license and the number of days before the license in this status will expire.

The system supports the following license states:

- Normal: normal license
- Demo: demonstration license
- Trial: trial license that has expired but is still valid during the trial period
- Emergency: emergency license
- Default: default license

This command helps you locate license problems and verify the license status on the device.

Prerequisites

A license file has been stored on the main control board of the device and has been activated. This ensures that valid entries are displayed after the execution of the command. If the license file is not activated, no command output is displayed.

Example

Display the status of the license on the device.

```
<HUAWEI> display license state
Info: Current license state is Trial. 60 days remain.
```

2.10.11 display module-information

Function

The **display module-information** command displays information about dynamically uploaded modules.

Format

display module-information [**verbose** | **next-startup**]

Parameters

Parameter	Description	Value
verbose	Displays detailed information about dynamically uploaded modules.	-
next-startup	Displays information about the module packages to be uploaded at the next startup.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

After modules are uploaded, you can run the **display module-information** command to check information about these modules.

Example

Display information about dynamically uploaded modules.

```
<HUAWEI> display module-information

                        Module Information
------------------------------------------------------------------------
Module     Version   InstallTime                   PackageName
------------------------------------------------------------------------
MACSEC     SPH       2011-01-16 16:39:18+00:00     s5720hi.mod

Total = 1
```

Display detailed information about dynamically uploaded modules.

```
<HUAWEI> display module-information verbose

                        Module Information
------------------------------------------------------------------------
Module     Version   InstallTime                   PackageName
------------------------------------------------------------------------
MACSEC     SPH       2011-01-16 16:39:18+00:00     s5720hi.mod

Total = 1
Board Info:

------------------------------------------------------------------------
Slot       Module         State     Count Time(YYYY-MM-DD HH:MM:SS)
------------------------------------------------------------------------
0          MACSEC         Using     1     2011-01-16 16:39:17+00:00

Total = 1
```

Table 2-69 Description of the **display module-information** command output

Item	Description
Module Information	Module information.
Module	Name of a dynamically uploaded module.
Version	Module package version.
PackageName	Module package name.
InstallTime	Time when the module package was uploaded to the memory.
Total	The **Total** field under **Module Information** displays the number of module packages that take effect. The **Total** field under **Board Info** displays the number of boards that have modules installed.

Item	Description
Board Info	Board information.
Slot	Slot ID of the board where a module resides.
State	Status of the module.
Count	Number of modules that take effect on the board.
Time(YYYY-MM-DD HH:MM:SS)	Time when the module took effect, that is, time when the current module was loaded to the current state.

Display information about the next startup modules configured in the system.

```
<HUAWEI> display module-information next-startup
Info: The result will be shown in several minutes. Please wait for a moment......

                   Next startup module packages
Total = 1
------------------------------------------------------------------------
No.  PackageName
------------------------------------------------------------------------
1    flash:/$_install_mod/s5720hi.mod
```

Table 2-70 Description of the **display module-information next-startup** command output

Item	Description
Next startup module packages	Information about module packages to be installed at the next startup.
Total	Number of module packages to be installed at the next startup.
No.	Sequence number of a module package to be installed at the next startup.
PackageName	Name of a module package to be installed at the next startup.

2.10.12 display paf

Function

The **display paf** command displays information about the product adaptive file (PAF) in the system.

Format

display paf { **all** | { **resource** | **service** } *item-name* }

Parameters

Parameter	Description	Value
all	Displays all information about the PAF file.	-
resource	Specifies the value set for a resource item in the PAF file.	-
service	Specifies the value set for a service item in the PAF file.	-
item-name	Specifies the name of a resource item or a service item.	The value is a string of 1 to 64 characters.

Views

All views

Default Level

3: Management level

Usage Guidelines

A PAF file provides only required resources and features. This command can display all the specification information about the PAF file.

Example

Display the value set for a resource item in the PAF file.

```
<HUAWEI> display paf resource PAF_LCS_NQA_SPECS_NUM_ENTRY
 PAF_LCS_NQA_SPECS_NUM_ENTRY = 1, 32, 32, 0
```

Display the value set for a service item in the PAF file.

```
<HUAWEI> display paf service PAF_LCS_IPV6_BASE_SPECS_ENABLED
 PAF_LCS_IPV6_BASE_SPECS_ENABLED = 1, 1
```

Table 2-71 Description of the display paf resource command output

Item	Description
PAF_LCS_NQA_SPECS_NUM_ENTRY	Resource item name in the PAF file.
1	Whether a resource item is controlled by a license. ● 1: yes ● 0: no

Item	Description
32	Default value of the resource item in the PAF file.
32	Maximum value of the resource item in the PAF file.
0	Minimum value of the resource item in the PAF file.

Table 2-72 Description of the display paf service command output

Item	Description
PAF_LCS_IPV6_BASE_SPECS_ENABLED	Service item name in the PAF file.
1	Whether a service item is controlled by a license. ● 1: yes ● 0: no
1	Service status. ● 1: enabled ● 0: disabled

2.10.13 display patch-information

Function

The **display patch-information** command displays information about the patch in the current system.

Format

display patch-information [**history**]

Parameters

Parameter	Description	Value
history	Displays historical information about the patch in the current system.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

After a patch is loaded or deleted, run this command to view information about the patch, including its version, name, and status.

Example

Display current information about the patch in the system.

```
<HUAWEI> display patch-information
Patch Package Name   :flash:/patch_pack.pat
Patch Package Version:V200R013SPH
The state of the patch state file is: Running
The current state is: Running

****************************************************************************
*           Information about hot patch errors is as follows:          *
****************************************************************************

    Slot            CurrentVersion
------------------------------------------------------------

No hot patch error occurs on any board.

****************************************************************************
*                The hot patch information, as follows:              *
****************************************************************************

------------------------------------------------------------
    4              BOOTLOAD      Running       1
```

Display historical information about the patch in the system.

```
<HUAWEI> display patch-information history
****************************************************************************
*                The patch command history, as follows:              *
****************************************************************************

 time(Y.M.D/HH:MM:SS)   state        size     patch-package name
 -----------------------------------------------------------------------
```

```
2014.01.29/14:07:39  Startup       827318      patch_all_pack.pat
2014.10.13/11:33:12  Running         8404      patch_all_pack1.pat
2014.10.13/10:48:36     Idle       827318      patch_all_pack2.pat
```

Table 2-73 Description of the display patch-information command output

Item	Description
Patch Package Name	Name of the patch file.
Patch Package Version	Version of the patch.
The state of the patch state file is	Status of the patch file.
The current state is	Current status of the patch.
Slot	Slot ID.
Type	Patch type. ● C: single-core patch. ● BOOTLOAD, CPLD, BOOTROOM, KERNEL, DTB, OSPKG, RAMDISK, FPGA, MCU_POE, or SUBCARD_CPLD: indicates a firmware patch. ● SEFU: multi-core patch type. ● ENP: indicates an ENP patch. (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this patch type.) ● Kernel: indicates a kernel patch. (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this patch type.) ● BIN: indicates a process patch. ● C-WMP: multi-core WMP patch. (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this patch type.) ● C-NAC: multi-core NAC patch. (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this patch type.)

Item	Description
State	Running status of the patch. ● Deactive ● Active ● Running ● Idle: no patch in the system ● Startup: indicates the Startup state after the patch to be loaded at the next startup is set. If the next state change is recorded, the current Startup state is overwritten.
Count	Number of patch units. For kernel patches, the number of kernel patches in **Active** and **Running** states is displayed.
Time(YYYY-MM-DD HH:MM:SS)	Time when the patch takes effect.
size	Size of the patch.

2.10.14 display rollback

Function

The **display rollback** { **information** \| **result** } command displays rollback information in the system.

Format

display rollback { **information** | **result** }

Parameters

Parameter	Description	Value
information	Displays version information after the system is rolled back.	-
result	Checks whether the rollback is successful.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If an error occurs during an upgrade and you need to cancel the upgrade, run the **rollback** command to roll back the system to the previous version.

- Before performing a rollback, you can run the **display rollback information** command to preview the version status after the rollback, including the system software, configuration file, and patch file used after the rollback, as well as the remaining time for the rollback function to take effect.
- After completing the rollback, you can run the **display rollback result** command to check whether the rollback is successful.

Example

Display rollback information in the system.

```
<HUAWEI> display rollback information
---------------------------------------------------------------------
MainBoard:
 Software package:        flash:/basicsoft.cc
 Configuration file:      flash:/vrpcfg201506011523.zip
 Patch file:              NULL
 Rollback remain time:    00:16:49
---------------------------------------------------------------------
```

Table 2-74 Description of the **display rollback information** command output

Item	Description
Software package	System software used after the rollback.
Configuration file	Configuration file used after the rollback. This configuration file is the backup configuration file automatically generated by the system after the upgrade. The file name is in the format of **filenameYYYYMMDDhhmm.zip**. • **filename**: indicates the name of the configuration file before the upgrade. • **YYYY**: indicates the year. • **MM**: indicates the month. • **DD**: indicates the day. • **hh**: indicates the hour. • **mm**: indicates the minute. If the file name is too long, the system automatically shortens the file name length to the required length.

Item	Description
Patch file	Patch file used after the rollback.
Rollback remain time	Remaining time for the rollback function to take effect.

Check whether the rollback is successful after the rollback is complete.

```
<HUAWEI> display rollback result
Rollback result: Success.
```

Table 2-75 Description of the **display rollback result** command output

Item	Description
Rollback result	Rollback result: • Success: The rollback is successful. • Fail: The rollback fails. If the rollback fails, the system displays specific rollback failure information: – Software rollback fail: The system software fails to be rolled back. – Configuration rollback fail: The configuration file fails to be rolled back. – Patch rollback fail: The patch file fails to be rolled back.

2.10.15 display virtual license

Function

The **display virtual license** command displays information about the virtual license file in the current system.

Format

display virtual license [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	- Specifies the slot ID if stacking is not configured. - Specifies the stack ID if stacking is configured.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The controller delivers a virtual license to perform management. You do not need to load the entity license for the switch. This facilitates the management and control of the functions related to the entity license.

You can run this command to check detailed information about the virtual license file in the current system, including the name of the virtual control item, status of the virtual license, and expiration date of the virtual license.

Example

Display information about the virtual license file on the device.

```
<HUAWEI> display virtual license

Slot 0
------------------------------------------------------------------------------
Item       Resource  License     Expired     Trial days  Item
Name         Value     Status     Date        Total       Description
------------------------------------------------------------------------------
VXLAN      1         Demo       2019-08-16  -           VXLAN Control Function
```

Table 2-76 Description of the **display virtual license** command output

Item	Description
Slot	- Specifies the slot ID if stacking is not configured. - Specifies the stack ID if stacking is configured.

Item	Description
Item Name	Name of a control item in the virtual license. VXLAN: Control over the enhanced VXLAN functions. The enhanced VXLAN functions include the distributed VXLAN gateway function and the BGP EVPN function. **NOTE** The license does not control route exchange between devices, but controls the status of the dynamic VXLAN tunnel established using BGP EVPN. If no license is loaded or the license becomes invalid, the dynamic VXLAN tunnel cannot be established using BGP EVPN.
Resource Value	Resource value of the control item.
License Status	Status of the virtual license. ● Default: By default, no virtual license is installed on a device and the dynamic VXLAN tunnel is in Down status. ● Normal: The commercial virtual license is activated. The device status is changed to Normal after the controller delivers a commercial virtual license to the device. The status can be restored to Default only through online retrieving. ● Demo: The temporary virtual license is activated. The device status is changed to Demo after the controller delivers a temporary virtual license to the device. The status can be restored to Default through online retrieving, and trial keepalive. ● Trial: The license is in keepalive status, indicating that the device status is automatically changed to trial keepalive after the validity period for the device in Demo status expires. The keepalive period is 90 days. After the keepalive period expires, the status is restored to Default and the dynamic VXLAN tunnel is in Down status.
Expired Date	Expiration date of the virtual license.
Trial days Total	Total trial period of the virtual license.
Item Description	Description of a control item in the virtual license.

2.10.16 install-module

Function

The **install-module** command installs module packages.

By default, no module package is installed.

Format

install-module *file-name* [**next-startup**]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a module package to be installed. *file-name* supports file name association. The related file can be associated and displayed after you enter a specified character string.	The value is a string of 5 to 64 case-insensitive characters without spaces.
next-startup	Specifies the name of the module package to be installed during next startup.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Software upgrade is a common method to add new services on a network. This method, however, is complex and affects services. To solve these problems, you can run the **install-module** command to install the module package of a desired function, without upgrading or powering off your device.

- Run the **install-module** *file-name* command to load a module in the module package to the device. The module directly takes effect after being loaded. If the device is in a stack, the module is loaded to all the devices in the stack, including the master, standby, and slave switches.
- Run the **install-module** *file-name* **next-startup** command to add the module package to the next startup module list. The device automatically loads the module next time it starts. Before a module package is installed dynamically, the system checks the module package validity. In the next startup module list, one module can exist in only one module package.

Precautions

- The file name extension of the module package must be .MOD, and the file must be saved in the directory **$_install_mod** on the device.
- The module package version must match the current system software version. Otherwise, the module package will fail to be installed.

- The system allows you to install up to 16 modules.

Example

Load the module package s5720hi.mod.

```
<HUAWEI> install-module s5720hi.mod
Info: Installing the module flash:/$_install_mod/s5720hi.mod..
.
Info: Succeeded in installing the module on the master board....
```

Configure the module package to be loaded during next startup.

```
<HUAWEI> install-module s5720hi.mod next-startup
Info: The result will be shown in several minutes. Please wait for a moment.....
...
Info: Succeeded in setting the next-startup module.
```

2.10.17 license active

Function

The **license active** command activates the license file saved in the storage of the device.

NOTE

This command takes effect only on the device that loads the license control item.

Format

license active *file-name*

Parameters

Parameter	Description	Value
file-name	Specifies the name of a license file. *file-name* supports file name association. The disk where the file resides can be automatically associated. ● Full help: All the disks of the device can be associated and displayed. ● Partial help: The related disk and file can be associated and displayed after you enter a specified character string.	The value is a string of 5 to 64 characters without spaces.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Change or upgrade the license file when the current license file is outdated or needs higher specifications and more features. The initial state of a license file is inactive and the license file does not take effect in the system. Run this command to activate the new or updated license file.

The **license active** command can be used to activate a license file in the following situations:

- The license needs to be activated for the first time.

  You can directly run this command to activate a license.
- The current license file needs to be updated.

  If the specifications of the new license file are lower than those of the current license file, the system displays a message asking you whether to continue. If you choose **No**, the system retains the current license file. If you choose **Yes**, the master switch activates the current license file and the system uses the new license file.

NOTICE

If the configuration items of the new license file are lower than those of the current license file, check whether the configuration items required by services exist in the new license file. If not, apply for a correct license file and activate it. Otherwise, services may be interrupted due to lack of dependent license configuration items after the board or the device is restarted.

Prerequisites

The new license file has been uploaded to the device.

Follow-up Procedure

When the system restarts, the system activates the license file that was activated last time to ensure the license files are the same before and after restart.

Precautions

- The license file must use .dat as file name extension and be saved to the default root directory in the storage of the device.
- If no path is specified, the license file in the working path is activated by default.
- If the specifications of the new license file are lower than those of the current license file (some functions are authorized in the current license file, but not

in the new license file, or the new license file allows fewer resources than the current one), the system displays a message asking you whether to continue.

- When the switch is stacked, if the ESN in the license file does not match the ESN of each stack member, activating the license file will prompt that the license file is abnormal. There is a risk that the license file will enter the grace period when the stack master changes.

Example

Activate **license.dat** in the storage of the device.

```
<HUAWEI> license active license.dat
```

Activate the license file **license.dat** in the storage of the stacked device.

```
<HUAWEI> license active license.dat
Verify license passed with minor errors:
    ESN is mismatched with node esn of slot 0.
    ESN is mismatched with node esn of slot 1.
Info: This operation maybe use the trial license instead of current licnese, may be reduce current resource or
functions. Continue?[Y/N]:y
Warning: The ESN in board is different from that in the license file, Update the license file in time.
Continue? [Y/N]y
Info: The license is being activated. Please wait for a moment.
```

2.10.18 license emergency

Function

The **license emergency** command enables the emergency state for the license.

NOTE

This command takes effect only on the device that loads the license control item.

Format

license emergency

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The system configuration is classified into maximum configuration, authorized configuration, and minimum configuration.

- In maximum configuration, the maximum number of dynamic resource items are configured. Static resource items and function items are configured according to license configuration.
- Authorization configuration means the functions and resources of the software configured on the basis of contract or special authorization. Authorized configuration depends on feature authorization of license files.
- The minimum configuration is the default configuration when no activated license file exists in the system. The minimum configuration varies according to products.

Configurations are classified to limit the bearer capability of the system in different running status.

When you run the **license emergency** command to enable the emergency state for the license, the system is free from license control. In this case, the system can run with the maximum configuration of dynamic resources and the license-defined configuration of static resources and functions. When the validity period of the emergency state expires, dynamic resources are controlled by the license again. One version is provided with three validity periods of emergency state, each lasting for seven days.

The purpose for enabling the emergency state for the GTL license is disaster tolerance. If an earthquake takes place, for example, this mechanism protects users' services from being affected.

Precautions

- The emergency state cannot be disabled manually.
- The emergency state can only be enabled three times for each license, and the license can keep in emergency state for 7 days each time.
- The next emergency state can be enabled only on the last day when the last emergency state expires.
- After the emergency state is enabled, the device provides maximum number of resource control items contained in the loaded license. The device does not provide resource control items that are not contained in the loaded license even through the emergency state is enabled.

Example

Enable the license emergency state.

```
<HUAWEI> license emergency
Warning: This operation will cause LCS into the EMERGENCY state. Continue? [Y/N]:y
Info: Emergency started cannot be stopped.
```

2.10.19 virtual-license emergency

Function

The **virtual-license emergency** command enables the emergency state of the virtual license.

Format

virtual-license emergency

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **virtual-license emergency** command to enable the emergency state of the virtual license. After the emergency state is enabled, the VXLAN and AP cloud license control items are not controlled by the virtual license. After the validity period of the emergency state expires, the VXLAN and AP cloud license control items are controlled by the license. A version provides three validity periods of the emergency state, each of which lasts for seven days.

Precautions

- The emergency state cannot be disabled manually.
- The emergency state can only be enabled three times for each license, and the license can keep in emergency state for seven days each time.

Example

Enable the emergency state of the virtual license.

```
<HUAWEI> virtual-license emergency
```

2.10.20 license revoke

Function

The **license revoke** command revokes a license file.

NOTE

This command takes effect only on the device that loads the license control item.

Format

license revoke

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

License is an authorization file. You can apply for, upgrade, or activate the license file to get corresponding user rights.

If new devices are deployed, you can purchase new licenses as needed to enable license-controlled features and functions on the devices. This reduces purchase costs. If the capacities of the existing devices need to be expanded, you can update the licenses used on the devices to enable more license-controlled features and functions.

You can upgrade a license file to:

- Add new features.
- Optimizes device performance.
- Fix bugs in the current version.

Before updating a license file, run the **license revoke** command to revoke the existing license. The system then returns a license revocation code. This code is the evidence for license invalidation and is used to apply for a new license.

NOTE

A license revocation code is a character string generated after a license file becomes invalid. You can determine that a license file is invalid based on the corresponding revocation code.

Precautions

- When the existing license is going to expire, apply for a new license, upgrade, and activate the license. If the license has expired, the service modules are disabled and services are interrupted.
- After you run the **license revoke** command, the license file enters the Trial state and cannot be activated again regardless of how long the license file will expire.

Example

Revoke the current license file.

```
<HUAWEI> license revoke
Warning: The license will enter the Trial state and will not be activated again.
 Continue?[Y/N]: y
```

2.10.21 license verify

Function

The **license verify** command verifies the license file of the device.

NOTE

This command takes effect only on the device that loads the license control item.

Format

license verify *file-name*

Parameters

Parameter	Description	Value
file-name	Specifies the name of a license file. *file-name* supports file name association. The disk where the file resides can be automatically associated. ● Full help: All the disks of the device can be associated and displayed. ● Partial help: The related disk and file can be associated and displayed after you enter a specified character string.	The value is a string of characters without spaces.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before running the **license active** command to activate a license file, verify the license file.

The result of the **license verify** command can be the following:

- Major error

  The license file cannot be activated.
- Minor error

  The license file may be unable to be activated.
- Success

  The license file can be activated.

Prerequisites

The license file has been saved on the device.

Example

Verify the license file **license.dat**.

```
<HUAWEI> license verify license.dat
Info: Verify license succeeded.
```

2.10.22 patch active all

Function

The **patch active all** command activates the patches on the current system.

By default, the loaded patches on the current system are inactive.

Format

patch active all

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If you do not specify the **active** or **run** keyword when running the **patch load** command, run the **patch active all** command to activate all the loaded patches to make them effect.

Prerequisites

Patches have been loaded using the **patch load** command.

Configuration Impact

- After a non-incremental patch is loaded and the **patch active all** command is run, the patches in the current system are activated.
- If an incremental patch is loaded and the previous patch package is running, the previous patch package is still in running state after you run the **patch active all** command. The new patch package is activated.

Follow-up Procedure

After running the **patch active all** command, use the **patch run all** command to run the activated patch.

Precautions

After you run the **patch active all** command:

- If the device is restarted, all the active patches become inactive. To reactivate the patches, run the **patch active all** command.

To make the patches become active, run the **patch active all** command again.

The active state can prevent a patch error from causing continuous faults of the system. If a patch has a bug and the patch is in the active state, restart the device to prevent the patch from taking effect.

Example

Activate all patches.

```
<HUAWEI> patch active all
```

2.10.23 patch configuration-synchronize

Function

The **patch configuration-synchronize** command synchronizes the patch configuration and patch file of the master switch to other member switches in a stack.

Format

patch configuration-synchronize

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

After you replace or add a member switch in a stack and start the new member switch, run this command to synchronize the patch configuration and patch file from the master switch if the patch file of the new member switch is incorrect.

Example

Run the following commands on the new member switch to synchronize the patch configurations and patch files to the new member switch.

```
<HUAWEI> patch configuration-synchronize
Info: Finished synchronizing the patch package file and the patch configuration.
```

2.10.24 patch deactive all

Function

The **patch deactive all** command deactivates the patches on the current system.

Format

patch deactive all

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

This command does not take effect in the current version. During the operation, if a bug is detected in a patch and the system software problem cannot be solved, run the **patch delete all** command to delete the patches in the patch area in the memory.

Example

Deactivate patches on the current system.

```
<HUAWEI> patch deactive all
Warning: This function is no longer supported in the current version.
```

2.10.25 patch delete all

Function

The **patch delete all** command deletes patches on the current system.

Format

patch delete all

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

- If you find errors in patches that have been loaded to the system, run this command to delete the patches to prevent patch errors from affecting system operating.
- Before loading a non-incremental patch, run this command to delete the existing patches (if any). Otherwise, the non-incremental patch cannot be loaded.
- After the patch is deleted, it is recommended that you restart the switch.

Example

Delete all patches.

```
<HUAWEI> patch delete all
Warning: The device needs to restart after the patch is deleted.
This will delete the patch. Are you sure? [Y/N]
```

2.10.26 patch load

Function

The **patch load** command loads the patches to the patch areas in the system.

Format

patch load *filename* **all** [**active** | **run**]

Parameters

Parameter	Description	Value
filename	Specifies the path and file name of a patch package. The path can be an absolute path or a relative path. *file-name* supports file name association. The disk where the file resides can be automatically associated. ● Full help: All the disks of the device can be associated and displayed. ● Partial help: The related disk and file can be associated and displayed after you enter a specified character string.	The value is a string of 5 to 64 case-insensitive characters without spaces. The file name must have an extension of .pat.
all	Loads the patches of all member switches in a stack.	-
active	Activates loaded patches.	-
run	Runs loaded patches.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you load a patch to the current system, the system searches the patch package for a matching patch file according to the attributes of the patch file.

- If a matching patch file is found in the patch package, the system loads the patch.
- If no matching patch file is found in the patch package, the system does not load any patch.

Prerequisites

The patch package has been uploaded to the root directory of the storage device.

Before loading a patch, the system must resolve the patch package, check the validity of the patch files in the patch package, and obtain the attributes such as the patch type and version of the patch file.

Precautions

The patch file cannot be reloaded. When you reload a patch, the system displays an error message.

After this command is run, the system loads all types of patches in the patch package.

- If the **active** parameter is specified, the system activates the loaded patches directly. Then you can use the **patch run all** command to run the patches.
- If the **run** parameter is specified, the system runs the loaded patches directly.

Example

Load the patches to the patch area of the device and run the patches directly.

```
<HUAWEI> patch load patch.pat all run
```

2.10.27 patch run all

Function

The **patch run all** command runs the patches on the current system.

Format

patch run all

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the device is restarted, the active patches become deactivated and need to be activated again. To enable the active patches to retain in running start after a device restart, use this command to run these active patches.

Prerequisites

Patches have been loaded and activated on the system.

Configuration Impact

After you run this command to run patches on the current system, the patches remain in the running state if a device restart occurs.

After the **patch run all** command is run, the patches enter running state and cannot be restored to the previous state. Confirm the action before you run the command.

Example

Run active patches on the current system.

```
<HUAWEI> patch run all
```

2.10.28 reset patch-configure

Function

The **reset patch-configure** command deletes the configuration of the patch file for next startup.

Format

reset patch-configure [**next-startup**]

Parameters

Parameter	Description	Value
next-startup	Deletes the configuration of the patch file for next startup.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After you run the **startup patch** command to specify the patch file for next startup, you can use the **reset patch-configure** command to delete the configuration.

Precautions

If you run the **reset patch-configure** command, the patch file for next startup is empty. When the device restarts, the system does not load and run the patch file.

Example

Delete the configuration of the patch file for next startup.

```
<HUAWEI> reset patch-configure next-startup
Info: The result will be shown in several minutes. Please wait for a moment.....
...
Info: Succeeded in resetting the next-startup patch state.
```

2.10.29 rollback

Function

The **rollback** command rolls back the system to the previous version.

Format

rollback

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If an error occurs during an upgrade and you need to cancel the upgrade, run the **rollback** command to roll back the system to the previous version. After the rollback, the configuration of the device is the same as the previous configuration.

Precautions

- The rollback function takes effect only for an upgrade during which the **reboot** command is run to restart the device, and does not support other upgrade modes, such as the EasyDeploy upgrade and smooth stack upgrade. If the **reboot** command is run to complete an upgrade and then the system is upgraded using another mode, you can only run the **rollback** command to roll back the system to the latest version before the upgrade during which the **reboot** command is run. For example, if you run the **reboot** command to restart the device and upgrade the system from V1.0 to V1.1, and then upgrade the system to V1.2 using EasyDeploy, the system can only be rolled back to V1.0 when you run the **rollback** command to perform a system rollback.
- If a device runs continuously for more than 48 hours after being upgraded, the rollback function does not take effect. If the device runs continuously for less than 48 hours and restarts, the system sets the remaining time to zero

and the rollback function does not take effect. You can run the **display rollback information** command to check the remaining time for the rollback function to take effect.

- If the system software, configuration file, or patch file required in the rollback is deleted using the **delete (user view)** command, the system prompts that the rollback function cannot be used when you run the **rollback** command.

NOTICE

If you run the **rollback** command to roll back the system software, the current configuration of the device will be lost. Therefore, exercise caution when deciding to run this command.

Prerequisites

The device contains the system software, configuration file, and patch file that are used after the rollback and displayed in the **display rollback information** command output.

Example

Roll back the system to the previous version.

```
<HUAWEI> rollback
Info: Checking rollback version information...
Rollback software: flash:/basicsoft.cc
Rollback configuration: flash:/vrpcfg.zip
Rollback patch: NULL
Warning: The version running before the last reboot/reboot fast operation is performed will be restored,
and the current configuration will be lost. Continue? [Y/N]:y
```

2.10.30 uninstall-module

Function

The **uninstall-module** command uninstalls module packages.

Format

uninstall-module *file-name* [**next-startup**]

uninstall-module next-startup all

Parameters

Parameter	Description	Value
file-name	Specifies the name of a module package to be uninstalled.	The value is a string of 5 to 64 case-insensitive characters without spaces.
next-startup	Clears the module list for next startup.	-

Parameter	Description	Value
all	Clears the module list for next startup.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

If some services or functions are not required, run the **uninstall-module** command to uninstall the corresponding modules running in the system.

Example

Uninstall the module package s5720hi.mod from the system.

```
<HUAWEI> uninstall-module s5720hi.mod
This will uninstall the module. Are you sure? [Y/N]y....
Info: Succeeded in uninstalling the module on the master board.
```

Clear a specified module package in the next startup module list.

```
<HUAWEI> uninstall-module s5720hi.mod next-startup
Info: The result will be shown in several minutes. Please wait for a moment.....
...
Info: Succeeded in resetting the next-startup module.
```

3 Device Management Commands

3.1 Device Status Checking Commands

3.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.1.2 check hardware health

Function

The **check hardware health** command displays health check information about the device.

Format

check hardware health [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before upgrading a device's software package, run this command to check the health check information about the device. Ensure that all check items are normal before the upgrade to prevent a device upgrade failure.

Example

Display health check information about the device.

```
<HUAWEI> check hardware health
--------------------------------------------------------------------
Hardware health information of slot 0
--------------------------------------------------------------------
Board ID                              : Normal
PCB version                           : Normal
Bom ID                                : Normal
Flash read state                      : Normal
NAND bad block check result           : Normal
Remaining space                       : Normal
NOR flash erase state                 : Normal
CPLD erase state                      : Normal
CPLD self-check                       : Normal
DDR single-bit ECC error count        : 0
Cache single-bit ECC error count      : 0
Power PWR1(CML)                       : Normal
Power PWR1(TEMPERATURE)               : Normal
Power PWR1(VIN_UV)                    : Normal
Power PWR1(IOUT_OC)                   : Normal
Power PWR1(VOUT_OV)                   : Normal
```

```
Power PWR1(OFF)                    : Normal
Power PWR1(BUSY)                   : Normal
Power PWR1(UNKNOWN)                : Normal
Power PWR1(OTHER)                  : Normal
Power PWR1(FANS)                   : Normal
Power PWR1(POWER_GOOD)             : Normal
Power PWR1(MFR)                    : Normal
Power PWR1(INPUT)                  : Normal
Power PWR1(IOUT/POUT)              : Normal
Power PWR1(VOUT)                   : Normal
Board corrosion                    : No
```

Table 3-1 Description of the **check hardware health** command output and troubleshooting methods for abnormal devices

Item	Description	Troubleshooting methods for abnormal devices
Hardware health information of slot x	Health check information about the device.	-
Board ID	Status of the Printed circuit board (PCB) check. ● Normal: The status is normal. ● Abnormal: The status is abnormal.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
PCB version	Status of the PCB version check. ● Normal: The status is normal. ● Abnormal: The status is abnormal.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
Bom ID	Status of the Bom ID check. ● Normal: The status is normal. ● Abnormal: The status is abnormal. **NOTE** This field is not available for the S6720-EI and S6720S-EI.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
Flash read state	Status of the flash read/write check. ● Normal: The status is normal. ● Abnormal: The status is abnormal.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.

Item	Description	Troubleshooting methods for abnormal devices
NAND bad block check result	Status of the bad block check of the NAND flash. ● Normal: The status is normal. ● Abnormal: The status is abnormal. **NOTE** This field is not available for the S6735-S.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
Remaining space	Status of the flash remaining space check. ● Normal: The status is normal. ● Abnormal: The status is abnormal.	1. Enter the device directory. a. If the switch has a hard disk, run the **cd hda1:** command to enter the hard disk directory. b. If the switch has a flash rather than a hard disk, run the **cd flash:** command to enter the flash directory. 2. Run the **dir** command to check the size of the remaining storage space. If the remaining space is not enough, run the **delete** command to delete unneeded files. 3. Run the **dir** command to check whether the size of the remaining storage space is greater than the size of the PDF file. ● If so, go to Step 5. ● If not, go to Step 4. 4. Collect log information and configuration information, and then contact technical support personnel. 5. End.

Item	Description	Troubleshooting methods for abnormal devices
NOR flash erase state	Status of the erase and write check of the NOR flash. - Normal: The status is normal. - Abnormal: The status is abnormal. **NOTE** This field is not available for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
CPLD erase state	Status of the CPLD erase and write check. - Normal: The status is normal. - Abnormal: The status is abnormal. **NOTE** This field is not available for the S6720-EI and S6720S-EI.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
CPLD self-check	Status of the CPLD self-check. - Normal: The status is normal. - Abnormal: The status is abnormal.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
DDR single-bit ECC error count	DDR single-bit ECC error frequency.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.
Cache single-bit ECC error count	Cache single-bit ECC error frequency.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.

Item	Description	Troubleshooting methods for abnormal devices
Power PWR1(CML)	Whether the communication of the power module is normal: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(TEMPERATURE)	Whether the temperature of the power module is abnormal: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(VIN_UV)	Whether the input voltage of the power module is below the lower threshold: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(IOUT_OC)	Whether the power module has output overcurrent: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.

Item	Description	Troubleshooting methods for abnormal devices
Power PWR1(VOUT_OV)	Whether the output voltage of the power module exceeds the upper threshold: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(OFF)	Whether the power module is powered off: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(BUSY)	Whether the power module is busy and does not respond: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(UNKNOWN)	Whether the power module status is unknown: - Normal: The status is normal. - Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.

Item	Description	Troubleshooting methods for abnormal devices
Power PWR1(OTHER)	Whether the power module is faulty due to any other reasons: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(FANS)	Whether the fan of the power module is faulty: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(POWER_GOOD)	Whether the output of the power module is normal: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(MFR)	Whether a user-defined fault occurs on the power module: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.

Item	Description	Troubleshooting methods for abnormal devices
Power PWR1(INPUT)	Whether the input of the power module is normal: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(IOUT/POUT)	Whether the output current or power of the power supply is faulty: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Power PWR1(VOUT)	Whether the output voltage of the power module is normal: ● Normal: The status is normal. ● Abnormal: The status is abnormal. If this parameter is not supported, a hyphen (-) is displayed.	If the power supply is faulty, collect alarm and configuration information, and contact technical support personnel.
Board corrosion	Whether the device is corroded. ● Yes: Corrosion occurs. ● No: Corrosion does not occur. If this parameter is not supported, a hyphen (-) is displayed.	If the device hardware is damaged, collect alarm and configuration information and contact technical support personnel.

3.1.3 display built-in power

Function

The **display built-in power** command displays the built-in power supply status of switches with extended temperature range.

NOTE

Only S5720I-28X-SI-AC and S5720I-28X-PWH-SI-AC support this command.

Format

display built-in power

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display built-in power** command to check whether the built-in power supply status of switches with extended temperature range is normal.

If some member switches do not support this command, the system displays a prompt message.

Example

Display the built-in power supply status of switches with extended temperature range.

```
<HUAWEI> display built-in power
------------------------------------------------------------
 Slot    PowerID     State
------------------------------------------------------------
 1       PWR1        Normal
         PWR2        Abnormal
 2       PWR1        Normal
         PWR2        Abnormal
------------------------------------------------------------
Info: Slot 0 does not support the command.
```

Table 3-2 Description of the **display built-in power** command output

Item	Description
Slot	Slot ID.
PowerID	Power supply ID.
State	Power supply status: - Abnormal - Normal

3.1.4 display battery information

Function

The **display battery information** command displays lithium battery information.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

display battery information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view lithium battery information.

Example

Display lithium battery information.

```
<HUAWEI> display battery information
Info: This operation may take a few seconds. Please wait for a
moment....
------------------------------------------------------------
 Lithium battery information of integrated power
------------------------------------------------------------
Battery group information
```

```
   Battery status                                 : Float charging
   Battery voltage(V)                               : 54.26
   Battery current(A)                               : 0.00
   Total battery capacity(Ah)                          : 200
   Available battery capacity(%)                         : 100.00
   Battery temperature(degC)                            : 29.47

Table 3-3 Description of the **display battery information** command output

Item	Description
Lithium battery information of integrated power	Information about the integrated lithium battery system.
Battery group information	Battery group information.
Battery status	Battery status.
Battery voltage(V)	Battery voltage, in volts (V).

Item	Description
Battery current(A)	Battery current, in amperes (A).
Total battery capacity(Ah)	Total battery capacity, in Ah.
Available battery capacity(%)	Remaining battery capacity, in percentage.
Battery temperature(degC)	Battery temperature, in °C.
Battery run time(h)	Battery backup time, in hours.
Number of connected ESMUs	Number of connected ESMUs.
Device address	Device address.
Battery SOH(%)	Battery string SOH, in percentage.
Battery capacity(Ah)	Battery capacity, in Ah.
Electrochemical cell package voltage(V)	Electrochemical cell package voltage, in volts (V).
Maximum allowable current limiting coefficient(C10)	Maximum allowable current limiting coefficient, in C10.
Electric core(1-16) voltage(V)	Voltage of electrochemical cells 1 to 16, in Volt (V).
Electric core(1-16) degree(degC)	Temperature of electrochemical cells 1 to 16, in degrees Celsius.
SoftWare version	Software version. The value is in ASCII format.

3.1.5 display chip-temperature

Function

The **display chip-temperature** command displays the temperature of chip.

Format

display chip-temperature { **all** | **slot** *slot-id* }

Parameters

Parameter	Description	Value
all	Displays the temperature of chip of all slots.	-

Parameter	Description	Value
slot *slot-id*	Displays the temperature of chip of a specified slot.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A proper temperature range is the prerequisite for stable running of switches. If the temperature of chip is too high or too low, the hardware may be damaged.

Example

Display the temperature of chips of all slots. (The actual output information may differ from the following information.)

```
<HUAWEI> display chip-temperature all
--------------------------------------------------
 Slot      Chip      Status      Current(C)
--------------------------------------------------
 0          LSW       Normal       46
           CPU       Normal       60
           PHY       Normal       52
<HUAWEI> display chip-temperature all
--------------------------------------------------
 Slot      Chip      Status      Current(C)
--------------------------------------------------
 0          LSW1       Normal       46
           LSW2       Normal       50
           CPU       Normal       60
           PHY       Normal       52
```

Table 3-4 Description of the **display chip-temperature** command output

Item	Description
Slot	Slot ID.
Chip	Type of the chip. ● CPU: indicates a CPU chip. ● LSW: indicates a forwarding chip. If there are multiple chips, they are displayed as LSW1, LSW2, ..., and so on. ● PHY: indicates a PHY chip on the backplane. ● PHY1: indicates a PHY chip on a subcard.

Item	Description
Status	Temperature status. ● Normal: The temperature is normal. ● Abnormal: The temperature is abnormal or all interfaces on the device are down.
Current(C)	Current temperature of the chip, in the centigrade scale (°C). The temperature value is displayed as an integer, so there may be a maximum of 1°C error between the displayed value and actual temperature.

3.1.6 display compatible-information

Function

The **display compatible-information** command displays compatible information of a device.

Format

display compatible-information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Generally, device versions have matching NMS software. The NMS software needs to apply to all the devices supported by matching versions. Otherwise, the NMS cannot manage devices. If the NMS version is an earlier version but the current device is running a later version that does not match the current NMS version, the NMS cannot manage the current device.

To decouple the NMS version and device version, a compatible device model developed based on an earlier version is defined for each device model. If the NMS cannot manage a device because of version mismatch, obtain information about the device compatible with the current device. The NMS can then use the obtained information to manage the current device.

For example:

S5720-SI_R10 is a device model newly available in V200R010. The NMS software version that matches the device software version is V200R010.

S5720-SI_R8 is a device model newly available in V200R008. The NMS software version that matches the device software version is V200R008.

When you use the NMS of V200R008 to manage S5720-SI_R10, the device cannot be managed because of version mismatch. The NMS then obtains compatibility information about S5720-SI_R10 and learns that it is compatible with S5720-SI_R8. Subsequently, the NMS uses information about S5720-SI_R8 to manage the current device.

If the device does not have a compatible version, the system will display a message, indicating that no compatible information exists after the **display compatible-information** command is executed.

Compatible information of stacked devices can also be displayed.

Example

Display compatible information of a device.

```
<HUAWEI> display compatible-information
SlotID              : 0
Compatible SysOids  : 1.3.6.1.4.1.2011.2.23.331
Compatible Version  : V200R008C00
ProductName         : S5720-52X-SI-AC
```

Table 3-5 Description of the display compatible-information command output

Item	Description
SlotID	The slot ID.
Compatible SysOids	System OID of an old device version.
Compatible Version	Old device version compatible with the current device version.
ProductName	Product name of new devices.

3.1.7 display cpu-usage

Function

The **display cpu-usage** command displays CPU usage statistics.

Format

display cpu-usage [**slave** | **slot** *slot-id*] [**vcpu** *vcpu-index*]

NOTE

The **slave** parameter is not supported if the switch does not support the stacking function or does not have the stacking function enabled.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **vcpu** *vcpu-index* parameter.

Parameters

Parameter	Description	Value
slave	Displays the CPU usage of slave devices in a stack. This parameter is valid only in a stack system.	-
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
vcpu *vcpu-index*	Displays the usage of a specified virtual CPU.	Specify the *vcpu-index* parameter based on the hardware configuration.

1: Monitoring level

Usage Guidelines

CPU usage is an important indicator to evaluate device performance. A high CPU usage will cause service faults, for example, BGP route flapping, frequent VRRP active/standby switchover, and even failed device login. You can use the **display cpu-usage** command to view CPU usage to check whether devices are working properly.

When the CPU usage is high, rectify the fault according to "Troubleshooting: High CPU" in ***Huawei S Series Campus Switches Troubleshooting Guide***.

Example

Display the CPU usage on the device.

```
<HUAWEI> display cpu-usage
CPU Usage Stat. Cycle: 60 (Second)
CPU Usage            : 20% Max: 99%
CPU Usage Stat. Time : 2019-10-23  10:04:45
CPU utilization for five seconds: 5%: one minute: 5%: five minutes: 5%
Max CPU Usage Stat. Time : 2019-10-21 16:14:00.

Table 3-6 Description of the **display cpu-usage** command output

Item	Description
CPU Usage Stat. Cycle	Interval for collecting CPU usage statistics. The interval is 60 seconds and cannot be configured.
CPU Usage	Average CPU usage in the last 10 seconds.
Max	Highest CPU usage in history.
CPU Usage Stat. Time	Time when the latest CPU usage statistics are collected.
CPU utilization for five seconds	CPU usage in five seconds.
one minute	CPU usage in one minute.
five minutes	CPU usage in five minutes.
Max CPU Usage Stat. Time	Time when the highest CPU usage statistics are collected.

Item	Description
TaskName	Task that is being executed. For details about all the tasks and functions of the device, see "Troubleshooting: High CPU Usage - How to Locate the High CPU Usage Problem - Determining Fault Causes According to CPU Usages of Tasks (Fixed Switches)" and "Troubleshooting: High CPU Usage - Appendix - CPU-related Tasks and Functions for Fixed Switches" in ***Huawei S Series Campus Switches Troubleshooting Guide***.
CPU	Real-time CPU usage of each task.
Runtime(CPU Tick High/Tick Low)	System running time calculated based on CPU tick.
Task Explanation	Explanation to the task.

3.1.8 display cpu-usage configuration

Function

The **display cpu-usage configuration** command displays CPU usage configuration.

Format

display cpu-usage configuration [**slave** | **slot** *slot-id*]

NOTE

The **slave** parameter is not supported if the switch does not support the stacking function or does not have the stacking function enabled.

Parameters

Parameter	Description	Value
slave	Displays CPU usage configuration of standby switches in a stack.	-
slot *slot-id*	Displays device CPU usage configuration of a specified slot ID.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays the alarm threshold and recovery threshold.

- When CPU usage reaches the alarm threshold, the system generates a CPU usage alarm.
- When CPU usage falls within the recovery threshold, the system generates a clear alarm.

Example

Display CPU usage configuration.

```
<HUAWEI> display cpu-usage configuration
The CPU usage monitor is turned on.
The current monitor cycle is 60 seconds.
The current monitor warning threshold is 95%.
The current monitor restore threshold is 80%.
```

Table 3-7 Description of the **display cpu-usage configuration** command output

Item	Description
The CPU usage monitor	Whether the CPU usage monitoring function is enabled or disabled. To enable the CPU usage monitoring function, run the **cpu-usage monitor** command.
The current monitor cycle	CPU usage monitoring period, which cannot be configured.
The current monitor warning threshold	Alarm threshold. To set the CPU usage alarm threshold, run the **cpu-usage threshold** *threshold-value* [**restore** *restore-threshold-value*] [**slot** *slot-id*] command.
The current monitor restore threshold	Alarm recovery threshold. To set the CPU usage alarm recovery threshold, run the **cpu-usage threshold** *threshold-value* [**restore** *restore-threshold-value*] [**slot** *slot-id*] command.

3.1.9 display cpu-usage history

Function

The **display cpu-usage history** command displays CPU usage statistics within a period.

Format

display cpu-usage history [**1hour** | **24hour** | **72hour**] [**slave** | **slot** *slot-id*] [**vcpu** *vcpu-index*]

NOTE

The **slave** parameter is not supported if the switch does not support the stacking function or does not have the stacking function enabled.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **vcpu** *vcpu-index* parameter.

Parameters

Parameter	Description	Value
1hour	Displays CPU usage statistics within the last one hour.	-
24hour	Displays CPU usage statistics within the last 24 hours.	-
72hour	Displays CPU usage statistics within the last 72 hours.	-
slave	Displays the CPU usage statistics of slave devices in a stack. This parameter is valid only in a stack system.	-
slot *slot-id*	Displays the CPU usage statistics of a specified slot ID.	The value varies with the device configuration.
vcpu *vcpu-index*	Displays the CPU usage statistics of a specified virtual CPU.	Specify the *vcpu-index* parameter based on the hardware configuration.

1: Monitoring level

Usage Guidelines

Usage Scenario

The system collects CPU usage statistics at a specified interval (usually 60s) and saves them in the historical record table. To check CPU usage statistics within a period, run the **display cpu-usage history** command, and the command output helps you determine whether the CPU is working properly.

In the **display cpu-usage history** command output, the x-coordinate indicates the specified period, and the y-coordinate indicates the CPU usage.

Precautions

If CPU usage is constantly higher than the upper alarm threshold (95% by default) before the feature is deployed on a large scale, check the device to troubleshoot the fault.

Example

Display CPU usage statistics within the last one hour.

```
<HUAWEI> display cpu-usage history 1hour

                    System cpu-usage last 72 hours(Per Hour)
                   * = maximum cpu-usage    H = average cpu-usage
```

Table 3-8 Description of the **display cpu-usage history** command output

Item	Description
System cpu-usage last 60 minutes(Per Min)	CPU usage statistics within the last one hour, with a step of one minute.
System cpu-usage last 24 hours(Per Halfhour)	CPU usage statistics within the last 24 hours, with a step of half an hour.
System cpu-usage last 72 hours(Per Hour)	CPU usage statistics within the last 72 hours, with a step of an hour.
* = maximum cpu-usage	Maximum CPU usage. For example, the maximum CPU usage in the first hour in the latest 72 hours is 75%.

Item	Description
H = average cpu-usage	Average CPU usage. For example, the average CPU usage in the first hour in the latest 72 hours is 5%.

3.1.10 display device

Function

The **display device** command displays the type and status of the components on a device.

Format

display device [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you need to check whether a switch is working properly, run the **display device** command to view hardware information of the components and device registration status on the switch.

This command can also display the working status of the battery or redundant power supply (RPS) used for a device.

The following product models support the use of an RPS:

- S5720-LI series: S5720-28X-LI-AC, S5720-28X-LI-DC, S5720-28X-PWR-LI-AC, S5720-52X-LI-AC, S5720-52X-LI-DC, S5720-52X-PWR-LI-AC, S5720-28X-LI-24S-AC, S5720-28X-LI-24S-DC, S5720-28X-PWH-LI-AC, S5720-52X-PWR-LI-ACF, S5720-52X-LI-48S-AC, S5720-52X-LI-48S-AC1, S5720-52X-LI-48S-DC1, S5720-52X-LI-24S-AC1 S5720-28X-PWR-LI-ACF
- S5720S-LI series: S5720S-28X-LI-24S-AC and S5720S-52X-LI-24S-AC1

Example

Display information about the components on a device (with a built-in power supply unit or power module).

```
<<HUAWEI> display device
S5720-52P-LI-AC's Device status:
Slot Sub  Type              Online    Power     Register    Status   Role
-------------------------------------------------------------------------------
0    -    S5720-52P-LI       Present   PowerOn    Registered   Normal   Master
```

Display information about components on a device (connected to an RPS).

```
<HUAWEI> display device
S5720-28X-LI-AC's Device status:
Slot  Sub  Type             Online    Power     Register    Status   Role
--------------------------------------------------------------------------------
0     -    S5720-28X-LI      Present   PowerOn    Registered   Normal   Master
         RPS              Present   PowerOn    Registered   Self-powered
```

Display information about components on a device (where ports on the device panel and ports on subcards cannot be used together).

```
<HUAWEI> display device
S6720-32C-PWH-SI-AC's Device status:
Slot Sub  Type               Online    Power    Register    Status   Role
-------------------------------------------------------------------------------
0    -    S6720-32C-PWH-SI      Present   PowerOn  Registered   Normal
Master
     1    -                  Present   PowerOn  Unregistered -       NA
     PWR1 POWER                Present   PowerOn  Registered   Normal
NA
     FAN1 FAN                  Present   PowerOn  Registered   Normal
NA
Info: Slot 0 is in the port-on-card disable mode, so subcard 1 is unavailable and unregistered.
```

Display information about the component in slot 0.

```
<HUAWEI> display device slot 0
*down: administratively down

S5720-52P-LI-AC's Device status:
Slot Sub  Type              Online    Power     Register    Status   Role
-------------------------------------------------------------------------------
0    -    S5720-52P-LI       Present   PowerOn    Registered   Normal   Master
-------------------------------------------------------------------------------
  Board Type        : S5720-52P-LI
  Board Description : 48 Ethernet 10/100/1000 ports,4 Gig SFP,AC 110/220V

```

Table 3-9 Description of the display device command output

Item	Description
Slot	Slot ID.
Sub	Card ID. The value can be: - –: indicates that the component is a device, not a card. - n: indicates a card. *n* is a digit. - FANn: indicates a fan module. *n* indicates the serial number of the fan module. - PWRn: indicates a power module . *n* indicates the serial number of the power module.
Type	Component type. A component can be a device, RPS, or a card. Subcards are classified into the front subcard, rear subcard, power subcard and fan subcard. - Front card: The command displays the PCB model of a front card. For card classification and details about different cards, see the *Hardware Description*. - Rear card: The command displays the PCB model of a rear card. For card classification and details about different cards, see the *Hardware Description*. - Fan subcards include FAN. - Power subcard is POWER. - Lead-acid battery board: PBB-12AHA Redundant power supply: RPS
Online	Whether a component is available. If the component is available, this field displays Present. If the component is unavailable, it is not displayed in the command output.
Power	Power supply status. The value can be: - PowerOn - PowerOff
Register	Whether the device is registered: - Registered: indicates that the component is registered. - Unregistered: indicates that the component is unregistered.

Item	Description
Status	Status of the component. The value can be: ● Abnormal: indicates that the component is running abnormally or the component does not match the device model. ● Normal: indicates that the component is running normally. ● WarmingUp: indicates that a subcard is performing configuration restoration. If the device is connected to an RPS power supply, the following values may be displayed: ● Non-powered: The RPS power supply is not supplying power to the local device. ● Other-powered: The RPS power supply is supplying power to another device and cannot supply power to the local device. ● Self-powered: The RPS power supply is supplying power to the local device. ● –: The RPS power supply is initializing and has not registered.
Role	Role of a component. ● In a stack, the value can be: Master: The component is the master switch. Standby: The component is the standby switch. Slave: The component is a slave switch. ● On a standalone device, this field displays Master. ● The value NA indicates a card.
Board Type	Device type.
Board Description	Device description.
Port	Number of an interface on a device.
Port Type	Type of an interface. ● If the field value contains (C), this interface is an electrical interface. ● If the field value contains (F), this interface is an optical interface.
Optic Status	Whether an optical module is available on an interface. ● Present: An optical module is present on the interface. ● Absent: No optical module is present on the interface. ● -: Optical module information cannot be obtained.

Item	Description
MDI	Medium dependent interface (MDI) type, which can be any of the following: ● Auto ● Normal ● Across If this field displays -, the MDI type of the interface cannot be obtained.
Speed (Mbps)	Interface speed.
Duplex	Duplex mode of an interface. ● Half: The interface works in half-duplex mode. ● Full: The interface works in full-duplex mode. ● -: The interface duplex mode cannot be obtained. To set the duplex mode for an interface, run the **duplex** command.
Flow-Ctrl	Flow control status on an interface. ● Disable: The flow control and received flow control is disabled on the interface. ● Enable: The flow control function is enabled on the interface. ● Receive enable: The receive flow control is enabled on the interface. ● -: The flow control status cannot be obtained. To configure flow control, run the **flow-control** or **flow-control receive** command.
Port State	Status of an interface: ● down: The interface is physically Down. ● *down: The interface is manually shut down. ● up: The interface is in Up state.
PoE State	Status of the PoE function on an interface. ● Enable: The PoE function is enabled. ● Disable: The PoE function is disabled. ● -: PoE information cannot be obtained.

3.1.11 display device mac-number

Function

The **display device mac-number** command displays the number of MAC addresses of a switch.

Format

display device mac-number [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a device ID.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

One or more MAC addresses may be configured on a switch before delivery. To check the number of MAC addresses of a switch, run the **display device mac-number** command. If the switch has multiple MAC addresses configured, the MAC addresses of Layer 3 interfaces are different from the system MAC address. If the switch has only one MAC address configured, the MAC addresses of Layer 3 interfaces are the same as the system MAC address. On a switch with one or more MAC addresses configured, the MAC addresses of Layer 2 interfaces are the same as the system MAC address.

If **slot** *slot-id* is not specified in a stack, the **display device mac-number** command displays the number of MAC addresses of the master switch.

Example

Display the number of MAC addresses.

```
<HUAWEI> display device mac-number
The number of MAC address : 1
```

Table 3-10 Description of the **display device mac-number** command output

Item	Description
The number of MAC address	Number of MAC addresses.

3.1.12 display device manufacture-info

Function

The **display device manufacture-info** command displays manufacture information about the device.

Format

display device manufacture-info [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display device manufacture-info** command to view manufacture information about the device, including the serial number and manufacture date. The command output contains information about only service subcards and does not contain information about fans and power modules.

Example

Display manufacture information about the device.

```
<HUAWEI> display device manufacture-info
Slot  Sub  Serial-number          Manu-date
- - - - - - - - - - - - - - - - - - - - - -
0     -    2102353169107C800132   2011-08-24
      1    021ESN1234567890       2000-01-01
```

Display manufacture information about devices in a stack.

```
<HUAWEI> display device manufacture-info
Slot  Sub  Serial-number          Manu-date
- - - - - - - - - - - - - - - - - - - - - -
0     -    2102353169107C800132   2011-08-24
      1    021ESN1234567890       2000-01-01
3     -    2102353170107C800132   2011-08-23
4     -    2102353170107C800132   2011-08-23
      1    020WYG1234567892       2010-12-02
8     -    2102353170107C800235   2000-01-01
```

Table 3-11 Description of the display device manufacture-info command output

Item	Description
slot	Slot ID.
Sub	Subcard number.
Serial-number	Serial number.
Manu-date	Manufacture date of the device.

3.1.13 display diagnostic-information

Function

The **display diagnostic-information** command collects and displays all the current diagnostic information or saves diagnostic information in a specified file.

Format

display diagnostic-information [**acl** | **ap** | **arp** | **bfd** | **cmng** | **decoding** | **defend** | **dhcp | engine | evpn | gpm** | **l2adp** | **l3adp** | **lbdt** | **lldp** | **mcast** | **mpls** | **qos** | **rrpp | rumng | sa** | **sdk** | **smlk** | **srm** | **sta** | **stack** | **stat** | **stp** | **ucm** | **vxlan**] [*file-name*]

NOTE

- Only the S5720I-SI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **bfd**.
- Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730S-H, S6730-S, S6730S-S, and S6730-H support **mpls**.
- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **sdk**.
- The **stack** parameter is supported on a stack only.
- Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support **ap** and **sta**.
- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vxlan** and **evpn**.

Parameters

Parameter	Description	Value
acl	Displays ACL information.	-
ap	Displays AP information.	-
arp	Displays ARP information.	-

Parameter	Description	Value
bfd	Displays BFD information.	-
cmng	Displays cloud-based management information.	-
defend	Displays attack defense information.	-
decoding	Displays decoding information.	-
dhcp	Displays DHCP information.	-
engine	Displays engine information.	-
evpn	Displays EVPN information.	-
gpm	Displays GPM information.	-
l2adp	Displays L2 information.	-
l3adp	Displays L3 information.	-
lbdt	Displays LBDT information.	-
lldp	Displays LLDP information.	-
mcast	Displays multicast information.	-
mpls	Displays MPLS information.	-
qos	Displays QoS information.	-
rrpp	Displays RRPP information.	-
sa	Displays SA information.	-
sdk	Displays sdk information.	-
smlk	Displays Smart Link information.	-
stack	Displays stack information.	-

Parameter	Description	Value
srm	Displays device information.	-
sta	Displays STA information.	-
stat	Displays basic statistic information.	-
stp	Displays STP information.	-
ucm	Displays UCM module information.	-
vxlan	Displays VXLAN module information.	-
file-name	Specifies the name of the file where diagnostic information is stored.	The value is a string of 5 to 64 characters. The file name extension must be .txt. The default directory where files are stored is flash:/.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When a fault occurs in the system, you can use the **display diagnostic-information** command to collect diagnostic information for fault location.

The **display diagnostic-information** command output includes the output for multiple **display** commands, such as **display clock**, **display version**, and **display current-configuration**. Running the **display diagnostic-information** command is like running these **display** commands in batches.

Precautions

- If the *file-name* parameter is not specified, diagnostic information is only displayed on the screen. If the *file-name* parameter is specified, diagnostic information is only stored to a specified file but not displayed on the screen, and the command level is management level (3).
- The command output does not support split-screen display.

- If this command displays a long output, press **Ctrl+C** to abort this command.
- This command displays diagnostic information, which helps locate faults but may affect system performance. For example, CPU usage may become high. Therefore, do not use this command when the system is running properly.
- Running the **display diagnostic-information** command simultaneously on multiple terminals connected to the device is prohibited. This is because CPU usage of the device may obviously increase and the device performance may be degraded.
- When you run this command, the device obtains or uses some personal data of users, such as the STA MAC address. Delete the personal data immediately after the command is executed to ensure user data security.

Example

Display diagnostic information about the device.

```
<HUAWEI> display diagnostic-information

```

3.1.14 display elabel

Function

The **display elabel** command displays the electronic label of the device.

Format

display elabel [**slot** *slot-id* [*subcard-id*]]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
subcard-id	Specifies the subcard ID the ID of power module.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Electronic labels identify the hardware. You can use the **display elabel** command to view the electronic label information.

No electronic label is displayed for an electrical interface or a combo interface working as an electrical interface.

NOTE

The electronic label version of devices delivered since V200R011 has been updated to version 4.0. This version adds the following fields compared to earlier versions:

- Model indicates the hardware external model of the device.
- ExInfo indicates the hardware extension information of the device. This field is not provided in electronic labels of optical modules.
- ElabelVersion indicates the version of the elabel.

Example

Display the electronic label of the slot 0.

```
<HUAWEI> display elabel slot 0

3.1.15 display esn

Function

The **display esn** command displays the Equipment Serial Number (ESN) of a device.

Format

display esn

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An ESN uniquely identifies a device.

In a stack, the **display esn** command displays the ESNs of all member devices.

Example

Display the ESN of the device.

```
<HUAWEI> display esn
ESN of slot 0: 21023586001xxxxxxxx
```

Table 3-13 Description of the display esn command output

Item	Description
ESN of slot 0	SN of the device with the slot ID 0.

3.1.16 display fan

Function

The **display fan** command displays the fan status.

Format

display fan [**power**]

NOTE

Only the following models support the power parameter:

S5731-H, S5731S-H, S5732-H, S5735-L, S5735S-L, S5736-S, and S6730-H

Parameters

Parameter	Description	Value
power	Indicates the fan speed of the power module.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Devices can run properly when fans are working properly. If proper heat dissipation cannot be ensured for devices, devices may overheat, damaging the hardware. You can use the **display fan** command to view the fan status.

Different device models may support different numbers of fans.

Example

Display the fan status of the device.

```
<HUAWEI> display fan
-------------------------------------------------------------------------------------------------------
 Slot  FanID   Online    Status    Speed     Mode     Airflow        Auto Min-Speed
Name
-------------------------------------------------------------------------------------------------------
 2        1   Present   Normal      34%     Auto     Front-to-Back              -   FAN-031A-
B
 2        2   Present   Normal      34%     Auto     Front-to-Back              -   FAN-031A-B
```

Table 3-14 Description of the **display fan** command output

Item	Description
Slot	Slot ID.
FAN	Number of a fan.
Online	Whether a fan is available: ● Present: available ● Absent: unavailable
Status	Running status of a fan: ● Normal: The fan is running normally. ● Abnormal: The fan works abnormally. ● -: The fan is not present.
Speed	Percentage of the current fan speed to the full speed. If this field displays -, the fan is not present or the fan works abnormally.
Mode	Working mode of a fan: ● AUTO: The fan speed can be automatically adjusted. ● MANUAL: The fan works at a fixed speed. ● -: The fan is not present or the fan works abnormally.
Airflow	Airflow direction of a fan: ● Back-to-Side: Air flows from the rear to the left and right sides. ● Side-to-Back: Air flows from the left and right sides to the rear. ● Side-to-Side: Air flows from one side to the other side. ● Front-to-Back: Air flows from the front to the rear. ● -: The fan is not present.

Item	Description
Auto Min-Speed	Minimum fan speed in automatic fan speed adjustment mode. To configure the minimum fan speed in automatic fan speed adjustment mode, run the **set fan speed auto min-speed** command. If this field displays -, this command is not supported, or the fan is not present, or the fan works abnormally.
Name	Name of a fan: **NOTE** The information is displayed only for the S5731-H, S5732-H, and S6730-H.

Display the fan speed of the power module.

```
<HUAWEI> display fan power
----------------------------------------
 Slot  FanID   Online    PowerSpeed
----------------------------------------
 1         1   Absent            -
 1         2   Present         46%
```

Table 3-15 display fan power command output

Item	Description
Speed	Fan speed of the power module.

3.1.17 display integrated-power information

Function

The **display integrated-power information** command displays information about the built-in or external power supply of an extended-temperature switch.

NOTE

This command is available only on the following switch models:

S5735-S4T2X-IA150G1, S5735-S8P2X-IA200G1, S5735-S8P2X-IA200H1, S5735-L8P4X-IA1, S5735-L8T4X-IA1

Format

display integrated-power information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command on an extended-temperature switch to check the version and working status of the built-in or external power supply.

Example

Display information about the built-in power supply of the S5735-S4T2X-IA150G1.

```
<HUAWEI> display integrated-power information

Software version	Software version.

3.1.18 display memory-usage

Function

The **display memory-usage** command displays the memory usage of the device.

Format

display memory-usage [**slave** | **slot** *slot-id*] [**vcpu** *vcpu-index*]

NOTE

The **slave** parameter is not supported if the switch does not support the stacking function or does not have the stacking function enabled.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **vcpu** *vcpu-index* parameter.

Parameters

Parameter	Description	Value
slave	Displays memory usage of a slave switch in a stack. This parameter is valid only when multiple switches form a stack.	-
slot *slot-id*	Displays memory usage of a slot ID.	The value depends on the device configuration.

Parameter	Description	Value
vcpu *vcpu-index*	Specifies the virtual CPU number.	Specify the *vcpu-index* parameter based on the hardware configuration.

1: Monitoring level

Usage Guidelines

Memory usage is an important index to evaluate device performance. A high memory usage will cause service faults. You can use the **display memory-usage** command to view memory usage to check whether devices are working properly.

The memory usage displayed using the **display memory-usage** command is based on the total available memory of a process.

Example

Display memory usage of the current device.

```
<HUAWEI> display memory-usage
 Memory utilization statistics at 2008-12-15 15:17:42+08:00
 System Total Memory Is: 394152720 bytes
 Total Memory Used Is: 130975664 bytes
 Memory Using Percentage Is: 33%
```

Display memory usage of the virtual CPU 1 in slot 0.

```
<HUAWEI> display memory-usage slot 0 vcpu 1
 Vcpu 1 Memory utilization Info:
 Memory utilization statistics at 2017-08-26 06:11:20+00:00
 System Total Memory Is: 30408904 bytes
 Total Memory Used Is: 22938332 bytes
 Memory Using Percentage Is: 75%
```

Table 3-19 Description of the **display memory-usage** command output

Item	Description
Memory utilization statistics at	Time when memory usage is collected.
System Total Memory	Total memory of the device network operating system.
Total Memory Used	Total used memory of the device network operating system.
Memory Using Percentage	Memory usage.

3.1.19 display memory-usage threshold

Function

The **display memory-usage threshold** command displays the memory usage threshold on the device.

Format

display memory-usage threshold [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the memory usage threshold of a specified slot ID.	The value depends on the device configuration.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

You can view the memory usage alarm threshold to learn about the conditions for triggering alarms.

- When memory usage reaches the alarm threshold, the system generates an alarm.
- When memory usage falls within the alarm threshold, the system generates a clear alarm.

Example

Display the memory usage threshold on the main control board.

```
<HUAWEI> display memory-usage threshold
 Current memory threshold of the main board is 95%.
```

Table 3-20 Description of the display memory-usage threshold command output

Item	Description
Current memory threshold of the main board is 95%.	The memory usage threshold of the main control board is 95%. To set the memory usage threshold of the main control board, use the **set memory-usage threshold** *threshold-value* command.

3.1.20 display power

Function

The **display power** command displays information about all power supplies on the device.

Format

display power

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the status of all power supplies, and their power.

No information is displayed for built-in power supplies.

Example

Display the current power supply status.

```
<HUAWEI> display power
-----------------------------------------------------------------------
 Slot    PowerID  Online   Mode   State      Power(W)  CurrentPower(W)
-----------------------------------------------------------------------
 0       PWRI     Present  AC     Supply      500.00          70.50
 0       PWRII    Absent   -      -               -             -
```

Table 3-21 Description of the **display power** command output

Item	Description
Slot	• Slot ID if stacking is not configured. The value is 0. • Stack ID if stacking is configured. The value must be set according to the device configuration.

Item	Description
PowerID	ID of a power supply slot: ● PWRI: slot for a power module, or lead-acid battery board ● PWRII: slot for a power module **NOTE** On the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S series switches, the power supply slots are PWR1 and PWR2. If a device has only one power supply slot, only PWR1 is displayed.
Online	Whether a power supply is installed properly. ● Present: indicates that the power supply is installed properly. ● Absent: indicates that the power supply is not installed properly, or the power supply is a fixed power supply.
Mode	Type of the power module, or lead-acid battery board: ● AC: AC power module ● DC: DC power module ● –: Power supply invalid or absent ● PBB: Lead-acid battery board
State	Working status of a power module. ● Supply: Current is output. ● NotSupply: No current is output. ● –: Invalid or absent
Power(W)	Rated power of a power supply. If this field displays –, the power supply is invalid or is not installed properly.
CurrentPower(W)	Real-time power of a power supply. If this field displays –, the power supply is not supported.

3.1.21 display system-software information

Function

The **display system-software information** command displays the software versions supported by the device.

NOTE

Only the S1730S-S1, S200, S2730S-S, S300, S500, S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S5735-L, S5735S-L, S5735-L1, S5735S-L1, S5735S-L-M, S5735-S, S5735-S-I, S5735S-S, S5735S-H, S5736-S, S6730-H, S6730-S, and S6735-S support this command.

Format

display system-software information

Parameters

None

3: Management level

Usage Guidelines

Before upgrading a device, you can run this command to check the software versions supported by the device. This helps you select a software package supported by the device. Some models cannot be downgraded due to component upgrade. Before downgrading a device, run this command to check the software versions supported by the device.

Example

Display the software versions supported by the device.

```
<HUAWEI> display system-software information
Slot 0:
Device type        : S5735S-L48T4X-A
Supported versions : V200R021C00 and later versions
```

Table 3-22 Description of the **display system-software information** command output

Item	Description
Slot	Slot ID.
Device type	Device model.

Item	Description
Supported versions	Software versions to which the device can be upgraded.

3.1.22 display software information

Function

The **display software information** command displays information about the current system software package.

Format

display software information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before upgrading a device, you can run this command to check whether the current startup software package is supported by the device.

Example

Display the software version supported by the device.

```
<HUAWEI> display software information
Startup software name      : xxxx.cc
Startup software file name : xxxx.cc
```

Table 3-23 Description of the **display software information** command output

Item	Description
Startup software name	Name of the software package supported by the device.
Startup software file name	Name of the current startup software package.

3.1.23 display transceiver

Function

The **display transceiver** command displays information about the optical module on an interface.

NOTE

The command displays only information about optical interfaces.

Format

display transceiver [**interface** *interface-type interface-number* | **slot** *slot-id*] [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
verbose	Displays detailed information about the optical module on an interface, including the general information, manufacture information, alarm information, and diagnostic information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view general information, manufacture information, and alarm information about an optical module. If you specify the **verbose** keyword, diagnostic information is also displayed in addition to the preceding information.

If a device does not support optical modules, a message will be displayed after you run this command.

Some parameters including the current and optical power will be displayed for each lane of the 40GE interfaces.

Example

Display general information, manufacture information, and alarm information about the optical module on a specified interface.

```
<HUAWEI> display transceiver interface gigabitethernet 0/0/1
GigabitEthernet0/0/1 transceiver information:
-------------------------------------------------------------
Common information:
  Transceiver Type              :1000_BASE_SX_SFP

```

Table 3-24 Description of the **display transceiver** command output

Item	Description
Common information	Generic information about the optical module.
Transceiver Type	Type of the optical module.
Connector Type	Type of the fiber connector required by the optical module. The value depends on the protocol related to the optical module.
Wavelength (nm)	Wavelength of the optical module. If this field displays -, the optical module does not have wavelength information.

Item	Description
Transfer Distance (m)	Transmission distance of the optical module. 50 um and 62.5 um are fiber diameters. Fibers with a diameter of 50 um or 62.5 um are multimode fibers. Fibers with a diameter of 9 um are single-mode fibers. For a GPS module, this field indicates the maximum length of the antenna between the GPS module and signal receiver. **NOTE** Only the maximum transmission distance of the optical module is displayed if different optical fibers are used.
Digital Diagnostic Monitoring	Whether diagnostic information about the optical module is monitored.
Vendor Name	Vendor name of the optical module. If the system has not determined whether the optical module is a Huawei-customized one, this field displays Judging. If the vendor name of an optical module is not HUAWEI, check whether the optical module is a Huawei-certified optical module. For details, see "How Can I Determine Whether an Optical Module Is Huawei-Certified?" in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Device Management – Device Status Query*.
Vendor Part Number	Vendor part number or product name. If the system has not determined whether the optical module is a Huawei-customized one, this field displays Judging.
Ordering Name	External name of the optical module. Currently, this field is not supported and is empty.
Extended information	GPS module information. Only the S5720I-SI and S5735-S-I support this item.
Longitude(°)	Longitude of the location of the GPS module. Only the S5720I-SI and S5735-S-I support this item.
Latitude(°)	Latitude of the location of the GPS module. Only the S5720I-SI and S5735-S-I support this item.
Altitude(mm)	Altitude of the location of the GPS module. Only the S5720I-SI and S5735-S-I support this item.
Manufacture information	Manufacture information of the optical module.
Manu. Serial Number	Vendor sequence number of the optical module.
Manufacturing Date	Manufacturing date of the optical module.

Item	Description
Diagnostic information	Diagnostic information about the optical module.
Temperature (°C)	Current temperature of the optical module.
Temp High Threshold (°C)	Upper temperature threshold for the optical module.
Temp Low Threshold (°C)	Lower temperature threshold for the optical module.
Voltage (V)	Current voltage of the optical module.
Volt High Threshold(V)	Upper voltage threshold for the optical module.
Volt Low Threshold(V)	Lower voltage threshold for the optical module.
Bias Current (mA)	Bias current of the optical module.
Bias High Threshold (mA)	Upper threshold for the bias current of the optical module.
Bias Low Threshold (mA)	Lower threshold for the bias current of the optical module.
RX Power (dBM)	Input power of the optical module. When the Input power is 0 W, **-Inf** is displayed.
RX Power High Warning(dBM)	Upper warning threshold for the receive power of the optical module.
RX Power Low Warning(dBM)	Lower warning threshold for the receive power of the optical module.
RX Power High Threshold (dBM)	Upper input power threshold for the optical module.
RX Power Low Threshold (dBM)	Lower input power threshold for the optical module.
TX Power (dBM)	Output power of the optical module. When the output power is 0 W, **-Inf** is displayed.
TX Power High Warning(dBM)	Upper warning threshold for the transmit power of the optical module.
TX Power Low Warning(dBM)	Lower warning threshold for the transmit power of the optical module.
TX Power High Threshold (dBM)	Upper output power threshold for the optical module.

Item	Description
TX Power Low Threshold (dBM)	Lower output power threshold for the optical module.
Transceiver phony alarm:Yes	The device has generated an alarm on an optical module not certified for Huawei switches. This field is displayed only when the following conditions are met: ● The device is enabled to generate alarms on non-Huawei-customized optical modules. This alarm function is enabled by default. If it is disabled, you can run the **undo transceiver phony-alarm-disable** command to enable it. ● This optical module is a non-Huawei-customized one.

3.1.24 display transceiver diagnosis interface

Function

The **display transceiver diagnosis interface** command displays the diagnosis parameters of an optical module.

Format

display transceiver diagnosis interface [*interface-type interface-number*]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display transceiver diagnosis interface** command to view digital diagnostic monitoring (DDM) information about optical modules installed on all interfaces of a device.

If *interface-type interface-number* is specified, only diagnostic information about the optical module installed on the specified interface is displayed.

Example

Display the diagnosis parameters of the optical module installed in GigabitEthernet0/0/4.

```
<HUAWEI> display transceiver diagnosis interface gigabitethernet 0/0/4
Port GigabitEthernet0/0/4 transceiver diagnostic information:
-------------------------------------------------------------------------------------
Item                  Value    HighAlarm     HighWarn     LowAlarm      LowWarn     Status
-------------------------------------------------------------------------------------
TxPower lane0(dBm)      0.23        7.00        4.00       -7.40       -4.40    Normal

```

NOTE

If the parameter displays **-**, the parameter value cannot be obtained. If the **Status** field displays **-**, this parameter does not support diagnosis.

Table 3-25 Description of the **display transceiver diagnosis interface** command output

Item	Description
Item	Parameter type.
Value	Real-time value of a parameter.
HighAlarm	Upper alarm threshold.
HighWarn	Upper warning threshold.
LowAlarm	Lower alarm threshold.
LowWarn	Lower warning threshold.

Item	Description
Status	Parameter value status: - **Normal**: indicates that the current value is within the normal range, that is, the current value does not exceed the upper alarm threshold or fall below the lower upper alarm threshold. - **Abnormal**: indicates that the current value is not within the normal range.
TxPower lane0(dBm) TxPower lane1(dBm)	Transmit power of an optical module. lane*i* indicates a physical channel. If an optical module has multiple physical channels, this parameter is displayed multiple times.
RxPower lane0(dBm) RxPower lane1(dBm)	Indicates the receiving power of the optical module, in dBm.lane*i* indicates a physical channel. If an optical module has multiple physical channels, this parameter is displayed multiple times.
Current lane0(mA) Current lane1(mA)	Indicates the current of the optical module, in mA. lane*i* indicates a physical channel. If an optical module has multiple physical channels, this parameter is displayed multiple times.
Temperature(C)	Indicates the temperature of the optical module, in degree Celsius.
Voltage(V)	Indicates the voltage of the optical module, in V.
LaserTemp(C)	Laser temperature of an optical module. If an optical module has multiple channels, this parameter is displayed for multiple times for lane 0, lane 1, and so on.
TecCurrent(mA)	Indicates the tec current of the optical module.If an optical module has multiple channels, this parameter is displayed for multiple times for lane 0, lane 1, and so on.
MediaSNR(dB)	Indicates the media SNR of the optical module. If an optical module has multiple channels, this parameter is displayed for multiple times for lane 0, lane 1, and so on.
Ber	BER of an optical module. If an optical module has multiple channels, this parameter is displayed for multiple times for lane 0, lane 1, and so on.
Fer	FER of an optical module. If an optical module has multiple channels, this parameter is displayed for multiple times for lane 0, lane 1, and so on.
Minimum	Minimum BER and FER of an optical module.

Item	Description
Maximum	Maximum BER and FER of an optical module.
Average	Average BER and FER of an optical module.
Current	Real-time BER and FER of an optical module.
PriorPeriod	BER and FER of an optical module in the previous period.

3.1.25 display temperature

Function

The **display temperature** command displays the working status temperature information of the device's internal components.

Format

display temperature { **all** | **slot** *slot-id* }

Parameters

Parameter	Description	Value
all	Displays the working status temperature information of internal components in all slots on the device.	-
slot *slot-id*	Displays the working status temperature information of internal components on the specified slot.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A high or low device temperature may damage the hardware. This command displays the working status temperature information of internal components instead of the operating temperature that indicates the temperature range of the surrounding environment. When the device temperature exceeds the upper threshold or falls below the lower threshold, the device generates an alarm to alert you that the device temperature is abnormal.

Example

Display the working status temperature information of internal components in all slots.

```
<HUAWEI> display temperature all
-------------------------------------------------------------------------------
 Slot  Card  Sensor Status    Current(C) Lower(C) Lower     Upper(C) Upper
                                          Resume(C)         Resume(C)
-------------------------------------------------------------------------------
0     NA    NA     Normal          44        0        4       72        68
```

Table 3-26 Description of the **display temperature** command output

Item	Description
Slot	Slot ID.
Card	Subcard ID. This field is invalid on the device and displays NA.
Sensor	Number of a sensor on a card. This field is invalid on the device and displays NA.
Status	Temperature status of a device. ● Normal: The device temperature is within the normal range. ● Abnormal: The device temperature is out of the normal range.
Current(C)	Working status temperature information of internal components of a device, expressed in the centigrade scale (°C). The temperature value is displayed as an integer, so there may be a maximum of 1°C error between the displayed value and actual temperature. This field displays - when the sensor is abnormal or the obtained temperature is higher than 200°C or lower than 100°C.
Lower(C)	Low-temperature alarm threshold, expressed in the centigrade scale (°C). To set the low-temperature alarm threshold, run the **temperature threshold** command.
Lower Resume(C)	Low-temperature alarm clear threshold, expressed in the centigrade scale (°C). To set the low-temperature alarm clear threshold, run the **temperature threshold** command. The low-temperature alarm clear threshold is 4°C higher than the low-temperature alarm threshold.

Item	Description
Upper(C)	High-temperature alarm threshold, expressed in the centigrade scale (°C). To set the high-temperature alarm threshold, run the **temperature threshold** command. On the devices that support fan speed adjustment using the **set fan speed-adjust threshold minus** command, the default value of this field changes based on the PoE power load.
Upper Resume(C)	High-temperature alarm clear threshold, expressed in the centigrade scale (°C). To set the high-temperature alarm clear threshold, run the **temperature threshold** command. The high-temperature alarm clear threshold is 4°C lower than the high-temperature alarm threshold.

3.1.26 display version

Function

The **display version** command displays the device version.

Format

display version [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display version** command to view the device version to determine whether the device needs to be upgraded.

Example

Display the device version.

```

Table 3-27 Description of the display version command output

Item	Description
Huawei Versatile Routing Platform Software	-
VRP (R) software, Version	Versions of the VRP and the software of the device.
Copyright (C) 2000-2020 HUAWEI TECH Co., Ltd.	Huawei copyright.
Routing Switch uptime	System power-on time.
ES5D2S50Q002 1(Master) : uptime	Hardware type, role, and startup time of the device. **NOTE** The names in the instance are taken as an example.
DDR Memory Size	Device's physical memory capacity, which stores data when the program is running. The **System Total Memory** field value displayed using the **display memory-usage** command is part of the physical memory capacity and varies depending on the device model.
FLASH Total Memory Size	Total size of the flash memory.
FLASH Available Memory Size	Available flash memory size. This value is the **total** field value displayed using the **dir** command divided by 1024.
Pcb Version	Version of the printed circuit board (PCB).
MAB Version	MAB version information.
BootROM Version	Version of the BootROM software.
BootLoad Version	Version of the BootLoad software.
CPLD Version	Version of the complex programmable logic device (CPLD).

Item	Description
MCU Version	Micro Control Unit (MCU) version. **NOTE** The information is displayed only for the S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720-16X-PWH-LI-AC, S5720-28X-PWH-LI-AC, and the PoE devices of S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5731-H, S5731-S, S5731S-S, S5732-H, S5735S-H, and S5736-S.
Software Version	Versions of the VRP and the software of the device.
FLASH Version	Version of the flash memory.
Power Version	Firmware version of the power module. **NOTE** The information is displayed only for the PoE devices of S5735-S-I.
CARD1 information	Information about a front card. If no front card is available, this field is not displayed.
CARD2 information	Information about a rear card. If no rear card is available, this field is not displayed.
FAN1 information	Information about a pluggable fan module. If no pluggable fan module is available, this field is not displayed. If a pluggable fan module does not have an electronic label, its PCB version is displayed as NA.
PWR2 information	Information about a pluggable power module. If no pluggable power module is available, this field is not displayed. If a pluggable power module does not have an electronic label, its PCB version is displayed as NA.
RPS Version	RPS management software version. If the device does not support RPS, this information is not displayed.

3.2 Hardware Configuration Commands

3.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.2.2 assign resource-mode

Function

The **assign resource-mode** command configures the resource allocation mode of the device.

The **undo assign resource-mode** command restores the default resource allocation mode of the device.

By default, the resource allocation mode of the S5731-H, S5731S-H, S500, S5735-S, S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735S-S, S5735-L-I, S5735-L1,S5735S-L1, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6730-H, S6730S-H, S6735-S, S6720-EI, and S6720S-EI is enhanced-arp.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S500, S5735-S, S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735S-S, S5735-L-I, S5735-L1,S5735S-L1, S6730-S, S6730S-S, S6730-H, S6730S-H, S6735-S, S6720-EI, and S6720S-EI support this command.

Format

assign resource-mode { **enhanced-mac** | **enhanced-arp** | **enhanced-ipv4** | **ipv4-ipv6 6:1** | **super-arp** } [**slot** *slot-id* | **all**] (S6720-EI and S6720S-EI)

assign resource-mode { **enhanced-mac** | **enhanced-arp** | **enhanced-ipv4** | **super-arp** } [**slot** *slot-id* | **all**] (S6735-S)

assign resource-mode { **enhanced-arp** | **enhanced-sac** | **enhanced-sipfpm** | **eca** | **sac** } [**slot** *slot-id* | **all**] (S5731-H, S5731S-H, S5731-S, and S5731S-S)

assign resource-mode { **enhanced-arp** | **enhanced-sac** | **enhanced-sipfpm** | **sac** } [**slot** *slot-id* | **all**] (S6730-S, S6730S-S, and S5732-H)

assign resource-mode { **enhanced-mac** | **enhanced-arp** | **enhanced-fib** | **enhanced-sac** | **sac** | **enhanced-sipfpm** } [**slot** *slot-id* | **all**] (S6730-H and S6730S-H)

assign resource-mode { **enhanced-mac** | **enhanced-arp** } **global** (S500, S5735-S, S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735S-S, S5735-L-I, S5735-L1,and S5735S-L1)

undo assign resource-mode global (S500, S5735-S, S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735S-S, S5735-L-I, S5735-L1,and S5735S-L1)

undo assign resource-mode [**slot** *slot-id* | **all**]

Parameters

Parameter	Description	Value
enhanced-mac	Sets the resource allocation mode to enhanced-mac.	-

Parameter	Description	Value
enhanced-ipv4	Sets the resource allocation mode to enhanced-ipv4.	-
enhanced-ipv6	Sets the resource allocation mode to enhanced-ipv6.	-
enhanced-arp	Sets the resource allocation mode to enhanced-arp.	-
enhanced-fib	Sets the resource allocation mode to enhanced-fib.	-
enhanced-sac	Sets the resource allocation mode to enhanced-sac.	-
enhanced-sipfpm	Sets the resource allocation mode to enhanced-sipfpm.	-
ipv4-ipv6 6:1	Sets the resource allocation mode to ipv4-ipv6 6:1.	-
super-arp	Sets the resource allocation mode to super-arp.	-
eca	Sets the resource allocation mode to eca.	-
sac	Sets the resource allocation mode to sac.	-
slot *slot-id*	● Specifies a slot ID on a standalone switch where stacking is not enabled. ● Specifies a stack ID in a stack.	In a stack, the value is an integer and must be set according to the configuration in the stack. On a standalone switch where stacking is not enabled, the default value is 0.
all	Configures a resource allocation mode for all devices that are present in slots.	-

Parameter	Description	Value
global	Configures the resource allocation mode of the system.	-

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a device's MAC address entries, FIB entries, or ARP entries are insufficient to meet service requirements, you can use this command to change the resource allocation mode so as to extend the entry space.

Precautions

- The configured resource allocation mode takes effect only after the configuration is saved and the device is restarted. To view the resource allocation modes that take effect currently and take effect after the device restarts, run the **display resource-mode configuration** command.
- The requirements for different entry spaces will change when service configuration is adjusted. In this case, you can change the resource allocation mode to meet the new service requirements. Subsequently, entry spaces in different resource allocation modes will change. Therefore, before changing the resource allocation mode, consider the benefit and loss that the new mode will bring.
- In versions earlier than V200R012C00, the resource allocation mode used by the device is recorded in only the flash memory but not the configuration file. In V200R012C00 and later versions, the resource allocation mode used by the device is recorded in both the flash memory and configuration file. If the resource allocation mode used by the device is not the default mode, and the **save** command is executed to save the configuration after the device is upgraded to V200R012C00 or later, the corresponding configuration is added to the configuration file.
- In a stack, member switches synchronize MAC addresses with each other. Therefore, the MAC address specifications of the stack are not the sum of MAC address specifications of multiple member switches.
  - If member switches have the same MAC address specifications, the MAC address specifications of the stack are those of any member switch.
  - If member switches have different MAC address specifications, when uplink and downlink traffic is forwarded by the same member switch, the MAC address specifications of the stack are those of the member switch. When uplink and downlink traffic is forwarded across member switches,

the MAC address specifications of the stack are those of the member switch with smaller MAC address specifications.

When the resource allocation mode of the following models is changed, the specifications of MAC, FIB, ARP, ND, or multicast entries will be modified.

Table 3-28 Number of entries supported in different resource allocation modes on the S5731-H and S5731S-H

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp	288K	512K(share)	64K(share)	128K(share)	64K(share)	16K(share)	16K(share)	10000
enhanced-sac	288K	512K(share)	64K(share)	128K(share)	64K(share)	16K(share)	16K(share)	10000
enhanced-sipfpm	288K	512K(share)	64K(share)	128K(share)	64K(share)	16K(share)	16K(share)	10000
eca	288K	512K(share)	64K(share)	128K(share)	64K(share)	16K(share)	16K(share)	10000
sac	288K	512K(share)	64K(share)	128K(share)	64K(share)	16K(share)	16K(share)	10000

NOTE

On the S5731-H and S5731S-H, when the resource allocation mode is set to **enhanced-sipfpm**, the specifications of MAC, FIB, ARP, ND, and multicast entries will not be modified, and NetStream aggregation flows cannot be configured.

Table 3-29 Number of entries supported in different resource allocation modes on the S5731-S and S5731-S-S

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp	64K	32K	8K	16K	8K	1K	1K	10000

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-sac	64K	32K	8K	16K	8K	1K	1K	10000
enhanced-sipfpm	64K	16K 32K	8K	16K	8K	1K	1K	10000
eca	64K	32K	8K	16K	8K	1K	1K	10000
sac	64K	32K	8K	16K	8K	1K	1K	10000

NOTE

On the S5731-S and S5731-S-S, when the resource allocation mode is set to **enhanced-sipfpm**, the specifications of MAC, FIB, ARP, ND, and multicast entries will not be modified, and NetStream aggregation flows cannot be configured.

Table 3-30 Number of entries supported in different resource allocation modes on the S5732-H

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp (default)	128K	192K (shared)	80K (shared)	140K (shared)	80K (shared)	64K-1 (shared)	4K	10000
sac	96K	192K (shared)	80K (shared)	96K (shared)	80K (shared)	64K-1 (shared)	4K	10000
enhanced-sac	96K	64K(Share)	24K(Share)	96K(Share)	80K(Share)	20(Share)	4K	10000

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-sipfpm	32K	128K(Share)	64K(Share)	128K(Share)	64K(Share)	4K(Share)	4K	10000

NOTE

On the S5732-H, IPv4 FIB, IPv6 FIB, ARP, ND, and Multicast IPv4 share hardware resources. The specifications listed in the preceding table indicate the maximum number of entries of a single type and cannot reach the maximum value simultaneously.

Table 3-31 Number of entries supported in different resource allocation modes on the S500, S5735-S, and S5735S-S

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp(Default)	16512	8192	3072	8180(share)	3072(share)	1500(Share)	1500(Share)	N/A
enhanced-mac	32896(Share)	128	64	128(share)	64(share)	128	64(Share with Multicast Ipv4)	N/A

Table 3-32 Number of entries supported in different resource allocation modes on the S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735-L-I, S5735-L1,and S5735S-L1

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp(Default)	16512	4096	1024	4096	1024	1500	1500	N/A
enhanced-mac	32896(Share)	128	64	128(share)	64(share)	128	64(Share with Multicast Ipv4)	N/A

Table 3-33 Number of entries supported in different resource allocation modes on the S6720-EI and S6720S-EI

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB (0-64 Bits Mask)	IPv6 FIB (Over 64 Bits Mask)	ARP	ND	Multicast IPv4 &IPv6	Number of NAC Users
enhanced-arp (default)	160K	12K	6K (shared with IPv4 FIB)	1K	48K	44K (shared with ARP)	4000	2K
enhanced-mac	288K	12K	6K (shared with IPv4 FIB)	1K	16K	8K (shared with ARP)	4000	2K
enhanced-ipv4	32K	256000	128K (shared with IPv4 FIB)	0K	16K	8K (shared with ARP)	4000	2K
ipv4-ipv6 6:1	32K	64K	10K	10K	16K	8K (shared with ARP)	4000	2K

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB (0-64 Bits Mask)	IPv6 FIB (Over 64 Bits Mask)	ARP	ND	Multicast IPv4 &IPv6	Number of NAC Users
super-arp	96K	12K	6K (shared with IPv4 FIB)	1K	128K	48K (shared with ARP)	4000	2K

NOTE

- On the S6720-EI and S6720S-EI, ARP and ND share hardware resources. The value listed in the preceding table indicates the maximum number of entries of a single type. Numbers of the two types of entries cannot reach the maximum value simultaneously.
- When the S6720-EI and S6720S-EI work in enhanced-arp, enhanced-mac, enhanced-ipv4, or super-arp mode, IPv4 FIB and IPv6 FIB (0-64 bits mask) share hardware resources. The value listed in the preceding table indicates the maximum number of FIB entries of a single type. Numbers of the two types of FIB entries cannot reach the maximum value simultaneously.
- When the S6720-EI and S6720S-EI work in ipv4-ipv6 6:1 mode, IPv6 FIB (0-64 bits mask) and IPv6 FIB (over 64 bits mask) share hardware resources. The value listed in the preceding table indicates the maximum number of FIB entries of a single type. Numbers of the two types of FIB entries cannot reach the maximum value simultaneously.
- On the S6720-EI and S6720S-EI, if the **assign resource-mode** command sets the resource allocation mode to enhanced-ipv4 or ipv4-ipv6 6:1, and the **ipv4 destination-unreachable drop** or **ipv6 destination-unreachable drop** command has been executed, the function that dropping the packets that do not match routing entries does not take effect.
- On the S6720-EI and S6720S-EI, redirection to a low-priority next hop is not supported in enhanced-ipv4 or ipv4-ipv6 6:1 resource allocation mode.
- On the S6720-EI and S6720S-EI, MPLS and Layer 3 VXLAN Gateway are not supported in super-arp resource allocation mode.

Table 3-34 Number of entries supported in different resource allocation modes on the S6735-S

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB (0-64 Bits Mask)	IPv6 FIB (Over 64 Bits Mask)	ARP	ND	Multicast IPv4 &IPv6	Number of NAC Users
enhanced-arp (default)	160K	12K	6K (shared with IPv4 FIB)	1K	48K	44K (shared with ARP)	4000	2K

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB (0-64 Bits Mask)	IPv6 FIB (Over 64 Bits Mask)	ARP	ND	Multicast IPv4 &IPv6	Number of NAC Users
enhanced-mac	288K	12K	6K (shared with IPv4 FIB)	1K	16K	8K (shared with ARP)	4000	2K
enhanced-ipv4	32K	256000	128K (shared with IPv4 FIB)	0K	16K	8K (shared with ARP)	4000	2K
super-arp	96K	12K	6K (shared with IPv4 FIB)	1K	128K	48K (shared with ARP)	4000	2K

NOTE

- On the S6735-S, ARP and ND share hardware resources. The value listed in the preceding table indicates the maximum number of entries of a single type. Numbers of the two types of entries cannot reach the maximum value simultaneously.
- When the S6735-S works in enhanced-arp, enhanced-mac, enhanced-ipv4, or super-arp mode, IPv4 FIB and IPv6 FIB (0-64 bits mask) share hardware resources. The value listed in the preceding table indicates the maximum number of FIB entries of a single type. Numbers of the two types of FIB entries cannot reach the maximum value simultaneously.
- On the S6735-S, if the **assign resource-mode** command sets the resource allocation mode to enhanced-ipv4, and the **ipv4 destination-unreachable drop** or **ipv6 destination-unreachable drop** command has been executed, the function that dropping the packets that do not match routing entries does not take effect.
- On the S6735-S, redirection to a low-priority next hop is not supported in enhanced-ipv4 resource allocation mode.
- On the S6735-S, MPLS and Layer 3 VXLAN Gateway are not supported in super-arp resource allocation mode.

Table 3-35 Number of entries supported in different resource allocation modes on the S6730-S and S6730S-S

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp(Default)	64K	64K	32K	64K	32K	4K	4K	N/A
enhanced-sac	64K	64K	32K	64K	32K	4K	4K	N/A
enhanced-sipfpm	64K	64K	32K	64K	32K	4K	4K	N/A

NOTE

On the S6730-S and S6730S-S, when the resource allocation mode is set to **sac**, **enhanced-sipfpm**, or **enhanced-sac**, the specifications of MAC, FIB, ARP, ND, and multicast entries will not be modified.

Table 3-36 Number of entries supported in different resource allocation modes on the S6730-H and S6730S-H

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-arp (default)	128K	192K (shared)	80K (shared)	140K (shared)	80K (shared)	64K-1 (shared)	4K	10000
enhanced-mac	384K	32K	8K	32K (shared with FIBv4)	8K (shared with FIBv6)	4K	4K	8K
enhanced-fib	32K	256K (shared)	80K (shared)	128K (shared)	80K (shared)	4K	4K	8K

Resource Allocation Mode	MAC	IPv4 FIB	IPv6 FIB	ARP	ND	Multicast IPv4	Multicast IPv6	Number of NAC Users
enhanced-sac	96K	148K(Share)	80K(Share)	96K(Share)	80K(Share)	64K-1(Share)	4K	10000
sac	96K	192K (shared)	80K (shared)	96K (shared)	80K (shared)	64K-1 (shared)	4K	10000
enhanced-sipfpm	32K	128K(Share)	64K(Share)	128 K(Share)	64K(Share)	4K	4K	8K

NOTE

On the S6730-H and S6730S-H, the value listed in the preceding table indicates the maximum number of entries of a single type. Numbers of the two types of entries cannot reach the maximum value simultaneously. For example, ARP and FIBv4 share hardware resources, while ND and FIBv6 share hardware resources.

Example

Set the resource allocation mode to enhanced-ipv4.

```
<HUAWEI> system-view
[HUAWEI] assign resource-mode enhanced-ipv4
Info: It is executing, please wait...
Info: The resource mode in slot 0 has been set to enhanced-ipv4
successfully.
Warning: It will take effect after rebooting this device.
```

3.2.3 backup elabel

Function

The **backup elabel** command backs up electronic labels of the device to the flash memory. The default file name format is elabel-slot*slotid*.fls, for example, elabel-slot0.fls.

The **backup elabel ftp** command backs up electronic labels of the device to a specified FTP server.

The **backup elabel sftp** command backs up electronic labels of the device to a specified SFTP server.

Format

backup elabel [**slot** *slot-id* [*subcard-id*]]

backup elabel ftp *ftp-server-address filename username password* [**slot** *slot-id* [*subcard-id*]]

backup elabel sftp *sftp-server-address filename username password* [**slot** *slot-id* [*subcard-id*]]

Parameters

Parameter	Description	Value
ftp-server-address	Specifies the IP address of the FTP server that stores electronic labels.	The value is in dotted decimal notation.
sftp-server-address	Specifies the IP address of the SFTP server that stores electronic labels.	The value is in dotted decimal notation.
filename	Specifies the name of the file that stores electronic labels.	The value is a string of 5 to 28 case-sensitive characters without spaces, in the format of elabel-slot*slotid*.fls, for example, elabel-slot0.fls.
username	Specifies the user name used to log in to the FTP or SFTP server.	The value is a string of 1 to 64 case-sensitive characters without spaces.
password	Specifies the password used to log in to the FTP or SFTP server.	The value is a string of 1 to 16 case-sensitive characters without spaces.
slot *slot-id*	Specifies the slot ID.	The value must be set according to the device configuration.
subcard-id	Specifies the subcard ID.	The value must be set according to the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

When electronic labels are stored on a device, run the **backup elabel** command to save electronic labels to a file. This file can be saved to the flash memory, to the

FTP or SFTP server using FTP or SFTP. FTP cannot ensure secure file transfer. SFTP is recommended on networks that require high security.

Example

Save electronic labels of the device to the **elabel-slot0.fls** file in the flash memory.

```
<HUAWEI> backup elabel slot 0
Info: Output information to file: flash:/elabel-slot0.fls. Please wait for a mom
ent...

Info: Put file to flash successfully.
```

Save electronic labels of the device to FTP server 192.168.12.91. Set the FTP user name to **user** and password to **123**. Save electronic labels in the **elabel-slot0.fls** file.

```
<HUAWEI> backup elabel ftp 192.168.12.91 elabel-slot0.fls user 123
Warning: FTP is not a secure protocol, and it is recommended to use SFTP.
Info: It is executing, please wait...

Info: Put file to FTP server successfully.
```

Save electronic labels of the device to SFTP server 192.168.12.91. Set the SFTP user name to **client001** and password to YsHsjx_202206. Save electronic labels in the **elabel-slot0.fls** file.

```
<HUAWEI> backup elabel sftp 192.168.12.91 elabel-slot0.fls client001 YsHsjx_202206
Info: It is executing, please wait...

Info: Put file to SFTP server successfully.
```

3.2.4 cpu-usage monitor

Function

The **cpu-usage monitor** command enables the CPU usage monitoring.

The **undo cpu-usage monitor** command disables the monitoring function.

By default, the CPU usage monitoring is enabled.

Format

cpu-usage monitor [{ **slot** *slot-id* } | **slave**]

undo cpu-usage monitor [{ **slot** *slot-id* } | **slave**]

NOTE

Devices that do not support the stack function or do not have the stack function enabled do not support the **slave** parameter.

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
slave	Indicates information about the CPU usage of the slave device. This Parameter is invalid.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

If you want to check the status and performance of the device, run the **cpu-usage monitor** command to enable the CPU usage monitoring, and then run the **display cpu-usage** command to check information about the CPU usage.

Example

Enable the CPU usage monitoring.

```
<HUAWEI> system-view
[HUAWEI] cpu-usage monitor
```

3.2.5 cpu-usage threshold

Function

Using the **cpu-usage threshold** command, you can set the alarm threshold and alarm recovery threshold of CPU usage.

Using the **undo cpu-usage threshold** command, you can restore the alarm threshold and alarm recovery threshold of CPU usage.

By default, the alarm threshold of CPU usage is 95% and alarm recovery threshold is 80%.

Format

cpu-usage threshold *threshold-value* [**restore** *restore-threshold-value*] [**slot** *slot-id*]

undo cpu-usage threshold [*threshold-value* [**restore** [*restore-threshold-value*]]] [**slot** *slot-id*]

Parameters

Parameter	Description	Value
threshold *threshold-value*	Specifies the alarm threshold of CPU usage.	The value is an integer that ranges from 2 to 100. The default value is 95.
restore *restore-threshold-value*	Specifies the alarm recovery threshold of CPU usage.	The value is an integer that ranges from 1 to 99. The alarm recovery threshold must be smaller than the alarm threshold.
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

When the CPU usage exceeds the alarm threshold, a log is recorded. When the CPU usage reduces by equal to or smaller than 5% and exceeds the threshold again, no log is recorded. A log is recorded only when the CPU usage is reduced by greater than 5% and reaches the threshold again. Through log information, you can know the CPU usage more conveniently.

If **slot** *slot-id* is not configured, the alarm threshold and alarm recovery threshold of CPU usage are set. In addition, the system automatically synchronizes the threshold on the master switch with those on the member switches.

Example

Set the alarm threshold of CPU usage to 85% and alarm recovery threshold to 70% of the switch.

```
<HUAWEI> system-view
[HUAWEI] cpu-usage threshold 85 restore 70
```

3.2.6 clear battery-group esmu communication-failure

Function

The **clear battery-group esmu communication-failure** command clears alarms indicating that a battery module fails to communicate with its connected ESMUs.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

clear battery-group esmu communication-failure

Parameters

None

2: Configuration level

Usage Guidelines

An Energy Storage System Management Unit (ESMU) is a unit for monitoring lithium batteries. You can run this command to clear alarms indicating that a battery module fails to communicate with its connected ESMUs.

Example

Clear alarms indicating that a battery module fails to communicate with its connected ESMUs.

```
<HUAWEI> system-view
[HUAWEI] clear battery-group esmu communication-failure
```

3.2.7 clear battery-group module-missing alarm

Function

The **clear battery-group module-missing alarm** command clears alarms indicating that a lithium battery group module is lost.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

clear battery-group module-missing alarm

Parameters

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to clear alarms indicating that a lithium battery group module is lost.

Example

Clear alarms indicating that a lithium battery group module is lost.

```
<HUAWEI> system-view
[HUAWEI] clear battery-group module-missing alarm
```

3.2.8 display device dc-output information

Function

The **display device dc-output information** command displays detailed information about DC output on the switch.

NOTE

Only the S5720I-10X-PWH-SI-AC supports this command.

Format

display device dc-output information

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When PDs require DC power supply, run the **display device dc-output information** command to view information about the switch output voltage, current, and power and determine whether the switch meets power supply requirements of PDs.

Example

Display detailed information about DC output on the switch.

```
<HUAWEI> display device dc-output information
-------------------------------------------------------
Output Line    Voltage(V)   Current(mA)   Power(mW)
-------------------------------------------------------
12V            12           147           1762
24V            24           0             0
-------------------------------------------------------
```

Table 3-37 Description of the **display device dc-output information** command output

Item	Description
Output Line	DC output line: - 12V: 12 V output line - 24V: 24 V output line
Voltage(V)	DC output voltage, in volts (V).
Current(mA)	DC output current, in milliamperes (mA).
Power(mW)	DC output power, in milliwatts (mW).

3.2.9 display device ac-output status

Function

The **display device ac-output status** command displays AC output status of the switch.

NOTE

Only the S5735-S8P2X-IA200H1, S5720I-6X-PWH-SI-AC, S5735-S4T2X-IA150G1, and S5735-S8P2X-IA200G1 support this command.

Format

display device ac-output status

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When PDs require AC power supply, check whether the AC output function has been enabled on the switch based on the device AC output status displayed using the **display device ac-output status** command.

Example

Display AC output status of the Switch.

```
<HUAWEI> display device ac-output status
----------------------------------------------------
OutputLine      ConfiguredState      PowerStatus
----------------------------------------------------
 24V            Enable               On
----------------------------------------------------
```

Table 3-38 Description of the **display device ac-output status** command output

Item	Description
OutputLine	AC output line. 24V: 24 V AC output line.
ConfiguredState	AC output configuration: ● Enable: AC output is enabled. ● Disable: AC output is disabled. To enable AC output, run the **set device ac-output 24v enable** command.
PowerStatus	AC output power status: ● On: Power is being supplied. ● Off: No power is supplied.

3.2.10 display device dc-output status

Function

The **display device dc-output status** command displays DC output status of the switch.

NOTE

Only the S5720I-10X-PWH-SI-AC supports this command.

Format

display device dc-output status

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When PDs require DC power supply, check whether the DC output function has been enabled on the switch based on the device DC output status displayed using the **display device dc-output status** command.

Example

Display DC output status of the Switch.

```
<HUAWEI> display device dc-output status
-----------------------------------------------------
OutputLine       ConfiguredState       PowerStatus
-----------------------------------------------------
12V-line1        Enable                On
12V-line2        Disable               Off
24V              Disable               Off
-----------------------------------------------------
```

Table 3-39 Description of the **display device dc-output status** command output

Item	Description
OutputLine	DC output line: • 12V-line1: 12 V line 1 DC output line • 12V-line2: 12 V line 2 DC output line • 24V: 24 V DC output line
ConfiguredState	DC output configuration: • Enable: DC output is enabled. • Disable: DC output is disabled. To enable DC output, run the **set device dc-output enable** command.
PowerStatus	DC output power status: • On: Power is being supplied. • Off: No power is supplied.

3.2.11 display device fault-light

Function

The **display device fault-light** command displays status of fault indicator on a device.

Format

display device fault-light

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After using the **display device fault-light** command to check the fault indicator status, you can determine whether to set the fault indicator on a device to indicate that the device is faulty using the **set device fault-light** command.

Example

Display the fault indicator status.

```
<HUAWEI> display device fault-light
----------------------------------------------------------------
Slot    Status      Keeptime(s)
----------------------------------------------------------------
0       UnderRepair    45
----------------------------------------------------------------
```

Table 3-40 Description of the display device fault-light command output

Item	Description
Slot	Slot ID.
Status	Status of the fault indicator. - Normal: Indicate that the device is running normally. - UnderRepair: Indicate that the device is faulty.

Item	Description
Keeptime(s)	Time during which the fault indicator indicates that the device is faulty. When the **Status** displays **Normal**, the value displays "--".

3.2.12 display fan speed-adjust threshold minus

Function

The **display fan speed-adjust threshold minus** command displays the temperature thresholds for fan speed adjustment.

Format

display fan speed-adjust threshold minus [**slot** *slot-id*]

NOTE

The following switches do not support this command:

- S2730S-S series
- S5720-LI series: S5720-12TP-LI-AC, S5720-12TP-PWR-LI-AC, S5720-28P-LI-AC, S5720-28TP-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28X-LI-AC, S5720-28X-LI-DC, and S5720-16X-PWH-LI-AC
- S5735-L, S5735S-L, S5735-L1, S5735S-L1, and S5735S-L-M series: S5735-L12T4S-A, S5735-L24T4S-A, S5735-L24T4S-A1, S5735S-L24T4S-MA, S5735S-L24FT4S-A, S5735S-L12T4S-A, S5735S-L24T4S-A1, S5735-L8T4S-QA1, S5735-L24T4X-QA1, S5735-L24T4S-QA1, and S5735S-L24T4S-A
- S5720S-LI series: S5720S-12TP-LI-AC, S5720S-12TP-PWR-LI-AC, S5720S-28P-LI-AC, S5720SV2-28P-LI-AC, S5720S-28TP-PWR-LI-AC, and S5720S-28X-LI-AC
- S5720I-SI series: S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-SI-AC, and S5720I-12X-PWH-SI-DC
- S5735-S-I series
- S5731-H series, S5731S-H series, S5731-S series, S5731S-S series, S5732-H series
- S6730-H series, S6730S-H series, S6730-S series, S6730S-S series
- S6735-S

If one of the preceding switches can set up a stack with other switch models that support this command, this switch also supports this command so that this command can be executed and delivered in the stack.

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID. If this parameter is not specified, the threshold settings in all slots are displayed.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays the temperature thresholds for fan speed adjustment, including the default values and current values.

In some situations, the higher the device temperature, the slower the fan speed may be. This is because the device temperature range when the fan speed increases overlaps with that when the fan speed decreases.

For example, if the threshold for fan speed adjustment is as follows:

- When the fan speed is 55%, the device temperature may be lower than or equal to 60°C.
- When the fan speed is 60%, the device temperature may be in the range from 55°C to 60°C.
- When the fan speed is 65%, the device temperature may be in the range from 56°C to 58°C.
- When the fan speed is 70%, the device temperature may be in the range from 54°C to 56°C.
- When the fan speed is 80%, the device temperature may be in the range from 52°C to 56°C.
- When the fan speed is 90%, the device temperature may be in the range from 53°C to 56°C.
- When the fan speed is 100%, the device temperature may be higher than 54°C.

The fan speed remains at 55% before the device temperature reaches 60°C from the startup temperature. If the temperature exceeds 60°C, the fan speed increases to 60%.

- If the temperature decreases to a value between 55°C and 60°C, the fan speed remains at 60%. If the temperature decreases to lower than 55°C, the fan speed reduces to 55% accordingly.

- If the temperature is still higher than 60°C, the fan speed increases to 65%.

The same rule applies to other temperatures.

Example

Display the temperature thresholds for fan speed adjustment.

```
<HUAWEI> display fan speed-adjust threshold minus
-----------------------------------------------------------
 Slot     Default Range  Current Range  Speed Rate Adjusted
-----------------------------------------------------------
 0          NA - 56         NA - 56        35%
           53 - 58        53 - 58       40%
           55 - 58        55 - 58       45%
           55 - 58        55 - 58       50%
           52 - 57        52 - 57       60%
           54 - 56        54 - 56       70%
           54 - 57        54 - 57       80%
           55 - 58        55 - 58       90%
           56 - NA         56 - NA       100%
```

Table 3-41 Description of the **display fan speed-adjust threshold minus** command output

Item	Description
Slot	Slot ID.
Default Range	Default temperature thresholds, which change based on the PoE power load.
Current Range	Current temperature thresholds. To set temperature thresholds, run the **set fan speed-adjust threshold minus** command. The new thresholds are the fixed temperature thresholds minus the configured value. After this command is executed, both the threshold for increasing the fan speed and the threshold for lowering the fan speed are reduced.
Speed Rate Adjusted	Fan speed adjustment range.

3.2.13 display flash threshold

Function

The **display flash threshold** command displays the alarm threshold for flash memory usage.

Format

display flash threshold

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

To view the configured alarm threshold for flash memory usage, run the **display flash threshold** command.

Example

Display the alarm threshold for flash memory usage.

```
<HUAWEI> display flash threshold
Info: The current flash usage threshold is 80%.
```

3.2.14 display otdr capture history-record interface

Function

The **display otdr capture history-record interface** command displays historical Optical Time Domain Reflectometer (OTDR) test results on an interface.

Format

display otdr capture history-record interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **otdr capture interface** command to perform an OTDR test on a specified interface, you can run the **display otdr capture history-record interface** command to view historical OTDR test results on the interface. Each test result displays reflection distances of 16 optical fibres, and the command output can display the latest 10 OTDR test results at most. If the reflection distance of an optical fiber is 0, the optical module connected to the optical fiber does not support OTDR testing.

After the device is restored to factory settings or the **reset otdr capture history-record** command is executed, historical OTDR test results are cleared and cannot be queried by running the **display otdr capture history-record interface** command.

Example

Display historical OTDR test results on GE0/0/1.

```
<HUAWEI> display otdr capture history-record interface gigabitethernet 0/0/1
----------------------------------------------------------------------------------------------
Index     Reflections Distance(m)                                                  Time
----------------------------------------------------------------------------------------------
 0        2027      0      0      0      0      0      0      0      2019-12-31 
14:34:03
           0      0      0      0      0      0      0      0
 1        2021      0      0      0      0      0      0      0      2019-12-26 
20:14:05
           0      0      0      0      0      0      0      0
 2        2019      0      0      0      0      0      0      0      2019-12-26 
20:14:04
           0      0      0      0      0      0      0      0

           0      0      0      0      0      0      0      0
```

Table 3-42 Description of the **display otdr capture history-record interface** command output

Item	Description
Index	Sequence number of an OTDR test result.

Item	Description
Reflections Distance(m)	Reflection distance, in meters.
Time	Time when an OTDR test is performed.

3.2.15 display otdr certificate interface

Function

The **display otdr certificate interface** command displays the OTDR test result which is configured as the OTDR birth certificate on an interface.

Format

display otdr certificate interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After you run the **otdr certificate interface** command to configure an OTDR test result as the OTDR birth certificate for an interface, you can run the **display otdr certificate interface** command to view the OTDR birth certificate.

After the device is restored to factory settings or the **reset otdr certificate** command is executed, OTDR birth certificates of interfaces are cleared and cannot be queried using the **display otdr certificate interface** command.

Example

Display the OTDR birth certificate on GE0/0/1.

```
<HUAWEI> display otdr certificate interface gigabitethernet 0/0/1
----------------------------------------------------------------------------------------------------
Reflections       Distance(m)                                           Time
----------------------------------------------------------------------------------------------------
```

```
     2021      0      0      0      0      0      0      0           2019-12-31
14:34:03
       0      0      0      0      0      0      0      0
```

Table 3-43 Description of the **display otdr certificate interface** command output

Item	Description
Reflections Distance(m)	Reflection distance, in meters.
Time	Time when an OTDR test is performed.

3.2.16 display resource-mode configuration

Function

The **display resource-mode configuration** command displays the resource allocation mode configuration on the device.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S500, S5735-S, S300, S5735-L, S5735S-L, S5735-S-I, S5735S-L-M, S5735S-S, S5735-L-I, S5735-L1,S5735S-L1, S6730-S, S6730S-S, S6730-H, S6730S-H, S6735-S, S6720-EI, and S6720S-EI support this command.

Format

display resource-mode configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before configuring or modifying the resource allocation mode, run the **display resource-mode configuration** command to check the resource allocation mode configuration.

Example

Display the resource allocation mode.

```
<HUAWEI> display resource-mode configuration
Slot       Current Mode    Next Mode
- - - - - - - - - - - - - - - - - - - - - - -
0          enhanced-mac    enhanced-mac
```

Table 3-44 Description of the display resource-mode configuration command output

Item	Description
Slot	Slot ID.
Current Mode	Current resource allocation mode.
Next Mode	Resource allocation mode configured using the **assign resource-mode** command. **NOTE** If the Next Mode is different from the Current Mode, the device is not restarted after the resource allocation mode is modified.

3.2.17 display root-key configuration

Function

The **display root-key configuration** command displays information about the currently used root key.

Format

display root-key configuration

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can use the **display root-key configuration** command to check information about the currently used root key.

Example

Display information about the currently used root key.

```
<HUAWEI> display root-key configuration
Master:
  Current root-key:  User-configured
  Next root-key:     System default
```

Table 3-45 Description of the **display root-key configuration** command output

Item	Specification
Current root-key	Information about the currently used root key: ● User-configured: user-configured root key ● System default: system default root key
Next root-key	Information about the root key used after the device restarts: ● User-configured: user-configured root key ● System default: system default root key To set the root key, run the **set root-key** command.

3.2.18 display service-mode configuration

Function

The **display service-mode configuration** command displays the working mode of the device.

NOTE

This command is supported only by S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Format

display service-mode configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the working mode of the device, run the **display service-mode configuration** command.

Example

Display the working mode of the device.

```
<HUAWEI> display service-mode configuration
Service mode status: Normal
```

Display the working mode of the S6730-H.

```
<HUAWEI> display service-mode configuration
Service mode status: BFD-enhanced, OAM-normal, PTP-normal
```

Table 3-46 Description of the **display service-mode configuration** command output

Item	Description
Service mode status	Working mode of the device: ● Normal ● Enhanced ● BFD-normal ● BFD-enhanced ● OAM-normal ● OAM-enhanced ● PTP-normal ● PTP-enhanced To set the working mode, run the **set service-mode** command.

3.2.19 display switchover state

Function

The **display switchover state** command displays information about active/standby switchover, which helps check whether the stack meets switchover requirements.

Format

display switchover state

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In a stack containing multiple switches, you can run the **display switchover state** command to view the status of master and standby switches to determine whether to perform an active/standby switchover. When performing active/standby switchover, ensure that the standby switch is in real-time backup state.

Example

Display information about active/standby switchover, which helps check whether the stack meets switchover requirements.

```
<HUAWEI> display switchover state
Slot 1 HA FSM State(master): waiting for the slave to be inserted.
```

Table 3-47 Description of the display switchover state command output

Item	Description
HA FSM State(master)	Master switch status: ● The slave has been inserted: The slave switch has been inserted. ● waiting for the slave to be inserted: The master switch is waiting for the slave switch to be inserted. ● waiting the batch backup request from the slave: The master switch is waiting for the batch backup request from the slave switch. ● batch global data: Backup global data in batch ● batch backup: Backup data in batch ● batch check: Check the backup data in batch ● realtime or routine backup: Backup data periodically or promptly ● data smooth: Synchronize data

Item	Description
HA FSM State(slave)	Standby switch status: • ready: The standby switch is started and ready for receiving the batch backup data. • receiving batch data: The standby switch is receiving the batch backup data. • receiving realtime or routine data: The standby switch is ready for receiving data in real time.

3.2.20 display system resource-template

Function

The **display system resource-template** command displays system resource template information.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S6735-S, S5735S-H, S5736-S, and S6720S-S support this command.

Format

display system resource-template [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	• Specifies a slot ID on a standalone device. • Specifies the stack ID in a stack.	The value is an integer. In a stack, the value must be set according to the device configuration. On a standalone device, the default value is 0.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display system resource-template** command to view system resource template information, including the resource type, currently running resource template information and resource template for the next startup.

Example

Display information about the system resource template. For example, the S5720-LI.

```
<HUAWEI> display system resource-template
Resource Template Information:
------------------------------------------------------------
 Slot    Type        RunningTemplate     NextTemplate
------------------------------------------------------------
 0       acl-mode    dual-ipv4-ipv6      dual-ipv4-ipv6
------------------------------------------------------------
```

Table 3-48 Description of the **display system resource-template** command output

Item	Description
Slot	Slot ID.
Type	Resource type. Currently, only one system resource template (acl-mode) is supported.
RunningTemplate	Currently running resource template information. To configure a resource template, run the **assign resource-template acl-mode** command.
NextTemplate	Resource template for the next startup.

3.2.21 display wavelength-map

Function

The **display wavelength-map** command displays the mapping between the wavelength channel, wavelength, and frequency.

Format

display wavelength-map

Parameters

None

Views

System view

Default Level

1: Monitoring level

Usage Guidelines

Before using the **wavelength-channel** command to add an optical module to a specific wavelength channel, run the **display wavelength-map** command to view the mapping between the wavelength channel, wavelength, and frequency.

Example

Display the mapping between the wavelength channel, wavelength, and frequency.

```
<HUAWEI> system-view
[HUAWEI] display wavelength-map
-------------------------------------------
Channel     Frequency(THz)    Wavelength(nm)
-------------------------------------------
1          192.10          1560.606
2          192.15          1560.200
3          192.20          1559.794
4          192.25          1559.389
5          192.30          1558.983
6          192.35          1558.578
7          192.40          1558.173
8          192.45          1557.768
9          192.50          1557.363
10          192.55          1556.959
11          192.60          1556.555
12          192.65          1556.151
13          192.70          1555.747
14          192.75          1555.344
15          192.80          1554.940
16          192.85          1554.537
17          192.90          1554.134
18          192.95          1553.731
19          193.00          1553.329
20          193.05          1552.927
21          193.10          1552.524
22          193.15          1552.122
23          193.20          1551.721
24          193.25          1551.319
25          193.30          1550.918
26          193.35          1550.517
27          193.40          1550.116
28          193.45          1549.715
29          193.50          1549.315
30          193.55          1548.915
31          193.60          1548.515
32          193.65          1548.115
33          193.70          1547.715
34          193.75          1547.316
35          193.80          1546.917
36          193.85          1546.518
37          193.90          1546.119
38          193.95          1545.720

74        195.75        1531.507
75        195.80        1531.116
76        195.85        1530.725
77        195.90        1530.334
78        195.95        1529.944
79        196.00        1529.553
80        196.05        1529.163
---------------------------------------------
```

Table 3-49 Description of the **display wavelength-map** command output

Item	Description
Channel	Channel ID.
Frequency(THz)	Frequency, in THz.
Wavelength(nm)	Wavelength, in nm.

3.2.22 mib-data optical-module sample-interval

Function

The **mib-data optical-module sample-interval** command sets the sampling interval for optical module information in the MIB performance module.

The **undo mib-data optical-module sample-interval** command restores the default setting.

By default, the interval is 30 seconds.

Format

mib-data optical-module sample-interval *interval-value*

undo mib-data optical-module sample-interval

Parameters

Parameter	Description	Value
interval-value	Specifies a sampling interval for optical module information in the MIB performance module.	The value is an integer in the range from 10 to 300, in seconds.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

It takes a long time for the NMS to query real-time optical module information on a device using hwOpticalModuleInfoTable in the MIB, especially when the device has a large number of optical modules installed. To solve this problem, you can configure devices to periodically sample optical module information. Then, the NMS can directly obtain sampling information about optical modules, which improves efficiency.

Precautions

- When you run the **mib-data optical-module sample-interval** command multiple times, only the latest configuration takes effect.
- The shorter the sampling interval, the higher the CPU usage.

Example

Set the sampling interval of optical module information in the MIB performance module to 35 seconds.

```
<HUAWEI> system-view
[HUAWEI] mib-data optical-module sample-interval 35
```

3.2.23 otdr capture interface

Function

The **otdr capture interface** command triggers an optical time domain reflectometer (OTDR) test on an interface.

Format

otdr capture interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To perform an OTDR test to obtain reflection distances of optical fibers, run the **otdr capture interface** command. The reflection distances are used for fiber fault diagnosis. To query historical OTDR test results, run the **display otdr capture history-record interface** command.

To ensure that historical OTDR test results are not lost after the device is restarted, historical OTDR test results are recorded in the **flash:/otdr_capture.bin** file. This file is set as a system file and cannot be deleted. To clear historical OTDR test results, you need to run the **reset otdr capture history-record** command. After the **reset otdr capture history-record** command is executed and the device is restarted, historical OTDR test results are cleared and cannot be queried by running the **display otdr capture history-record interface** command.

Precautions

- The command can be run multiple times.
- This command can be configured only when a specific optical module is installed on an interface. For details about the optical module, contact Huawei technical support.

Example

Trigger an OTDR test on GE0/0/1.

```
<HUAWEI> otdr capture interface gigabitethernet 0/0/1
```

3.2.24 otdr certificate interface

Function

The **otdr certificate interface** command configures an OTDR test result as the OTDR birth certificate on an interface.

Format

otdr certificate interface *interface-type interface-number capture-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-
capture-number	Specifies the sequence number of an OTDR test result.	The value is an integer ranging from 0 to 9.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To configure an OTDR test result as the OTDR birth certificate, run the **otdr certificate interface** command. The OTDR birth certificate is used as a baseline for fault detection. You can run the **display otdr certificate interface** command to view the OTDR birth certificate. By comparing the fiber reflection distances in OTDR test results (in the **display otdr capture history-record interface** command output) and the OTDR birth certificate (in the **display otdr certificate interface** command output), you can determine whether a fault occurs on an optical fiber.

To ensure that birth certificates of interfaces are not lost after the device restarts, the birth certificates are recorded in the **flash:/otdr_certificate.bin** file. This file is set as a system file and cannot be deleted. To clear OTDR birth certificates of interfaces, you need to run the **reset otdr certificate** command. After the **reset otdr certificate** command is executed and the device is restarted, OTDR birth certificates of interfaces are cleared and cannot be queried by running the **display otdr certificate interface** command.

Precautions

- This command can be run multiple times, but the latest configuration takes effect.
- This command can be configured only when a specific optical module is installed on an interface. For details about the optical module, contact Huawei technical support.

Example

Configure the second OTDR test result as the OTDR birth certificate on GE0/0/1.

```
<HUAWEI> otdr certificate interface gigabitethernet 0/0/1 2
port_no=GigabitEthernet0/0/1
capture_no=2
```

3.2.25 reset battery esmu

Function

The **reset battery** command resets ESMUs that monitor a specific battery.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command. This command takes effect only when the backup lithium battery is unavailable.

Format

reset battery *battery-id* **esmu**

Parameters

Parameter	Description	Value
battery-id	Specifies the battery number.	The value is an integer and must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

An ESMU is a unit for monitoring a lithium battery. You can run this command to reset ESMUs.

Example

Reset the ESMUs that monitor the battery whose number is 1.

```
<HUAWEI> system-view
[HUAWEI] reset battery 1 esmu
```

3.2.26 reset cpu-usage record

Function

The **reset cpu-usage record** command clears CPU usage records.

Format

reset cpu-usage record [**slot** *slot-id* | **slave** | **all**]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID.	Set the value according to the device configuration.
slave	Clears CPU usage records on the slave switch.	-
all	Clears CPU usage records on all switches	-

Views

System view, User view

Default Level

3: Management level

Usage Guidelines

If the **slot** *slot-id* or **slave** parameter is not specified, CPU usage records of the master switch is cleared.

Example

Clear CPU usage records of the master switch.

```
<HUAWEI> system-view
[HUAWEI] reset cpu-usage record
Waiting for clearing . . . Done
```

3.2.27 reset integrated-power output

Function

The **reset integrated-power output** command resets the outputs of a PC510 power supply.

Format

reset integrated-power output

NOTE

This command is supported only by the S5735-L8P4X-IA1, S5735-L8T4X-IA1.

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the switch is connected to a PC510 power supply through a network cable, the PC510 power supply can provide 12 V DC and 24 V AC outputs. When the power outputs are abnormal or the downstream devices of the switch need to be restarted, you can run this command on the switch to reset the PC510 power supply outputs.

Resetting the outputs of the PC510 power supply does not reset the output to the switch. Therefore, the switch does not restart.

Precautions

Before running this command, run the **set power protocol modbus** command on the switch to set up a connection with the PC510 power supply. If the connection fails to be set up, this command does not take effect.

Example

Reset the outputs of the PC510 power supply.

```
<HUAWEI> reset integrated-power output
```

3.2.28 reset power-detect status

Function

The **reset power-detect status** command restores the power supply to its factory defaults.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

reset power-detect status

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to restore the power supply to its factory defaults.

Example

Restore the power supply to its factory defaults.

```
<HUAWEI> system-view
[HUAWEI] reset power-detect status
```

3.2.29 reset otdr capture history-record

Function

The **reset otdr capture history-record** command clears historical OTDR test results on an interface.

Format

reset otdr capture history-record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **otdr capture interface** command to obtain the fiber reflection distance for fiber fault diagnosis. You can run the **display otdr capture history-record interface** command to view historical OTDR test results.

To ensure that historical OTDR test results are not lost after the device is restarted, historical OTDR test results are recorded in the **flash:/otdr_capture.bin** file. This file is set as a system file and cannot be deleted. To clear historical OTDR test results, you need to run the **reset otdr capture history-record** command. After the **reset otdr capture history-record** command is executed and the device is restarted, historical OTDR test results are cleared and cannot be queried by running the **display otdr capture history-record interface** command.

Example

Clear historical OTDR test results on interfaces.

```
<HUAWEI> reset otdr capture history-record
```

3.2.30 reset otdr certificate

Function

The **reset otdr certificate** command clears the OTDR test results configured as birth certificates on interfaces.

Format

reset otdr certificate

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **otdr certificate interface** command to configure a historical OTDR test result as the OTDR birth certificate for an interface and run the **display**

otdr certificate interface command to view the OTDR birth certificate of an interface.

To ensure that birth certificates of interfaces are not lost after the device restarts, the birth certificates are recorded in the **flash:/otdr_certificate.bin** file. This file is set as a system file and cannot be deleted. To clear OTDR birth certificates of interfaces, you need to run the **reset otdr certificate** command. After the **reset otdr certificate** command is executed and the device is restarted, OTDR birth certificates of interfaces are cleared and cannot be queried by running the **display otdr certificate interface** command.

Example

Clear the OTDR test results used as birth certificates on interfaces.

```
<HUAWEI> reset otdr certificate
```

3.2.31 reset slot

Function

The **reset slot** command resets a device.

Format

reset slot *slot-id* [**cold**]

NOTE

Only the following devices support cold reset. Other devices that support the **cold** parameter do not support cold reset.

- S5735-S8P2X-IA200H1, S5735-L24P4S-A, S5735-L24P4S-A1, S5735S-L24P4S-A, S5735S-L24P4S-A1, S5735S-L24P4S-MA, S5735-L24P4X-A, S5735-L24P4X-A1, S5735S-L24P4X-A, S5735S-L24P4X-A1, S5735-S4T2X-IA150G1, S5735-S8P2X-IA200G1
- Devices that use a 300 W AC power module (PAC300S12-CL)
- Devices that use a 600 W AC power module (PAC600S12-CB, PAC600S12-EB, PAC600S12-DB, and PAC600S56-CB)
- Devices that use a 600 W AC PoE power module (PAC600S56-EB)
- Devices that use a 1000 W DC power module (PDC1000S12-DB)
- Devices that use a 1000 W DC Poe power module (PDC1000S56-CB and PDC1000S56-EB)
- Devices that use a 1000 W AC PoE power module (PAC1000S56-CB, PAC1000S56-EB, and PAC1000S56-DB)

The **cold** parameter is supported only in the user view.

Parameters

Parameter	Description	Value
slot-id	Specifies a slot ID.	The value must be set according to the device configuration.

Parameter	Description	Value
cold	Indicates cold reset.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a stack, you can restart stack members. Restarting a stack member will interrupt services on this device, but the configuration of this device still exists.

Precautions

- Before commands have been executed, if a master/standby switchover occurs because the **reset slot** command is used to reset the master switch, you need to execute the commands that have not been executed on the new master switch again after the standby switch becomes the new master switch.
- For the S5735-S8P2X-IA200H1, after this command is run, the switch will not restart, but its output power supply will be reset.
- Due to the component upgrade of some device models, some devices cannot be downgraded. If the message "Error: The hardware version VER.B of slot %u does not support the configured system software package." (%u indicates the actual slot number) is displayed after the command is run, you can solve this problem by installing the patch that matches the version. For details about the first supported version of the device and matching patch version, see the device overview in the "Hardware Description"..

Example

Restart the switch with the slot ID 0.

```
<HUAWEI> reset slot 0
Warning: Confirm to reset slot 0? [Y/N]:y
Info: The board 0 is reset successfully.
```

Perform a cold reset on the switch with the slot ID 0.

```
<HUAWEI> reset slot 0 cold
Warning: The device in slot 0 will be cold reset. Ensure that the configuration has been saved. Otherwise,
the configuration will be lost after cold restart. Continue? [Y/N]: y
Info: Succeeded in cold resetting the device in slot 0.
```

3.2.32 set battery-group

Function

The **set battery-group** command configures the float charging voltage or equalized charging voltage for the lithium battery group.

The **undo set battery-group** command restores the default float charging voltage or equalized charging voltage of the lithium battery group.

By default, the float charging voltage of the lithium battery group is 54.50 V, and the equalized charging voltage is 56.40 V.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

set battery-group { **equalized-charge-voltage** | **float-charge-voltage** } *value*

undo set battery-group { **equalized-charge-voltage** | **float-charge-voltage** }

Parameters

Parameter	Description	Value
equalized-charge-voltage	Configures the float charging voltage.	-
float-charge-voltage	Configures the equalized charging voltage.	-
value	Indicates the voltage value.	The value range is as follows: • **equalized-charge-voltage**: The value ranges from 43.20 to 56.40, in volts (V). • **float-charge-voltage**: The value ranges from 43.20 to 56.40, in volts (V). **NOTE** The equalized charging voltage must be greater than or equal to the float charging voltage.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the float charging voltage or equalized charging voltage for the lithium battery group.

Example

Configure the float charging voltage of the lithium battery group to 55.11 V.

```
<HUAWEI> system-view
[HUAWEI] set battery-group equalized-charge-voltage 55.11
```

3.2.33 set battery-group charge current-limit

Function

The **set battery-group charge current-limit** command configures the charge current limiting coefficient for the lithium battery group.

The **undo set battery-group charge current-limit** command restores the default charge current limiting coefficient for the lithium battery group.

By default, the charge current limiting coefficient for the lithium battery group is 0.30.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

set battery-group charge current-limit *value*

undo set battery-group charge current-limit

Parameters

Parameter	Description	Value
value	Specifies the charge current limiting coefficient for the lithium battery group.	The value ranges from 0.05 to 1.00, in C10.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure the charge current limiting coefficient for the lithium battery group.

Example

Set the charge current limiting coefficient of the lithium battery group to 0.61.

```
<HUAWEI> system-view
[HUAWEI] set battery-group charge current-limit 0.61
```

3.2.34 set battery-group install date

Function

The **set battery-group install date** command sets the installation date of the lithium battery group.

The **undo set battery-group date** command restores the default installation date of the lithium battery group.

By default, the installation date of the lithium battery group is 2014-01-01.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

set battery-group install date *date-value*

undo set battery-group install date

Parameters

Parameter	Description	Value
date-value	Specifies the installation date of the lithium battery group.	The value is in YYYY-MM-DD format. It ranges from 2014-01-01 to 2037-12-31.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to record the installation date of the lithium battery group.

Example

Set the installation date of the lithium battery group to November 11, 2021.

```
<HUAWEI> system-view
[HUAWEI] set battery-group install date 2021-11-11
```

3.2.35 set device dc-output enable

Function

The **set device dc-output enable** command enables the DC output function on the switch.

The **undo set device dc-output enable** command disables the DC output function on the switch.

By default, the DC output function is enabled on a switch.

NOTE

Only the S5720I-10X-PWH-SI-AC supports this command.

Format

set device dc-output [**12V** [**line1** | **line2**] | **24V**] **enable**

undo set device dc-output [**12V** [**line1** | **line2**] | **24V**] **enable**

Parameters

Parameter	Description	Value
12V	Specifies the DC output voltage as 12 V.	-
line1	Configures DC output of 12 V line 1.	-
line2	Configures DC output of 12 V line 2.	-
24V	Specifies the DC output voltage as 24 V.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If PDs require DC power supply, enable DC output on the switch.

Precautions

If you run the **set device dc-output 12V** [**line1** | **line2**] **enable** command to enable the 12 V DC output function of the switch, and then run the **set device dc-output 24V enable** command to enable the 24 V DC output function of the switch, both the 12 V and 24 V DC output functions have been enabled on the switch. To determine the state of each DC output line, run the **display device dc-output status** command.

Example

Enable DC output of 12 V line 1 and set the DC output voltage to 12 V.

```
<HUAWEI> system-view
[HUAWEI] set device dc-output 12V line1 enable
Warning: The total PoE power and DC output power is 0mW, and the remaining power is 175000mW.
Continue? [Y/N]:Y
Warning: After the 12V line1 DC output is enabled, PoE power and DC output power may be disabled if the
total PoE power and DC output power exceeds 175000mW. Continue? [Y/N]:Y
```

Enable DC output of all lines.

```
<HUAWEI> system-view
[HUAWEI] set device dc-output enable
Warning: The total PoE power and DC output power is 731mW, and the remaining power is 174269mW.
Continue? [Y/N]:Y
Warning: After all DC output is enabled, PoE power and DC output power may be disabled if the total PoE
power and DC output power exceeds 175000mW. Continue? [Y/N]:Y
```

3.2.36 set device ac-output 24v enable

Function

The **set device ac-output 24v enable** command enables the 24 V AC output function on a switch.

The **undo set device ac-output 24v enable** command disables the 24 V AC output function on a switch.

By default, the 24 V AC output function is enabled on switches.

NOTE

Only the S5735-S8P2X-IA200H1, S5720I-6X-PWH-SI-AC, S5735-S4T2X-IA150G1, and S5735-S8P2X-IA200G1 support this command.

Format

set device ac-output 24v enable

undo set device ac-output 24v enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If PDs require AC power supply, enable the AC output function on the switch.

Precautions

- For the S5720I-6X-PWH-SI-AC, when the sum of the PoE power, DC output power, and AC output power is greater than 150000 mW, the switch restarts.
- For the S5735-S4T2X-IA150G1 and S5735-S8P2X-IA200G1, when the sum of the PoE power, DC output power, and AC output power is greater than 160000 mW, the switch restarts.
- For the S5735-S8P2X-IA200H1, when the sum of the PoE power, DC output power, and AC output power is greater than 200000 mW, the switch restarts.

Example

Enable the 24 V AC output function on a switch.

```
<HUAWEI> system-view
[HUAWEI] set device ac-output 24v enable
Warning: After this command is excuted, the 24V AC output will be enabled. Continue? [Y/N]:y
Warning: After the 24V AC output is enabled, the switch will reboot if the total power of PoE power, DC
output power and AC output power exceed 150000mW. Continue? [Y/N]:y
```

3.2.37 set device fault-light

Function

The **set device fault-light** command sets the fault indicator status on a device.

The **undo set device fault-light** command restores the default fault indicator status.

By default, the fault indicator status of the device is not set. The fault indicator status is displayed based on the current device running status.

Format

set device fault-light { **normal** | **under-repair** [**keeptime** *time*] } [**slot** *slot-id*]

undo set device fault-light [**slot** *slot-id*]

Parameters

Parameter	Description	Value
normal	Displays the fault indicator status based on the current device running status.	-
under-repair	Configures the fault indicator to indicate that the device is faulty.	-
keeptime *time*	Sets the time during which the fault indicator indicates that the device is faulty.	The value is an integer that ranges from 45 to 600, in seconds. The default value is 45.
slot *slot-id*	Specifies a slot ID. If not slot ID is specified in a stack, this command sets the fault indicator status of the stack master.	The value range depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

If a switch is faulty, run the **set device fault-light** command to set the mode indicators or system indicator to the faulty state so that O&M personnel can find the faulty switch onsite.

- For the S500, S5735-S, S5735S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

  When the **set device fault-light under-repair** command is executed, the ID indicator is steady blue and turns off after it is steady blue for the time specified by **keeptime** *time* (the default time is 45s if this parameter is not specified). The **set device fault-light normal** command and the **undo set device fault-light** command have the same functions. That is, after either of the two commands is executed, the ID indicator turns off.
- For the S5720I-6X-PWH-SI-AC and S5720I-10X-PWH-SI-AC

  The switch has only one fault indicator, WiFi indicator. When the **set device fault-light under-repair** command is executed, the WiFi indicator blinks red fast and turns off after it blinks red fast for the time specified by **keeptime**

time (the default time is 45s if this parameter is not specified). The **set device fault-light normal** and **undo set device fault-light** commands have the same functions. That is, after either of the two commands is executed, the WiFi indicator turns off.

- For the S5735-S-I

  The switch has only one fault indicator, SYS indicator. When the **set device fault-light under-repair** command is executed, the SYS indicator blinks red fast and returns to the previous state after it blinks red fast for the time specified by **keeptime** *time* (the default time is 45s if this parameter is not specified). The **set device fault-light normal** and **undo set device fault-light** commands have the same functions. That is, after either of the two commands is executed, the SYS indicator returns to the previous state.

- For other switches that support this command

  When the **set device fault-light under-repair** command is executed, the SYS indicator and mode indicators (STAT, SPED, PoE, and STCK) blink red fast. After these indicators blink red fast for the time specified by **keeptime** *time* (the default time is 45s if this parameter is not specified), the SYS indicator returns to the previous state, and the STAT indicator is steady on.

  The **set device fault-light normal** and **undo set device fault-light** commands have the same functions. That is, after either of the two commands is executed, the SYS indicator returns to the previous state, and the STAT indicator is steady on.

  If **slot** *slot-id* is not specified in a stack, the configuration takes effect on indicators on the master switch.

Example

Configure the fault indicator to indicate that the device is faulty.

```
<HUAWEI> system-view
[HUAWEI] set device fault-light under-repair
```

3.2.38 set fan speed auto min-speed

Function

The **set fan speed auto min-speed** command configures the minimum fan speed in automatic fan speed adjustment mode.

The **undo set fan speed auto min-speed** command restores the default minimum fan speed in automatic fan speed adjustment mode.

By default, the minimum fan speed in automatic fan speed adjustment mode is not configured.

NOTE

The following switches do not support this command:

- S2730S-S series
- S5720-LI series: S5720-12TP-LI-AC, S5720-12TP-PWR-LI-AC, S5720-28P-LI-AC, S5720-28TP-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28X-LI-AC, S5720-28X-LI-DC, and S5720-16X-PWH-LI-AC
- S5735-L, S5735S-L, S5735-L1, S5735S-L1, and S5735S-L-M series: S5735-L12T4S-A, S5735-L24T4S-A, S5735-L24T4S-A1, S5735S-L24T4S-MA, S5735S-L24FT4S-A, S5735S-L12T4S-A, S5735S-L24T4S-A1, S5735-L8T4S-QA1, S5735-L24T4X-QA1, S5735-L24T4S-QA1, and S5735S-L24T4S-A
- S5720S-LI series: S5720S-12TP-LI-AC, S5720S-12TP-PWR-LI-AC, S5720S-28P-LI-AC, S5720SV2-28P-LI-AC, S5720S-28TP-PWR-LI-AC, and S5720S-28X-LI-AC
- S5720I-SI series: S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-SI-AC, and S5720I-12X-PWH-SI-DC
- S5735-S-I series
- S5731-H series, S5731S-H series, S5731-S series, S5731S-S series, S5732-H series
- S6730-H series, S6730S-H series, S6730-S series, S6730S-S series
- S6735-S

If one of the preceding switches can set up a stack with other switch models that support this command, this switch also supports this command so that this command can be executed and delivered in the stack.

Format

set fan speed auto min-speed *value* [**slot** *slot-id* | **all**]

undo set fan speed auto min-speed [**slot** *slot-id* | **all**]

Parameters

Parameter	Description	Value
value	Sets the percentage of the minimum fan speed. For example, if this parameter is set to 35, the minimum fan speed in automatic fan speed adjustment mode is 35% of the full fan speed.	The value is an integer that ranges from 1 to 100.
slot *slot-id*	Specifies a slot ID. If this parameter is not specified, the minimum fan speed in automatic fan speed adjustment mode is configured for the fans on the master switch.	The value depends on the device configuration.
all	Specifies all slots.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The fan speed affects the device temperature. When the device temperature is high, increase the fan speed to lower the device temperature. When the device temperature is low, reduce the fan speed to save energy. A proper fan speed ensures stable device operation. By default, fans run in automatic fan speed adjustment mode. In this mode, the system adjusts the fan speed when detecting that the device temperature increases or decreases. To control the fan speed in a timely manner, run the **set fan speed auto min-speed** command to configure the minimum fan speed in automatic speed adjustment mode.

Precautions

- If the automatically calculated fan speed is lower than the configured minimum speed, the configured minimum speed takes effect. If the automatically calculated fan speed is greater than the configured minimum speed, the calculated fan speed takes effect. To obtain the minimum fan speed of a device, view the **Speed Rate Adjusted** field in the **display fan speed-adjust threshold minus** command output.
- To obtain the minimum fan speed in automatic fan speed adjustment mode on a device, view the **Auto Min-speed** field in the **display fan** command output.
- The following assumes that the device can set up a stack with other device models and has the minimum fan speed in automatic fan speed adjustment mode configured before the stack is set up. After the stack is set up, if this device functions as the master switch, the configured minimum fan speed still takes effect. If this device functions as the standby or slave switch, the configured minimum fan speed does not take effect.
- This configuration takes effect only when fan modules work in automatic speed adjustment mode. You can check the **Mode** field in the **display fan** command output to check the fan speed adjustment mode. If a fan module works at a fixed speed, run the **fan speed mandatory** command in the diagnostic view to configure the fan module to work in automatic speed adjustment mode.

Example

Set the minimum fan speed in automatic fan speed adjustment mode to 20% of the full fan speed.

```
<HUAWEI> system-view
[HUAWEI] set fan speed auto min-speed 20
Info: The configuration is successful and takes effect only when the specified value is greater than the value
calculated based on the intelligent fan speed adjustment policy.
```

3.2.39 set fan speed-adjust threshold minus

Function

The **set fan speed-adjust threshold minus** command adjusts the temperature thresholds for fan speed adjustment.

The **undo set fan speed-adjust threshold minus** command restores the default temperature thresholds for fan speed adjustment.

The default temperature thresholds on different devices are different. You can get to run the **display fan speed-adjust threshold minus** command.

NOTE

The following switches do not support this command:

- S2730S-S series
- S5720-LI series: S5720-12TP-LI-AC, S5720-12TP-PWR-LI-AC, S5720-28P-LI-AC, S5720-28TP-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28X-LI-AC, S5720-28X-LI-DC, and S5720-16X-PWH-LI-AC
- S5735-L, S5735S-L, S5735-L1, S5735S-L1, and S5735S-L-M series: S5735-L12T4S-A, S5735-L24T4S-A, S5735-L24T4S-A1, S5735S-L24T4S-MA, S5735S-L24FT4S-A, S5735S-L12T4S-A, S5735S-L24T4S-A1, S5735-L8T4S-QA1, S5735-L24T4X-QA1, S5735-L24T4S-QA1, and S5735S-L24T4S-A
- S5720S-LI series: S5720S-12TP-LI-AC, S5720S-12TP-PWR-LI-AC, S5720S-28P-LI-AC, S5720SV2-28P-LI-AC, S5720S-28TP-PWR-LI-AC, and S5720S-28X-LI-AC
- S5720I-SI series: S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-SI-AC, and S5720I-12X-PWH-SI-DC
- S5735-S-I series
- S5731-H series, S5731S-H series, S5731-S series, S5731S-S series, S5732-H series
- S6730-H series, S6730S-H series, S6730-S series, S6730S-S series
- S6735-S

If one of the preceding switches can set up a stack with other switch models that support this command, this switch also supports this command so that this command can be executed and delivered in the stack.

Format

set fan speed-adjust threshold minus *threshold-value* [**slot** *slot-id*]

undo set fan speed-adjust threshold minus [**slot** *slot-id*]

Parameters

Parameter	Description	Value
threshold-value	Specifies the deduction to the temperature thresholds.	The value is an integer that ranges from 1 to 20.

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID. If this parameter is not specified, the thresholds in all slots are set.	The value depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The device uses fixed temperature thresholds to increase and decrease the fan speed by default. The fan speed increases when the device temperature exceeds the upper threshold and decreases when the device temperature falls below the lower threshold. If you want to keep the device working at a lower temperature, you can set deduction for the fixed temperature thresholds. The adjusted temperature threshold is lower than the default temperature threshold.

Precautions

- The new thresholds are the fixed temperature thresholds minus *threshold-value*. After the **set fan speed-adjust threshold minus** command is executed, the thresholds for increasing and lowering the fan speed decrease.
- To view the fixed temperature thresholds, run the **display fan speed-adjust threshold minus** command.

NOTE

If a device uses intelligent fan control, this command reduces the temperature thresholds for starting and stopping the fans. Fans in intelligent heat dissipation mode can only start and stop rotating at a fixed speed that cannot be increased or reduced.

You can run the **display fan speed-adjust threshold minus** command to check temperature thresholds for fan speed adjustment of fans in intelligent heat dissipation mode. Assume you view that the current temperature threshold of the fans is 40-50, in which 40°C is the threshold for stopping the fans, and 50°C is the threshold for starting the fans. When the current device temperature is 45°C, you need to determine whether fans will rotate according to the fan temperature change:

- When the device temperature is increased to 45°C from a lower temperature (30°C for example), fans do not rotate because the device temperature does not reach the threshold for starting the fans.
- When the device temperature is reduced to 45°C from a higher temperature (65°C for example), fans keep rotating because the device temperature does not fall below the threshold for stopping the fans.

Example

Set the deduction to the temperature thresholds to 10.

```
<HUAWEI> system-view
[HUAWEI] set fan speed-adjust threshold minus 10
Info: Succeeded in setting the fan speed-adjust threshold.
```

3.2.40 set fan speed mandatory

Function

The **set fan speed mandatory** command sets a fixed speed for fans on a device.

The **undo set fan speed mandatory** command restores the automatic fan speed mode.

By default, the automatic fan speed mode is used.

Format

set fan speed mandatory { **minimal** | **middle** | **maximal** | **fixed40** | **fixed50** | **fixed60** | *speed* } [**slot** *slot-id*]

undo set fan speed mandatory { **minimal** | **middle** | **maximal** | **fixed40** | **fixed50** | **fixed60** | *speed* } [**slot** *slot-id*]

Parameters

Parameter	Description	Value
minimal	Sets the fan speed to the minimum speed of the device.	-
middle	Sets the fan speed to 70% of the full speed.	-
maximal	Sets the fan speed to the full speed.	-
fixed40	Sets the fan speed to 40% of the full speed.	-
fixed50	Sets the fan speed to 50% of the full speed.	-
fixed60	Sets the fan speed to 60% of the full speed.	-
speed	Specifies the percentage of the fan speed to the full speed.	The value is an integer from 20 to 100.

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The command for manually setting the fan speed is used only for fault locating. Generally, automatic fan speed adjustment is recommended.

Only devices installed with variable-speed fans support this command. Such fans support fan speed adjustment at two or multiple levels. The system can display the matching parameters according to the type of the fan installed on the device, and you do not need to know how many speed levels the fan supports.

Precautions

In a stack, the **set fan speed mandatory minimal** command will set the fan speed of each member switch to the minimum fan speed.

Example

Set the fan speed to 70% of the full speed.

```
<HUAWEI> system-view
[HUAWEI] set fan speed mandatory middle
```

3.2.41 set flash threshold

Function

The **set flash threshold** command sets the alarm threshold for flash memory usage.

The **undo set flash threshold** command restores the default alarm threshold for flash memory usage.

By default, the alarm threshold for flash memory usage is 80.

Format

set flash threshold *value*

undo set flash threshold *value*

Parameters

Parameter	Description	Value
value	Sets the alarm threshold for flash memory usage.	The value is an integer that ranges from 1 to 99.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To ensure that the switch has sufficient flash memory, run the **set flash threshold** command to set the alarm threshold for flash memory usage. When flash memory of the switch is insufficient, the system prompts that flash memory is insufficient so that you can determine the flash memory usage.

Example

Set the alarm threshold for flash memory usage on an MPU to 50%.

```
<HUAWEI> system-view
[HUAWEI] set flash threshold 50
Info: Now the flash usage threshold is 50%.
```

3.2.42 set integrated-power

Function

The **set integrated-power** command configures a voltage threshold for the device.

The **undo set integrated-power** command restores the default voltage threshold of the device.

By default, the DC overvoltage threshold is 58.00 V, the DC undervoltage threshold is 50.00 V, the low-load voltage threshold is 49.00 V, and the 53 V DC output voltage threshold is 53.00 V.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

set integrated-power { **53v-dc output-voltage** | **dc-overvoltage** | **dc-undervoltage** | **low-load-voltage** } **threshold** *value*

undo set integrated-power { **53v-dc output-voltage** | **dc-overvoltage** | **dc-undervoltage** | **low-load-voltage** } **threshold**

Parameters

Parameter	Description	Value
53v-dc output-voltage	Configures a 53 V DC output voltage threshold.	-
dc-overvoltage	Configures a DC overvoltage threshold.	-
dc-undervoltage	Configures a DC undervoltage threshold.	-
low-load-voltage	Configures a low-load voltage threshold.	-
threshold *value*	Specifies a voltage threshold.	-
value	Specifies the threshold value.	The value range is as follows: ● **53v-dc output-voltage**: The value ranges from 53 to 56.4, in volts (V). ● **dc-overvoltage**: The value ranges from 53 to 60, in volts (V). ● **dc-undervoltage**: The value ranges from 35 to 57, in volts (V). ● **low-load-voltage**: The value ranges from 35 to 51.49, in volts (V).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to configure a voltage threshold.

Example

Set the low-load voltage threshold to 39.11 V.

```
<HUAWEI> system-view
[HUAWEI] set integrated-power low-load-voltage threshold 39.11
```

3.2.43 set memory-usage threshold

Function

The **set memory-usage threshold** command sets the memory usage threshold.

The **undo set memory-usage threshold** command restores the default memory usage threshold.

By default, the following describes the memory usage alarm threshold on the S1720GFR:

- If the memory capacity on the device is lower than or equal to 256 MB, the memory usage alarm threshold is 85% and the memory usage alarm recovery threshold is 80%.
- If the memory capacity on the device is larger than 256 MB and smaller than or equal to 512 MB, the memory usage alarm threshold is 90% and the memory usage alarm recovery threshold is 85%.
- If the memory capacity on the device is higher than 512 MB, the memory usage alarm threshold is 95% and the memory usage alarm recovery threshold is 90%.

The following describes the memory usage alarm threshold on other switch models:

- If the memory capacity on the device is lower than or equal to 512 MB, the memory usage alarm threshold is 85% and the memory usage alarm recovery threshold is 80%.
- If the memory capacity on the device is larger than 512 MB and smaller than or equal to 1.5 GB, the memory usage alarm threshold is 90% and the memory usage alarm recovery threshold is 85%.
- If the memory capacity on the device is higher than 1.5 GB, the memory usage alarm threshold is 95% and the memory usage alarm recovery threshold is 90%.

Format

set memory-usage threshold *threshold-value* [**slot** *slot-id*]

undo set memory-usage threshold [*threshold-value*] [**slot** *slot-id*]

Parameters

Parameter	Description	Value
threshold-value	Specifies the memory usage threshold.	The value is an integer that ranges from 75 to 100.

Parameter	Description	Value
slot *slot-id*	Specifies the memory usage threshold of a specified slot ID.	The value depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can use the **set memory-usage threshold** command to set the memory usage threshold. When memory usage exceeds the threshold, the system logs the event and generates an alarm. By viewing log information, you can learn about memory usage.

Precautions

You are advised to use the default threshold. If the memory usage threshold is set too low, the system frequently generates alarms. If the memory usage threshold is set too high, you cannot learn about memory usage in a timely manner.

Example

Set the memory usage threshold to 85%.

```
<HUAWEI> system-view
[HUAWEI] set memory-usage threshold 85
```

3.2.44 set power protocol modbus

Function

The **set power protocol modbus** command configures the IP address and port number of a PC510 power supply for the switch to connect to.

The **undo set protocol modbus** command deletes the configuration.

By default, the IP address and port number of a PC510 power supply for the switch to connect to are not configured.

NOTE

This command is supported only by the S5735-L8P4X-IA1, S5735-L8T4X-IA1.

Format

set power protocol modbus [**ip-address** *ip-address-value*] [**tcp-port** *port-value*]

undo set power protocol modbus

Parameters

Parameter	Description	Value
ip-address *ip-address-value*	Specifies the IP address of a PC510 power supply.	The value is in dotted decimal notation. The default value is 192.168.18.88.
tcp-port *port-value*	Specifies the port number of a PC510 power supply.	The value is an integer ranging from 0 to 65535. The default value is 502.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A PC510 power module provides multiple types of power outputs and can supply power to devices, such as switches and cameras, at the same time. To be powered by a PC510 power supply, the switch needs to set up a connection with the PC510 power supply using the Modbus TCP protocol. After connecting to a PC510 power supply, the switch can manage this power supply, for example, obtain its version information and restart it.

You need to run this command on the switch to configure the IP address and port number of the PC510 power supply so that the switch can set up a connection with it.

Precautions

- After running this command, to ensure that the switch can set up a connection with the power supply successfully, you need to create a VLANIF interface on the switch, configure an IP address on the same subnet as the power supply for the VLANIF interface, and add the interface connecting the switch to the power supply to the VLAN of the VLANIF interface.
- The IP address and port number of a PC510 power module are fixed at 192.168.18.88 and 502, respectively. Therefore, the IP address and port number configured using this command can only be 192.168.18.88 and 502.

Example

Configure the IP address and port number of a PC510 power supply for the switch to connect to.

```
<HUAWEI> system-view
[HUAWEI] set power protocol modbus ip-address 192.168.18.88 tcp-port 502
```

3.2.45 set root-key

Function

The **set root-key** command configures a root key for a switch.

The **undo set root-key** command restores the default root key of a switch.

By default, a switch uses the system default root key.

Format

set root-key [**auto**]

undo set root-key

Parameters

Parameter	Description	Value
auto	Automatically generates the root key of the device.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A root key is located at the bottom of the key management infrastructure to protect confidentiality of upper-layer keys (such as key encryption key). Therefore, a root key is important to data security. A switch's root key is often stored in the system. If attackers illegally obtain the root key, encrypted data will become insecure. To improve data security and prevent attackers from obtaining encrypted packets, configure another root key on the switch. The configured root key will take effect after the switch restarts.

If the device has high security requirements and its configuration file needs to be prevented from being used by other devices, run the **set root-key auto** command to automatically generate a root key for the device. You can run this command to automatically generate a root key only for an unconfigured device.

Precautions

- The root key can only be configured when the switch has no service configuration. If service configuration has been performed on the switch, an error message will be displayed when you configure the root key.
- If you configure a password (not the administrator password) and key after configuring the root key, the password and key configuration will not be restored after the switch software version is changed to V200R009 or an earlier version.
- After the root key is configured and the device is restarted, run the **display root-key configuration** command to check whether the configuration takes effect. After the configuration takes effect on the device, if you export the device's configuration file and apply it to other devices, other devices cannot work properly.
- Do not run this command to set the root key to the weak password preset by running the **load security weak-password-dictionary** command.

Example

Set the root key that meets the length requirements, for example, 98765432109876543210abc. Set this parameter based on the site requirements.

```
<HUAWEI> set root-key
Warning: A new root key can take effect only after the device is restarted. Continue? [Y/N]:y
Please enter a new key of no more than 32 and no less than 20 characters:
Please enter the new key again:
Info: Succeed in setting next root-key on the master board.
```

Configure automatic root key generation.

```
<HUAWEI> set root-key auto
```

3.2.46 set rtc to power

Function

The **set rtc to power** command synchronizes the time of the power supply with the device time.

NOTE

Only the S5735-S8P2X-IA200H1 supports this command.

Format

set rtc to power

undo set rtc to power

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to synchronize the time of the power supply with the device time.

Example

Synchronize the time of the power supply with the device time.

```
<HUAWEI> system-view
[HUAWEI] set rtc to power
```

3.2.47 set service-mode

Function

The **set service-mode** command sets the working mode of the device to enhanced.

The **undo set service-mode** command restores the working mode of the device to normal.

By default, the working mode of the device is normal.

NOTE

This command is supported only by S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Format

Command format on the S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H:

set service-mode { **enhanced-bfd** | **enhanced-oam** | **enhanced-ptp** }

undo set service-mode { **enhanced-bfd** | **enhanced-oam** | **enhanced-ptp** }

Command format on other switches:

set service-mode enhanced

undo set service-mode enhanced

Parameters

Parameter	Description	Value
enhanced	Sets the working mode of the device to enhanced.	-

Parameter	Description	Value
enhanced-bfd	Sets the BFD working mode of the device to enhanced.	-
enhanced-oam	Sets the OAM working mode of the device to enhanced.	-
enhanced-ptp	Sets the PTP working mode of the device to enhanced.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In normal mode, the interval for receiving BFD packets must be more than or equal to 100 ms. If the interval cannot meet requirements, run the **set service-mode** command to change the working mode of the switch to enhanced or **enhanced-bfd** mode so that the switch supports a minimum of 3 ms interval.

To implement some OAM functions, you need to run the **set service-mode** command to change the working mode of the switch to enhanced or **enhanced-oam** mode. For more details, see the OAM description.

To configure PTP, you need to run the **set service-mode** command to change the working mode of the switch to enhanced **enhanced-ptp** mode.

Precautions

- Running the **set service-mode** command will reduce the device forwarding performance. Therefore, confirm the action before you use the command.
- If BFD has been enabled before this command is executed, disable BFD first.
- Before changing the working mode from enhanced to normal, disable the PTP function.
- On the S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H, you can run the **set service-mode** command multiple times to set the working mode of BFD, PTP, and OAM to enhanced.

Example

Set the working mode of the device to enhanced.

```
<HUAWEI> system-view
[HUAWEI] set service-mode enhanced
Warning: This command will effect forward performance. Continue? [Y/N]:y
```

3.2.48 slave restart

Function

Using the **slave restart** command, you can reload the system software of the standby device and then restart it.

NOTE

This function is supported only on member devices in a stack.

Format

slave restart

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the standby switch is not working normally, you can reset it to restore its functions without affecting existing services.

Precautions

Due to the component upgrade of some device models, the devices whose first supported version is V200R021C10 cannot be downgraded. If the message "Error: The hardware version VER.B of slot %u does not support the configured system software package." (%u indicates the actual slot number) is displayed after the command is run, you can solve this problem by installing the patch that matches the version. For details about the first supported version of the device and matching patch version, see the device overview in the "Hardware Description".

NOTICE

The command may interrupt services on the device. Therefore, exercise caution when using this command.

Example

Restart the standby device.

```
<HUAWEI> system-view
[HUAWEI] slave restart
```

3.2.49 slave switchover

Function

The **slave switchover** command performs an active/standby switchover.

NOTE

This function is supported only on member devices in a stack.

Format

slave switchover

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a stack of multiple switches, you can manually perform an active/standby switchover on the master and standby switches during a software upgrade or system maintenance. After the active/standby switchover is complete, the original master switch restarts, becomes the new standby switch or a slave switch, and joins the stack, and the original standby switch becomes the new master switch.

Prerequisites

- The forcible active/standby switchover function has been enabled on devices.
- The **display switchover state** command output shows that system has met requirements for an active/standby switchover. The requirements for an active/standby switchover are met only when the value of **HA FSM State(master)** is **realtime or routine backup** and the value of **HA FSM State(slave)** is **receiving realtime or routine data**. This indicates that data is consistent on the master and standby switches.

Precautions

- You can run the **slave switchover** command to perform an active/standby switchover only in a stack of multiple switches.
- If an unregistered member switch exists in the stack, to prevent the stack from being split, do not run the **slave switchover** command to perform an active/standby switchover.
- If the **slave switchover** command is executed when other commands are being executed, you need to execute the commands that have not taken effect on the new master switch again after the original standby switch becomes the new master switch.
- Due to the component upgrade of some device models, some devices cannot be downgraded. If the message "Error: The hardware version VER.B of slot %u does not support the configured system software package." (%u indicates the actual slot number) is displayed after the command is run, you can solve this problem by installing the patch that matches the version. For details about the first supported version of the device and matching patch version, see the device overview in the "Hardware Description"..

Example

Perform an active/standby switchover.

```
<HUAWEI> system-view
[HUAWEI] slave switchover enable
[HUAWEI] slave switchover
Warning: This operation will switch the slave board to the master board. Continue? [Y/N]:y
```

3.2.50 slave switchover { disable | enable }

Function

The **slave switchover** { **disable** | **enable** } command enables or disables forcible master/slave switchover.

undo slave switchover disable command enables forcible master/slave switchover.

By default, master/slave switchover is enabled.

NOTE

This function is supported only on member devices in a stack.

Format

slave switchover { **disable** | **enable** }

undo slave switchover disable

Parameters

Parameter	Description	Value
disable	Disables forcible master/slave switchover.	-

Parameter	Description	Value
enable	Enables forcible master/slave switchover.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **slave switchover** command takes effect only after forcible master/slave switchover is enabled. If forcible master/slave switchover is disabled, the **slave switchover** command does not take effect.

Example

Disable forcible master/slave switchover.

```
<HUAWEI> system-view
[HUAWEI] slave switchover disable
```

3.2.51 system memory-usage monitor disable

Function

The **system memory-usage monitor disable** command disables the function of generating an alarm when the system memory usage reaches the threshold.

The **undo system memory-usage monitor disable** command enables the function of generating an alarm when the system memory usage reaches the threshold.

By default, the function of generating an alarm when the system memory usage reaches the threshold is enabled.

Format

system memory-usage monitor disable

undo system memory-usage monitor disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

When the system memory is insufficient, services are abnormal. For example, configurations cannot be delivered or traffic cannot be forwarded. For the Linux operating system, when the system memory usage reaches 90%, the device reports an alarm indicating that the memory usage reaches the threshold by default.

If the memory is sufficient and the memory insufficiency alarm does not need to be reported, you can run this command to disable the function of reporting an alarm when the system memory usage reaches the threshold.

Example

Disable the function of generating an alarm when the system memory usage reaches the threshold.

```
<HUAWEI> system-view
[HUAWEI] system memory-usage monitor disable
```

3.2.52 temperature threshold

Function

The **temperature threshold** command sets the temperature alarm thresholds.

The **undo temperature threshold** command restores the default temperature alarm thresholds.

By default, the lower temperature threshold is -40°C on the S5720I-SI and S5735-S-I, and -3°C on the S5731-H, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S, S5735S-S, S5736-S, and S6730-H, and 0°C on other switch models, and the upper temperature threshold varies according to hardware of various models, ranging from 44°C to 88°C.

Format

temperature threshold slot { *slot-id* | **all** } **lower-limit** *min-temperature* **upper-limit** *max-temperature*

undo temperature threshold slot { *slot-id* | **all** }

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Parameter	Description	Value
all	Sets the temperature alarm threshold for all member switches in a stack.	-
lower-limit *min-temperature*	Specifies the lower temperature alarm threshold.	The value is an integer that ranges from -40 to 88. *min-temperature* specifies the value of the temperature. The value of *min-temperature* varies according to device models. The minimum value of *min-temperature* is the default lower threshold. In a stack of multiple member switches, when **all** is specified in the **temperature threshold** command and the temperature alarm thresholds of all member switches are set, the *min-temperature* value is the largest value among the lower temperature alarm thresholds of the member switches.

Parameter	Description	Value
upper-limit *max-temperature*	Specifies the upper temperature alarm threshold.	The value is an integer that ranges from -40 to 88. *max-temperature* specifies the value of the temperature. The value of *max-temperature* varies according to device models. The maximum value of *max-temperature* is the default upper threshold. *max-temperature* must be at least 10 greater than *min-temperature*. In a stack of multiple member switches, when **all** is specified in the **temperature threshold** command and the temperature alarm thresholds of all member switches are set, the *max-temperature* value is the smallest value among the upper temperature alarm thresholds of the member switches.

Views

system view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The device generates an alarm and records log information when the device temperature falls below the lower threshold or rises above the upper threshold.

Precautions

- If the configured threshold values are out of the allowed range, the configuration fails and the upper and lower thresholds are restored to the maximum values.

- Configuration commands are generated in a configuration file regardless of whether the configured threshold values are default values. These commands can be cleared only when the **undo temperature threshold** command is executed.

Example

Set the lower temperature alarm threshold to 20°C and upper temperature alarm threshold to 60°C.

```
<HUAWEI> system-view
[HUAWEI] temperature threshold slot all lower-limit 20 upper-limit 60
```

3.2.53 transceiver diagnosis threshold rx-power

Function

The **transceiver diagnosis threshold rx-power** command sets the upper and lower thresholds for the receive optical power of the optical transceiver installed in an interface.

The **undo transceiver diagnosis threshold rx-power** command restores the upper and lower thresholds to the default values for the receive optical power of the optical transceiver installed in an interface.

By default, the optical power upper and lower thresholds vary according to optical module vendors.

Format

transceiver diagnosis threshold rx-power { **default** | **low-alarm** *low-alarm* **high-alarm** *high-alarm* }

undo transceiver diagnosis threshold rx-power

Parameters

Parameter	Description	Value
default	Sets the upper and lower thresholds for the receive optical power of the optical transceiver installed in an interface to default values.	-
high-alarm *high-alarm*	Sets the upper threshold for the receive optical power of the optical transceiver installed in an interface.	The value varies according to the optical module vendor.

Parameter	Description	Value
low-alarm *low-alarm*	Sets the lower threshold for the receive optical power of the optical transceiver installed in an interface.	The value varies according to the optical module vendor.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

You can run the **transceiver diagnosis threshold rx-power** command to adjust the receive optical power of the optical transceiver.

Example

Set the upper and lower thresholds for the receive optical power of the optical transceiver installed in GigabitEthernet 0/0/2 to default values.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/2
[HUAWEI-GigabitEthernet0/0/2] transceiver diagnosis threshold rx-power default
```

3.2.54 transceiver diagnosis threshold tx-power

Function

The **transceiver diagnosis threshold tx-power** command sets the upper and lower thresholds for the transmit optical power of the optical transceiver installed in an interface.

The **undo transceiver diagnosis threshold tx-power** command restores the upper and lower thresholds for the transmit optical power of the optical transceiver installed in an interface to default values.

By default, the optical power upper and lower thresholds vary according to optical module vendors.

Format

transceiver diagnosis threshold tx-power { **default** | **low-alarm** *low-alarm* **high-alarm** *high-alarm* }

undo transceiver diagnosis threshold tx-power

Parameters

Parameter	Description	Value
default	Sets the upper and lower thresholds for the transmit optical power of the optical transceiver installed in an interface to default values.	-
high-alarm *high-alarm*	Sets the upper threshold for the transmit optical power of the optical transceiver installed in an interface.	The value varies according to the optical module vendor.
low-alarm *low-alarm*	Sets the lower threshold for the transmit optical power of the optical transceiver installed in an interface.	The value varies according to the optical module vendor.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

You can run the **transceiver diagnosis threshold tx-power** command to adjust the transmit optical power of the optical transceiver.

Example

Set the upper and lower thresholds for the transmit optical power of the optical transceiver installed in GigabitEthernet 0/0/2 to default values.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/2
[HUAWEI-GigabitEthernet0/0/2] transceiver diagnosis threshold tx-power default
```

3.2.55 transceiver phony-alarm-disable

Function

The **transceiver phony-alarm-disable** command disables the alarm function for non-Huawei-certified switch optical modules.

The **undo transceiver phony-alarm-disable** command enables the alarm function for non-Huawei-certified switch optical modules.

By default, the alarm function is enabled for non-Huawei-certified switch optical modules.

Format

transceiver phony-alarm-disable

undo transceiver phony-alarm-disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Non-Huawei-certified switch optical modules may fail to work normally. If non-Huawei-certified switch optical modules are used on devices produced since July 1, 2013 (January 1, 2016 for QSFP+ 40GE optical modules), the devices generate a large number of alarms to prompt users to replace these optical modules with Huawei-certified switch optical modules. However, vendor information of optical modules early delivered from Huawei may not be recorded. Therefore, non-Huawei-certified switch optical module alarms are generated. These optical modules can still be used to protect customer investment. In this case, you can disable the alarm function for non-Huawei-certified switch optical modules.

Example

Disable the alarm function for non-Huawei-certified switch optical modules.

```
<HUAWEI> system-view
[HUAWEI] transceiver phony-alarm-disable
Info:Transceiver-phony-alarm disable.
```

Enable the alarm function for non-Huawei-certified switch optical modules.

```
<HUAWEI> system-view
[HUAWEI] undo transceiver phony-alarm-disable
Info:Transceiver-phony-alarm enable.
```

3.2.56 wavelength-channel

Function

The **wavelength-channel** command sets the wavelength channel of a wavelength-tunable optical module.

The **undo wavelength-channel** command restores the default wavelength channel of a wavelength-tunable optical module.

The default wavelength channel of a wavelength-tunable optical module is channel 1.

Format

wavelength-channel *channelnum*

undo wavelength-channel

Parameters

Parameter	Description	Value
channelnum	Specifies a wavelength channel number.	The value is an integer that ranges from 1 to 80.

Views

XGE interface view, 25GE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To adjust the wavelength of a wavelength-tunable optical module on an interface, run the **wavelength-channel** *channelnum* command on this interface. This command will add the wavelength-tunable optical module to a specified wavelength channel. Each wavelength channel has a fixed center wavelength and frequency. To view the mapping between the wavelength channel, center wavelength, and frequency, run the **display wavelength-map** command.

You can also run the **wavelength-channel frequency** *frequency-value* and **wavelength-channel wavelength** *wavelength-value* commands to set the wavelength and frequency of a wavelength-tunable optical module.

Precautions

- When the **wavelength-channel** command configuration exists on the interface, after the interface has a wavelength-tunable optical module installed, this optical module will automatically adjust its wavelength to the configured wavelength. If a copper module is installed, the command configuration remains but does not take effect. If a non-wavelength-tunable optical module is installed, the command configuration will not take effect and the system displays an alarm.
- Running the **wavelength-channel** command will open and close the laser, resulting in interface flapping.
- The **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, and **wavelength-channel wavelength** *wavelength-value*

commands are mutually exclusive with the **wavelength-channel trust sfp** command.

Example

Add a wavelength-tunable optical module to wavelength channel 20 on XGigabitEthernet0/0/2.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/2
[HUAWEI-XGigabitEthernet0/0/2] wavelength-channel 20
```

3.2.57 wavelength-channel frequency

Function

The **wavelength-channel frequency** command sets the frequency of a wavelength-tunable optical module.

The **undo wavelength-channel frequency** command restores the default frequency of a wavelength-tunable optical module.

The default frequency of a wavelength-tunable optical module is the same as that of wavelength channel 1.

Format

wavelength-channel frequency *frequency-value*

undo wavelength-channel frequency

Parameters

Parameter	Description	Value
frequency-value	Specifies a frequency.	The value is an integer ranging from 0 to 4294967295, in MHz.

Usage Guidelines

Usage Scenario

When two interfaces installed with optical modules are connected through optical fibers, the wavelengths of the two optical modules must match, and so do their frequencies; otherwise, the interfaces cannot go Up or transmit traffic. When a wavelength-tunable optical module is connected to an optical module with a fixed wavelength and frequency, you need to change the wavelength and frequency of the wavelength-tunable optical module to match with those of its connected optical module, respectively.

You can run the **wavelength-channel frequency** *frequency-value* command to set the frequency of a wavelength-tunable optical module and run the **wavelength-channel wavelength** *wavelength-value* command to set the wavelength of a wavelength-tunable optical module. You can also run the **wavelength-channel** *channelnum* command to set the wavelength channel of a wavelength-tunable optical module. This changes its wavelength and frequency at the same time. To view the mapping between the wavelength channel, wavelength, and frequency, run the **display wavelength-map** command.

Precautions

- When the **wavelength-channel** command configuration exists on the interface, after the interface has a wavelength-tunable optical module installed, this optical module will automatically adjust its wavelength to the configured wavelength. If a copper module is installed, the command configuration remains but does not take effect. If a non-wavelength-tunable optical module is installed, the command configuration will not take effect and the system displays an alarm.
- Running the **wavelength-channel** command will open and close the laser, resulting in interface flapping.
- The **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, and **wavelength-channel wavelength** *wavelength-value* commands are mutually exclusive with the **wavelength-channel trust sfp** command.

Example

Set the frequency of the wavelength-tunable optical module on XGigabitEthernet 0/0/2 to 192100000 MHz.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/2
[HUAWEI-XGigabitEthernet0/0/2] wavelength-channel frequency 192100000
```

3.2.58 wavelength-channel wavelength

Function

The **wavelength-channel wavelength** command sets the wavelength of a wavelength-tunable optical module.

The **undo wavelength-channel wavelength** command restores the default wavelength of a wavelength-tunable optical module.

The default wavelength of a wavelength-tunable optical module is the same as that of wavelength channel 1.

Format

wavelength-channel wavelength *wavelength-value*

undo wavelength-channel wavelength

Parameters

Parameter	Description	Value
wavelength-value	Specifies a wavelength.	The value is an integer ranging from 0 to 4294967295, in pm.

Usage Guidelines

Usage Scenario

When two interfaces installed with optical modules are connected through optical fibers, the wavelengths of the two optical modules must match, and so do their frequencies; otherwise, the interfaces cannot go Up or transmit traffic. When a wavelength-tunable optical module is connected to an optical module with a fixed wavelength and frequency, you need to change the wavelength and frequency of the wavelength-tunable optical module to match with those of its connected optical module, respectively.

You can run the **wavelength-channel frequency** *frequency-value* command to set the frequency of a wavelength-tunable optical module and run the **wavelength-channel wavelength** *wavelength-value* command to set the wavelength of a wavelength-tunable optical module. You can also run the **wavelength-channel** *channelnum* command to set the wavelength channel of a wavelength-tunable optical module. This changes its wavelength and frequency at the same time. To view the mapping between the wavelength channel, wavelength, and frequency, run the **display wavelength-map** command.

Precautions

- When the **wavelength-channel** command configuration exists on the interface, after the interface has a wavelength-tunable optical module installed, this optical module will automatically adjust its wavelength to the configured wavelength. If a copper module is installed, the command configuration remains but does not take effect. If a non-wavelength-tunable optical module is installed, the command configuration will not take effect and the system displays an alarm.
- Running the **wavelength-channel** command will open and close the laser, resulting in interface flapping.
- The **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, and **wavelength-channel wavelength** *wavelength-value*

commands are mutually exclusive with the **wavelength-channel trust sfp** command.

Example

Set the wavelength of the wavelength-tunable optical module on XGigabitEthernet 0/0/2 to 1560606 pm.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/2
[HUAWEI-XGigabitEthernet0/0/2] wavelength-channel wavelength 1560606
```

3.2.59 wavelength-channel trust sfp

Function

The **wavelength-channel trust sfp** command configures a device to trust the wavelength channel of an optical module.

The **undo wavelength-channel trust sfp** command deletes the configuration.

By default, a device does not trust the wavelength channel of an optical module.

Format

wavelength-channel trust sfp

undo wavelength-channel trust sfp

Parameters

None

Views

XGE interface view, 25GE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a wavelength-tunable optical module is installed on a device, the device forcibly sets the wavelength channel to the default value 1 or a value configured using the **wavelength-channel** *channelnum* command. This makes the wavelength channel on the local device be different from that of on the remote device. As a result, the two devices fail to communicate. In this case, you can run the **wavelength-channel trust sfp** command to configure the device to trust the wavelength channel of the optical module.

Precautions

The **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, and **wavelength-channel wavelength** *wavelength-value* are mutually exclusive with the **wavelength-channel trust sfp** command. That is:

- After the **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, or **wavelength-channel wavelength** *wavelength-value* command is configured, the **wavelength-channel trust sfp** command cannot be configured.
- After the **wavelength-channel trust sfp** command is configured, the **wavelength-channel** *channelnum*, **wavelength-channel frequency** *frequency-value*, or **wavelength-channel wavelength** *wavelength-value* command cannot be configured.

Example

Configure the device to trust the wavelength channel of the optical module on XGigabitEthernet0/0/2.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/2
[HUAWEI-XGigabitEthernet0/0/2] wavelength-channel trust sfp
```

3.3 Stack Configuration Commands

3.3.1 Command Support

Table 3-50 Applicable product models and versions

Product	Software Version	Stack Connection Mode	Product Model
S200	Not supported	-	All S200 switches do not support stacking.
S300	V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S300 switches support stacking.
S300	V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S500 switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S1720 and S1730	Not supported	-	All S1720 and S1730 switches do not support stacking.
S2700-SI	Not supported	-	All S2700-SI switches do not support stacking.
S2710-SI	V100R006(C03&C05)	Service port connection using ordinary cables	All S2710-SI switches support stacking.
S2700-EI	V100R005C01, V100R006(C00&C01&C03&C05)	Service port connection using ordinary cables	S2700-9TP-EI-AC, S2700-9TP-EI-DC, S2700-9TP-PWR-EI, S2700-18TP-EI-AC, S2700-26TP-EI-AC, S2700-26TP-EI-DC, and S2700-26TP-PWR-EI do not support stacking, whereas other models support.

Product	Software Version	Stack Connection Mode	Product Model
S2720-EI	Versions supporting service port connection using ordinary cables: V200R006C10, V200R009C00, V200R010C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00	Service port connections using ordinary and dedicated cables	All S2720-EI switches support stacking.
S2730S-S	Versions supporting service port connection using ordinary cables: V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S2730S-S switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S2750-EI	Versions supporting service port connection using ordinary cables: V200R003C00, V200R005C00SPC300, V200R006C00, V200R007C00, V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00 Versions supporting service port connection using dedicated cables: V200R011C10 and V200R012C00	Service port connections using ordinary and dedicated cables	All S2750-EI switches support stacking.
S3700-SI	V100R005C01, V100R006(C00&C01&C03&C05)	Service port connection using ordinary cables	All S3700-SI switches support stacking.
S3700-EI	V100R005C01, V100R006(C00&C01&C03&C05)	Service port connection using ordinary cables	All S3700-EI switches support stacking.
S3700-HI	Not supported	-	All S3700-HI switches do not support stacking.
S5700-EI	V100R005C01, V100R006(C00&C01), V200R001(C00&C01), V200R002C00, V200R003C00, V200R005(C00&C01&C02&C03)	Stack card connection	All S5700-EI switches support stacking.
S5700-SI	V100R005C01, V100R006C00, V200R001C00, V200R002C00, V200R003C00, V200R005C00	Stack card connection	S5700-26X-SI-12S-AC does not support stacking, whereas other models support.

Product	Software Version	Stack Connection Mode	Product Model
S5700-HI	V200R003C00, V200R005C00	Service port connection using ordinary cables	All S5700-HI switches support stacking.
S5700-LI	Versions supporting service port connection using ordinary cables: V200R001C00, V200R002C00, V200R003(C00&C02&C10), V200R005C00SPC300, V200R006C00, V200R007C00, V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00 Versions supporting service port connection using dedicated cables: V200R011C10 and V200R012C00	Service port connections using ordinary and dedicated cables	S5700-10P-LI-AC, S5700-10P-PWR-LI-AC, S5700-28P-LI-BAT, and S5700-28P-LI-24S-BAT do not support stacking, whereas other models support.
S5700S-LI	Versions supporting service port connection using ordinary cables: V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00 Versions supporting service port connection using dedicated cables: V200R011C10 and V200R012C00	Service port connections using ordinary and dedicated cables	S5700S-28P-LI-AC and S5700S-52P-LI-AC do not support stacking, whereas other models support.
S5710-EI	V200R001C00, V200R002C00, V200R003C00, V200R005(C00&C02)	Service port connection using ordinary cables	All S5710-EI switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5710-HI	V200R005C03	Service port connection using ordinary cables	All S5710-HI switches support stacking.
S5710-C-LI	V200R001C00	Stack card connection	All S5710-C-LI switches support stacking.
S5710-X-LI	Versions supporting service port connection using ordinary cables: V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00 Versions supporting service port connection using dedicated cables: V200R011C10 and V200R012C00	Service port connections using ordinary and dedicated cables	All S5710-X-LI switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5720-LI and S5720S-LI	Versions supporting service port connection using ordinary cables: V200R010C00, V200R011C00, V200R011C10, V200R012(C00&C20), V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5720-LI and S5720S-LI switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5720-SI and S5720S-SI	Versions supporting service port connection using ordinary cables: V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S5720-SI and S5720S-SI switches support stacking.
S5720I-SI	V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	S5720I-6X-PWH-SI-AC and S5720I-10X-PWH-SI-AC do not support stacking, whereas other models support.

Product	Software Version	Stack Connection Mode	Product Model
S5720-EI	V200R007C00, V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connection using ordinary cables: S5720-C-EI, S5720-PC-EI Stack card connection: S5720-P-EI, S5720-C-EI, S5720-X-EI, S5720-PC-EI When using the stack card connection mode, note the following: ● S5720-C-EI and S5720-PC-EI series switches use dedicated stack cards to set up stacks. ● S5720-X-EI and S5720-P-EI series switches use stack ports fixed on cards to set up stacks.	All S5720-EI switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5720-HI	Versions supporting service port connection using ordinary cables: V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S5720-HI switches support stacking.
S5730-HI	V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S5730-HI switches support stacking.
S5731-H	V200R013C02, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5731-H switches support stacking.
S5731S-H	V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5731S-H switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5731-L and S5731S-L	Not supported	-	All S5731-L and S5731S-L switches do not support stacking.
S5731-S and S5731S-S	V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5731-S and S5731S-S switches support stacking.
S5732-H	Versions supporting service port connection using ordinary cables: V200R019C00, V200R019C10, V200R019C20, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00 Versions supporting service port connection using dedicated cables: V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5732-H switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5730-SI	Versions supporting service port connection using ordinary cables and dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting stack card connection: V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables, and stack card connection	All S5730-SI switches support stacking.
S5730S-EI	Versions supporting service port connection using ordinary cables and dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting stack card connection: V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables, and stack card connection	All S5730S-EI switches support stacking.
S5735-L, S5735S-L, and S5735S-L-M	V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5735-L, S5735S-L, and S5735S-L-M switches support stacking.
S5735-L-I	V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5735-L-I switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S5735-L1 and S5735S-L1	V200R020C10, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	S5735-L8T4S-A1(98011284-001), S5735-L8P4S-A1(98011295-001), S5735-L24T4S-A1(98011306-001), and S5735-L24P4S-A1(98011321-001) do not support stacking, whereas other models support.
S5735-S and S5735S-S	V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S5735-S and S5735S-S switches support stacking.
S5735-S-I	V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	Only the S5735-S24T4X-I switch supports stacking.
S5735S-H	V200R020C00, V200R020C10, V200R020C30, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connection using ordinary cables	All S5735S-H switches support stacking.
S5736-S	V200R020C00, V200R020C10, V200R020C30, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connection using ordinary cables	All S5736-S switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S6700-EI	V100R006C00, V200R001(C00&C01), V200R002C00, V200R003C00, V200R005(C00&C01&C02)	Service port connection using ordinary cables	All S6700-EI switches support stacking.
S6720-EI	Versions supporting service port connection using ordinary cables: V200R008C00, V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6720-EI switches support stacking.
S6720-HI	V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S6720-HI switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S6720S-EI	Versions supporting service port connection using ordinary cables: V200R009C00, V200R010C00, V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6720S-EI switches support stacking.
S6720S-S	V200R020C00, V200R020C10, V200R020C30, V200R021C00, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connection using ordinary cables	All S6720S-S switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S6720-SI and S6720S-SI	Versions supporting service port connection using ordinary cables: V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S6720-SI and S6720S-SI switches support stacking.
S6720-LI and S6720S-LI	Versions supporting service port connection using ordinary cables: V200R011C00, V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10 Versions supporting service port connection using dedicated cables: V200R011C10, V200R012C00, V200R013C00, V200R019C00, V200R019C10	Service port connections using ordinary and dedicated cables	All S6720-LI and S6720S-LI switches support stacking.
S6730-H	V200R013C02, V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6730-H switches support stacking.

Product	Software Version	Stack Connection Mode	Product Model
S6730S-H	V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6730S-H switches support stacking.
S6730-S and S6730S-S	V200R019C00, V200R019C10, V200R020C00, V200R020C10, V200R021C00, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6730-S and S6730S-S switches support stacking.
S6735-S	V200R021C00SPC600, V200R021C01, V200R021C10, V200R022C00, V200R022C10, V200R023C00	Service port connections using ordinary and dedicated cables	All S6735-S switches support stacking.

3.3.2 display mad

Function

The **display mad** command displays the multi-active detection (MAD) configuration.

Format

display mad [**proxy** | **verbose**]

Parameters

Parameter	Description	Value
proxy	Displays information about the proxy device.	-
verbose	Displays detailed MAD configuration.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the MAD configuration, run the **display mad** command. If the **verbose** parameter is specified, detailed MAD configuration is displayed, including MAD-enabled interfaces and interfaces excluded from shutdown.

When MAD in relay mode is configured, you can run the **display mad proxy** command on the proxy device to check its MAD configuration.

Example

Display MAD configuration.

```
<HUAWEI> display mad
Current MAD domain: 0
MAD direct detection enabled: YES
MAD relay detection enabled: NO
```

Display detailed MAD configuration.

```
<HUAWEI> display mad verbose
Current MAD domain: 0
Current MAD status: Detect
Mad direct detect interfaces configured:
 GigabitEthernet2/0/8
 GigabitEthernet2/0/9
Mad relay detect interfaces configured:
Excluded ports(configurable):
 GigabitEthernet2/0/4
Excluded ports(can not be configured):
```

Display information about the specified proxy device.

```
<HUAWEI> display mad proxy
Mad relay interfaces configured:
 Eth-Trunk1
```

Table 3-51 Description of the **display mad** command output

Item	Description
Current MAD domain	MAD domain configured in the system. To configure this parameter, run the **mad domain** command.
MAD direct detection enabled	MAD in direct mode is configured. To configure MAD in direct mode, run the **mad detect mode direct** command.
MAD relay detection enabled	MAD in relay mode is configured. To configure MAD in relay mode, run the **mad detect mode relay** command.

Item	Description
Current MAD status	Current MAD status: ● Detect: The stack is running properly. ● Recovery: The switch that fails master switch election in a MAD scenario enters the Recovery state and blocks all of its service ports except those excluded from shutdown.
Mad direct detect interfaces configured	Interface on which MAD in direct mode is configured. To configure MAD in direct mode on an interface, run the **mad detect mode direct** command.
Mad relay detect interfaces configured	Interface on which MAD in relay mode is configured. To configure MAD in relay mode on an interface, run the **mad detect mode relay** command.
Excluded ports(configurable)	Interfaces excluded from shutdown. To configure interfaces excluded from shutdown, run the **mad exclude** command.
Excluded ports(can not be configured)	Interfaces that are excluded from shutdown in the system by default.
Mad relay interfaces configured	Interface on which the relay function is configured. To configure the relay function on an interface, run the **mad relay** command.

3.3.3 display stack

Function

The **display stack** command displays information about the member switches in a stack.

Format

display stack

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check stack information, including stack topology and stack member switches, run the **display stack** command.

This command can be used only after the stack function is enabled (default status).

Example

Display stack information.

```
<HUAWEI> display stack
Stack mode: Service-port
Stack topology type: Link
Stack system MAC: xxxx-xxxx-xxxx
MAC switch delay time: 10 min
Stack reserved VLAN: 4093
Slot of the active management port: 0
Slot   Role        MAC address      Priority   Device type
-------------------------------------------------------------
  0    Master      xxxx-xxxx-xxxx   200        S5720-28P-LI-AC
  1    Standby     xxxx-xxxx-xxxx   150        S5720-28P-LI-AC
```

Table 3-52 Description of the **display stack** command output

Item	Description
Stack mode	Stack connection mode supported by the switch: ● Service-port: Service port connection ● Card: Stack card connection
Stack topology type	Stack topology type: ● Link: chain topology ● Ring: ring topology
Stack system MAC	Stack system MAC address.
MAC switch delay time	Time after which the system MAC address of the stack is switched. To configure this parameter, run the **stack timer mac-address switch-delay** command.

Item	Description
Stack reserved VLAN	Stack reserved VLAN. To configure this parameter, run the **stack reserved-vlan** command.
Active management slot	Slot ID of the effective management interface in the stack. If no member switch in the stack has a management interface or all the management interfaces are Down, this field displays **--**. **NOTE** After a stack is set up, you can log in to the stack through any member switch's management interface or console interface. A stack can have only one effective management interface at a time.
Slot	Stack ID of the member switch.
Role	Member switch role: ● Master ● Standby ● Slave
MAC address	MAC address of the member switch.
Priority	Stack priority. To configure this parameter, run the **stack slot priority** command.
Device Type	Device model of the member switch.

3.3.4 display stack peers

Function

The **display stack peers** command displays information about the neighbors of a member switch.

Format

display stack peers

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check information about the neighbors of a member switch, run the **display stack peers** command.

This command can be used only after the stack function is enabled (default status).

Example

Display information about the neighbors of a member switch.

```
<HUAWEI> display stack peers
(B): Block all
Slot     Port1              Peer1     Port2              Peer2
--------------------------------------------------------------------------
0        STACK 1              1       STACK 2             None
1        STACK 1            None       STACK 2              0
```

Table 3-53 Description of the **display stack peers** command output

Item	Description
(B): Block all	Indicates that the stack port is blocked.
Slot	Stack ID of a member switch.
Port1	Stack port 1.
Peer1	Stack ID of the switch to which stack port 1 connects. If this field displays **ID(B)**, stack port 1 is blocked. If this field displays **None**, there is no peer device.
Port2	Stack port 2.
Peer2	Stack ID of the switch to which stack port 2 connects. If this field displays **ID(B)**, stack port 2 is blocked. If this field displays **None**, there is no peer device.

3.3.5 display stack port

Function

The **display stack port** command displays information about stack ports.

Format

display stack port [**brief** | **slot** *slot-id*]

Parameters

Parameter	Description	Value
brief	Displays summary of stack ports.	-
slot *slot-id*	Displays configuration of stack ports on a specified switch. *slot-id* specifies the stack ID of a switch.	Set the value according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display stack port** command to check summary and detailed information about stack ports.

Example

Display summary of stack ports on the S5720-LI (service port connection).

```
<HUAWEI> display stack port brief
PHY     :Physical state
Protocol:Stack link protocol state
*down   :administratively down
(r)     :Runts trigger error down
(c)     :CRC trigger error down
(l)     :Link-flapping trigger error down
(m)     :Media mismatch trigger error down
Stack Port              PHY    Protocol  InUti  OutUti    InErrors   OutErrors
------------------------------------------------------------------------------
stack-port0/1            up     up        0.00%  0.00%     0          0
  XGigabitEthernet0/0/1  up     up        0.00%  0.00%     0          0
  XGigabitEthernet0/0/2  up     up        0.00%  0.00%     0          0
stack-port0/2            up     up        0.00%  0.00%     0          0
  XGigabitEthernet0/0/3  up     up        0.00%  0.00%     0          0
  XGigabitEthernet0/0/4  up     up        0.00%  0.00%     0          0
```

Display summary of stack ports on the S6720-EI (service port connection).

```
<HUAWEI> display stack port brief
PHY     :Physical state
Protocol:Stack link protocol state
*down   :administratively down
(r)     :Runts trigger error down
(c)     :CRC trigger error down
(l)     :Link-flapping trigger error down
(m)     :Media mismatch trigger error down
Stack Port              PHY    Protocol  InUti  OutUti    InErrors   OutErrors
------------------------------------------------------------------------------
stack-port0/1
  XGigabitEthernet0/0/1  down   down      0.00%   0.00%          0
0
```

```
unAllocated
  XGigabitEthernet0/0/2  down   --       0.00%   0.00%          0          0
  XGigabitEthernet0/0/3  down   --       0.00%   0.00%          0          0
  XGigabitEthernet0/0/4  down   --       0.00%   0.00%          0          0
```

Table 3-54 Description of the **display stack port brief** command output

Item	Description
Stack Port	Number of a stack port. unAllocated indicates that a service port has become a stack member port but has not been bound to a logical stack port.
PHY	Physical status of an interface: ● down: The interface is physically disabled. ● up: The interface is physically enabled. ● *down: The interface is manually shut down. ● down(r): Runts error continuously occurs on a stack port. ● down(c): There are CRC error packets on a stack port. ● down(l): A stack port repeatedly alternates between Up and Down states. ● down(m): The rate of the optical module installed in a stack member port is not the rate required by the member port. ● down(s): A self-loop occurs on a stack port. **NOTE** Only the S5736-S, S5735-L, S5735S-L, S5735-L-I, S5735-L1,S5735S-L1, S5735S-L-M, S5735-S, S5735-S-I, S5735S-S, S5735S-H, and S6720S-S support this status.
Protocol	Link layer protocol status of the interface: ● down: A stack port does not receive stack link packets. ● up: A stack port can receive stack link detection packets.
InUti	Average inbound bandwidth usage of an interface within the last 300 seconds.
OutUti	Average outbound bandwidth usage within the last 300 seconds.
InErrors	Number of error packets received by an interface.
OutErrors	Number of error packets sent by an interface.

Display detailed information about stack ports (stack card connection).

```
<HUAWEI> display stack port
stack-port1/1:
---------------------------------------------
```

```
Current state : DOWN
Speed : NA

Input:  0 packets, 0 bytes

Table 3-55 Description of the **display stack port** command output (stack card connection)

Item	Description
stack-port1/1	Stack port 1 in slot 1.
Speed	Interface forwarding rate.
current state	Stack port status: - DOWN: The stack port is disabled. - UP: The stack port is enabled.

Item	Description
Input	Total number of packets received by the stack port.
Output	Total number of packets sent by the stack port.
Unicast	Number of unicast packets sent or received by the stack port.
Multicast	Number of multicast packets sent or received by the stack port.
Broadcast	Number of broadcast packets sent or received by the stack port.
Jumbo	Number of jumbo frames sent or received by the stack port.
Discard	Number of packets discarded by the stack port during physical layer detection.
Total Error	Total number of error packets found by the stack port during physical layer detection.
CRC	Number of CRC error packets received by the stack port.
Giants	Number of jumbo frames with correct FCS received by the stack port.
Jabbers	Number of jumbo frames with incorrect FCS received by the stack port.
Fragments	Number of undersized frames with incorrect FCS received by the stack port.
Runts	Number of undersized frames with correct FCS received by the stack port.
DropEvents	Number of received packets that are discarded because the GBP is full or there is back pressure.
Alignments	Number of frames with alignment errors received by the stack port.
Symbols	Number of coding error frames received by the stack port.
Ignoreds	Number of received MAC control frames whose OpCode is not PAUSE.
Frames	Number of packets with an incorrect 802.3 length received by the stack port.
Collisions	Number of packets that encountered 1 to 15 conflicts and sent by the stack port.
ExcessiveCollisions	Number of packets that encountered 16 conflicts and fail to be sent by the stack port.

Item	Description
Late Collisions	Number of packets sent by the stack port after a delay due to conflicts.
Deferreds	Number of packets sent by the stack port after a delay without any conflict.
Buffers Purged	Number of packets aged due to existence in the buffer for an extended time before being sent out by the stack port.

Display detailed information about stack ports (service port connection).

```
<HUAWEI> display stack port
*down : administratively down
Logic Port         Phy Port                    Online       Status
---------------------------------------------------------------------------
stack-port0/1      XGigabitEthernet0/0/1        present      up
                   XGigabitEthernet0/0/2        present      down
                   XGigabitEthernet0/0/4        present      down
stack-port0/2      XGigabitEthernet0/0/3        present      up
stack-port3/1      XGigabitEthernet3/0/1        present      up
stack-port3/2      XGigabitEthernet3/0/3        present      up
stack-port4/1      XGigabitEthernet4/0/1        present      up
stack-port4/2      XGigabitEthernet4/0/3        present      up
stack-port8/1      XGigabitEthernet8/0/1        present      up
stack-port8/2      XGigabitEthernet8/0/3        present      up
```

Table 3-56 Description of the **display stack port** command output (service port connection)

Item	Description
Logic Port	Number of a stack port.
Phy Port	Type and number of a physical member port.
Online	Presence of a physical member port. ● present: The current installed service card type is consistent with that configured on the switch. ● absent: The current installed service card type is inconsistent with that configured on the switch.

Item	Description
Status	Physical status of an interface: - down: The interface is physically disabled. - up: The interface is physically enabled. - *down: The interface is manually shut down. - down(r): Runts error continuously occurs on a stack port. - down(c): There are CRC error packets on a stack port. - down(l): A stack port repeatedly alternates between Up and Down states. - down(m): The rate of the optical module installed in a stack member port is not the rate required by the member port. - down(s): A self-loop occurs on a stack port. **NOTE** Only the S5736-S, S5735-L, S5735S-L, S5735-L-I, S5735-L1,S5735S-L1, S5735S-L-M, S5735-S, S5735-S-I, S5735S-S, S5735S-H, and S6720S-S support this status.

3.3.6 display stack port auto-cable-info

Function

The **display stack port auto-cable-info** command displays information about dedicated stack cables.

Format

display stack port auto-cable-info slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID of a member switch.	The value range depends on the device.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display stack port auto-cable-info** command to check interfaces supporting dedicated stack cables and whether dedicated stack cables have been connected to interfaces.

Example

Display information about dedicated stack cables on the switch with the slot ID 0.

```
<HUAWEI> display stack port auto-cable-info slot 0
Logic Port        Phy Port                   Cable-role
---------------------------------------------------------
stack-port0/1     XGigabitEthernet0/0/1      Slave
stack-port0/1     XGigabitEthernet0/0/2      --
stack-port0/2     XGigabitEthernet0/0/3      --
stack-port0/2     XGigabitEthernet0/0/4      Master
```

Table 3-57 Description of the **display stack port auto-cable-info** command output

Item	Description
Logic Port	Logical stack port.
Phy Port	Physical member port.
Cable-role	Role of a dedicated stack cable: ● Master: The installed dedicated stack cable is the master end. ● Slave: The installed dedicated stack cable is the slave end. ● --: No dedicated stack cable is connected to the current port.

3.3.7 display stack port speed

Function

The **display stack port speed** command displays the stack port working speed.

NOTE

Only the S5720-X-LI, S5720I-SI, S5732-H, and S5720S-X-LI support this command.

The S5720-P-LI does not support this command before the license is loaded and supports this command after the license is loaded and it restarts.

Format

display stack port speed

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display stack port speed** command to check the stack port's current working speed and working speed taking effect after a restart. To set the stack port working speed, run the **stack port speed** command.

Example

Display the stack port's current working speed and working speed taking effect after a restart.

```
<HUAWEI> display stack port speed
Stack Port                Current Speed    Next Speed
-----------------------------------------------------
stack-port2/1
  XGigabitEthernet2/0/1    10G              12G
stack-port2/2
  XGigabitEthernet2/0/4    10G              12G
stack-port3/1
  XGigabitEthernet3/0/1    10G              12G
  XGigabitEthernet3/0/3    10G              12G
stack-port3/2
  XGigabitEthernet3/0/28   10G              12G
  XGigabitEthernet3/0/30   10G              12G
```

Table 3-58 Description of the **display stack port speed** command output

Item	Description
Stack Port	Stack port.
Current Speed	Stack port's current working speed.
Next Speed	Stack port's working speed taking effect after a restart. To configure the parameter, run the **stack port speed** command.

3.3.8 display stack-port load-balance

Function

The **display stack-port load-balance** command displays the load balancing modes of stack ports.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display stack-port { **global load-balance** | **load-balance** [*slot-id*/*port-id*] }

Parameters

Parameter	Description	Value
slot-id	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.
port-id	Specifies the ID of a stack port.	The value is 1 or 2.
global	Displays the global load balancing mode. **NOTE** The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S only support this parameter.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display stack-port load-balance** command to check the load balancing modes of stack ports and then locate data transmission failures between stack links.

Example

Display the load balancing modes of stack ports.

```
<HUAWEI> display stack-port load-balance
Global load balance mode: ENHANCED
Stack-port0/1 load balance mode: ENHANCED
Stack-port0/2 load balance mode: ENHANCED
Stack-port1/1 load balance mode: DST-MAC
Stack-port1/2 load balance mode: SRC-MAC
Stack-port2/1 load balance mode: DST-IP
Stack-port2/2 load balance mode: SRC-DST-IP
```

Table 3-59 Description of the **display stack-port load-balance** command output

Item	Description
Global load balance mode	Global load balancing mode: - DST-IP: performs load balancing based on destination IP addresses. - DST-MAC: performs load balancing based on destination MAC addresses. - SRC-IP: performs load balancing based on source IP addresses. - SRC-MAC: performs load balancing based on source MAC addresses. - SRC-DST-IP: performs load balancing based on the Exclusive-OR result of source and destination IP addresses. - SRC-DST-MAC: performs load balancing based on the Exclusive-OR result of source and destination MAC addresses. - ENHANCED: enhanced load balancing mode, that is, load balancing based on the Exclusive-OR result of the source and destination MAC addresses. To set the global load balancing mode, run the **stack-port load-balance mode** command in the system view.

Item	Description
Stack-port0/1 load balance mode Stack-port0/2 load balance mode Stack-port1/1 load balance mode Stack-port1/2 load balance mode Stack-port2/1 load balance mode Stack-port2/2 load balance mode	Load balancing mode of a stack port: ● DST-IP: performs load balancing based on destination IP addresses. ● DST-MAC: performs load balancing based on destination MAC addresses. ● SRC-IP: performs load balancing based on source IP addresses. ● SRC-MAC: performs load balancing based on source MAC addresses. ● SRC-DST-IP: performs load balancing based on the Exclusive-OR result of source and destination IP addresses. ● SRC-DST-MAC: performs load balancing based on the Exclusive-OR result of source and destination MAC addresses. ● ENHANCED: enhanced load balancing mode, that is, load balancing based on the Exclusive-OR result of the source and destination MAC addresses. To set the load balancing mode for a stack port, run the **stack-port load-balance mode** command in the stack port view.

3.3.9 display stack configuration

Function

The **display stack configuration** command displays stack configuration commands configured in a stack.

Format

display stack configuration [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the stack commands configured on a stack member switch. *slot-id* specifies the stack ID of the member switch.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

Stack configuration will only be written to the flash memory instead of the configuration file. As a result, Stack configuration cannot be obtained through the configuration file. To view stack configuration, run the **display stack configuration** command.

Precautions

- This command is valid only when the stack function is enabled and has taken effect. By default, the stack function is enabled.
- This command displays only the stack commands that have been executed. The displayed command configuration is not necessarily the running stack configuration, because most stack configuration commands take effect after a system restart.

Example

Display the stack configuration commands that have been executed in a stack.

```
<HUAWEI> display stack configuration
*    : Invalid-configuration
#    : Unsaved configuration
---------------Configuration on slot 2
Begin---------------

stack enable
stack slot 0 renumber 2
stack slot 2 priority 150
stack reserved-vlan 4093
stack timer mac-address switch-delay 10

interface stack-port 2/1
 *port interface XGigabitEthernet2/0/1 enable

interface stack-port 2/2
 #port interface XGigabitEthernet2/0/4 enable
---------------Configuration on slot 2 End-----------------
```

- If a stack member port is marked with an asterisk (*), the current configuration does not take effect because of the following reasons:
  - The current configuration is the preconfiguration that has not taken effect.
  - Insert different types of subcards.
  - The stack member port is located on a subcard that is not available.
  - When ports on the device panel and ports on subcards cannot be used together, one of the two port types is configured as stack member ports but not configured as the ports that take effect on the device, and the device is restarted.
- If a stack member port is marked with a number sign (#), the current configuration is automatically generated for dedicated cable stacking but not

saved to the flash memory using the **save stack configuration** or **save** command.

- If a stack member port is marked with *#, the switch is using stack card stacking. In this case, the **display stack configuration** command displays the stack configuration that is automatically generated after dedicated stack cables are installed. To change stack card stacking to dedicated stack cable stacking, run the **save stack configuration** or **save** command to save the stack configuration to the flash memory and then restart the switch.

3.3.10 display stack channel

Function

The **display stack channel all** command displays stack link connections and status.

Format

display stack channel [**all** | **slot** *slot-id*]

Parameters

Parameter	Description	Value
all	Displays stack link connections and status of all the member switches.	-
slot *slot-id*	Displays stack link connections and status of the member switch with a specified stack ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check stack link connections and status, run the **display stack channel all** command. If you do not specify **all** or **slot** *slot-id* in the command, this command displays the stack link connections and status of the master switch.

Example

Display stack link connections and status of all the member switches.

```
<HUAWEI> display stack channel all
!     : Port have received packets with CRC error.
L-Port: Logic stack port
```

```
P-Port: Physical port
Slot  L-Port  P-Port    Speed  State  ||  P-Port    Speed  State  L-Port  Slot
--------------------------------------------------------------------------------
1     1/2     GE1/0/28  2.5G   UP         GE2/0/27  2.5G   UP     2/1     2
2     2/1     GE2/0/27  2.5G   UP         GE1/0/28  2.5G   UP     1/2     1
--------------------------------------------------------------------------------
```

The following output information shows that the physical member port GE1/0/28 works at 2.5 Gbit/s and is in Up state; it is bound to stack port 1/2 and belongs to the member switch with stack ID 1; GE1/0/28 is connected to the physical member port GE2/0/27; GE2/0/27 works at 2.5 Gbit/s and is in Up state; It is bound to stack port 2/1 and belongs to member switch with stack ID 2.

```
1     1/2     GE1/0/28  2.5G   UP         GE2/0/27  2.5G   UP     2/1     2
```

Table 3-60 Description of the **display stack channel** command output

Item	Description
!	A physical member port has received CRC error packets. **NOTE** If a physical member port receives CRC error packets, its **Speed** field displays the speed value and an exclamation mark (!), for example, 2.5G!.
Slot	Stack ID of a device.
L-Port	Number of a stack port.
P-Port	Number of a physical member port.
Speed	Speed of a physical member port.
Status	Status of a physical member port.

3.3.11 display upgrade area

Function

The **display upgrade area** command displays area status and whether a smooth upgrade can start.

Format

display upgrade area

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the stack topology changes after the areas for smooth upgrade are divided, members in the active and backup areas may change, resulting in a smooth upgrade failure. To check whether a smooth upgrade can start in these areas, run the **display upgrade area** command.

If the areas fail the check, re-define the active and backup areas according to the current stack topology.

The active area contains the master switch.

Example

Display the current area status and whether a smooth upgrade can start.

```
<HUAWEI> display upgrade area
Slot      Area         Upgrade-Check
-----------------------------------
   0      backup       passed
   3      active       passed
   4      active       passed
   8      active       passed
```

Table 3-61 Description of the **display upgrade area** command output

Item	Description
Slot	Stack ID of a device.
Area	Area to which a device belongs. ● active ● backup ● unknown: The device does not belong to any area.
Upgrade-Check	Upgrade check result. ● passed ● failed

3.3.12 display upgrade state

Function

The **display upgrade state** command displays the smooth upgrade status of member switches in a stack.

Format

display upgrade state [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the status of member switches in the active and backup areas before or after a smooth upgrade, run the **display upgrade state** command.

If you specify the **slot** *slot-id* parameter in the command, you can check whether the member switch with this slot ID has been upgraded successfully.

If the master switch of a stack restarts or experiences a master/standby switchover after a smooth upgrade, area information will be deleted from the master switch, and the **Area** field of the master switch will be displayed as **unknown**.

Example

Display the smooth upgrade status of member switches in a stack.

```
<HUAWEI> display upgrade state
Slot      Area          Status
-----------------------------
   0      backup        backup rebooting
   3      backup        backup rebooting
   4      active       backup rebooting
   8      active       backup rebooting
```

Display the smooth upgrade status of the member switch with stack ID 4.

```
<HUAWEI> display upgrade state slot 4
--------------------------------------
  Slot         : 4
  Area         : backup
  Status       : successful
  ErrorCode   : 0
  Description :
--------------------------------------
```

Table 3-62 Description of the **display upgrade state** command output

Item	Description
Slot	Stack ID of a device.

Item	Description
Area	Area to which a device belongs. ● active ● backup ● unknown: The device does not belong to any area.
Status	Upgrade progress of a device. ● idle: The upgrade has not been performed yet. ● backup rebooting: The backup area is upgrading. ● active rebooting: The active area is upgrading. ● failed: The upgrade failed. ● successful: The upgrade succeeded.
ErrorCode	Error code of an upgrade failure. For details, see **3.3.38 upgrade start**. The value 0 indicates that the upgrade succeeded.
Description	Description about the failure if an upgrade fails.

3.3.13 interface stack-port

Function

The **interface stack-port** command displays the stack port view.

NOTE

Only devices supporting service port stacking support this command.

Format

interface stack-port *member-id*/*port-id*

Parameters

Parameter	Description	Value
member-id	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.
port-id	Specifies a stack port number.	The value is 1 or 2.

Views

System view

Default Level

3: Management level

Usage Guidelines

Each member switch has two stack ports, which are named Stack-Port*n*/1 and Stack-Port*n*/2. *n* specifies the stack ID of a member switch. After you run the **interface stack-port** command to enter the view of a stack port, you can configure attributes for the stack port.

Example

Display the view of Stack-Port1/1.

```
<HUAWEI> system-view
[HUAWEI] interface stack-port 1/1
[HUAWEI-stack-port1/1]
```

3.3.14 mad backup ip address

Function

The **mad backup ip address** command configures a backup IP address for the management interface in a stack.

The **undo backup ip address** command deletes the backup IP address for the management interface in a stack.

By default, no backup IP address is configured for the management interface in a stack.

Format

mad backup ip address *ip-address* { *mask* | *mask-length* }

undo mad backup ip address

Parameters

Parameter	Description	Value
ip-address	Specifies the backup IP address for the management interface.	The value is in dotted decimal notation.
mask	Specifies the subnet mask of the backup IP address for the management interface.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the backup IP address for the management interface.	The value is an integer that ranges from 0 to 32.

Views

MEth0/0/1 management interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When MAD detects a stack split fault, all interfaces (including the management interface) of the member device that fails in the election are shut down to prevent network flapping caused by identical MAC and IP addresses, reducing the impact on the network. After the management interface of the member device is shut down, you cannot remotely log in to and manage the device, and can only log in to the device through the console interface, which is inconvenient for device maintenance.

To prevent this problem, you can configure a backup IP address for the management interface on the device. If the stack splits, the IP address of the management interface on the member device that fails in the election is set to the configured backup IP address. This prevents packet forwarding from being affected due to conflicting management IP addresses upon the stack split. In addition, you can remotely log in to and manage the device, which facilitates device maintenance.

If the stack splits after a backup IP address is configured for the management interface on the device, the management interface on the member device that fails in the election is not shut down, and only the backup IP address is configured as the IP address of the management interface. Other non-reserved service interfaces are still shut down.

Precautions

- This command does not take effect if the device does not have a management interface.
- The backup IP address cannot be on the same network segment as the IP addresses used by other interfaces on the device. Otherwise, the function does not take effect due to address conflicts.
- This command can only be used to configure the IP address of the management interface, regardless of the Up/Down status of the management interface. For example, if the management interface is shut down using a command or the management interface is not connected using a cable, the management interface is Down.

Example

Configure a backup IP address for the management interface in a stack.

```
<HUAWEI> system-view
[HUAWEI] interface meth 0/0/1
[HUAWEI-MEth0/0/1] mad backup ip address 10.1.1.1 24
```

3.3.15 mad detect mode direct

Function

The **mad detect mode direct** command configures multi-active detection (MAD) in direct mode on an interface.

The **undo mad detect** command cancels the configuration.

By default, MAD in direct mode is disabled on an interface.

Format

mad detect mode direct

undo mad detect [**mode direct**]

Parameters

None

Views

GE interface view, XGE interface view, 25GE interface view, 40GE interface view, port group view, MultiGE interface view, 100GE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure that only one switch becomes the master switch after a stack splits, thereby enhancing stack stability, run the **mad detect mode direct** command to configure MAD in direct mode on an interface.

Configuration Impact

Configuring MAD in direct mode on an interface blocks the interface. Disabling MAD in direct mode on an interface restores the forwarding function of the interface. If a loop exists on the network, a broadcast storm occurs.

Precautions

The **undo mad detect** command is not supported in the port group view. You can only run the **undo mad detect mode direct** command in the port group view to disable MAD in direct mode.

Example

Configure MAD in direct mode on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] mad detect mode direct
Warning: This command will block the port, and no other configuration running on this port is
recommended. Continue? [Y/N]:y
```

3.3.16 mad detect mode relay

Function

The **mad detect mode relay** command configures multi-active detection (MAD) in relay mode on an interface.

The **undo mad detect** command cancels the configuration.

By default, MAD in relay mode is disabled on an interface.

Format

mad detect mode relay

undo mad detect [**mode relay**]

Parameters

None

Views

Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure that only one switch becomes the master switch after a stack splits, thereby enhancing stability of the stack, run the **mad detect mode relay** command to configure MAD in relay mode on an Eth-trunk.

Precautions

The **undo mad detect** command is not supported in the port group view. You can only run the **undo mad detect mode relay** command in the port group view to disable MAD in relay mode.

Example

Configure MAD in relay mode on Eth-Trunk 10.

```
<HUAWEI> system-view
[HUAWEI] interface eth-trunk 10
[HUAWEI-Eth-Trunk10] mad detect mode relay
```

3.3.17 mad domain

Function

The **mad domain** command sets a MAD domain ID for a stack.

The **undo mad domain** command restores the default MAD domain ID for a stack.

By default, the MAD domain ID of a stack is 0.

Format

mad domain *domain-id*

undo mad domain

Parameters

Parameter	Description	Value
domain-id	Specifies the MAD domain ID for a stack.	The value is an integer that ranges from 0 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

In most MAD scenarios, configuring a MAD domain ID for a stack is unnecessary. When two stack systems function as a proxy of each other to implement MAD, configure different MAD domain IDs for the stack systems.

Example

Set the MAD domain ID for a stack to 1.

```
<HUAWEI> system-view
[HUAWEI] mad domain 1
```

3.3.18 mad exclude

Function

The **mad exclude** command excludes specified interfaces of a stack from shutdown.

The **undo mad exclude** command cancels excluding specified interfaces of a stack from shutdown.

By default, only physical member ports are excluded from shutdown.

Format

mad exclude interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

undo mad exclude interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

Parameters

Parameter	Description	Value
interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] }	Specifies the type and number of an interface: ● *interface-type* specifies the type of the interface. ● *interface-number1* specifies the number of the first interface. ● *interface-number2* specifies the number of the second interface.	The value of *interface-number2* must be larger than that of *interface-number1*.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If MAD detects a stack split, all service ports of the member switch that fails master switch election must be shut down to prevent network flapping caused by MAC or IP address flapping. If some interfaces only transparently transmit packets, they do not affect network operation in a dual-active condition. You can run the **mad exclude** command to exclude these interfaces from shutdown before a stack split occurs.

Precautions

- After an interface is shut down because of MAD, it cannot be enabled if the **mad exclude** command is executed to exclude it from shutdown.
- When the **to** parameter is specified to exclude multiple ports from shutdown, these ports must reside on the same card and the port number following this parameter must be larger than the port number followed by this parameter.

Example

Exclude GigabitEthernet0/0/2 and GigabitEthernet0/0/3 from shutdown.

```
<HUAWEI> system-view
[HUAWEI] mad exclude interface gigabitethernet 0/0/2 to gigabitethernet 0/0/3
```

3.3.19 mad relay

Function

The **mad relay** command enables the relay function on an interface of a proxy device.

The **undo mad relay** command disables the relay function on an interface of a proxy device.

By default, the relay function is disabled on an interface.

Format

mad relay

undo mad relay

Parameters

None

Views

Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

For MAD working in relay mode, run the **mad relay** command to configure the relay function on an Eth-Trunk interface of a proxy device. Member interfaces of the Eth-Trunk interface exchange MAD packets between member switches.

Example

Enable the relay function on Eth-Trunk 10 of a proxy device.

```
<HUAWEI> system-view
[HUAWEI] interface eth-trunk 10
[HUAWEI-Eth-Trunk10] mad relay
```

3.3.20 mad restore

Function

The **mad restore** command restores all the blocked interfaces of a standby switch that enters the Recovery state after its stack splits.

Format

mad restore

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When MAD detects a multi-active event, the member switch elected as the master switch remains in the Detect state. The elected standby switch enters the Recovery state, shuts down all its service ports except those excluded from shutdown, and stops forwarding service packets.

If the switch in the Detect state fails or is removed before the split stack is restored, run the **mad restore** command on the switch in the Recovery state to restore the interfaces in shutdown state. The switch in the Recovery state then goes to the Detect state. You can then restore the original switch in the Detect state and rectify the faulty stack links. After the faults are rectified, the two switches form a stack again.

Example

Restore all the blocked interfaces of the standby switch that enters the Recovery state after its stack splits.

```
<HUAWEI> system-view
[HUAWEI] mad restore
```

3.3.21 port interface enable

Function

The **port interface enable** command configures a service interface as a physical member port and adds it to a stack port.

The **undo port interface enable** command restores a physical member port to being a service interface.

By default, service interfaces are not used as physical member ports of a stack port.

NOTE

Only the switches supporting service port stacking support this command.

Format

port interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10> **enable**

undo port interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10> **enable**

Parameters

Parameter	Description	Value
interface-type interface-number1 [**to** *interface-type interface-number2*]	Specifies the type and number of an interface: ● *interface-type* specifies the type of the interface. ● *interface-number1* specifies the number of the first interface. ● *interface-number2* specifies the number of the second interface.	The value of *interface-number2* must be larger than that of *interface-number1*.

Views

Stack interface view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In service interface connection mode, run the **port interface enable** command to configure a service interface as a physical member port to implement the stack function.

Configuration Impact

A stack physical member port supports only stack-related functions, and other functions cannot be configured on the interface. All the commands irrelevant to the stack function are masked in the interface view, and only basic configuration commands, such as **description**, are retained.

After configuring a service port of a switch as a physical stack member port, you are advised to save the configuration if this service port has been referenced by other commands. Otherwise, the commands that reference this service port may be retained after the switch restarts.

On the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S the electrical or optical port stack configuration on the front panel is mutually exclusive with the SVF client mode configuration. If electrical or optical ports on the front panel have been configured as stack physical member ports, SVF management VLAN cannot be configured. If an SVF management VLAN has been configured, electrical or optical ports on the front panel cannot be configured as stack physical member ports.

On the S6720-EI, S6735-S, and S6720S-EI, every four of XGE interfaces from the left are added to one group. For example, XGE interfaces numbered 1 to 4 can be added to one group, but XGE interfaces numbered 2 to 5 cannot. That is, the number of the last XGE interface in each group must be the multiple of 4. If you configure any interface in each group as a physical member port, configurations on the other three interfaces in the group will be lost and the three interfaces cannot be used as service ports.

Precautions

- The stack member ports of a logical stack port must be the same type.
- After a UCL group is created on the S5720I-SI, S5720-LI, S5720S-LI, or S5720-SI, using the **ucl-group** command, the **port interface enable** command cannot be used to configure a service interface as a stack member port.
- To restore a physical member port as a service interface, run the **shutdown interface** command in the stack port view and then run the **undo port interface enable** command.
- On the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S, after a service interface is configured as a stack member port, the following priority mapping rules apply to packets on this interface:
  - Packets sent to the CPU are mapped to queue 7.
  - Packets with priority 0 or 1 are mapped to queue 0.
  - Packets with priorities 2 to 7 are mapped to queues 1 to 6, respectively.
- If the switch functions as an AS in an SVF system and its downlink service ports have been configured as member ports of an uplink fabric port, all the downlink ports of the AS cannot be configured as stack member ports.

Example

Configure XGigabitEthernet0/0/28 as a physical member port and add it to stack port 0/1.

```
<HUAWEI> system-view
[HUAWEI] interface stack-port 0/1
[HUAWEI-stack-port0/1] port interface xgigabitethernet 0/0/28 enable
Warning: Enabling stack function may cause configuration loss on the interface. Continue? [Y/N]:y
Info: This operation may take a few seconds. Please wait....
```

On the S6720-EI, configure XGigabitEthernet0/0/15 as a physical member port and add it to stack port 0/1.

```
<HUAWEI> system-view
[HUAWEI] interface stack-port 0/1
[HUAWEI-stack-port0/1] port interface xgigabitethernet 0/0/15 enable
Warning: Enabling stack function may cause configuration loss on the interface XGigabitEthernet0/0/13 to
XGigabitEthernet0/0/16. Continue? [Y/N]:y
Info: This operation may take a few seconds. Please wait....
Info: Ports XGigabitEthernet0/0/13 to XGigabitEthernet0/0/16 in a port group have been configured as
physical stack ports.
```

3.3.22 reset stack configuration

Function

The **reset stack configuration** command clears all stack configuration. That is, this command restores the default stack configuration.

Format

reset stack configuration

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The cleared stack configuration includes: switch slot ID, stack priority, stack reserved VLAN, stack MAC address switching delay, stack port configuration, and stack port rate configuration. For example, when switches are stacked using dedicated stack cables, to ensure that slot IDs are automatically generated for the switches based on the sequence in which dedicated stack cables are connected, run the **reset stack configuration** command to clear all stack configuration.

Precautions

Running this command will cause the stack to split and member switches to restart.

Example

Clear all stack configuration.

```
<HUAWEI> system-view
[HUAWEI] reset stack configuration
Warning: This operation will clear all stack configurations and may lead to the loss of the slot ID
configuration and cause the device to reset immediately. Are you sure you want to continue? [Y/N]:y
```

3.3.23 reset stack port statistics

Function

The **reset stack port statistics** command clears stack port statistics.

Format

reset stack port statistics [*slot-id*/*port-id*]

Parameters

Parameter	Description	Value
slot-id	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.
port-id	Specifies the number of a stack port.	The value is 1 or 2.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting interface traffic statistics in a certain period of time, run the **reset stack port statistics** command to clear existing traffic statistics. If you do not specify the port number, statistics on all stack ports are cleared. If you specify the port number, only statistics on the specified port are cleared.

Precautions

The cleared statistics cannot be restored. Therefore, exercise caution when you run the **reset stack port statistics** command.

This command can be used only after the stack function is enabled (default status).

Example

Clear the statistics from all stack ports.

```
<HUAWEI> reset stack port statistics
```

3.3.24 save stack configuration

Function

The **save stack configuration** command saves the stack configuration automatically generated for dedicated cable stacking to the flash memory.

By default, the stack configuration automatically generated for dedicated cable stacking is not saved to the flash memory.

Format

save stack configuration

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After dedicated stack cables are connected to ports, stack configuration is automatically generated but not saved to the flash memory. If these cables are removed or other cables are connected, the stack configuration is automatically deleted. To ensure that the stack configuration still takes effect when these cables are removed or other cables are connected, run the **save stack configuration** command.

Precautions

- Removing dedicated stack cables from ports after this command is executed will cause these ports unable to automatically become service ports.
- No stack configurations can be manually modified before the stack configuration automatically generated for dedicated cable stacking is saved to the flash memory.

Example

Save the stack configuration that is automatically generated for dedicated cable stacking to the flash memory.

```
<HUAWEI> system-view
[HUAWEI] save stack configuration
Warning: This operation will save all stack configurations to flash. Are you sure you want to continue? [Y/
N]:y
```

3.3.25 set l2-traffic fast-recover

Function

The **set l2-traffic fast-recover enable** command enables fast recovery of Layer 2 traffic.

The **undo set l2-traffic fast-recover enable** command disables fast recovery of Layer 2 traffic.

By default, fast recovery of Layer 2 traffic is disabled.

Format

set l2-traffic fast-recover enable

undo set l2-traffic fast-recover enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After fixed switches set up a stack and the standby switch starts, the standby switch restores configurations and then implements batch backup from the master switch.

By default, interfaces on the standby switch become Up when batch backup is complete. In this case, Layer 2 and Layer 3 traffic can be normally forwarded but there is a delay in Layer 2 traffic recovery. To enable fast recovery of Layer 2 traffic, run the **set l2-traffic fast-recover enable** command. Interfaces on the standby switch then immediately go Up when configuration restoration is complete. This way, however, cannot ensure Layer 3 traffic forwarding through the Up interfaces.

Example

Enable fast recovery of Layer 2 traffic.

```
<HUAWEI> system-view
[HUAWEI] set l2-traffic fast-recover enable
```

3.3.26 shutdown interface

Function

The **shutdown interface** command shuts down a physical member interface.

The **undo shutdown interface** command enables a physical member interface.

By default, a physical member interface is enabled after being configured.

NOTE

Only devices supporting service port stacking support this command.

Format

shutdown interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

undo shutdown interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

Parameters

Parameter	Description	Value
interface-type interface-number1 [**to** *interface-type interface-number2*]	Specifies the type and number of an interface: ● *interface-type* specifies the type of the interface. ● *interface-number1* specifies the number of the first interface. ● *interface-number2* specifies the number of the second interface.	The value of *interface-number2* must be larger than that of *interface-number1*.

Views

Stack interface view

Default Level

3: Management level

Usage Guidelines

To restore a physical member interface to being a service interface, run the **shutdown interface** command in the stack interface view and then run the **undo port interface enable** command.

If there is only one available link on a stack interface, running the **shutdown interface** command will change the stack status or split the stack. After you run the **undo shutdown interface** command on the stack interface, the stack will be set up again when a link on the stack interface becomes available.

Example

Shut down physical member interface XGigabitEthernet0/0/3.

```
<HUAWEI> system-view
[HUAWEI] interface stack-port 0/1
[HUAWEI-stack-port0/1] shutdown interface XGigabitEthernet0/0/3
Warning: Shutting down the last active stack-port will cause a topology change. Continue? [Y/N]:y
Info: This operation may take a few seconds. Please wait...succeeded.
```

3.3.27 stack authentication

Function

The **stack authentication** command configures the authentication mode and authentication information used when a switch needs to join a stack.

The **undo stack authentication** command deletes the authentication mode and authentication information used when a switch needs to join a stack.

By default, a switch does not need to be authenticated when joining a stack.

Format

stack authentication slot *slot-id* { **mac-address** *mac-address* | **esn** *esn-value* | **shared-key cipher** *shared-key* }

undo stack authentication slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID of a switch.	The value is an integer that ranges from 0 to 8.
mac-address *mac-address*	Configures MAC-based authentication.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits.
esn *esn-value*	Configures ESN-based authentication.	The value is a string of 10 to 32 characters.
shared-key cipher *shared-key*	Configures shared key-based authentication.	The value is a string of case-sensitive characters without spaces. A plain text key contains 1 to 64 characters, and a cipher text key contains 48 to 108 characters. **NOTE** It is recommended that a shared key contains at least seven characters, including at least two types of lowercase letters, uppercase letters, digits, and special characters. The master switch and the specified slot must configure the same shared key. If a shared key is used for authentication, the master switch and the member switch specified in this command must be configured with the same shared key.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A switch can join a stack without being authenticated. In this situation, an attacker can add any switch to a stack to obtain the configuration file of the stack master switch, resulting in information leak. To solve this problem, configure authentication when a switch needs to join a stack. This configuration ensures that this switch joins the stack only when it is authenticated successfully.

A switch will be authenticated only when its stack ID is the same as that specified in the **stack authentication** command. Otherwise, this switch can join a stack without being authenticated. Therefore, before adding a switch to a stack, you are advised to change the slot ID of the switch to an unused stack ID in the stack and then configure an authentication mode for this stack ID.

Precautions

- This command can be executed only after the stacking function is enabled.
- Only one authentication mode can be configured for a stack ID, and the latest configuration takes effect.
- If a switch to join a stack fails the authentication, this switch will restart repeatedly.

Example

Configure MAC-based authentication to be used when a switch with the stack ID 4 needs to join a stack.

```
<HUAWEI> system-view
[HUAWEI] stack authentication slot 4 mac-address 3-3-3
```

3.3.28 stack led enable

Function

The **stack led enable** command enables a service port indicator to indicate the stack ID of a stack switch.

The **stack led disable** command disables a service port indicator from indicating the stack ID of a stack switch.

By default, a service port indicator does not indicate the stack ID of a stack switch.

NOTE

S6735-S does not support this command.

Format

stack led enable [**duration** *duration-value*]

stack led disable

Parameters

Parameter	Description	Value
duration *duration-value*	Specifies how long a service port indicator indicates the stack ID of a stack switch.	The value is an integer that ranges from 30 to 600, in seconds. By default, a stack ID indicator stays on for 45 seconds.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Stack IDs can be allocated by the master switch when a stack is set up, or you can configure them yourself. If stack IDs are allocated by the master switch, you cannot identify which ID a device maps to. To enable a service port indicator to indicate the stack ID of a stack switch, run the **stack led enable** command.

A service port indicator indicates the stack ID of a stack switch as follows:

- For a switch whose stack ID ranges from 1 to 8: Only the indicator whose serial number matches the stack ID is on. For example, if the stack ID is 1, the first indicator is on. If the stack ID is 2, the second indicator is on.
- For a switch whose stack ID is 0: If the stack contains *N* stack switches, the first *N* indicators are on. For example, if the stack contains 9 stack switches, the first 9 indicators are on, indicating the stack ID is 0.
- After service port indicators are configured to indicate the stack IDs, the service port indicator of the master switch blinks, and that of the slave switch is steady on.

The configuration of this command becomes invalid when port indicators show stack IDs of member switches for the specified time.

Example

Enable a service port indicator to indicate the stack ID of a stack device for a period of 30s.

```
<HUAWEI> stack led enable duration 30
```

3.3.29 stack-port load-balance mode

Function

The **stack-port load-balance mode** command sets a load balancing mode for the physical member ports of a stack port.

The **undo stack-port load-balance mode** command restores the default load balancing mode.

By default, the physical member ports of a stack port perform load balancing in enhanced mode, that is, load balancing based on the Exclusive-OR result of the source and destination MAC addresses.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

stack-port load-balance mode { **dst-ip** | **dst-mac** | **src-dst-ip** | **src-dst-mac** | **src-ip** | **src-mac** }

undo stack-port load-balance mode

Parameters

Parameter	Description	Value
dst-ip	Performs load balancing based on destination IP addresses.	-
dst-mac	Performs load balancing based on destination MAC addresses.	-
src-dst-ip	Performs load balancing based on the Exclusive-OR result of the source and destination IP addresses.	-
src-dst-mac	Performs load balancing based on the Exclusive-OR result of the source and destination MAC addresses.	-
src-ip	Performs load balancing based on source IP addresses.	-

Parameter	Description	Value
src-mac	Performs load balancing based on source MAC addresses.	-

Views

System view

Logical stack port view (The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support the **stack-port load-balance mode** command in this view.)

Default Level

3: Management level

Usage Guidelines

Use Scenario

To transmit traffic from a stack port to a destination over different links, run the **stack-port load-balance mode** command to configure an appropriate load balancing mode for the physical member ports of the stack port. Outgoing traffic is then properly balanced among the physical links, preventing congestion on these links. If you run this command multiple times to set different load balancing modes, the last configuration takes effect. The load balancing mode configured in the system view takes effect globally, and the load balancing mode configured in a stack port view takes effect only on the specified stack port. You can run the **display stack-port** command to view the load balancing mode on a stack port.

Precautions

- If a non-default load balancing mode is configured on a stack port, the configured load balancing mode takes effect. If a stack port uses the default load balancing mode and the global load balancing mode is not the default one, the global load balancing mode takes effect.
- If the source MAC address-based load balancing mode is used, Layer 3 packets forwarded to a downstream device may fail to be balanced among the stack links because the source MAC address of the packets is the fixed system MAC address. If the traffic rate exceeds the bandwidth of a single stack link, some packets may be dropped.

Example

Set the global load balancing mode to **src-ip**.

```
<HUAWEI> system-view
[HUAWEI] stack-port load-balance mode src-ip
```

Set the load balancing mode on stack port 0/1 to **dst-ip**.

```
<HUAWEI> system-view
[HUAWEI] interface stack-port 0/1
[HUAWEI-stack-port0/1] stack-port load-balance mode dst-ip
```

3.3.30 stack port speed

Function

The **stack port speed** command sets the working speed for stack member ports.

The **undo stack port speed** command restores the working speed of stack member ports to the default value.

For the default working speeds of stack member ports on different switch models, see "Stack Support and Version Requirements" in Stack Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Device Management*.

NOTE

Only the S5720-X-LI, S5720I-SI, S5732-H, and S5720S-X-LI support this command.

The S5720-P-LI does not support this command before the license is loaded and supports this command after the license is loaded and it restarts.

Format

stack port speed { **12G** | **2.5G** | **40GE** }

undo stack port speed

Parameters

Parameter	Description	Value
12G	Sets the working speed of stack member ports to 12 Gbit/s. This speed can be set only on the S5720-P-LI, S5720-X-LI, S5720I-SI, and S5720S-X-LI,.	-
2.5G	Sets the working speed of stack member ports to 2.5 Gbit/s. This speed can be set only on the S5720-P-LI, S5720-X-LI, and S5720S-X-LI.	-

Parameter	Description	Value
40GE	Sets the working speed of stack member ports to 40 Gbit/s. This speed can be set only on the S5732-H.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

On the S5720-P-LI, S5720-X-LI, S5720I-SI, and S5720S-X-LI,, if optical ports are used as stack member ports and are connected using 1 m or 3 m SFP+ passive copper cables, you can use this command to increase their working speed from 10 Gbit/s to 12 Gbit/s, expanding the stack bandwidth. After their working speed is increased to 12 Gbit/s, switches using these ports cannot set up a stack with switches using ports with the working speed 10 Gbit/s.

If S5720-P-LI, S5720-X-LI, and S5720S-X-LI switches use XGE optical ports to stack with other switches that have GE optical ports, use this command to reduce the working speed of the XGE optical ports from 10 Gbit/s to 2.5 Gbit/s, so that the XGE optical ports can work with the remote GE optical ports.

On the S5732-H, if 100GE and 40GE ports need to be connected using 2 m QSFP28 dedicated stack cables for stack setup, run this command to reduce the working speed of the 100GE ports that function as stack member ports to 40 Gbit/s.

You can run the **display stack port speed** command to check the working speed of stack member ports.

Precautions

After changing the working speed of stack member ports, you need to restart the switch for the new speed to take effect.

Example

Set the working speed of stack member ports to 12 Gbit/s.

```
<HUAWEI> system-view
[HUAWEI] stack port speed 12G
```

3.3.31 stack port { crc | link-flap } trigger

Function

The **stack port { crc | link-flap } trigger** command sets the stack port error-down parameters.

The **undo stack port { crc | link-flap } trigger** command restores the default settings of the stack port error-down parameters.

By default, the stack port receives 20 CRC error packets (include Symbols error packets) per minute or alternates between Up and Down states 10 times per minute, the error-down check interval is 3 minutes, and the alarm clearance interval is 0 (not cleared automatically).

Format

stack port { **crc** | **link-flap** } **trigger** { **threshold** *threshold* | **interval** *interval* } *

undo stack port { **crc** | **link-flap** } **trigger** { **threshold** | **interval** }

stack port { **crc** | **link-flap** } **trigger error-down auto-recovery-interval** *auto-recovery-interval*

undo stack port { **crc** | **link-flap** } **trigger error-down auto-recovery-interval**

Parameters

Parameter	Description	Value
crc	Sets the parameters for stack port error-down alarms triggered by CRC error packets (include Symbols error packets).	-
link-flap	Sets the parameters for stack port error-down alarms triggered by port Up/Down transitions.	-
threshold *threshold*	Specifies the error-down alarm threshold.	The value is an integer. It ranges from 1 to 10000 for error-down alarms triggered by CRC error packets (include Symbols error packets) and ranges from 3 to 30 for error-down alarms triggered by port Up/Down transitions. The unit is times per minute.

Parameter	Description	Value
interval *interval*	Specifies the error-down check interval.	The value is an integer that ranges from 3 to 30, in minutes.
auto-recovery-interval *auto-recovery-interval*	Specifies the error-down alarm clearance interval.	The value is an integer that ranges from 3 to 30, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

After the stack port error-down function is enabled, you can run the **stack port { crc | link-flap } trigger** command to adjust the related parameters.

Example

Set the clearance interval of stack port error-down alarms triggered by CRC error packets (include Symbols error packets) to 3 minutes. That is, if the rate of received CRC error packets (include Symbols error packets) stays below the threshold for 3 minutes, the stack port changes to Up state and the error-down alarm is cleared.

```
<HUAWEI> system-view
[HUAWEI] stack port crc trigger error-down auto-recovery-interval 3
```

3.3.32 stack port { crc | link-flap } trigger error-down

Function

The **stack port { crc | link-flap } trigger error-down** command enables the stack port error-down function.

The **undo stack port { crc | link-flap } trigger error-down** command disables the stack port error-down function.

By default, the stack port error-down function is enabled.

Format

stack port { **crc** | **link-flap** } **trigger error-down**

undo stack port { **crc** | **link-flap** } **trigger error-down**

Parameters

Parameter	Description	Value
crc	Enables stack port error-down triggered by CRC error packets (include Symbols error packets).	-
link-flap	Enables stack port error-down triggered by port Up/Down transitions.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a stack system, if a stack port continuously receives CRC error packets (include Symbols error packets) or flaps between Up and Down states, the corresponding stack link cannot forward traffic normally, thereby affecting network services. This command enables the stack port error-down function. This function can shut down a stack port and switch traffic to other stack links if the rate of received CRC error packets (include Symbols error packets) or the number of Up/Down transitions on the stack port reaches the specified threshold, reducing the impact on services. Additionally, the system generates stack port error-down alarms to help in fault location.

Follow-up Procedure

Run the **stack port { crc | link-flap } trigger** command to set stack port error-down parameters.

Precautions

- When one end is a stack port and the other end is a service port, the system does not set the stack port to error-down state or generate an error-down alarm even if this stack port continuously receives CRC error packets (include Symbols error packets).
- The stack port error-down alarm OID is 1.3.6.1.4.1.2011.5.25.183.1.22.59.
- The stack port error-down alarm clearance OID is 1.3.6.1.4.1.2011.5.25.183.1.22.60.

Example

Enable stack port error-down triggered by CRC error packets (include Symbols error packets).

```
<HUAWEI> system-view
[HUAWEI] stack port crc trigger error-down
```

3.3.33 stack reserved-vlan

Function

The **stack reserved-vlan** command configures a reserved VLAN for a stack.

By default, a stack uses VLAN 4093 as the reserved VLAN.

Format

stack reserved-vlan *vlan-id*

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of a reserved VLAN.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

3: Management level

Usage Guidelines

By default, a stack uses VLAN 4093 as the reserved VLAN. A reserved VLAN is used only to exchange stack protocol packets.

To deploy services in VLAN 4093, run the **stack reserved-vlan** command to change the reserved VLAN of the stack.

NOTICE

If the reserved VLAN is used for other services, the stack cannot be set up. You must specify an unused VLAN as the reserved VLAN for a stack.

Example

Configure VLAN 4000 as the reserved VLAN of a stack.

```
<HUAWEI> system-view
[HUAWEI] stack reserved-vlan 4000
Warning: Do not frequently modify the stack reserved VLAN because it will make the stack split. Continue?
[Y/N]:y
```

3.3.34 stack slot priority

Function

The **stack slot priority** command sets a stack priority for a member switch in a stack.

By default, the stack priority of a member switch is 100.

Format

stack slot *slot-id* **priority** *priority*

Parameters

Parameter	Description	Value
slot-id	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.
priority	Specifies a stack priority.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To set a stack priority for a member switch in a stack, run the **stack slot priority** command. A larger priority indicates a higher priority, meaning that a switch is more likely to be selected as a master switch.

Example

Set the stack priority of the member switch with stack ID 4 to 150.

```
<HUAWEI> system-view
[HUAWEI] stack slot 4 priority 150
Warning: Do not frequently modify the priority because it will make the stack split. Continue? [Y/N]:y
```

3.3.35 stack slot renumber

Function

The **stack slot renumber** command changes the stack ID of a specified stack member switch.

Format

stack slot *slot-id* **renumber** *new-slot-id*

Parameters

Parameter	Description	Value
slot-id	Specifies the current stack ID.	The value is an integer that ranges from 0 to 8.
new-slot-id	Specifies a new stack ID.	The value is an integer that ranges from 0 to 8.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To change the stack ID of a stack member switch, run the **stack slot renumber** command.

Precautions

- After changing the stack ID of a switch, if you do not restart the switch, the switch continues to use the original stack ID, and all physical resources are identified by the original stack ID.
- After changing the stack ID of a switch, if you restarts the switch, the new stack ID takes effect and all physical resources are identified by the new stack ID. In the configuration file, only the global stack configuration and stack priority of the switch continue to take effect. All other configurations related to the old stack ID (such as interface configuration) become invalid and must be reconfigured.

- After a UCL group is created on the S5720I-SI, S5720-LI, S5720S-LI, or S5720-SI, using the **ucl-group** command, the **stack slot renumber** command cannot be used to change the stack ID of a specified stack member switch.

Example

Change the stack ID of a stack member switch from 4 to 5.

```
<HUAWEI> system-view
[HUAWEI] stack slot 4 renumber 5
Warning: All the configurations related to the slot ID will be lost after the slot ID is
modified.
Do not frequently modify the slot ID because it will make the stack split. Continue? [Y/
N]:y
Info: Stack configuration has been changed, and the device needs to restart to make the configuration
effective.
```

3.3.36 stack timer mac-address switch-delay

Function

The **stack timer mac-address switch-delay** command sets a period after which a stack changes its system MAC address.

The **undo stack timer mac-address switch-delay** command configures a stack to change the system MAC address immediately after the owner of the original system MAC address leaves the stack.

By default, a stack changes the system MAC address after 10 minutes.

NOTICE

When a stack is configured to switch the system MAC address immediately, the system begins using the MAC address of the new master switch the moment the previous master switch fails or leaves the stack. This may cause protocols such as LACP and STP to flap, thereby affecting services.

Format

stack timer mac-address switch-delay *delay-time*

undo stack timer mac-address switch-delay

Parameters

Parameter	Description	Value
delay-time	Specifies a period after which a stack changes the system MAC address.	The value ranges from 0 to 60, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

When a member switch leaves a stack, if you specify the MAC address of the leaving switch as the stack MAC address and it does not rejoin the stack within the time specified by *delay-time*, the master switch changes the stack MAC address to its own MAC address.

The stack MAC address switchover delay time of any member switch in a stack is the same as that of the master switch.

If the value of the MAC address switchover timer is set to 0, no stack MAC address switchover will be performed.

This command can be used only after the stack function is enabled (default status).

Example

Set the MAC address switchover delay of the local switch to 4 minutes.

```
<HUAWEI> system-view
[HUAWEI] stack timer mac-address switch-delay 4
Warning: Do not frequently modify the MAC switching time because it will make the stack split. Continue?
[Y/N]:y
```

3.3.37 upgrade backup-area slot

Function

The **upgrade backup-area slot** command defines the active and backup areas in a stack in preparation for a smooth upgrade.

Format

upgrade backup-area slot *slot-id* **to** *slot-id*

Parameters

Parameter	Description	Value
slot-id	Specifies the stack ID of a member switch.	The value is an integer that ranges from 0 to 8.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before upgrading a reliable stack with uplinks and downlinks working in redundancy mode, you can divide the stack into an active area and a backup area for redundancy. After an upgrade is started, member switches in the two areas are upgraded in sequence, shortening the service interruption duration and reducing the impact of the upgrade on the network.

Precautions

- Member switches in the active and backup areas form the entire stack. When dividing active and backup areas, note that:
  - The active and backup areas cannot have the same member switch, and both areas must have at least one member switch.
  - The backup area cannot contain the master switch of the stack.
  - Member switches in each area must be directly connected.
- After this command is run, the member switches with specified stack IDs join the backup area. The other member switches automatically join the active area.
- To ensure mutual backup, it is recommended that the two areas have similar quantities of member switches.

Example

Add member switches with stack IDs 0 to 3 to the backup area.

```
<HUAWEI> system-view
[HUAWEI] upgrade backup-area slot 0 to 3
```

3.3.38 upgrade start

Function

The **upgrade start** command starts a smooth upgrade.

Format

upgrade start

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Before running this command, run the **upgrade backup-area slot** command to define the active and backup areas and ensure that all member switches in the stack are running the same system software and support smooth upgrades.

If an upgrade fails, error codes and displayed message help locate the cause. Table 3-63 lists the error codes and displayed messages in different upgrade failure scenarios.

Table 3-63 Error codes and displayed messages in different upgrade failure scenarios

Upgrade Failure Scenario	Error Code	Displayed Message
Record in the backup area: The upgrade in the backup area times out and rolls back.	1	Rollback due to timeout.
Record in the active area: The upgrade in the backup area times out and rolls back.	2	
Record in the backup area: The upgrade in the active area times out and rolls back.	3	
Record in the active area: The upgrade in the active area times out and rolls back.	4	
Record in the backup area: Rollback occurs due to a topology change in the backup area.	257	Rollback due to topology changes.
Record in the active area: Rollback occurs due to a topology change in the backup area.	258	

Upgrade Failure Scenario	Error Code	Displayed Message
Record in the backup area: Rollback occurs due to a topology change in the active area.	259	
Record in the active area: Rollback occurs due to a topology change in the active area.	260	
A member switch records that the master switch is not upgraded.	512	Master is not upgraded.
During a backup area upgrade, the master switch instructs switches in the backup area to roll back (after the active area instructs the backup area to upgrade and switches in the backup area restart).	769	Master notifies others of rollback.
During a backup area upgrade, the master switch instructs switches in the backup area to roll back (after the active area instructs the backup area to upgrade and before switches in the backup area restart).	770	
During an active area upgrade, the master switch instructs switches in the active area to roll back (after the backup area instructs the active area to upgrade and before switches in the active area restart).	771	

Upgrade Failure Scenario	Error Code	Displayed Message
During an active area upgrade, the master switch instructs switches in the active area to roll back (after the backup area instructs the active area to upgrade and switches in the active area restart).	772	
During a backup area upgrade, the master switch in the active area instructs switches in the backup area to roll back (after switches in the backup area restart).	1025	Master of the active area notifies others of rollback.
During a backup area upgrade, the master switch in the active area instructs switches in the backup area to roll back (before switches in the backup area restart).	1026	
During an active area upgrade, the master switch in the active area instructs switches in the active area to roll back (before switches in the active area restart).	1027	
During an active area upgrade, the master switch in the active area instructs switches in the active area to roll back (after switches in the active area restart).	1028	
During a backup area upgrade, the master switch in the backup area instructs switches in the backup area to roll back (after switches in the backup area restart).	1281	Master of the backup area notifies others of rollback.

Upgrade Failure Scenario	Error Code	Displayed Message
During a backup area upgrade, the master switch in the backup area instructs switches in the backup area to roll back (before switches in the backup area restart).	1282	
During an active area upgrade, the master switch in the backup area instructs switches in the active area to roll back (before switches in the active area restart).	1283	
During an active area upgrade, the master switch in the backup area instructs switches in the active area to roll back (after switches in the active area restart).	1284	
A load event occurs, and switches in the backup area roll back.	1537	Rollback due to a load event.
A load event occurs, and switches in the active area roll back.	1549	
The system software package is incorrect in the active area.	5	Active startup file is incorrect.
The system software package is incorrect in the backup area.	6	Backup startup file is incorrect.

Example

Start a smooth upgrade.

```
<HUAWEI> system-view
[HUAWEI] upgrade start
Warning: Upgrade will begin. Continue? [Y/N]:y
```

3.4 Intelligent Simplified Campus Network Configuration Commands

3.4.1 Command Support

All commands in this chapter are run on a central switch. The following table lists the device models that can function as central switches.

Table 3-64 Device models that can function as central switches

Series	Sub-series or MPU
S12700E	MPUE, MPUEC
S12700	MPUD
S7700	SRUHX1, SRUE1, SRUH1, SRUHA1, MCUD, SRUHD, SRUED, SRUH, SRUE
S6700	S6730-H, S6730S-H, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI, S6720S-S
S5700	S5732-H, S5731-H, S5731S-H, S5731-S, S5731S-S, S5736-S, S5736S-S, S5735S-H, S5735-S, S5735S-S, S5735-S-I, S5720I-SI, S5735-L, S5735S-L, S5735-L1, S5735S-L1, S5735-L-I, S5720-LI, S5720S-LI
S500, S300	-

3.4.2 bind interface

Function

The **bind interface** command binds an interface on the central switch to an RU for interconnection.

The **undo bind** command unbinds the interconnection interface from an RU.

By default, no interconnection interface is bound to an RU.

Format

bind interface *interface-type interface-number*

undo bind

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To deliver configurations to an RU, you need to bind an interface on the central switch to the RU for interconnection. After interface binding, you can run the **remote-unit connect-interface** *interface-type interface-number* command on the central switch to enter the view of an RU by specifying an interconnection interface, and run the **display remote-unit connect-interface** *interface-type interface-number* command to view information about an RU bound to a specific interconnection interface.

Precautions

- An interface can be bound to only one RU.
- An Eth-Trunk physical member interface cannot be bound to an RU.

Example

Bind XGigabitEthernet0/0/1 to the RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] bind interface XGigabitEthernet 0/0/1
```

3.4.3 commit (remote-unit N view)

Function

The **commit** command delivers configurations to a single RU.

Format

commit

Parameters

None

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After configuring an RU by running commands on the central switch, such as configuring the port rate, port isolation, port shutdown, or port negotiation, you need to run the **commit** command to make the configuration take effect.

Precautions

A central switch does not deliver configurations to RUs that fail to be authenticated or are not authenticated.

RUs do not save their configurations. After the central switch or an RU is restarted and works normally, the central switch preferentially delivers the configuration in the single RU view. If no configuration is available in the single RU view, the central switch delivers the configuration in the global RU view.

Example

Deliver configurations to RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] commit
```

3.4.4 commit (remote-unit view)

Function

The **commit** command delivers configurations to RUs.

Format

commit { **all** | **name** *remote-unit-name* | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Commits configurations of all RUs.	-

Parameter	Description	Value
name *remote-unit-name*	Specifies the alias of an RU.	The value is a string of 1 to 32 case-sensitive characters without spaces.
interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-

Views

remote-unit view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After configuring an RU by running commands on the central switch, such as the port rate, port isolation, port shutdown, and port negotiation, you need to run the **commit** command to deliver the configurations to the RU for the configurations to take effect.

The **commit** command can be run to deliver configurations to offline RUs. After an offline RU goes online, the central switch automatically applies the committed configurations to this RU.

Precautions

A central switch does not deliver configurations to RUs that fail to be authenticated or are not authenticated.

RUs do not save their configurations. After the central switch or an RU is restarted and works normally, the central switch preferentially delivers the configuration in the single RU view. If no configuration is available in the single RU view, the central switch delivers the configuration in the global RU view.

Follow-up Procedure

Run the **display remote-unit commit configuration** command to check the configurations that are successfully delivered to RUs, and run the **display remote-unit commit result** command to check configuration delivery results of RUs.

Example

Deliver configurations to the RU connected to XGigabitEthernet0/0/1 on the central switch.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] commit interface XGigabitEthernet 0/0/1
```

3.4.5 description (remote-unit N view)

Function

The **description** command sets a description for an RU.

The **undo description** command restores the default description of an RU.

By default, an RU has no description.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of an RU.	The value is a string of 1 to 64 case-sensitive characters, and can contain spaces.

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To facilitate management and maintenance of RUs, you can set descriptions for RUs to help you understand the usage of each RU.

Precautions

The description is displayed from the first non-space character.

Follow-up Procedure

Run the **display remote-unit commit configuration** command to check the configurations that are successfully delivered to RUs, and run the **display remote-unit commit result** command to check configuration delivery results of RUs.

Example

Set the description of an RU to **ru for office**.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] description ru for office
```

3.4.6 display remote-unit

Function

The **display remote-unit** command displays RU information.

Format

display remote-unit [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*][**verbose**]

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.
verbose	Displays detailed RU information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view RU information, including the ESN, alias, MAC address, device type, online duration, and firmware version of an RU.

Precautions

The central switch does not maintain information about RUs that attempt to go online when the number of connected RUs has reached the upper limit.

The **display remote-unit** command output displays information only about online RUs. You can run the **display current-configuration configuration remote-unit** command to view global configurations of RUs, or run the **display current-configuration configuration remote-unit-n** command to view the configuration of a specific RU.

Example

Display RU information.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit
------------------------------------------------------------------------------------------------------------------------
ESN                     ID        Type                ConnectInterface  Status      VersionMatch  Name
------------------------------------------------------------------------------------------------------------------------
219801176601XXXXXXXX    1         S5731-L8P2HT-RUA    XGE0/0/6          Normal      NO            RU1
219801176601XXXXXXXX    16777214  S5731-L8P2HT-RUA    XGE0/0/7          Normal      NO            RU2
------------------------------------------------------------------------------------------------------------------------
Total: 2, printed: 2
```

Table 3-65 Description of the **display remote-unit** command output

Item	Description
ESN	ESN of an RU.
ID	ID of an RU. This field displays a hyphen (-) if an RU is not configured with an ID.
Type	Device type of an RU.
ConnectInterface	Interconnection interface.
Status	Status of an RU: ● **Normal**: The RU is online. ● **Upgrading**: The RU is being upgraded. ● **Configuring**: The RU is being configured. ● **Idle**: The RU is in the initialization state. ● **Abnormal**: The link connecting the RU and central switch is faulty, or the RU is an excess one because the number of connected RUs has reached the upper limit.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.

Item	Description
VersionMatch	Whether the firmware version of the RU matches that of the central switch. ● **YES**: The version matches. ● **NO**: The version does not match. ● **-**: The firmware version of the HUAWEI S5731-L16P2SR-RUA or S5731S-L16P2SR-RUA cannot be upgraded to that of the central switch or that of the patch.
Total: *m*, printed: *n*	Total number of RUs (*m*) and number of RUs whose information is displayed (*n*).

Display detailed RU information.

```
<HUAWEI> display remote-unit verbose
Total number: 2

--------------------------------------------------------------------------
```

Table 3-66 Description of the **display remote-unit verbose** command output

Item	Description
Total number	Total number of RUs.
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
ID	ID of an RU. If an RU is not configured with an ID, a hyphen (-) is displayed.
Device mac	System MAC address of an RU.
Device type	Device type of an RU.
Item	Code of an RU.
Manufacture Date	Manufacture date of an RU.
Up time	Online duration of an RU.
APP version	APP firmware version.
POE version	PoE firmware version.
BIOS version	BIOS firmware version.
Connect interface	Interface connecting the central switch to an RU. If the central switch uses a physical Eth-Trunk member interface to connect to an RU, this field displays the Eth-Trunk interface to which the member interface belongs.
Disk usage	Disk usage of an RU.
Memory usage	Memory usage of an RU.
Temperature	Current temperature of an RU. **NOTE** If the temperature value cannot be read properly, this field displays a hyphen (-). In this case, check whether the central switch receives an alarm from the RU, indicating that the IIC channel is faulty. For details, see the description of the hwRuIICFault alarm.
Mac usage	MAC address table usage of an RU.
Disk space(MB)	Disk size of an RU.

Item	Description
Status	Status of an RU: - **Unknown** - **Idle**: The RU is in the initialization state. - **Normal**: The RU is online. - **Upgrading**: The RU is being upgraded. - **Configuring**: The RU is being configured. - **Abnormal**: The link connecting the RU and central switch is faulty, or the RU is an excess one because the number of connected RUs has reached the upper limit. - **Offline**: The RU is offline.
VersionMatch	Whether the firmware version of the RU matches that of the central device. - **YES**: The version matches. - **NO**: The version does not match.
Version support	Whether the RU supports the firmware of the central switch: - YES: compatible - NO: incompatible
Authen Result	Authentication result of an RU: - **Success** - **Authenticating** - **Fail** - **-**: The RU is not authenticated.

3.4.7 display remote-unit commit configuration

Function

The **display remote-unit commit configuration** command displays the configurations successfully delivered to RUs.

Format

display remote-unit commit configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

RUs do not support web-based management and cannot have commands run on them for configuration. All RU configurations are delivered by the central switch. You can run the **display remote-unit commit configuration** command on the central switch to view the configurations successfully delivered to RUs.

Example

Display the configurations successfully delivered to RUs.

```
<HUAWEI> display remote-unit commit configuration
#
remote-unit 3
 isolate disable
#
#
remote-unit 0
 isolate disable
 undo negotiation auto port 1
 speed 100 port 1
#
```

3.4.8 display remote-unit commit result

Function

The **display remote-unit commit result** command displays configuration delivery results of RUs.

Format

display remote-unit commit result

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

RUs do not support web-based management and cannot have commands run on them for configuration. All RU configurations are delivered by the central switch.

You can run the **display remote-unit commit result** command on the central switch to view configuration delivery results of RUs. A maximum of 500 result records are supported.

Example

Display configuration delivery results of RUs.

```
<HUAWEI> display remote-unit commit result
[HUAWEI-remote-unit-0] display remote-unit commit result
------------------------------------------------------------------------------
StartTime            ConnectInterface       CfgType        Result   SendCnt
------------------------------------------------------------------------------
2022/01/27 16:04:02   GE0/0/27              isolate        success  2
2022/01/27 16:04:02   GE0/0/27              shutdown        success  2
2022/01/27 16:04:02   GE0/0/27              negotiation     success  2
2022/01/27 16:04:02   GE0/0/27              speed           success  2
2022/01/27 16:04:02   XGE0/0/1              isolate        success  2
2022/01/27 16:04:02   XGE0/0/1              shutdown        success  2
2022/01/27 16:04:02   XGE0/0/1              negotiation     success  2
2022/01/27 16:04:02   XGE0/0/1              speed           success  2
```

Table 3-67 Description of the **display remote-unit commit result** command output

Item	Description
StartTime	Time when the configuration is delivered.
ConnectInterface	Interconnection interface.
CfgType	Configuration type.
Result	Delivery result: - **success** - **failed**
SendCnt	Number of times that the configurations of the same type are delivered to an RU.

3.4.9 display remote-unit connect record

Function

The **display remote-unit connect record** command displays onboarding and disconnection records of RUs.

Format

display remote-unit connect record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view onboarding and disconnection records of RUs, you can run the **display remote-unit connect record** command. In the command output, you can check when an RU is onboarded or disconnected and the disconnection cause. A maximum of 1024 records are supported.

Example

Display onboarding and disconnection records of RUs.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit connect record
-------------------------------------------------------------------------------------------------------
ESN                          ConnectInterface    Type    Offline Reason         Time
-------------------------------------------------------------------------------------------------------
219801177001XXXXXXXX           GE0/0/27          OnLine  -                   2022-02-08/17:00:36

Total records: 7
```

Table 3-68 Description of the **display remote-unit record** command output

Item	Description
ESN	ESN of an RU.
ConnectInterface	Interface connecting the central switch to an RU.
Type	Record type: ● **OnLine**: onboarding ● **OffLine**: disconnection

Item	Description
Offline Reason	Disconnection cause: - **Upgrade**: The RU was upgraded and restarted. - **Manual**: The RU was manually restarted. - **No heartbeat**: The RU lost heartbeats and went offline. - **Port down**: The interconnection interface went Down. - **Multi-RU on port**: Multiple RUs were connected to the same interface. - **Abnormal temperature**: The RU goes offline due to abnormal temperature. - **Unknown**
Time	Time when an RU entered this state.
Total records	Total number of records.

3.4.10 display remote-unit poe

Function

The **display remote-unit poe** command displays the global PoE power supply status of an RU.

Format

display remote-unit poe [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-

Parameter	Description	Value
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

1: Monitoring level

Usage Guidelines

You can use this command to view PoE power supply information about an RU, including the configured maximum power, current power consumption, peak power consumption, and PoE firmware status.

Example

Display the global PoE power supply information about the RU connected to XGigabitEthernet0/0/1.

```
<HUAWEI> display remote-unit poe connect-interface XGigabitEthernet 0/0/1
ESN                :21980117760123xxxxxxxx
Name                 :-
Device type          :S5731-L8P2HT-RUA
Connect interface  :XGigabitEthernet0/0/1
-----------------------------------------------------
PSE information    :
  PoE power supply(mW)                              :83000
  Total available power(mW)                         :83000
  Total power consumption(mW)                          :0
  Power peak value(mW)                              :0
  Power voltage(V)                              :54
  PSE reset times                             :0
  PoE failure                               :NO
-----------------------------------------------------
```

Table 3-69 Description of the **display remote-unit poe** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Connect interface	Interface connecting the central switch to an RU.
PoE power supply(mW)	Power supply.

Item	Description
Total available power(mW)	Total available power.
Total power consumption(mW)	Total output power.
Power peak value(mW)	Peak output power.
Power voltage(V)	Output voltage.
PSE reset times	Number of times that the PSE chip is reset.
PoE failure	Whether the PoE firmware is abnormal: ● **NO**: normal ● **YES**: abnormal

3.4.11 display remote-unit poe realtime

Function

The **display remote-unit poe realtime** command displays real-time PoE information about an RU.

Format

display remote-unit poe { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **realtime**

Parameters

Parameter	Description	Value
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.
interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-

3.4.12 display remote-unit port brief

Function

The **display remote-unit port brief** command displays brief information about interfaces on an RU.

Format

display remote-unit port [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*] **brief**

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To monitor interfaces on an RU or locate faults on interfaces, you can run the **display remote-unit port brief** command to view information about the interfaces, including the physical status, auto-negotiation status, working mode, and rate. If no parameter is specified, brief information about interfaces on all RUs is displayed.

Precautions

- An uplink 2.5GE optical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.
- An uplink 2.5GE hybrid optical-electrical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical or hybrid module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical or hybrid module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical or hybrid module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.

Example

Display brief information about interfaces on the RUs connected to Eth-Trunk 10 on the central switch.

```
<HUAWEI> display remote-unit port connect-interface Eth-Trunk 10 brief
ESN               :219801177801xxxxxxxx
Name              :-
Device type       :S5731-L8P2HT-RUA
Connect interface :Eth-Trunk10
-------------------------------------------------------------------------------------------
Interface    PHY    Negotiation   Duplex   Mode     Speed(Mbps)   Neighbor-Interface
-------------------------------------------------------------------------------------------
GE1          Up     Enable        Full     Copper   1000          -
GE2          Down   Enable        Full     Copper   1000          -
GE3          Down   Enable        Full     Copper   1000          -
GE4          Down   Enable        Full     Copper   1000          -
GE5          Down   Enable        Full     Copper   1000          -
GE6          Down   Enable        Full     Copper   1000          -
GE7          Down   Enable        Full     Copper   1000          -
GE8          Up     Enable        Full     Copper   1000          -
GE9          Down   Enable        Full     Copper   1000          -
GE10         Up     Enable        Full     Fiber    1000          GE0/0/36
-------------------------------------------------------------------------------------------
```

Table 3-71 Description of the **display remote-unit port brief** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.

Item	Description
Connect interface	Interconnection interface.
Interface	Interface on an RU.
PHY	Physical status of an RU interface: ● **up**: The interface is Up. ● **down**: The interface is Down.
Negotiation	Auto-negotiation status of an RU interface: ● **Enable**: The interface works in auto-negotiation mode. ● **Disable**: The interface works in non-auto negotiation mode.
Duplex	Duplex mode of an RU interface: ● **Full**: The interface works in full-duplex mode. ● **Half**: The interface works in half-duplex mode.
Mode	Working mode of an RU interface: ● **Copper**: electrical mode ● **Fiber**: optical mode
Speed(Mbps)	Rate at which an RU interface works.
Neighbor-Interface	Physical interface used by the central switch for connection with an RU.

3.4.13 display remote-unit port poe

Function

The **display remote-unit port poe** command displays PoE running information about an interface on an RU.

Format

display remote-unit port [*port-id*] **poe** [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface connecting the central switch to an RU. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display remote-unit port poe** command to view PoE running information about interfaces on an RU, including the current power, class of the power device (PD) connected to each interface, reference power of the PD, and power supply status.

If no parameter is specified, the PoE running information about all interfaces on all RUs is displayed.

Precautions

- An uplink 2.5GE optical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.
- An uplink 2.5GE hybrid optical-electrical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical or hybrid module. In V200R022C10 and earlier versions, the uplink interface configured with a

GE optical or hybrid module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical or hybrid module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.

Example

Display the running PoE information about all interfaces on the RU connected to XGigabitEthernet0/0/1 on the central switch.

```
<HUAWEI> display remote-unit port poe connect-interface XGigabitEthernet0/0/1

Table 3-72 Description of the **display remote-unit port poe** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Connect interface	Interface connecting the central switch to an RU.
PD class	Class of the PD connected to an interface. This field displays a hyphen (-) if **Power status** is **Detecting**.
PD reference power(mW)	Reference power of an interface. This field displays a hyphen (-) if **Power status** is **Detecting**.
PD current power(mW)	Current output power of an interface.
PD peak power(mW)	Peak output power of an interface.
PD average power(mW)	Average output power of an interface.
Power-up mode	Power supply mode of an interface.
Force power	Whether forcible PoE power supply is enabled on an interface. To configure this function, run the **poe force-power port** command.
Power ON/OFF	Whether the interface is supplying power: ● **on**: The interface is supplying power. ● **off**: The interface does not supply power.
Power-on delay(s)	Power supply delay of an interface, in seconds. The value 0 indicates no delay. To set this parameter, run the **poe power-on delay port** command.

Item	Description
Power status	Power supply status of an interface: - **Test mode**: indicates the testing state. - **Detecting**: indicates the detection state. - **Disabled**: indicates that PoE is disabled on the interface. - **Power-deny**: indicates that the reference power is greater than the maximum output power of the interface. - **Classification overcurrent**: indicates that the current of the PDs on the interface exceeds the threshold. - **Unknown**: indicates an unknown class. - **Power overcurrent**: indicates that the interface is in overcurrent condition. - **Power-on failed**: indicates that the interface fails to be powered on. - **Power-ready**: indicates that the interface is ready to be powered on. - **Powering**: indicates that the interface is being powered on. - **Powered**: indicates that the interface has been powered on. - **Overloaded**: indicates that the power is overloaded. - **Time-range power-off**: indicates that the interface is in the power-off time range. - **Unstable voltage**: indicates that the interface voltage is unstable. - **Legacy disable**: indicates that PD compatibility check is disabled on the interface. - **Class mismatch**: indicates that the interface does not support PD classification.
Current(mA)	Output current of an interface.
Voltage(V)	Output voltage of an interface.

3.4.14 display remote-unit port poe realtime

Function

The **display remote-unit port poe realtime** command displays real-time PoE information about an interface on an RU.

Format

display remote-unit port [*port-id*] **poe** { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **realtime**

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface connecting the central switch to an RU. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

```

Table 3-73 Description of the **display remote-unit port poe** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Connect interface	Interconnection interface.
PD class	Class of the PD connected to an interface. This field displays a hyphen (-) if **Power status** is **Detecting**.
PD reference power(mW)	Reference power of an interface. This field displays a hyphen (-) if **Power status** is **Detecting**.
PD current power(mW)	Current output power of an interface.
PD peak power(mW)	Peak output power of an interface.
PD average power(mW)	Average output power of an interface.
Power-up mode	Power supply mode of an interface.
Force power	Whether forcible PoE power supply is enabled on an interface. To configure this function, run the **poe force-power port** command.
Power ON/OFF	Whether the interface is providing power: ● **on**: The interface is supplying power. ● **off**: The interface does not supply power.
Power-on delay(s)	Power supply delay of an interface, in seconds. The value 0 indicates no delay. To set this parameter, run the **poe power-on delay port** command.

Item	Description
Power status	Power supply status of an interface: - **Test mode**: indicates the testing state. - **Detecting**: indicates the detection state. - **Disabled**: indicates that PoE is disabled on the interface. - **Power-deny**: indicates that the reference power is greater than the maximum output power of the interface. - **Classification overcurrent**: indicates that the current of the PDs on the interface exceeds the threshold. - **Unknown**: indicates an unknown class. - **Power overcurrent**: indicates that the interface is in overcurrent condition. - **Power-on failed**: indicates that the interface fails to be powered on. - **Power-ready**: indicates that the interface is ready to be powered on. - **Powering**: indicates that the interface is being powered on. - **Powered**: indicates that the interface has been powered on. - **Overloaded**: indicates that the power is overloaded. - **Time-range power-off**: indicates that the interface is in the power-off time range. - **Unstable voltage**: indicates that the interface voltage is unstable. - **Legacy disable**: indicates that PD compatibility check is disabled on the interface. - **Class mismatch**: indicates that the interface does not support PD classification.
Current(mA)	Output current of an interface.
Voltage(V)	Output voltage of an interface.

Item	Description
Insertion and removal status	Whether the interface has PD removal and installation records. ● **0**: initial value, which is meaningless. If an RU is started with a PD, this field displays **0**. ● **1**: indicates that the interface has PD installation records. ● **2**: indicates that the interface has PD removal records. ● **3**: indicates that the interface has PD removal and installation records

3.4.15 display remote-unit port realtime

Function

The **display remote-unit port realtime** command displays real-time information about interfaces on an RU.

Format

display remote-unit port { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **realtime**

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface connecting the central switch to an RU. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To monitor interfaces on a specific RU or locate faults on interfaces, you can run the **display remote-unit port realtime** command to view real-time information about the interfaces, including the physical status, auto-negotiation status, working mode, and rate.

Precautions

- An uplink 2.5GE optical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.
- An uplink 2.5GE hybrid optical-electrical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical or hybrid module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical or hybrid module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical or hybrid module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.

Example

Display information about all interfaces on the RUs connected to Eth-Trunk 10 on the central switch.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit port connect-interface Eth-Trunk 10 realtime
Info: This operation will take several seconds. Please wait...
ESN                :219801177801xxxxxxxx
Name               :-
Device type        :S5731-L4P2HW-RUA
Connect interface  :Eth-Trunk10
-----------------------------------------------------------------------------------------
Interface    PHY      Negotiation    Duplex    Mode     Speed(Mbps)   Neighbor-Interface
-----------------------------------------------------------------------------------------
GE1          Up       Enable         Full      Copper   1000          -
GE2          Down       Enable         Full      Copper   1000          -
GE3          Down       Enable         Full      Copper   1000          -
GE4          Down       Enable         Full      Copper   1000          -
GE5          Down       Enable         Full      Copper   1000          -
GE6          Up       Enable         Full      Fiber    1000          GE0/0/36
-----------------------------------------------------------------------------------------
```

Table 3-74 Description of the **display remote-unit port brief** command output

Item	Description
ESN	ESN of an RU.

Item	Description
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Connect interface	Interface connecting the central switch to an RU.
Interface	Interface of an RU.
PHY	Status of an RU interface: ● **up**: The interface is Up. ● **down**: The interface is Down.
Negotiation	Auto-negotiation status of an RU interface: ● **Enable**: The interface works in auto-negotiation mode. ● **Disable**: The interface works in non-auto negotiation mode.
Duplex	Duplex mode of an RU interface: ● **Full**: The interface works in full-duplex mode. ● **Half**: The interface works in half-duplex mode.
Mode	Working mode of an RU interface: ● **Copper**: electrical mode ● **Fiber**: optical mode
Speed(Mbps)	Rate at which an RU interface works.
Neighbor-Interface	Physical interface used by the central switch for connection with an RU.

3.4.16 display remote-unit port statistics

Function

The **display remote-unit port statistics** command displays traffic statistics about an interface on an RU.

Format

display remote-unit port [*port-id*] **statistics** [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34. If this parameter is not specified, statistics about all interfaces on the RU are displayed.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface connecting the central switch to an RU. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view the status and statistics of interfaces on an RU, including the interface physical status, basic configuration, and packet forwarding information. The information is refreshed every 60 seconds. You can use this command to collect traffic statistics or locate faults on an interface. If no index of an RU interface is specified, traffic statistics about all interfaces on the RU are displayed.

Precautions

- An uplink 2.5GE optical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical module. In V200R022C10 and earlier versions, the uplink interface configured with a GE optical module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.
- An uplink 2.5GE hybrid optical-electrical interface of an RU does not support a copper module, and supports only a GE or 2.5GE optical or hybrid module.

In V200R022C10 and earlier versions, the uplink interface configured with a GE optical or hybrid module can connect to a central switch only when it works at the rate of 1 Gbit/s. In V200R023C00 and later versions, the uplink interface configured with a 2.5GE optical or hybrid module can connect to a central switch when it works at the rate of 2.5 Gbit/s. After the rate of the uplink interface is changed, the RU automatically restarts for the change to take effect.

Example

Display traffic statistics on interface 1 of the RU connected to Eth-Trunk 10 on the central switch.

```
<HUAWEI> display remote-unit port 1 statistics connect-interface Eth-Trunk 10
ESN               :219801177601XXXXXXXX
Name              :S5731S-4P
Device type       :S5731-L8P2HT-RUA
Connect interface  :Eth-Trunk10
-------------------------------------------------------------------------------
GE1 current state : DOWN
Speed: 1000,  Duplex: Full,  Negotiation: Enable,  Mode: Copper,  Congestion: No
Input rate 0 bits/sec, 0 packets/sec
Output rate 0 bits/sec, 0 packets/sec

Input: 0 packets, 0 bytes
  Unicast:                       0,  Multicast:                       0
  Broadcast:                     0,  Jumbo:                           0
  Discard:                       0,  Pause:                           0
  Frames:                        0

  Total Error:                   0

    Input bandwidth utilization threshold : 80.00%
    Output bandwidth utilization threshold: 80.00%
    Last 60 seconds input utility rate : 0.00%
    Last 60 seconds output utility rate: 0.00%

-------------------------------------------------------------------------------
```

Table 3-75 Description of the **display remote-unit port statistics** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.

Item	Description
Device type	Device type of an RU.
Connect interface	Interconnection interface.
GE*n* current state	Physical status of the GE*n* interface on an RU. - **DOWN**: indicates that a fault occurs at the physical layer of the interface. The possible cause can be that no terminal is connected to the interface or the interface is shut down. - **Up**: indicates that the interface is physically Up.
Speed	Current rate of an interface. - In auto-negotiation mode, this field displays the interface rate after auto-negotiation with terminals. - In non-auto-negotiation mode, you can run the **speed** command to configure an interface rate.
Duplex	Duplex mode of an interface: - **Full**: The interface works in full-duplex mode. - **Half**: The interface works in half-duplex mode.
Negotiation	Auto-negotiation status of an interface. To configure auto-negotiation for an interface, run the **negotiation auto** command. - **Enable**: The interface works in auto-negotiation mode. - **Disable**: The interface works in non-auto negotiation mode.
Mode	Working mode of an interface: - **Copper**: electrical mode - **Fiber**: optical mode
Congestion	Congestion status of an RU interface: - **YES**: The RU interface is congested. - **NO**: The RU interface is not congested.
Input rate 0 bits/sec, 0 packets/sec	Rate of incoming packets on an interface.

Item	Description
Output rate 0 bits/sec, 0 packets/sec	Rate of outgoing packets on an interface.
Input	Total number of received packets. **NOTE** ● Packets that are longer than jumbo frames and have correct CRC values are counted in **Jumbo** statistics but not in **Input** statistics. ● An RU can forward a packet with a maximum size of 10240 bytes.
Output	Total number of sent packets.
Unicast	Number of unicast packets received or sent by an interface.
Multicast	Number of multicast packets received or sent by an interface.
Broadcast	Number of broadcast packets that are received or sent by the interface.
Jumbo	Statistics about outgoing packets on an interface. The following packets are counted: ● Ethernet frames longer than 1518 bytes and with correct FCS values Statistics about incoming packets on an interface. The following packets are counted: ● Ethernet frames with the length greater than or equal to 1519 bytes and less than the maximum jumbo frame length and correct FCS values ● VLAN frames with the length greater than or equal to 1519 bytes and less than the maximum jumbo frame length and correct FCS values ● Packets with the length greater than the maximum jumbo frame length
Discard	Number of packets discarded by an interface during physical layer detection. A possible cause can be interface congestion. **NOTE** Currently, this item is not supported, and the value is displayed as 0.

Item	Description
Frames	Number of packets with the incorrect 802.3 length received by an interface.
Pause	Number of pause frames.
Total Error	Number of error frames found during physical layer detection.
CRC	Number of packets longer than 63 bytes and with incorrect FCS values.
Giants	Number of received packets with the length exceeding the maximum jumbo frame length. **NOTE** Currently, this item is not supported, and the value is displayed as 0. Such packets are counted in the **Jumbo** field.
Runts	Number of received undersized frames with correct CRC values. An undersized frame is a frame that is shorter than 64 bytes, in correct format, and contains a valid CRC field. **NOTE** Packets with incorrect CRC values and the length shorter than 64 bytes are also counted in **Runts**.
DropEvents	Number of received packets that are discarded due to GBP full or back pressure.
Alignments	Number of received frames with alignment errors. **NOTE** Currently, this item is not supported, and the value is displayed as 0.
Symbols	Number of received frames with coding errors.
Ignoreds	Number of received MAC control frames whose OpCode is not PAUSE. **NOTE** If an RU interface receives an **Ignoreds** packet, the packet is not only counted as an Ignoreds packet, but also is counted as a unicast, multicast, or a broadcast packet. The total number of incoming packets on an interface has excluded repeated counts. Therefore, the statistics are correct.

Item	Description
Collisions	Number of collision frames. A collision frame is a frame that is not sent due to a detected collision.
Late Collisions	Number of deferred collision frames. A deferred collision frame is a frame that is delayed to be sent because of a deferred collision detected after the frame's first 512 bits are sent.
Deferreds	Number of deferred packets. A deferred packet refers to a packet that is delayed due to a detected collision.
Input bandwidth utilization threshold	Threshold for inbound bandwidth usage.
Output bandwidth utilization threshold	Threshold for outbound bandwidth usage.
Last 60 seconds input utility rate	Inbound bandwidth usage within the last 60 seconds.
Last 60 seconds output utility rate	Outbound bandwidth usage within the last 60 seconds.

3.4.17 display remote-unit port statistics realtime

Function

The **display remote-unit port statistics realtime** command displays real-time traffic statistics about an interface on an RU.

Format

display remote-unit port [*port-id*] **statistics** { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **realtime**

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34. If this parameter is not specified, statistics about all interfaces on the RU are displayed.

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

1: Monitoring level

Usage Guidelines

You can view the status and statistics of interfaces on an RU, including the interface physical status, basic configuration, and packet forwarding information. You can run this command when you need to collect real-time traffic statistics or diagnose faults on an interface in real time, or when you cannot locate faults according to the information reported by RUs at an interval of 60s.

Example

Display real-time traffic statistics about interface 1 on the RU connected to XGigabitEthernet0/0/5 on the central switch

```
<HUAWEI> display remote-unit port 1 statistics  connect-interface XGigabitEthernet 0/0/5 realtime
ESN               :219801176601XXXXXXXX
Name              :-
Device type       :S5731-L8P2HT-RUA
Connect interface :XGigabitEthernet 0/0/5
----------------------------------------------------------------------------------
GE1 current state : UP
Speed: 1000,  Duplex: Full,  Negotiation: Enable,  Mode: Copper,  Congestion: No
Input rate 0 bits/sec, 0 packets/sec
Output rate 2294 bits/sec, 2 packets/sec

Input: 0 packets, 0 bytes
  Unicast:                    0,  Multicast:                   0
  Broadcast:                  0,  Jumbo:                       0
  Discard:                    0,  Pause:                       0
  Frames:                     0

  Total Error:                0
  CRC:                        0,  Giants:                      0
  Runts:                      0,  DropEvents:                  0
  Alignments:                 0,  Symbols:                     0
  Ignoreds:                   0

Output : 2719354134 packets, 503308078504 bytes
  Unicast:                    0,  Multicast:               50766
  Broadcast:         2719303368,  Jumbo:                       0
```

```
Discard:                        0,  Pause:                          0

Total Error:                    0
Collisions:                     0,  Late Collisions:                0
Deferreds:                      0

  Input bandwidth utilization threshold : 80.00%
  Output bandwidth utilization threshold: 80.00%
  Last 60 seconds input utility rate : 0.00%
  Last 60 seconds output utility rate: 0.00%

------------------------------------------------------------------------------------------
```

Table 3-76 Description of the **display remote-unit port statistics realtime** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Connect interface	Interconnection interface.
GE*n* current state	Physical status of the GE*n* interface on an RU. ● **DOWN**: indicates that a fault occurs at the physical layer of the interface. The possible cause can be that no terminal is connected to the interface or the interface is shut down. ● **Up**: indicates that the interface is physically Up.
Speed	Current rate of an interface. ● In auto-negotiation mode, this field displays the interface rate after auto-negotiation with terminals. ● In non-auto-negotiation mode, you can run the **speed** command to configure an interface rate.
Duplex	Duplex mode of an interface: ● **Full**: The interface works in full-duplex mode. ● **Half**: The interface works in half-duplex mode.

Item	Description
Negotiation	Auto-negotiation status of an interface. To configure auto-negotiation for an interface, you can run the **negotiation auto** command. - **Enable**: The interface works in auto-negotiation mode. - **Disable**: The interface works in non-auto negotiation mode.
Mode	Working mode of an interface: - **Copper**: electrical mode - **Fiber**: optical mode
Congestion	Congestion status of an RU interface: - **YES**: The RU interface is congested. - **NO**: The RU interface is not congested.
Input rate 0 bits/sec, 0 packets/sec	Rate of incoming packets on an interface.
Output rate 0 bits/sec, 0 packets/sec	Rate of outgoing packets on an interface.
Input	Total number of received packets. **NOTE** - Packets that are longer than jumbo frames and have correct CRC values are counted in **Jumbo** statistics but not in **Input** statistics. - An RU can forward a packet with a maximum size of 10240 bytes.
Output	Total number of sent packets.
Unicast	Number of unicast packets received or sent by an interface.
Multicast	Number of multicast packets received or sent by an interface.
Broadcast	Number of broadcast packets that are received or sent by the interface.

Item	Description
Jumbo	Statistics about outgoing packets on an interface. The following packets are counted: ● Ethernet frames longer than 1518 bytes and with correct FCS values Statistics about incoming packets on an interface. The following packets are counted: ● Ethernet frames with the length greater than or equal to 1519 bytes and less than the maximum jumbo frame length and correct FCS values ● VLAN frames with the length greater than or equal to 1519 bytes and less than the maximum jumbo frame length and correct FCS values ● Packets with the length greater than the maximum jumbo frame length
Discard	Number of packets discarded by an interface during physical layer detection. A possible cause can be interface congestion. **NOTE** Currently, this item is not supported, and the value is displayed as 0.
Frames	Number of packets with the incorrect 802.3 length received by an interface.
Pause	Number of Pause frames.
Total Error	Number of error frames found during physical layer detection.
CRC	Number of packets longer than 63 bytes and with incorrect FCS values.
Giants	Number of received packets with the length exceeding the maximum jumbo frame length. **NOTE** Currently, this item is not supported, and the value is displayed as 0. Such packets are counted in the **Jumbo** field.

Item	Description
Runts	Number of received undersized frames with correct CRC values. An undersized frame is a frame that is shorter than 64 bytes, in correct format, and contains a valid CRC field. **NOTE** Packets with incorrect CRC values and the length shorter than 64 bytes are also counted in **Runts**.
DropEvents	Number of received packets that are discarded due to GBP full or back pressure.
Alignments	Number of received frames with alignment errors. **NOTE** Currently, this item is not supported, and the value is displayed as 0.
Symbols	Number of received frames with coding errors.
Ignoreds	Number of received MAC control frames whose OpCode is not PAUSE. **NOTE** If an RU interface receives an **Ignoreds** packet, the packet is not only counted as an Ignoreds packet, but also is counted as a unicast, multicast, or a broadcast packet. The total number of incoming packets on an interface has excluded repeated counts. Therefore, the statistics are correct.
Collisions	Number of collision frames. A collision frame is a packet that is not sent due to a detected collision.
Late Collisions	Number of deferred collision frames. A deferred collision frame is a frame that is delayed to be sent because of a deferred collision detected after the transmission of the frame first 512 bits.
Deferreds	Number of deferred packets. A deferred packet refers to a packet that is delayed due to a detected collision.
Input bandwidth utilization threshold	Threshold for the inbound bandwidth usage.
Output bandwidth utilization threshold	Threshold for the outbound bandwidth usage.

Item	Description
Last 60 seconds input utility rate	Inbound bandwidth usage within the last 60 seconds.
Last 60 seconds output utility rate	Outbound bandwidth usage within the last 60 seconds.

3.4.18 display remote-unit port transceiver

Function

The **display remote-unit port transceiver** command displays information about the optical module installed on an interface of an RU.

Format

display remote-unit port [*port-id*] **transceiver** [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34. If this parameter is not specified, statistics about all interfaces on the RU are displayed.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

Table 3-77 Description of the **display remote-unit port transceiver** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Connect interface	Interconnection interface.
GE*n* transceiver information	Information about the optical module installed on the GE*n* interface of an RU.
Common information	General information.
Transceiver type	Type of an optical module.

Item	Description
Transfer distance(m)	Transmission distance of an optical module. ● **OM1**: indicates traditional 62.5 µm/125 µm multimode fibers. ● **OM2**: indicates traditional 50 µm/125 µm multimode fibers. ● **OM3**: indicates next-generation multimode fibers, with longer transmission distances than OM1 and OM2 fibers. For a GPS optical module, this field indicates the maximum length of the antenna between the GPS optical module and signal receiver. **NOTE** The device displays only the maximum transmission distances supported by different optical fibers of an optical module.
Digital diagnostic monitoring	Whether diagnostic information about an optical module is monitored.
Vendor name	Vendor of an optical module.
Manufacture information	Manufacture information.
Manu. serial Number	Manufacturing sequence number of an optical module.
Manufacturing date	Manufacturing date of an optical module.
Diagnostic information	Diagnostic information.
Temperature(Celsius)	Current temperature of an optical module.
Temp high threshold(Celsius)	Upper temperature threshold of an optical module.
Temp low threshold(Celsius)	Lower temperature threshold of an optical module.
Voltage(V)	Current voltage of an optical module.
Volt high threshold(V)	Upper voltage threshold of an optical module.
Volt low threshold(V)	Lower voltage threshold of an optical module.
Bias current(mA)	Bias current of an optical module.

Item	Description
Bias high threshold(mA)	Upper threshold for the bias current of an optical module.
Bias low threshold(mA)	Lower threshold for the bias current of an optical module.
RX power(dBM)	Receive power of an optical module. When the receive power is 0 W, this field displays **-Inf**.
RX power high warning(dBM)	Upper warning threshold for the receive power of an optical module.
RX power low warning(dBM)	Lower warning threshold for the receive power of an optical module.
RX power high threshold(dBM)	Upper receive power threshold of an optical module.
RX power low threshold(dBM)	Lower receive power threshold of an optical module.
TX power(dBM)	Transmit power of an optical module. When the transmit power is 0 W, this field displays **-Inf**.
TX power high warning(dBM)	Upper warning threshold for the transmit power of an optical module.
TX power low warning(dBM)	Lower warning threshold for the transmit power of an optical module.
TX power high threshold(dBM)	Upper transmit power threshold of an optical module.
TX power low threshold(dBM)	Lower transmit power threshold of an optical module.

3.4.19 display remote-unit port transceiver realtime

Function

The **display remote-unit port transceiver** command displays real-time information about the optical module installed on an interface of an RU.

Format

display remote-unit port [*port-id*] **transceiver** { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **realtime**

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34. If this parameter is not specified, statistics about all interfaces on the RU are displayed.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

RX power low threshold(dBM)	Lower receive power threshold of an optical module.
TX power(dBM)	Transmit power of an optical module. When the transmit power is 0 W, this field displays **-Inf**.
TX power high warning(dBM)	Upper warning threshold for the transmit power of an optical module.
TX power low warning(dBM)	Lower warning threshold for the transmit power of an optical module.
TX power high threshold(dBM)	Upper transmit power threshold of an optical module.
TX power low threshold(dBM)	Lower transmit power threshold of an optical module.

3.4.20 display remote-unit upgrade

Function

The **display remote-unit upgrade** command displays RU upgrade information.

Format

display remote-unit upgrade { **record** | **information** }

Parameters

Parameter	Description	Value
record	Displays upgrade records of RUs.	-
information	Displays the upgrade information about the RUs that are being upgraded.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An RU has three types of firmware: APP firmware (controlling the forwarding process, parsing XLDP packets, and processing configurations), PoE firmware, and BIOS firmware. The three types of firmware can all be upgraded. System software packages or patches (containing firmware) of the central switch can be used to upgrade RUs.

You can run this command to view the upgrade information about RUs. The information includes the firmware version of an RU connected to the central switch, information about the RUs that fail to be upgraded and enter the cooldown period, information about RUs which have the firmware package of the new version successfully pre-loaded and wait to be reset, information about RUs that are being upgraded, and the upgrade progress in percentage. After the upgrade is complete, you can run this command to check upgrade records.

If an RU fails to be upgraded, it enters the cooldown period. You can upgrade it again only after the cooldown period ends.

Example

Display RU upgrade information.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit upgrade information
Firmware information:
-------------------------------------------------------------------------------
Type          Version            From              Note
-------------------------------------------------------------------------------
APP           220207016            Startup software    -
POE           -                  -                 -
BIOS          220207016            Startup software    -

Remote-unit during cooling down:
-------------------------------------------------------------------------------
Type          ConnectInterface      FailCnt          CoolDownInSeconds
-------------------------------------------------------------------------------

Waiting for restart to apply new firmware's remote-unit information:
-------------------------------------------------------------------------------
```

```
Type            ConnectInterface        NextVersion(APP/POE/BIOS)
-------------------------------------------------------------------------------

Upgrading remote-unit information:
-------------------------------------------------------------------------------
Type            ConnectInterface        Firmware           Percent
-------------------------------------------------------------------------------
S5731-L8P2HT-RUA  XGigabitEthernet0/0/1    APP                3%
```

Table 3-79 Description of the **display remote-unit upgrade information** command output

Item	Description
Firmware information	Firmware of the RU to be upgraded.
Type	Firmware type. The options include **APP**, **POE**, and **BIOS**.
Version	Firmware version. **NOTE** For an RU of the S5731-L16P2SR-RUA or S5731S-L16P2SR-RUA model, only the following firmware versions are supported: APP firmware: 221207011 PoE firmware: 7701 BIOS firmware: 220225001 The S5731-L8LP2ST-RUA supports only the following firmware versions: APP firmware: 230109001 and later
From	Source file used for upgrading the RU. It can be a patch or software package of the central switch.
Note	Whether the current firmware is successfully signed. ● **-**: The signature is correct. ● **Bad signature**: The firmware patch signature is incorrect. In this case, the firmware will not be upgraded. ● **No signature**: The firmware patch does not have a digital signature. In this case, the firmware will not be upgraded.
Remote-unit during cooling down	RUs that fail to be upgraded and are in the cooldown period. You can end the cooldown period of an RU by resetting the RU.
Type	Device type of an RU.
ConnectInterface	Interconnection interface.
FailCnt	Number of upgrade failures.

Item	Description
CoolDownInSeconds	Remaining seconds in the cooldown period. When the value becomes 0, the RU can be upgraded again.
Waiting for restart to apply new firmware's remote-unit information	Information about the RUs that have new firmware successfully pre-loaded and wait to be reset. **NOTE** If the function of applying new functions after the upgrade at a specified time is enabled, the information about the RUs to be reset at a specified time is displayed. If this function is disabled and an RU cannot be reset in time, the information about the RU is displayed in this field for a short time. After the RU is reset, the corresponding information is automatically cleared.
NextVersion(APP/POE/BIOS)	Version number for the next startup. **NOTE** If the upgrade command is run in the remote-unit view, the version for the next RU startup is displayed. For the firmware not supported by the RU, a hyphen (-) is displayed. If the forcible upgrade command is run in the remote-unit N view, the version number only of the upgraded firmware is displayed. For the firmware not upgraded, a hyphen (-) is displayed.
Upgrading remote-unit information:	Information about the RUs that are being upgraded.
Firmware	Firmware type. The options include **APP**, **POE**, and **BIOS**.
Percent	Upgrade progress, in percentage.

Display upgrade records of RUs.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit upgrade record
------------------------------------------------------------------------------
StartTime            ConnectInterface       Firmware   UpdateResult
------------------------------------------------------------------------------
2021/12/25 03:25:54   XGigabitEthernet0/0/1   APP        Success
2021/12/25 03:30:08   XGigabitEthernet0/0/1   APP        Success
```

Table 3-80 Description of the **display remote-unit upgrade record** command output

Item	Description
StartTime	Start time.
ConnectInterface	Interconnection interface.
Firmware	Firmware type. The options include **APP**, **POE**, and **BIOS**.
UpdateResult	Upgrade result. **Success** indicates that the upgrade is successful. Other values indicate that the upgrade fails.

3.4.21 display remote-unit verbose realtime

Function

The **display remote-unit** command displays detailed real-time information about an RU.

Format

display remote-unit { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **verbose realtime**

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of the interface connecting the central switch to an RU. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value is a string of 1 to 32 case-sensitive characters without spaces.

1: Monitoring level

Usage Guidelines

You can run this command to view detailed real-time information about an RU, including the ESN, name, MAC address, device type, online duration, and firmware version.

Example

Display detailed real-time information about the RU connected to Eth-Trunk 10 on the central switch.

```
<HUAWEI> system-view
[HUAWEI] display remote-unit connect-interface Eth-Trunk 10 verbose realtime
------------------------------------------------------------------------
ESN                :219801177002xxxxxxxx
Name                 :-
ID                 :10
Device mac          :xxxx-xxxx-xxxx
Device type         :S5731-L4T2S-RUA
Item                :98011768
Manufacture Date   :2021-12-17
Up time             :0 day, 4 hours, 12 minutes, 20 seconds
APP version         :220123020
POE version         :-
BIOS version        :220207016
Connect interface  :Eth-Trunk10
Disk usage          :44%
Memory usage        :40%
Temperature         :34(Celsius)
Mac usage           :0%
Status              :Normal
Authen Result       :-
------------------------------------------------------------------------
```

Table 3-81 Description of the **display remote-unit verbose realtime** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
ID	ID of an RU.
Device mac	System MAC address of an RU.
Device type	Device type of an RU.
Item	Code of an RU.
Manufacture Date	Manufacture date of an RU.
Up time	Online duration of an RU.
APP version	APP firmware version.
POE version	PoE firmware version.
BIOS version	BIOS firmware version.

Item	Description
Connect interface	Interface connecting the central switch to an RU. If the central switch uses a physical Eth-Trunk member interface to connect to an RU, this field displays the corresponding Eth-Trunk interface.
Disk usage	Disk usage of an RU.
Memory usage	Memory usage of an RU.
Temperature	Current temperature of an RU.
Mac usage	MAC address table usage of an RU.
Disk space(MB)	Disk size of an RU.
Status	Status of an RU: ● **Normal**: online ● **Upgrading** ● **Configuring**: the RU is being configured. ● **Abnormal**: The link connecting the RU and central switch is faulty, or the RU is an excess one because the number of connected RUs has reached the upper limit. ● **Idle**: the RU is in the initialization state.
Authen Result	Authentication result of an RU: ● **Success** ● **Fail** ● **-**: the RU is not authenticated.

3.4.22 display remote-unit vlan

Function

The **display remote-unit vlan** command displays VLAN information about interfaces on an RU.

Format

display remote-unit vlan [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

display remote-unit vlan { **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* } **vlan** *vlan-id*

Parameters

Parameter	Description	Value
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer in the range from 1 to 4094.

Views

All views

1: Monitoring level

Usage Guidelines

An RU supports interface-based VLAN configuration. After the central switch delivers a VLAN to an interface on an RU, you can run this command to view VLAN information about the interface.

Example

Display VLAN information about interfaces on the RU connected to XG0/0/6 of the central switch.

```
<HUAWEI> display remote-unit vlan connect-interface XGigabitEthernet0/0/6
----------------------------------------------------------------------
U:Up            D:Down           TG:Tagged           UT:Untagged
----------------------------------------------------------------------
ESN                :219801176601XXXXXXXX
Name                 :-
Device type         :S5731-L4P2HW-RUA
Remote unit ID      :16777215
Connect interface  :XGigabitEthernet0/0/6
----------------------------------------------------------------------
VlanID            Ports
----------------------------------------------------------------------
1                 UT:GE1(D)    GE2(D)    GE3(D)    GE4(D)
                    GE5(D)    GE6(U)    GE7(D)    GE8(D)
                    GE9(D)    UPLINK(U)
2                 UT:UPLINK(U)
3                 TG:GE1(D)    GE2(D)    GE3(D)    GE4(D)
                    UPLINK(U)
----------------------------------------------------------------------
```

Display information about interfaces in VLAN 3 on the RU connected to XG0/0/6 of the central switch.

```
<HUAWEI> display remote-unit vlan connect-interface XGigabitEthernet0/0/6 vlan 3
----------------------------------------------------------------------
U:Up          D:Down          TG:Tagged          UT:Untagged
----------------------------------------------------------------------
ESN              :219801176601XXXXXXXX
Name               :-
Device type        :S5731-L4P2HW-RUA
Remote unit ID     :16777215
Connect interface  :XGigabitEthernet0/0/6
----------------------------------------------------------------------
VlanID           Ports
----------------------------------------------------------------------
3               TG:GE1(D)    GE2(D)    GE3(D)    GE4(D)
                  UPLINK(U)
----------------------------------------------------------------------
```

Table 3-82 Description of the **display remote-unit vlan** command output

Item	Description
ESN	ESN of an RU.
Name	Alias of an RU. This field displays a hyphen (-) if an RU is not configured with an alias.
Device type	Device type of an RU.
Remote unit ID	ID of an RU. This field displays a hyphen (-) if an RU is not configured with an ID.
ConnectInterface	Interconnection interface.
VlanID	VLAN ID.
Ports	Interface of an RU. GE*n*: downlink interface on the RU. *n* indicates the interface number on the panel of the RU. UPLINK: uplink interface of the RU

3.4.23 display xldp statistics

Function

The **display xldp statistics** command displays statistics about XLDP packets sent and received by a switch.

Format

display xldp statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about XLDP packets sent and received by a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If no interface is specified, the command displays statistics about XLDP packets on all interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To display the XLDP packet statistics within a specified period of time, you need to run the **reset xldp statistics** command to clear the existing statistics first, and then run the **display xldp statistics** command to view new statistics.

Example

Display statistics about XLDP packets sent and received by all interfaces on the central switch.

```
<HUAWEI> display xldp statistics
Statistics for GigabitEthernet0/0/1:
Transmitted frames total      : 27664
  Hello frames                : 27664
  Channel frames              : 0
Received frames total         : 0
  Hello frames                : 0
  Channel ACK frames          : 0
```

Table 3-83 Description of the **display xldp statistics** command output

Item	Description
Statistics for *x*	Statistics about XLDP packets received and sent by interface *x*.
Transmitted frames total	Number of sent XLDP packets.
Received frames total	Number of received XLDP packets.
Hello frames	Number of heartbeat packets.
Channel frames	Number of channel packets.
Channel ACK frames	Number of channel ACK packets.

3.4.24 isolate (remote-unit view)

Function

The **isolate enable** command enables interface isolation on RUs globally.

The **undo isolate enable** command disable interface isolation on RUs globally.

By default, interface isolation is disabled on RUs.

Format

isolate enable

undo isolate enable

Parameters

None

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an RU is delivered, its downlink interfaces are in the same broadcast domain and are not isolated by default. This allows users connected to the same RU to communicate with each other before being authenticated. To prevent this, you can configure interface isolation on RUs. To isolate downlink interfaces on all RUs, run the **isolate enable** command in the remote-unit view.

Follow-up Procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Configure interface isolation on all RUs.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] isolate enable
```

3.4.25 isolate (remote-unit N view)

Function

The **isolate enable** command enables port isolation on an RU.

The **isolate disable** command disables port isolation on an RU.

The **undo isolate** command restores the default configuration.

By default, port isolation is disabled on an RU.

Format

isolate {enable | disable }

undo isolate

Parameters

Parameter	Description	Value
enable	Enables port isolation.	-
disable	Disables port isolation.	-

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an RU is delivered, its downlink interfaces are in the same broadcast domain and are not isolated by default. This allows users connected to the same RU to communicate with each other before being authenticated. To prevent this, you can configure port isolation on RUs. To isolate downlink interface on a single RU, run the **isolate enable** command in the view of the RU.

Precautions

The port isolation configuration specific to an RU has a higher priority than the global port isolation configuration.

Follow-up Procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Disable port isolation on an RU.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] isolate disable
```

3.4.26 led off (remote-unit view)

Function

The **led off** command turns off indicators on RUs.

The **undo led off** command restores the default status of indicators on RUs.

By default, indicators on RUs are turned on.

Format

led off [**time-range** *time-name*]

undo led off

Parameters

Parameter	Description	Value
time-range *time-name*	Specifies the name of a time range. If no time range is specified, the configuration is always valid.	The specified time range must exist.

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When RUs are deployed in places such as hotels and dormitories, the blinking of indicators on the RUs may affect users' rest at night. You can run the **led off** command to turn off indicators on RUs to reduce the impact on users, for example, to turn off the indicators from 8:00 p.m. every day to 7:00 a.m. the next day.

Follow-up Procedure

After you run this command to turn on or off indicators on RUs, you need to run the **commit** command to deliver the configuration to make the configuration take effect.

Precautions

If this command is configured in both the remote-unit view and remote-unit N view, the configuration in the remote-unit N view takes effect.

Example

Turn off indicators on all RUs from 8:00 p.m. every day to 7:00 a.m. the next day.

```
<HUAWEI> system-view
[HUAWEI] time-range test 20:00 to 00:00 daily
[HUAWEI] time-range test 00:00 to 07:00 daily
[HUAWEI] remote-unit
[HUAWEI-remote-unit] led off time-range test
[HUAWEI-remote-unit] commit
```

3.4.27 led (remote-unit N view)

Function

The **led** command sets the time period during which indicators on an RU are turned on or off.

The **undo led off** command restore the default status of indicators on an RU.

By default, indicators on RUs are turned on.

Format

led { **on** | **off** [**time-range** *time-name*] }

undo led off

Parameters

Parameter	Description	Value
time-range *time-name*	Specifies the name of a time range. If no time range is specified, the configuration is always valid.	The specified time range must exist.

Parameter	Description	Value
on	Turns on RU indicators.	-
off	Turns off RU indicators.	-

Views

remote-unit view, remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When RUs are deployed in places such as hotels and dormitories, the blinking of indicators on the RUs may affect users' rest at night. You can run the **led** command to set the time period during which indicators on an RU are turned on or off to reduce the impact on users, for example, to turn off the indicators from 8:00 p.m. every day to 7:00 a.m. the next day.

Follow-up Procedure

After you run this command to configure the time period during which indicators on an RU are turned on or off, you need to run the **commit** command to deliver the configuration to make the configuration take effect.

Precautions

If this command is configured in both the remote-unit view and remote-unit N view, the configuration in the remote-unit N view takes effect.

Example

Turns off indicators on RU 0 from 8:00 p.m. every day to 7:00 a.m. the next day.

```
<HUAWEI> system-view
[HUAWEI] time-range test 20:00 to 00:00 daily
[HUAWEI] time-range test 00:00 to 07:00 daily
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] led off time-range test
[HUAWEI-remote-unit-0] commit
```

3.4.28 loopbacktest internal port

Function

The **loopbacktest internal port** configures an interface on an RU to perform an internal loopback test.

By default, internal loopback testing is not configured for an RU interface.

Format

loopbacktest internal port *port-id*

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

You can run this command to check whether the internal forwarding chip of an RU works properly.

Example

Configure internal loopback testing for interface 2 on RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] loopbacktest internal port 2
```

3.4.29 name

Function

The **name** command configures an alias for an RU.

The **undo name** command deletes the alias of an RU.

By default, no alias is configured for an RU.

Format

name *remote-unit-name*

undo name

Parameters

Parameter	Description	Value
remote-unit-name	Specifies the alias of an RU.	The value is a string of 1 to 32 case-sensitive characters without spaces.

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

If a central switch is connected to multiple RUs, you can configure an alias for each RU to facilitate management, since aliases are easier to remember than IDs. In addition, after specifying an alias for an RU, you can run the **remote-unit name** *remote-unit-name* command to enter the view of an RU by its alias directly.

Example

Set the alias of RU 0 to **access_1**.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] name access_1
```

3.4.30 negotiation auto port

Function

The **negotiation auto port** command configures an interface on an RU to work in auto-negotiation mode.

The **undo negotiation auto port** command configures an interface on an RU to work in non-auto-negotiation mode.

By default, an interface on an RU works in auto-negotiation mode.

Format

negotiation auto port { *portid1* [**to** *portid2*] } &<1-32>

undo negotiation auto port { *portid1* [**to** *portid2*] } &<1-32>

Parameters

Parameter	Description	Value
portid1 [**to** *portid2*]	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In auto-negotiation mode, interfaces on both ends of a link negotiate their operating parameters, including the duplex mode and rate. If the negotiation succeeds, the two interfaces work at the same operating parameters and the transmission capability can reach the maximum value supported by both ends.

Follow-up Procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Configure interface 8 on RU 0 to work in auto-negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] negotiation auto port 8
```

3.4.31 poe anti-interference frequency

Function

The **poe anti-interference frequency** command configures the PoE anti-interference frequency for an RU.

The **undo poe anti-interference frequency** command restores the default configuration.

By default, the PoE anti-interference frequency of an RU is 50 Hz.

NOTE

Only PoE-capable RUs support this command.

Format

poe anti-interference frequency { **50** | **60** }

undo poe anti-interference frequency

Parameters

Parameter	Description	Value
50	Sets the anti-interference frequency to 50 Hz.	-
60	Sets the anti-interference frequency to 60 Hz.	-

Views

remote-unit view, remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The mains frequency varies in different countries and regions. Some are 60 Hz and some are 50 Hz. When RUs provide PoE power supply, incorrect grounding may occur. As a result, industrial frequency interference is coupled to network cables, resulting in abnormal PoE detection classification. You can run the **poe anti-interference frequency** command to modify the filtering algorithm on the PoE port to make the PoE anti-interference frequency become the same as the mains frequency, reducing the impact of the mains frequency on PD detection.

Follow-up Procedure

After configuring the PoE anti-interference frequency for an RU, you need to run the **commit** command to make the configuration take effect.

Precautions

If this command is configured in both the remote-unit view and remote-unit N view, the configuration in the remote-unit N view takes effect.

Example

Set the PoE anti-interference frequency of RU 0 to 60 Hz.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] poe anti-interference frequency 60
```

3.4.32 poe enable port

Function

The **poe enable port** command sets the power supply mode for an interface on an RU.

The **undo poe enable port** command restores the default power supply mode of a PoE interface on an RU.

By default, interfaces supporting the PoE++ mode provide power in that mode (also referred to as the **bt-inrush** mode). Interfaces that do not support the PoE++ mode provide power in **at-inrush** mode.

Format

poe { *at-inrush* | *af-inrush* } **enable port** *port-id*

undo poe { *at-inrush* | *af-inrush* } **enable port** *port-id*

NOTE

The following RUs work in PoE++ mode by default:

S5731-L4P2HW-RUA, S5731S-L4P2HW-RUA, S5731-L4P2S-RUA, S5731S-L4P2S-RUA, S5731-L4P2ST-RUA, S5731S-L4P2ST-RUA, S5731-L4P2HT-RUA, S5731S-L4P2HT-RUA

The following RUs work in PoE+ mode by default:

S5731-L8P2ST-RUA, S5731S-L8P2ST-RUA, S5731-L8P2HT-RUA, S5731S-L8P2HT-RUA, S5731-L8LP2ST-RUA

Parameters

Parameter	Description	Value
poe *at-inrush*	Sets an RU interface to work in PoE+ power supply mode.	-
poe *af-inrush*	Sets an RU interface to work in 802.3af power supply mode.	-
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To power the PDs requiring the standard power supply mode, you can run the **poe at-inrush enable** command. This command configures PoE interfaces to work in PoE+ power supply mode. Some non-IEEE standard PDs do not support high-current power supply, and instead only support low-current power supply. To power on such non-standard PDs, you can run the **poe af-inrush enable** command to configure PoE interfaces on RUs to work in 802.3af power supply mode.

Follow-up procedure

After running this command, run the **commit** command to make the configuration take effect.

Precautions

Switching the PoE power supply mode of an RU interface between the at-inrush and bt-inrush modes will cause PDs to be powered off.

Example

Set interface 1 on RU 0 to work in PoE+ power supply mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] poe at-inrush enable port 1
```

3.4.33 poe force-power port

Function

The **poe force-power port** command enables forcible PoE power supply for an interface on an RU.

The **undo poe force-power port** command disables forcible PoE power supply for an interface on an RU.

By default, forcible PoE power supply is disabled on interfaces of RUs.

Format

poe force-power port *port-id*

undo poe force-power port *port-id*

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the system power is sufficient, you can run this command to enable forcible power supply on RU interfaces connected to non-standard PDs when the RU, as the PSE, cannot detect the PDs.

Precautions

This command forcibly increases the power supplied by the RU. Ensure that the total power of PDs connected to the RU does not exceed the RU's available power.

Follow-up procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Enable forcible power supply on interface 1 of RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] poe force-power port 1
```

3.4.34 poe power-on delay port

Function

The **poe power-on delay port** command sets the power supply delay for an interface on an RU.

The **undo poe power-on delay port** command restores the default power supply delay for an interface on an RU.

By default, the power supply delay for an interface on an RU is 0, which indicates no delay.

Format

poe power-on delay *delay-time* **port** *port-id*

undo poe power-on delay port *port-id*

Parameters

Parameter	Description	Value
delay-time	Specifies the power supply delay for an interface on an RU.	The value is an integer in the range from 1 to 60, in seconds. The default value is 0, indicating no delay.
port-id	Specifies the index of a downlink interface on an RU.	The value is an integer that ranges from 1 to 32. If some of the specified interface indexes are greater than the largest one on the RU, commands concerning these interfaces are not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

As the holding current of a non-standard PD is insufficient at the power-on moment, an RU assumes that the PD has been disconnected and powers it off.

To solve this problem, you can set the power supply delay for RU interfaces on the central switch. When the delay expires, the RUs detect the holding current to ensure that non-standard PDs can be properly powered on.

Follow-up procedure

After running this command, run the **commit** command to make the configuration take effect.

Precautions

If a PD is connected to an interface configured with a power supply delay, do not replace the PD within the delay. Otherwise, the new PD cannot work properly.

Example

Set the power supply delay to 5 seconds for interface 1 on RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] poe power-on delay 5 port 1
```

3.4.35 poe xldp-proxy

Function

The **poe xldp-proxy** command binds an optical interface to a MultiGE electrical interface on the central switch.

The **undo poe xldp-proxy** command restores the default configuration.

By default, no optical interface is bound to a MultiGE electrical interface.

Format

poe xldp-proxy interface multige *interface-number*

undo poe xldp-proxy

NOTE

Only the S5732-H48XUM2CC supports this command.

Parameters

Parameter	Description	Value
interface multige *interface-number*	Specifies the number of a MultiGE electrical interface.	-

Views

XGE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an S5732-H48XUM2CC functions as a central switch and connects to RUs using first-generation hybrid copper-fiber cables (that is, electrical interfaces are used for power supply and optical interfaces are used for communication), the central switch needs to provide PoE power for RUs through its electrical interfaces. To implement this, run the **poe xldp-proxy** command to bind an optical interface to an electrical interface, so that the optical interface can function as a proxy for the electrical interface to provide PoE power for its connected RU.

If this command is not configured, the central switch provides 60 W power for RUs by default.

Precautions

XLDP has been enabled on a 10GE optical interface. By default, XLDP is enabled.

Example

Bind XGE0/0/1 optical interface to MultiGE0/0/1 electrical interface.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/1
[HUAWEI-XGigabitEthernet0/0/1] poe xldp-proxy interface MultiGE 0/0/1
```

3.4.36 port default vlan (remote-unit N view)

Function

The **port default vlan** command configures the default VLAN for downlink interfaces on an RU.

The **undo port default vlan** command restores the default setting.

By default, a downlink interface on an RU uses VLAN 1 as its default VLAN.

Format

port { *portid1* [**to** *portid2*] } &<1-32> **default vlan** *vlanid*

undo port { *portid1* [**to** *portid2*] } &<1-32> **default vlan**

Parameters

Parameter	Description	Value
portid1 [**to** *portid2*]	Indicates numbers of downlink interfaces: *portid1* specifies the number of the first interface. **to** *portid2* specifies the number of the last interface. *portid2* must be greater than or equal to *portid1*.	*portid1* is an integer that ranges from 1 to 32. *portid2* is an integer that ranges from 1 to 32.
vlanid	Specifies the default VLAN ID for the downlink interfaces on the RU.	The value is an integer in the range from 1 to 4094.

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. You can run the **port default vlan** command to configure a downlink interface on an RU as a hybrid interface and configure the default VLAN for the interface. As such, different VLANs can be configured for downlink interfaces of an RU to carry services of different terminals.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Run the **port uplink** { **tagged** | **untagged** } **vlan** *vlan-id1* command to configure the default VLAN of the downlink interfaces on an RU as an allowed VLAN for the RU's uplink interface.

Example

Configure VLAN 2 as the default VLAN for downlink interfaces 1 to 4 on RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] port 1 to 4 default vlan 2
```

3.4.37 port uplink default vlan

Function

The **port uplink default vlan** command configures the default VLAN for the uplink interface on an RU.

The **undo port uplink default vlan** command restores the default setting.

By default, the uplink interface on an RU uses VLAN 1 as its default VLAN.

Format

port uplink default vlan *vlan-id*

undo port uplink default vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies the default VLAN ID for the uplink interface on an RU.	The value is an integer in the range from 1 to 4094.

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If terminals connected to an RU run the same service, they can reside in the same service VLAN. In this situation, you can run the **port uplink default vlan** command to configure the service VLAN as the default VLAN for the uplink interface on the RU.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Run the **port uplink untagged vlan** command to configure the default VLAN as an allowed VLAN in untagged mode for the uplink interface.

Example

Set VLAN 10 as the default VLAN for the uplink interface on RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] port uplink default vlan 10
```

3.4.38 port uplink vlan

Function

The **port uplink vlan** command configures allowed VLANs for the uplink interface on an RU.

The **undo port uplink vlan** command deletes the allowed VLAN configuration of the uplink interface on an RU.

By default, the uplink interface of an RU allows packets from VLAN 1 to pass through.

Format

port uplink { **tagged** | **untagged** } **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo port uplink { **tagged** | **untagged** } { **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies allowed VLANs: - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*.	*vlan-id1* is an integer that ranges from 1 to 4094. *vlan-id2* is an integer that ranges from 1 to 4094.
tagged	Configures the uplink interface to forward packets of the specified VLAN in tagged mode.	-
untagged	Configures the uplink interface to forward packets of the specified VLAN in untagged mode.	-
all	Deletes all allowed VLANs from the uplink interface on the RU.	-

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a downlink interface of an RU is configured with a default VLAN, the uplink interface must allow packets of this VLAN to pass through, so that service traffic can be forwarded normally.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Example

Configure the uplink interface on RU 0 to forward packets of VLAN 10 and VLAN 20 in tagged mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] port uplink tagged vlan  10 20
```

3.4.39 port vlan

Function

The **port vlan** command configures allowed VLANs for downlink interfaces on an RU.

The **undo port vlan** command deletes the allowed VLAN configuration of downlink interfaces on an RU.

By default, a downlink interface of an RU allows packets from VLAN 1 to pass through.

Format

port { *portid1* [**to** *portid2*] } &<1-32> { **tagged** | **untagged** } **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo port { *portid1* [**to** *portid2*] } &<1-32> { **tagged** | **untagged** } { **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
portid1 [**to** *portid2*]	Indicates numbers of downlink interfaces: *portid1* specifies the number of the first interface. **to** *portid2* specifies the number of the last interface. *portid2* must be greater than or equal to *portid1*.	*portid1* is an integer that ranges from 1 to 32. *portid2* is an integer that ranges from 1 to 32.
vlan-id1 [**to** *vlan-id2*]	Specifies allowed VLANs: ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*.	*vlan-id1* is an integer that ranges from 1 to 4094. *vlan-id2* is an integer that ranges from 1 to 4094.
tagged	Configures the downlink interfaces to forward packets of the specified VLANs in tagged mode.	-
untagged	Configures the downlink interfaces to forward packets of the specified VLANs in untagged mode.	-
all	Deletes all allowed VLANs from the downlink interfaces on the RU.	-

Views

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. You can run the **port vlan** command to configure allowed VLANs for downlink interfaces on an RU, so that different service VLANs can be assigned to different terminals.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Example

Configure downlink interfaces 1 to 4 on RU 0 to forward packets of VLAN 2 in tagged mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] port 1 to 4 tagged vlan 2
```

3.4.40 reboot

Function

The **reboot** command resets an RU.

By default, an RU is not reset.

Format

reboot [**all**]

Parameters

Parameter	Description	Value
all	Resets all RUs.	This parameter is supported only in the remote-unit view.

Views

remote-unit view, remote-unit N view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

- You can run this command to reset a faulty RU.
- If an RU fails to be upgraded and enters the cooldown period, you can run the **reboot** command to end the cooldown period.

Precautions

- An RU that has no interconnection interface bound cannot be reset.
- An RU that fails to be authenticated or is not authenticated cannot be reset.
- An RU that encounters a communication error will fail to be reset.
- RUs do not save their configurations. After an RU starts, it goes online on the central switch. After the RU is authenticated successfully, the central switch delivers configurations to the RU for them to take effect. For example, port isolation is required on an RU. After you restart the RU, its downlink interfaces can communicate with each other. The interfaces are isolated after the central switch authenticates the RU successfully and delivers the port isolation configuration.

Example

Reset a single RU.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] reboot
```

Reset all RUs.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] reboot all
```

3.4.41 remote-unit

Function

The **remote-unit** command displays the remote-unit view.

Format

remote-unit

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to enter the global RU view to perform global configurations for RUs.

Example

Enter the remote-unit view.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
```

3.4.42 remote-unit N

Function

The **remote-unit** command displays the view of an RU.

The **undo remote-unit** command deletes all configurations of an RU from the central switch.

Format

remote-unit { *id* | **connect-interface** *interface-type interface-number* | **name** *remote-unit-name* }

undo remote-unit *id*

Parameters

Parameter	Description	Value
id	ID of an RU, which is the RU index. The value range does not indicate the number of RUs that can be configured.	The value is an integer ranging from 0 to 16777215.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

System view, remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure or operate a single RU by running this command to enter the view of the specific RU.

Prerequisites

To enter the view of a specific RU by specifying the **name** parameter, ensure that you have configured an alias for this RU by running the **name** command. To enter the view of a specific RU by specifying the interconnection interface, ensure that you have bound an interconnection interface to this RU by running the **bind interface** command.

Example

Enter the view of an RU by specifying the ID of the RU.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
```

Enter the view of an RU by specifying the interconnection interface.

```
<HUAWEI> system-view
[HUAWEI] remote-unit connect-interface XGigabitEthernet 0/0/1
```

Enter the view of an RU by specifying the RU alias.

```
<HUAWEI> system-view
[HUAWEI] remote-unit name test
```

3.4.43 remote-unit protect-action error-down

Function

The **remote-unit protect-action error-down enable** command enables RU protection by setting interfaces to the Error-Down state.

The **remote-unit protect-action error-down disable** command disables RU protection.

By default, this function is enabled.

Format

remote-unit protect-action error-down { **disable** | **enable** }

undo remote-unit protect-action error-down disable

Parameters

Parameter	Description	Value
disable	Disables RU protection.	-

Parameter	Description	Value
enable	Enables RU protection by setting interfaces to the Error-Down state.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During RU deployment, a configuration error or link fault may occur (for details, see "Usage Guidelines" in **error-down auto-recovery cause remote-unit-link interval**). When the central switch detects the fault, it sets the interface connected to the RU to the Error-Down state.

Prerequisites

XLDP has been enabled on all interfaces of the central switch.

Precautions

The **undo remote-unit protect-action error-down disable** command is equivalent to the **remote-unit protect-action error-down enable** command.

Example

Enable RU protection by setting interfaces to the Error-Down state.

```
<HUAWEI> system-view
[HUAWEI] undo remote-unit protect-action error-down disable
```

3.4.44 remote-unit port default vlan

Function

The **remote-unit port default vlan** command configures the default VLAN for downlink interfaces on RUs in batches.

The **undo remote-unit port default vlan** command restores the default setting.

By default, a downlink interface on an RU uses VLAN 1 as its default VLAN.

Format

remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port** { *portid1* [**to** *portid2*] } &<1-32> **default vlan** *vlanid*

undo remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port** { *portid1* [**to** *portid2*] } &<1-32> **default vlan**

Parameters

Parameter	Description	Value
ruid1 [**to** *ruid2*]	Specifies IDs of RUs: *ruid1* specifies the ID of the first RU. **to** *ruid2* indicates the ID of the last RU. *ruid2* must be greater than or equal to *ruid1*.	*ruid1* is an integer that ranges from 0 to 16777215. *ruid2* is an integer that ranges from 0 to 16777215.
portid1 [**to** *portid2*]	Indicates numbers of downlink interfaces: *portid1* specifies the number of the first interface. **to** *portid2* specifies the number of the last interface. *portid2* must be greater than or equal to *portid1*.	*portid1* is an integer that ranges from 1 to 32. *portid2* is an integer that ranges from 1 to 32.
vlanid	Specifies the default VLAN ID for the downlink interfaces on the RUs.	The value is an integer in the range from 1 to 4094.

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. You can run the **remote-unit port default vlan** command to configure downlink interfaces on RUs as hybrid interfaces in batches and configure default VLANs for the interfaces, so that different VLANs can be configured to carry services of different terminals.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Run the **port uplink tagged vlan** command to configure the default VLAN of the downlink interfaces on the RUs as an allowed VLAN in tagged mode for the uplink interfaces on the RUs.

Example

Configure VLAN 2 as the default VLAN for downlink interfaces 1 to 4 on RUs 0 to 4.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] remote-unit 0 to 4 port 1 to 4 default vlan 2
```

3.4.45 remote-unit port uplink default vlan

Function

The **remote-unit port uplink default vlan** command configures the default VLAN for uplink interfaces on RUs in batches.

The **undo remote-unit port uplink default vlan** command restores the default setting.

By default, an uplink interface on an RU uses VLAN 1 as its default VLAN.

Format

remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port uplink default vlan** *vlanid*

undo remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port uplink default vlan**

Parameters

Parameter	Description	Value
ruid1 [**to** *ruid2*]	Specifies IDs of RUs: *ruid1* indicates the ID of the first RU. **to** *ruid2* indicates the ID of the last RU. *ruid2* must be greater than or equal to *ruid1*.	*ruid1* is an integer that ranges from 0 to 16777215. *ruid2* is an integer that ranges from 0 to 16777215.
vlanid	Specifies the default VLAN for uplink interfaces on the RUs.	The value is an integer in the range from 1 to 4094.

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If terminals connected to multiple RUs carry the same service and use the same service VLAN, you can run the **remote-unit port uplink default vlan** command to configure the service VLAN as the default VLAN for the uplink interfaces on the RUs in batches.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Example

Set VLAN 10 as the default VLAN for the uplink interfaces on RUs 0 to 4.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] remote-unit 0 to 4 port uplink default vlan 10
```

3.4.46 remote-unit port uplink vlan

Function

The **remote-unit port uplink vlan** command configures allowed VLANs for uplink interfaces on RUs in batches.

The **undo remote-unit port uplink vlan** command deletes the allowed VLAN configuration from uplink interfaces on RUs in batches.

By default, the uplink interface of an RU allows packets from VLAN 1 to pass through.

Format

remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port uplink** { **tagged** | **untagged** } **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo remote-unit { *ruid1* [**to** *ruid2*] } &<1-8>] **port uplink** { **tagged** | **untagged** } { **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
ruid1 [**to** *ruid2*]	Specifies IDs of RUs: *ruid1* indicates the ID of the first RU. **to** *ruid2* indicates the ID of the last RU. *ruid2* must be greater than or equal to *ruid1*.	*ruid1* is an integer that ranges from 0 to 16777215. *ruid2* is an integer that ranges from 0 to 16777215.
vlan-id1 [**to** *vlan-id2*]	Specifies allowed VLANs: *vlan-id1* specifies the first VLAN ID. **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*.	*vlan-id1* is an integer that ranges from 1 to 4094. *vlan-id2* is an integer that ranges from 1 to 4094.
tagged	Configures the uplink interfaces to forward packets of the specified VLANs in tagged mode.	-
untagged	Configures the uplink interfaces to forward packets of the specified VLANs in untagged mode.	-
all	Deletes all allowed VLANs from the uplink interfaces on the specified RUs.	-

Views

remote-unit view

2: Configuration level

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. You can run the **remote-unit port uplink vlan** command to configure allowed VLANs for uplink interfaces on RUs in batches so that different service VLANs can be assigned to different terminals.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Example

Configure uplink interfaces on RUs 0 to 4 to forward packets of VLAN 2 in tagged mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI] remote-unit 0 to 4 port uplink tagged vlan 2
```

3.4.47 remote-unit port vlan

Function

The **remote-unit port vlan** command configures allowed VLANs for downlink interfaces on RUs in batches.

The **undo remote-unit port vlan** command deletes the allowed VLAN configuration from downlink interfaces on RUs.

By default, a downlink interface of an RU allows packets from VLAN 1 to pass through.

Format

remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port** { *portid1* [**to** *portid2*] } &<1-32> { **tagged** | **untagged** } **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo remote-unit { *ruid1* [**to** *ruid2*] } &<1-8> **port** { *portid1* [**to** *portid2*] } &<1-32> { **tagged** | **untagged** } { **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
ruid1 [**to** *ruid2*]	Specifies IDs of RUs: *ruid1* indicates the ID of the first RU. **to** *ruid2* indicates the ID of the last RU. *ruid2* must be greater than or equal to *ruid1*.	*ruid1* is an integer that ranges from 0 to 16777215. *ruid2* is an integer that ranges from 0 to 16777215.
portid1 [**to** *portid2*]	Indicates numbers of downlink interfaces: *portid1* specifies the number of the first interface. **to** *portid2* specifies the number of the last interface. *portid2* must be greater than or equal to *portid1*.	*portid1* is an integer that ranges from 1 to 32. *portid2* is an integer that ranges from 1 to 32.
vlan-id1 [**to** *vlan-id2*]	Specifies allowed VLANs: ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*.	*vlan-id1* is an integer that ranges from 1 to 4094. *vlan-id2* is an integer that ranges from 1 to 4094.
tagged	Configures the downlink interfaces to forward packets of the specified VLANs in tagged mode.	-
untagged	Configures the downlink interfaces to forward packets of the specified VLANs in untagged mode.	-
all	Deletes all allowed VLANs from downlink interfaces on the specified RUs.	-

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. You can run the **remote-unit port vlan** command to configure allowed VLANs for downlink interfaces on RUs in batches so that different service VLANs can be assigned to different terminals.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Prerequisites

You have run the **vlan mode manual** command to configure the manual VLAN mode for the RU.

Follow-up Procedure

After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Example

Configure downlink interfaces 1 to 4 on RUs 0 to 4 to forward packets of VLAN 2 in tagged mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] remote-unit 0 to 4 port 1 to 4 tagged vlan 2
```

3.4.48 reset xldp statistics

Function

The **reset xldp statistics** command clears XLDP packet statistics on all interfaces or on a specified interface.

Format

reset xldp statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the interface where statistics need to be cleared. In the command: ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If no interface is specified, XLDP packet statistics on all interfaces are cleared.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

To troubleshoot XLDP faults, you may need to view XLDP packet statistics within a certain period of time. In this case, you need to run this command to clear existing XLDP packet statistics, and run the **display xldp statistics** command to view new XLDP packet statistics.

Example

Clear XLDP packet statistics on all interfaces.

```
<HUAWEI> reset xldp statistics
```

Clear statistics about XLDP packets sent and received by GigabitEthernet0/0/1.

```
<HUAWEI> reset xldp statistics interface gigabitethernet 0/0/1
```

3.4.49 reset remote-unit commit result

Function

The **reset remote-unit commit result** command clears configuration delivery records of RUs.

Format

reset remote-unit commit result

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

RUs do not support web-based management and cannot have commands run on them for configuration. All RU configurations are delivered by the central switch. You can run the **display remote-unit commit result** command on the central switch to view configuration delivery results. To clear configuration delivery records, you can run the **reset remote-unit commit result** command.

After this command is run, configuration delivery records of RUs are cleared and cannot be restored.

Example

Clear configuration delivery records of RUs.

```
<HUAWEI> reset remote-unit commit result
```

3.4.50 reset remote-unit connect record

Function

The **reset remote-unit connect record** command clears onboarding and disconnection records of RUs.

Format

reset remote-unit connect record

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting onboarding and disconnection records of RUs, you can run this command to clear the existing records, and run the **display remote-unit connect record** command after a period of time to view new records.

Precautions

After this command is run, onboarding and disconnection records of RUs are cleared.

Example

Clear onboarding and disconnection records of RUs.

```
<HUAWEI> reset remote-unit connect record
```

3.4.51 reset remote-unit port statistics

Function

The **reset remote-unit port statistics** command clears the statistics on interfaces of an RU.

Format

reset remote-unit port [*port-id*] **statistics** [**connect-interface** *interface-type interface-number* | **name** *remote-unit-name*]

Parameters

Parameter	Description	Value
[*port-id*]	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34.
connect-interface *interface-type interface-number*	Specifies the type and number of an interface. The interface type and number can be closely next to each other or separated by a space character.	-
name *remote-unit-name*	Specifies the alias of an RU.	The value must be an existing RU alias.

Views

User view

Default Level

3: Management level

Usage Guidelines

Before collecting traffic statistics on an RU interface within a period of time, run this command to clear the existing traffic statistics.

Example

Clear the statistics on all interfaces of an RU.

```
<HUAWEI> reset remote-unit port statistics
```

3.4.52 reset remote-unit upgrade record

Function

The **reset remote-unit upgrade record** command clears upgrade records of RUs.

Format

reset remote-unit upgrade record

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can run this command to clear upgrade records of RUs.

Example

Clear upgrade records of RUs.

```
<HUAWEI> reset remote-unit upgrade record
```

3.4.53 restart port

Function

The **restart port** command restarts an interface on an RU.

By default, no interface on an RU will be restarted.

Format

restart port *port-id*

Parameters

Parameter	Description	Value
port-id	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 34. If the specified number is greater than the largest interface number on the RU, the RU will not execute this command.

Views

remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an interface on an RU is faulty, you can run this command to restart the interface.

Precautions

- If an interface is disabled (in the shutdown state) before the restart, the interface is enabled automatically (in the undo shutdown state) after the restart.
- An RU that has no interconnection interface bound cannot be restarted.

Example

Restart interface 1 on the RU.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] restart port 1
```

3.4.54 shutdown port

Function

The **shutdown port** command shuts down an interface on an RU.

The **undo shutdown port** command enables an interface on an RU.

By default, interfaces on an RU are enabled.

Format

shutdown port { *port-id*1 [**to** *port-id*2] } &<1-32>

undo shutdown port { *port-id*1 [**to** *port-id*2] } &<1-32>

Parameters

Parameter	Description	Value
port-id1 [**to** *port-id2*]	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

When an interface on an RU is not connected to a cable or fiber, you can run the **shutdown** command to shut down the interface to prevent exceptions caused by interference.

Follow-up procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Shut down interface 8 on RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] shutdown port 8
```

3.4.55 speed port

Function

The **speed port** command sets a fixed rate for an interface on an RU.

The **undo speed port** command restores the default rate of an interface on an RU.

By default, an interface on an RU works at the rate of 1000 Mbit/s.

Format

speed { **10** | **100** | **1000** } **port** { *portid1* [**to** *portid2*] } &<1-32>

undo speed { **10** | **100** | **1000** } **port** { *portid1* [**to** *portid2*] } &<1-32>

Parameters

Parameter	Description	Value
10	Sets the interface rate to 10 Mbit/s.	-
100	Sets the interface rate to 100 Mbit/s.	-
1000	Sets the interface rate to 1000 Mbit/s.	-
{ *portid1* [**to** *portid2*] }	Specifies the index of an interface on an RU.	The value is an integer that ranges from 1 to 32. If the specified interface index is larger than the largest one on the RU, the command is not issued to the RU.

Views

remote-unit N view

Default Level

3: Management level

Usage Guidelines

In non-auto negotiation mode, if interfaces on two connected devices work at different rates, the two devices cannot communicate with each other. In this case, you need to run this command to change the rates of the interfaces to be the same.

Prerequisites

The **undo negotiation auto port** command has been run to configure the interface to work in non-auto-negotiation mode.

Follow-up procedure

After running this command, run the **commit** command to make the configuration take effect.

Example

Configure interface 2 on RU 0 to work at the rate of 100 Mbit/s in non-auto-negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] undo negotiation auto port 2
[HUAWEI-remote-unit-0] speed 100 port 2
```

3.4.56 upgrade cutoff-time

Function

The **upgrade cutoff-time** command sets the RU deployment end time. After this command is run, the firmware of the RUs that go online before the specified time will be automatically upgraded, and automatic RU firmware upgrade is disabled after the specified time.

The **undo upgrade cutoff-time** command deletes the configuration.

By default, no RU deployment end time is configured.

Format

upgrade cutoff-time *YYYY/MM/DD HH:MM:SS*

undo upgrade cutoff-time

Parameters

Parameter	Description	Value
YYYY/MM/DD	Specifies the date when RUs restart with firmware of the new version.	The value is in the 12-month format of YYYY/MM/DD. YYYY specifies the year, which ranges from 2000 to 2099. MM specifies the month, which ranges from 1 to 12. DD specifies the day, which ranges from 1 to 31.

Parameter	Description	Value
HH:MM:SS	Specifies the time when RUs restart with firmware of the new version.	The value is in the 24-hour format of HH:MM:SS. HH indicates hours, and its value is an integer ranging from 0 to 23; MM indicates minutes, and its value is an integer ranging from 0 to 59; SS indicates seconds, and its value is an integer ranging from 0 to 59.

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is applicable to the deployment scenario. The deployment process usually lasts for several days, during which RUs may be connected to the central switch successively. You can run this command to specify the deployment end time (based on the system time of the central switch), so that the firmware of all RUs is automatically upgraded when the specified time is reached. As such, you do not need to run the **upgrade right-now** command to upgrade RU firmware each time a new RU is connected to the central switch. After this command is run, the firmware of the RUs that go online before the specified time will be automatically upgraded, and automatic RU firmware upgrade is disabled after the specified time.

Precautions

After you run the **upgrade cutoff-time** command to configure the RU deployment time, other upgrade commands that have been configured are overwritten. That is, all RUs that go online before the specified deployment time will immediately restart with firmware of the new version.

Example

Set the time when RUs restart with firmware of the new version in the deployment scenario.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] upgrade cutoff-time 2022/05/31 00:00:00
```

3.4.57 upgrade force

Function

The **upgrade force** command configures forcible firmware upgrade for RUs.

By default, the function of upgrading RU firmware is disabled.

Format

upgrade { **app** | **bios** | **poe** } **force**

Parameters

Parameter	Description	Value
app	Specifies the APP firmware of RUs.	-
bios	Specifies the BIOS firmware of RUs.	-
poe	Specifies the PoE firmware of RUs.	-

Views

remote-unit N view

2: Configuration level

Usage Guidelines

Usage Scenario

If an RU fails to be upgraded, it enters the cooldown period and can be upgraded again only after the cooldown period ends. To upgrade the firmware of RUs in the cooldown period, you can run this command to configure forcible upgrade.

Precautions

During the BIOS firmware upgrade of RUs, do not power off or disconnect the RUs. Otherwise, the RUs cannot be started.

The **upgrade force** command upgrades firmware of an RU, regardless of whether the RU has the upgrade function enabled. After this command is run in the view of a single RU, the RU immediately restarts with firmware of the new version.

Example

Configure forcible APP firmware upgrade for RUs.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] upgrade app force
```

3.4.58 upgrade right-now

Function

The **upgrade right-now** command upgrades the firmware of RUs immediately.

By default, the function of upgrading RU firmware is disabled.

Format

upgrade right-now

Parameters

None

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the firmware version of an RU is different from that in the system software package or patch package of the central switch, the central switch does not automatically upgrade the firmware version of the RU. You can run the **upgrade right-now** command to upgrade the firmware of all RUs. After the **upgrade right-now** command is run, the system checks whether the firmware version of an RU is the same as that in the system software package or patch package of the central switch. If not, the RU immediately loads the firmware package of the new version and restarts with new firmware.

Prerequisites

RUs are online and in the normal state.

Precautions

- RUs will restart after loading firmware packages, resulting in service interruption. To prevent this issue, upgrade RUs at a proper time.
- Do not power off RUs during the upgrade. Otherwise, RUs may fail to start.
- Only the firmware of the RUs that go online before the command is run is upgraded. To upgrade RUs that go online later, you need to run this command again.
- This command is executed only once and is not recorded in Buildrun information. You can run the **display remote-unit upgrade information** command to check whether an RU is being upgraded.
- After you run the **upgrade right-now** command, RUs are upgraded immediately. The **upgrade cutoff-time** and **upgrade start-time** upgrade commands that have been configured are overwritten.

Example

Enable RU firmware upgrade.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] upgrade right-now
```

3.4.59 upgrade start-time

Function

The **upgrade start-time** command restarts RUs with firmware of the new version at a specified time.

The **undo upgrade start-time** command deletes the configuration.

By default, no time is set for RUs to restart with firmware of the new version.

Format

upgrade start-time *HH:MM:SS*

undo upgrade start-time

Parameters

Parameter	Description	Value
HH:MM:SS	Specifies the time when RUs restart with firmware of the new version.	The value is in the 24-hour format of HH:MM:SS. HH indicates hours, and its value is an integer ranging from 0 to 23; MM indicates minutes, and its value is an integer ranging from 0 to 59; SS indicates seconds, and its value is an integer ranging from 0 to 59.

Views

remote-unit view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The firmware upgrade of an RU consists of two steps:

1. The RU loads firmware of the new version. In this step, the central switch sends the firmware package of the new version to the RU.
2. The RU restarts to make firmware of the new version take effect.

You can run the **upgrade start-time** command to configure RUs to restart with firmware of the new version at a specified time. This command configures the restart time in step 2.

Precautions

During the BIOS firmware upgrade of RUs, do not power off or disconnect the RUs. Otherwise, the RUs cannot be started.

After you run the **upgrade start-time** command to configure RUs to restart with firmware of the new version at a specified time, other upgrade commands that have been configured are overwritten. That is, RUs will restart with firmware of the new version at the time specified by the **upgrade start-time** command.

Example

Configure RUs to restart with firmware of the new version at midnight.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] upgrade start-time 00:00:00
```

3.4.60 vlan mode

Function

The **vlan mode** command configures the VLAN mode for an RU.

The **undo vlan mode** command restores the default VLAN mode for an RU.

By default, an RU uses the transparent VLAN mode.

Format

vlan mode { **manual** | **transparent** }

undo vlan mode

Parameters

Parameter	Description	Value
manual	Configures the manual VLAN mode. In manual mode, an interface uses VLAN 1 as its default VLAN and joins VLAN 1 in untagged mode.	-
transparent	Configures the transparent VLAN mode.	-

Views

remote-unit view, remote-unit N view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RU can connect to different types of terminals using its downlink interfaces and distinguish terminal services by joining its downlink interfaces to different VLANs. By default, all interfaces on an RU work in transparent VLAN mode. That is, the RU does not change the VLAN IDs of received packets. If services of downlink terminals connected to an RU need to be divided based on VLANs, you need to run the **vlan mode manual** command to configure the RU to work in manual VLAN mode, and then configure default and allowed VLANs for interfaces on the RU.

An RU saves the VLAN configuration delivered by the central switch to it in its flash memory and forwards traffic based on this VLAN configuration after being powered on. After the RU goes online on the central switch, the central switch synchronizes the latest VLAN configuration to the RU's flash memory.

Follow-up Procedure

- Configure default and allowed VLANs for interfaces on the RU.
- After you run the commands for configuring the VLAN mode for an RU and VLANs for RU interfaces, run the **commit** command to deliver the VLAN configuration to the RU or bring the RU offline and then online again for the configuration to take effect.

Precautions

You can configure the VLAN mode of an RU in the remote-unit view or remote-unit N view. If the VLAN mode is configured in both views, the configuration in the remote-unit N view takes effect. If no VLAN mode is configured in the remote-unit N view, the configuration in the remote-unit view takes effect.

Example

Configure all connected RUs to work in manual VLAN mode.

```
<HUAWEI> system-view
[HUAWEI] remote-unit
[HUAWEI-remote-unit] vlan mode manual
```

Configure the manual VLAN mode for the RU 0.

```
<HUAWEI> system-view
[HUAWEI] remote-unit 0
[HUAWEI-remote-unit-0] vlan mode manual
```

3.4.61 xldp enable (interface view)

Function

The **xldp enable** command enables XLDP on an interface.

The **xldp disable** command disables XLDP on an interface.

The **undo xldp disable** command restores the default configuration.

After XLDP is enabled in the system view, all interfaces are enabled with XLDP by default.

Format

xldp enable

xldp disable

undo xldp disable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After XLDP is enabled on an interface, the interface exchanges XLDP packets with XLDP-enabled neighbors. The interface receives status information from the neighbors and sends the local status information to the neighbors. An intelligent simplified campus network runs based on the XLDP protocol.

Prerequisites

XLDP has been enabled globally using the **xldp enable** in the system view.

Precautions

- XLDP can be enabled in the system view and the interface view.
  - After XLDP is enabled in the system view, all interfaces are enabled with XLDP.
  - After XLDP is disabled in the system view, all XLDP settings are restored to the default settings except the setting of XLDP trap. Therefore, XLDP is also disabled on all interfaces.
  - An interface can send and receive XLDP packets only after XLDP is enabled in both the system view and the interface view.
  - After XLDP is disabled globally, the commands for enabling and disabling XLDP on an interface do not take effect.
  - If some interfaces need to have XLDP enabled but some need to have XLDP disabled, you can globally enable XLDP and run the **xldp disable** command in the interface view to disable XLDP for the required interfaces. To re-enable XLDP on these interfaces, run the **xldp enable** command in the views of these interfaces.
- The **xldp enable (interface view)** command can be run only on an Ethernet interface, regardless of whether it works at Layer 2 or Layer 3 mode, and cannot be run on a logical interface such as a VLANIF or Eth-Trunk interface.

For an Eth-Trunk interface, XLDP can only be enabled on its member interfaces. XLDP-enabled interfaces and XLDP-disabled interfaces can be added to the same Eth-Trunk.

- If a large number of XLDP packets are sent to attack an interface, disable XLDP on the interface so that the interface does not send XLDP packets to the CPU for processing.

Example

Disable XLDP on the Ethernet interface GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] xldp disable
```

3.4.62 xldp enable (system view)

Function

The **xldp enable** command enables XLDP globally.

The **xldp disable** command disables XLDP globally.

The **undo xldp disable** command restores the default global XLDP configuration.

By default, XLDP is enabled globally.

Format

xldp enable

xldp disable

undo xldp disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view the status of Layer 2 links connecting the central switch and RUs for analyzing the network topology, you need to run this command to enable XLDP.

Configuration Impact

After XLDP is enabled globally, the device sends its own status information to XLDP-enabled neighbors and receives the status information from the neighbors.

Precautions

After global XLDP is disabled, the XLDP configuration is deleted from all interfaces.

XLDP can be enabled in the system view and the interface view.

- After XLDP is enabled in the system view, all interfaces are enabled with XLDP.
- After XLDP is disabled in the system view, all XLDP settings are restored to the default settings except the setting of XLDP trap. Therefore, XLDP is also disabled on all interfaces.
- An interface can send and receive XLDP packets only after XLDP is enabled in both the system view and the interface view.
- After XLDP is disabled globally, the commands for enabling and disabling XLDP on an interface do not take effect.

Example

Enable XLDP globally.

```
<HUAWEI> system-view
[HUAWEI] xldp enable
```

Disable XLDP globally.

```
<HUAWEI> system-view
[HUAWEI] xldp disable
```

3.5 SVF Configuration Commands

3.5.1 Command Support

NOTE

- When the parent version is earlier than V200R011C10, the AS version must be the same as the parent version. Otherwise, this AS cannot go online. For example, if the parent version is V200R010C00, the AS version must also be V200R010C00. When the parent version is V200R011C10 or later, the parent version and AS version can be different, but the parent version must be higher than or the same as the AS version and the AS version must also be V200R011C10 or later. **Table1** describes the version mapping between parent and AS. **Table2** describes supported Parent and AS switch models in different software versions.
- APs must use the software version matching that of the parent. For details, see "WLAN Service Configuration - Licensing Requirements and Limitations for WLAN" in the *Configuration Guide - WLAN-AC*.
- To check AP device types supported by the parent by default, run the **display ap-type all** command on the parent. The S6735-S, S6720-EI, S6720S-EI, S6720-SI, S6720S-SI, S6720S-S,S6730-S, or S6730S-S cannot manage APs when acting as a parent.

3.5.2 acl ipv6 number (AS administrator profile view)

Function

The **acl ipv6 number** command configures an IPv6 ACL rule number in an AS administrator profile.

The **undo acl ipv6 number** command deletes an IPv6 ACL rule number in an AS administrator profile.

By default, no IPv6 ACL rule number is configured in an AS administrator profile.

NOTE

This command can only be executed on a parent switch.

Format

acl ipv6 number { *acl-number* } &<1-16>

undo acl ipv6 number { *acl-number* } &<1-16>

Parameters

Parameter	Description	Value
acl-number	Specifies an ACL rule number.	The value is an integer in the range from 3000 to 3999.

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating an AS administrator profile, you can run the **acl ipv6 number** command to configure an IPv6 ACL rule number for an AS in the AS administrator profile. After the profile is bound to an AS, the following configuration is generated on the AS:

```
#
acl ipv6 number acl-number
 rule xxx
#
```

Precautions

- In SVF, only 5-tuple information (source IP address, destination IP address, source port, destination port, and protocol type) can be specified in ACL rules.
- The IPv6 ACL used in an AS administrator profile must have been created in the system view, and rules have been configured in the ACL view.
- A maximum of 64 IPv6 ACLs can be configured in an AS administrator profile, and a maximum of 1024 rules can be created in an ACL. The total number of IPv4 and IPv6 ACL rules cannot exceed 4096.

Example

Configure an IPv6 ACL rule number in an AS administrator profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] acl ipv6 number 3000 3002 3010 3011 3012
```

3.5.3 acl number (AS administrator profile view)

Function

The **acl number** command configures an ACL rule number in an AS administrator profile.

The **undo acl number** command deletes an ACL rule number in an AS administrator profile.

By default, no ACL rule number is configured in an AS administrator profile.

NOTE

This command can only be executed on a parent switch.

Format

acl number { *acl-number* } &<1-16>

undo acl number { *acl-number* } &<1-16>

Parameters

Parameter	Description	Value
acl-number	Specifies an ACL rule number.	The value is an integer in the range from 3000 to 3900.

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating an AS administrator profile, you can run the **acl number** command to configure an ACL rule number for an AS in the AS administrator profile. After the profile is bound to an AS, the following configuration is generated on the AS:

```
#
acl number acl-number
 rule xxx
#
```

Precautions

- In SVF, only 5-tuple information (source IP address, destination IP address, source port, destination port, and protocol type) can be specified in ACL rules.
- The ACL used in an AS administrator profile must have been created in the system view, and rules have been configured in the ACL view.
- A maximum of 64 ACLs can be configured in an AS administrator profile, and a maximum of 1024 rules can be created in an ACL. The total number of IPv4 and IPv6 ACL rules cannot exceed 4096.

Example

Configure an ACL rule number in an AS administrator profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] acl number 3000 3002 3010 3011 3012
```

3.5.4 arp anti-attack check user-bind enable (network enhanced profile view)

Function

The **arp anti-attack check user-bind enable** command configures dynamic ARP inspection (DAI) in a network enhanced profile.

The **undo arp anti-attack check user-bind enable** command disables DAI in a network enhanced profile.

By default, DAI is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

arp anti-attack check user-bind enable

undo arp anti-attack check user-bind enable

Parameters

None

Views

Network enhanced profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a network enhanced profile, you can configure DAI in the profile. After the profile is bound to an AS port, DAI is automatically enabled on the port. The following configuration is generated on the AS port:

```
#
 arp anti-attack rate-limit enable
 arp anti-attack rate-limit packet 5 interval 1
 arp anti-attack check user-bind enable
 arp anti-attack check user-bind alarm enable
#
```

You can configure DAI to prevent Man in The Middle (MITM) attacks and theft on authorized user information. When a device receives an ARP packet, it compares the source IP address, source MAC address, interface number, and VLAN ID of the

ARP packet with DHCP snooping binding entries. If the ARP packet matches a binding entry, the device allows the packet to pass through. If the ARP packet does not match any binding entry, the device discards the packet.

Prerequisites

DHCP snooping has been enabled in the network enhanced profile using the **dhcp snooping enable** command.

Example

Enable DAI in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] dhcp snooping enable
[HUAWEI-um-net-enhanced-profile_1] arp anti-attack check user-bind enable
```

3.5.5 as-admin-profile (AS group view)

Function

The **as-admin-profile** command binds an AS administrator profile to an AS group.

The **undo as-admin-profile** command unbinds an AS administrator profile from an AS group.

By default, no AS administrator profile is bound to an AS group.

NOTE

This command can only be executed on a parent switch.

Format

as-admin-profile *profile-name*

undo as-admin-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AS administrator profile.	The value must have an existing AS administrator profile name.

Views

AS group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can bind an AS administrator profile to an AS group to deliver the configurations in the profile to all the member ASs in the AS group.

Prerequisites

The AS administrator profile has been created.

Precautions

AS groups can only be bound to AS administrator profiles. Each AS group can be bound to only one AS administrator profile.

Example

Bind an AS administrator profile to an AS group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] quit
[HUAWEI-um] as-group name group_1
[HUAWEI-um-as-group-group_1] as-admin-profile profile_1
```

3.5.6 as-admin-profile name

Function

The **as-admin-profile name** command creates an AS administrator profile.

The **undo as-admin-profile name** command deletes an AS administrator profile.

By default, no AS administrator profile is configured.

NOTE

This command can only be executed on a parent switch.

Format

as-admin-profile name *profile-name*

undo as-admin-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an AS administrator profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In an AS administrator profile, you can configure AS administrator information and the rate limit for outgoing ARP and DHCP packets on an uplink fabric port.

Precautions

You can create a maximum of 16 AS administrator profiles.

Example

Create an AS administrator profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
```

3.5.7 as authentication configuration revert disable

Function

The **as authentication configuration revert disable** command enables the function of retaining the authentication configuration after an AS goes offline.

The **undo as authentication configuration revert disable** command disables the function of retaining the authentication configuration after an AS goes offline.

By default, the authentication configuration is cleared after an AS goes offline.

NOTE

This command can only be executed on a parent switch.

Format

as authentication configuration revert disable

undo as authentication configuration revert disable

Parameters

None

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

When an AS goes offline, it automatically clears its authentication configuration to ensure connectivity in the local area network (LAN) connected to it in case of an AS authentication failure. However, clearing the authentication configuration when the AS goes offline will lengthen the time taken for the AS to go online again. If the AS is not connected to a LAN or if the time taken for the AS to go online again needs to be shortened, enable the function of retaining the authentication configuration after the AS goes offline on the parent to shorten the time taken for the AS to go online again.

Example

Enable the function of retaining the authentication configuration after an AS goes offline.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as authentication configuration revert disable
```

3.5.8 as-auth

Function

The **as-auth** command displays the AS authentication view.

NOTE

This command can only be executed on a parent switch.

Format

as-auth

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

After entering the AS authentication view, you can configure the AS authentication mode, blacklist, and whitelist.

Example

Enter the AS authentication view.

```
<HUAWEI> system-view
[HUAWEI] as-auth
```

3.5.9 as-group name

Function

The **as-group name** command creates an AS group or displays the AS group view.

The **undo as-group name** command deletes an AS group.

By default, no AS group is created.

NOTE

This command can only be executed on a parent switch.

Format

as-group name *group-name*

undo as-group name *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of an AS group.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An AS group contains one or more ASs, which facilitates AS batch configuration.

Follow-up Procedure

Run the **as name** *as-name* or **as name-include** *string* command to add ASs to an AS group.

Precautions

You can create a maximum of 16 AS groups.

AS groups can only be bound to AS administrator profiles. Each AS group can be bound to only one AS administrator profile.

Example

Create an AS group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-group name group_1
```

3.5.10 as access dtls psk

Function

The **as access dtls psk** command configures a pre-shared key for Datagram Transport Layer Security (DTLS) encryption on an access switch (AS).

The **undo as access dtls psk** command deletes a pre-shared key used for DTLS encryption.

The default username and password are available in *S Series Switches Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

NOTE

This command can only be executed on an AS.

Format

as access dtls psk *psk-value*

undo as access dtls psk

Parameters

Parameter	Description	Value
psk-value	Specifies a pre-shared key.	The value is a string of 6 to 32 case-sensitive characters without spaces. The pre-shared key must be in plain text and contain at least two of the following: letters, digits, and special characters.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To encrypt CAPWAP-encapsulated packets between the parent and an AS, configure the same pre-shared key on the parent and AS. You can run the **as access dtls psk** command to configure a pre-shared key for DTLS encryption on the AS.

Precautions

- The default pre-shared key has security risks. You are advised to change the pre-shared key.
- After an AS has connected to an SVF system, configuring or deleting the pre-shared key for DTLS encryption is not allowed on the AS.

Example

Set the pre-shared key for DTLS encryption to **test@1234**.

```
<HUAWEI> as access dtls psk test@1234
```

3.5.11 as access manage-mac

Function

The **as access manage-mac** command configures the management MAC address of an AS.

The **undo as access manage-mac** command restores the default management MAC address of an AS.

By default, an AS uses the system MAC address as the management MAC address.

NOTE

This command can only be executed on an AS.

Format

as access manage-mac *mac-address*

undo as access manage-mac

Parameters

Parameter	Description	Value
mac-address	Specifies the management MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a Super Virtual Fabric (SVF) system, each AS has a unique management MAC address to identify itself. By default, an AS uses its system MAC address as the management MAC address to connect to an SVF system. When the management MAC address of an AS conflicts with that of another AS, you can run the **as access manage-mac** command to change the management MAC address so as to prevent MAC address conflicts.

Precautions

- Use of this command is not recommended when no MAC address conflict occurs, as an improper management MAC address may affect service operations.
- This command can be used only before an AS connects an SVF system. If an AS has connected to an SVF system, use of this command is not allowed.
- Before using this command to change the management MAC address of an AS, you must run the **undo as access manage-mac** command to delete the existing management MAC address.

Example

Configure the management MAC address of an AS.

```
<HUAWEI> as access manage-mac 00e0-fc91-52a0
```

3.5.12 as auto-replace enable

Function

The **as auto-replace enable** command enables AS automatic replacement.

The **undo as auto-replace enable** command disables AS automatic replacement.

By default, AS automatic replacement is disabled.

NOTE

This command can only be executed on a parent switch.

Format

as auto-replace enable

undo as auto-replace enable

Parameters

None

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In an SVF system, each AS is identified by its MAC address by default. When a new device is used to replace an AS, the SVF system considers the new device as a new AS because their MAC addresses are different. As a result, the new AS does not inherit services from the previous AS.

You can enable AS automatic replacement to solve this problem. When an AS is replaced by a new device connected to the same fabric port, the SVF system replaces the AS MAC address with the MAC address of the new device in the configuration. Consequently, the new device can inherit services from the AS.

Precautions

- An AS can only be replaced by a device of the same model. If the new device is a different model, the SVF system considers it as a new AS, which then cannot inherit services from the previous AS.
- Only a standalone AS can be replaced. If an AS is a stack, it cannot be replaced.
- AS automatic replacement is not supported when an AS connects to the parent through a network.
- To ensure that a replacement AS can be successfully authenticated, run the **auth-mode none** command to set the AS authentication mode to none, or run the **whitelist mac-address** command to add the management MAC address of the replacement AS to the whitelist. If the replacement AS has no management MAC address configured, its system MAC address is used as the management MAC address.

Example

Enable AS automatic replacement.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as auto-replace enable
```

3.5.13 as-mode disable

Function

The **as-mode disable** command changes the switch working mode to the parent mode.

The **undo as-mode disable** command restores the switch working mode to the AS mode.

Swich models supporting this command and the default working mode of them are as follows:

- S5731-H (excluding S5731-H24HB4XZ, S5731-H48HB4XZ), S5731S-H (excluding S5731S-H24HB4XZ-A, S5731S-H48HB4XZ-A), S5732-H24S6Q, S5732-H48S6Q, S6730S-H, S6730-H: Parent mode
- S5531-H48HB4XZ, S5731-H24HB4XZ, S5731-H48HB4XZ, S5731S-H24HB4XZ-A, S5731S-H48HB4XZ-A, S5732-H24UM2CC, S5732-H48UM2CC, S5732-H48XUM2CC, S6730-S, S6730S-S, S6720-SI, S6720S-S, S6720S-SI, S6720-EI, S6720S-EI, S6735-S: AS mode

Format

as-mode disable

undo as-mode disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Switch models supporting this command can function as the parent or AS in an SVF system.

Precautions

- After the working mode of a switch is changed, the switch restarts for the new working mode to take effect, and does not use any configuration file at the next startup. As such, the switch restarts without any configuration file. In this case, you are advised to back up the configuration file of the switch before it restarts.
- By default, the following switches work in AS mode: S5732-H24UM2CC, S5732-H48UM2CC, S5732-H48XUM2CC. To enable these switches to

automatically change the working mode to parent during unconfigured device deployment, run the **option 148 ascii** *ascii-string* command to configure Option 148 of the DHCP server. The format of *ascii-string* is svfmode=uc.

Example

Change the switch working mode to the parent mode.

```
<HUAWEI> system-view
[HUAWEI] as-mode disable
Warning: Switching the AS mode will clear current configuration and reboot the system. Continue? [Y/N]:y
```

3.5.14 as all (AS group view)

Function

The **as all** command adds all ASs to an AS group.

The **undo as all** command deletes all ASs from an AS group.

By default, no AS is added to an AS group.

NOTE

This command can only be executed on a parent switch.

Format

as all

undo as all

Parameters

None

Views

AS group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating an AS group, you need to add the ASs that require the same configuration to the AS group. This command adds all ASs to the same AS group.

Precautions

An AS can be added to only one AS group. For example, if you run the **as all** command in group_1 and then in group_2, the system displays a message, saying that the ASs need to be deleted from the previous AS group before they can be added to the new AS group.

Example

Add all ASs to the AS group group_1.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-group name group_1
[HUAWEI-um-as-group-group_1] as all
```

3.5.15 as name (AS group view)

Function

The **as name** command adds an AS with a specified name to an AS group.

The **as name-include** command adds an AS of which the name contains a specified string to an AS group.

The **undo as name** command deletes an AS with a specified name from an AS group.

The **undo as name-include** command deletes an AS of which the name contains a specified string from an AS group.

By default, no AS is added to an AS group.

NOTE

This command can only be executed on a parent switch.

Format

as name *as-name*

as name-include *string*

undo as name *as-name*

undo as name-include *string*

Parameters

Parameter	Description	Value
as-name	Specifies the name of an AS.	The value must have an existing AS name.
string	Specifies the string contained in an AS name.	The value is a string of 1 to 31 case-insensitive characters without spaces.

Views

AS group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating an AS group, add the ASs that need to be configured in a batch to the AS group. You can only add created ASs to an AS group.

Precautions

An AS can be added to only one AS group.

After an AS is added to an AS group, to change the AS group, run the **as name** command to add the AS to another AS group.

Example

Add the AS **as_1** to the AS group **group_1**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-group name group_1
[HUAWEI-um-as-group-group_1] as name as_1
```

3.5.16 as name interface (port group view)

Function

The **as name interface** command adds ports on the AS with a specified name to a port group.

The **as name-include interface** command adds ports on the AS of which the name contains a specified string to a port group.

The **undo as name interface** command deletes ports on the AS with a specified name from a port group.

The **undo as name-include interface** command deletes ports on the AS of which the name contains a specified string from a port group.

By default, no ports on an AS are added to a port group.

NOTE

This command can only be executed on a parent switch.

Format

as name *as-name* **interface** { { *interface-type interface-number1* [**to** *interface-number2*] } &<1-10> | **all** }

as name-include *string* **interface all**

undo as name *as-name* **interface** { { *interface-type interface-number1* [**to** *interface-number2*] } &<1-10> | **all** }

undo as name-include *string* **interface all**

Parameters

Parameter	Description	Value
as-name	Specifies the name of an AS.	The value must have an existing AS name.
string	Specifies the string contained in an AS name.	The value is a string of 1 to 31 case-insensitive characters without spaces.
interface-type interface-number1 [**to** *interface-number2*]	Specifies the type and number of AS interfaces. • *interface-type* specifies the interface type. • *interface-number1* specifies the first interface number. • *interface-number2* specifies the last interface number.	The following ports cannot be added to a port group: • Fabric port • Eth-Trunk member interface • Uplink port on an AS. You can run the **display port connection-type access all** command to view all downlink ports of the device. The ports that are not displayed in the command output are uplink ports. Note that an uplink port still cannot be added to a port group after it is configured as a downlink port using the **port connection-type access** command.
all	Indicates all downlink ports on an AS.	-

Views

Port group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a port group, add the AS ports that need to be configured in a batch to the port group.

Precautions

A port can be added to only one port group.

After ports on an AS are added to a port group, to change the port group, run the **as name interface** command to add the ports to another port group.

A fabric port in a port group takes effect only for a network QoS profile but not for any network basic profile, network enhanced profile, traffic policy profile, or user access profile.

Example

Add ports on the AS **as1** to the port group **group_1**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] as name as1 interface gigabitethernet 0/0/1 to 0/0/5
```

3.5.17 as name (uni-mng view)

Function

The **as name** command configures an AS name or displays the AS view.

The **undo as name** command deletes an AS.

By default, system default name-device MAC address is used as the AS name, for example, **huawei-000a-123d-2200**.

NOTE

This command can only be executed on a parent switch.

Format

as name *as-name* [**model** *as-model* **mac-address** *mac-address*]

undo as { **all** | **name** *as-name* }

Parameters

Parameter	Description	Value
as-name	Specifies the name of an AS.	The value is a string of 1 to 31 case-insensitive characters without spaces.
model *as-model*	Specifies the device model of an AS.	The value is of enumerated type. You can enter a question mark (?) and select a value from the displayed value range.
mac-address *mac-address*	Specifies the management MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Parameter	Description	Value
all	Deletes all ASs.	-

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can configure a name for an AS and use the name to uniquely identify the AS. This configuration facilitates AS identification and management.

If no AS name is configured, system default name-device MAC address is used as the AS name after the AS connects to an SVF system.

You can change the name of an AS that has connected to an SVF system when the following conditions are met:

1. The AS is not bound to any service profile.
2. The AS is not added to any AS group.
3. Ports of the AS are not added to any port group.

Precautions

- If the **model** *as-model* **mac-address** *mac-address* parameter is not specified, the AS view is displayed. You can enter the view of an AS only when the AS has been created.
- If an AS has connected to an SVF system, the AS leaves the SVF system and restarts after being deleted.
- If the message "A port instance in the AS (xxx) has been added to the PM. Please delete the configuration first." is displayed when you delete an AS, run the **undo binding** command in the PM statistics task view to delete the configuration. This command ensures that the AS can be deleted successfully.

Example

Configure an AS name.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1 model S5720-28P-LI-AC mac-address xxxx-xxxx-xxxx
```

3.5.18 as reset

Function

The **as reset** command restarts an AS.

NOTE

This command can only be executed on a parent switch.

Format

as reset { **all** | **name** *as-name* }

Parameters

Parameter	Description	Value
all	Restarts all ASs.	-
name *as-name*	Restarts an AS with a specified name.	The value must have an existing AS name.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

When an AS is upgraded or working abnormally, you can restart the AS.

Example

Restart the AS **as1**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as reset name as1
```

3.5.19 as service-vlan igmp-snooping

Function

The **as service-vlan igmp-snooping** command enables IGMP snooping for a service VLAN on an AS.

The **undo as service-vlan igmp-snooping** command disables IGMP snooping for a service VLAN on an AS.

By default, IGMP snooping is disabled for service VLANs on an AS.

NOTE

This command can only be executed on a parent switch.

Format

as service-vlan igmp-snooping { *vlan-id1* [**to** *vlan-id2*] } &<1-16>

undo as service-vlan igmp-snooping { *vlan-id1* [**to** *vlan-id2*] } &<1-16>

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies range of service VLANs: - *vlan-id1* specifies the start VLAN ID. - *vlan-id2* specifies the end VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*. *vlan-id1* and *vlan-id2* define a range together. - If the parameter **to** *vlan-id2* is not specified, only the VLAN specified by *vlan-id1* is a service VLAN ID.	The *vlan-id1* and *vlan-id2* are integers ranging from 1 to 4094.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, IGMP snooping is disabled for service VLANs on an AS. If IGMP snooping needs to be enabled on an AS, run the **as service-vlan igmp-snooping** command to deliver the configuration to the AS. After the configuration is delivered successfully, the igmp-snooping enable configuration will be generated in the corresponding VLAN view of the AS.

Precautions

This VLAN cannot be a stack reserved VLAN, SVF management VLAN, super VLAN, or RRPP/SEP/ERPS control VLAN.

Example

Enable IGMP snooping for the service VLAN 10 on an AS.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as service-vlan igmp-snooping 10
```

3.5.20 as service-vlan authorization

Function

The **as service-vlan authorization** command creates service VLANs on ASs.

The **undo as service-vlan authorization** command deletes service VLANs on ASs.

By default, all interfaces on an AS belong to the default VLAN, that is, VLAN 1.

NOTE

This command can only be executed on a parent switch.

Format

as service-vlan authorization { *vlan-id1* [**to** *vlan-id2*] } &<1-16>

undo as service-vlan authorization { *vlan-id1* [**to** *vlan-id2*] } &<1-16>

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies service VLAN IDs in a batch: ● *vlan-id1* specifies the first VLAN ID. ● *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be greater than or equal to *vlan-id1*. *vlan-id1* and *vlan-id2* together determine a VLAN range. ● If you do not specify **to** *vlan-id2*, only one service VLAN is specified by *vlan-id1*.	Values of *vlan-id1* and *vlan-id2* are integers in a range of 1 to 4094.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **as service-vlan authorization** command to deliver service VLANs to ASs in a batch. After these service VLANs are delivered successfully, corresponding VLANs are created on these ASs.

Precautions

This VLAN cannot be a stack reserved VLAN, SVF management VLAN, super VLAN, or RRPP/SEP/ERPS control VLAN.

In versions earlier than V200R019, a maximum of 32 service VLANs can be created. In V200R019 and later versions, a maximum of 1024 service VLANs can be created.

Example

Create the service VLAN 10 for ASs.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as service-vlan authorization 10
```

3.5.21 as type

Function

The **as type** command specifies the file to be loaded during the upgrade of an AS of a specified device type.

The **undo as type** command deletes the file to be loaded during the upgrade of an AS of a specified device type.

By default, the file to be loaded is not specified during the upgrade of an AS of a specified device type.

NOTE

This command can only be executed on a parent switch.

Format

as type *as-type* { **system-software** *system-software* | **patch** *patch* } *

undo as type *as-type* [**system-software** | **patch**]

Parameters

Parameter	Description	Value
as-type	Specifies the device type of an AS.	The value is an enumerated type. You can enter a question mark (?) and select a value from the displayed value range.
system-software *system-software*	Specifies the name of the system software file to be loaded on an AS.	The value is a string of 4 to 48 case-insensitive characters without spaces or special characters, including ~ * : ' " ? < > | [ ] % \ /.
patch *patch*	Specifies the name of the patch file to be loaded on an AS.	The value is a string of 5 to 48 case-insensitive characters without spaces or special characters, including ~ * : ' " ? < > | [ ] % \ /.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AS is automatically upgraded after going online, the AS is upgraded using the file specified by the **as type** command.

Precautions

You can run the **as type** command multiple times to specify different files for different types of ASs.

If the system software file is not specified and only the patch file is specified during a patch upgrade, the patch upgrade fails if the patch file does not match the system software.

Follow-up Procedure

Run the **upgrade as** command to upgrade the AS.

Example

Specify the file to be loaded on the AS of the S5720-P-LI type.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as type s5720-p-li system-software S5720-P-LI-V200R022C00SPC500.cc
```

3.5.22 attach as

Function

The **attach as** command allows you to log in to an AS from the parent.

NOTE

This command can only be executed on a parent switch.

Format

attach as name *as-name*

Parameters

Parameter	Description	Value
name *as-name*	Specifies the name of an AS for login.	The value must have an existing AS name.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In addition to local login through a console port, you can log in to an AS from the parent. This login mode is supported in two service configuration modes: centralized mode and independent mode.

After you log in to an AS in centralized mode, you can configure only commands related to file management and service diagnosis for fault location.

After you log in to an AS in independent mode, you can use more commands to configure services on the AS.

Prerequisites

In centralized mode, an AS administrator profile has been bound to the AS, and an AS user name and password have been configured.

In independent mode, an AS user name and password have been configured in the uni-mng view using the **independent-as-admin** command.

Precautions

After an AS user name and password are configured, you need to enter the correct user name and password when logging in to an AS through the console port. When you log in to an AS from the parent using the **attach as** command, you can log in to the AS without entering the user name or password.

In versions earlier than V200R011C10, at most one VTY user can log in to an AS at a time. In V200R011C10 and later versions, at most four VTY users can log in to an AS at a time.

Example

In centralized mode, log in to the AS **as1** from the parent.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] user asuser password YsHsjx_202206
[HUAWEI-um-as-admin-profile_1] quit
```

```
[HUAWEI-um] as-group name group_1
[HUAWEI-um-as-group-group_1] as name as1
[HUAWEI-um-as-group-group_1] as-admin-profile profile_1
[HUAWEI-um-as-group-group_1] quit
[HUAWEI-um] commit as all
Info: Commiting the configuration will take a long time. Are you sure you want to commit the
configuration? [Y/N]: y
[HUAWEI-um] attach as name as1
```

In independent mode, log in to the AS **as1** from the parent. Before the login, the independent mode needs to be enabled on the fabric-port connected to the AS **as1**. The following uses a level-1 AS as the AS **as1**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] independent-as-admin user asuser password YsHsjx_202206
[HUAWEI-um] interface fabric-port 1
[HUAWEI-um-fabric-port-1] port connect independent-as
[HUAWEI-um-fabric-port-1] quit
[HUAWEI-um] attach as name as1
```

3.5.23 authentication access-user maximum (user access profile view)

Function

The **authentication access-user maximum** command configures the maximum number of access users in a user access profile.

The **undo authentication access-user maximum** command deletes the maximum number of access users in a user access profile.

By default, the maximum number of access users is not configured in a user access profile.

NOTE

This command can only be executed on a parent switch.

Format

authentication access-user maximum *max-num*

undo authentication access-user maximum

Parameters

Parameter	Description	Value
max-num	Specifies the maximum number of access users in a user access profile.	The value is an integer that ranges from 1 to 1024. After the value is delivered to an AS, the effective value depends on the AS specifications. For details, see **authentication access-point max-user**.

Views

User access profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a user access profile, you can configure the maximum number of access users in the profile. When the profile is bound an AS port, the maximum number of access users is automatically configured for the port. The following configuration is generated on the AS port:

```
#
 authentication access-point max-user max-num
#
```

Precautions

The **authentication access-user maximum** command configuration takes effect only for new users.

Example

Set the maximum number of access users to 100 in the user access profile **profile_1**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
[HUAWEI-um-user-access-profile_1] authentication access-user maximum 100
```

3.5.24 auth-mode none

Function

The **auth-mode none** command sets the AS authentication mode to no authentication.

The **undo auth-mode** command restores the default AS authentication mode.

By default, authentication is required when an AS connects to an SVF system.

NOTE

This command can only be executed on a parent switch.

Format

auth-mode none

undo auth-mode

Parameters

None

Views

AS authentication view

Default Level

3: Management level

Usage Guidelines

By default, an AS needs to be authenticated using a blacklist or whitelist before connecting to an SVF system. You can also configure no authentication for ASs. In no authentication mode, an AS can connect to an SVF system regardless of whether it is in a blacklist or whitelist.

NOTE

Non-authentication has security risks. Therefore, authentication is recommended.

Example

Configure no authentication for ASs to connect to an SVF system.

```
<HUAWEI> system-view
[HUAWEI] as-auth
[HUAWEI-as-auth] auth-mode none
```

3.5.25 authentication-profile (user access profile view)

Function

The **authentication-profile** command binds an authentication profile to a user access profile.

The **undo authentication-profile** command deletes the authentication profile bound to a user access profile.

By default, no authentication profile is bound to a user access profile.

NOTE

This command can only be executed on a parent switch.

Format

authentication-profile *authentication-profile-name*

undo authentication-profile

Parameters

Parameter	Description	Value
authentication-profile-name	Specifies the name of an authentication profile.	The value is a string of 1-31 case-sensitive characters, which cannot be configured to - and --. It cannot contain spaces and the following symbols: / \ : * ? " < > | @ ' %.

Views

User access profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a user access profile, you can bind an authentication profile to the user access profile. When the user access profile is bound to an AS port, the user access authentication mode specified in the authentication profile is automatically configured on the AS port.

NAC provides three user authentication modes: 802.1X authentication, MAC address authentication, and Portal authentication. To implement user access authentication, run the **dot1x-access-profile name** *access-profile-name*, **mac-access-profile name** *access-profile-name*, and **portal-access-profile name** *access-profile-name* commands in the system view to create an access profile, bind one or multiple of the three user authentication modes to the authentication profile, and then bind the authentication profile to the user access profile in an SVF system.

Precautions

- If Portal authentication is deployed in an SVF system, you must run the **web-auth-server** *server-name* command to specify the Portal server template used in Portal authentication in the Portal access profile view. Additionally, only one Portal server template can be configured in a Portal access profile.
- If the Portal authentication mode has been set to **layer3** in the portal-access-profile bound to the authentication profile, it is not allowed to bind this authentication profile to the user access profile. If an authentication profile has been bound to the user access profile, it is now allowed to set the Portal authentication mode to **layer3**.
- In versions earlier than V200R019C10, user access profiles must be bound to the same authentication profile at any time. In V200R019C10 and later versions, user access profiles can be bound to different authentication profiles. However, if these user access profiles are bound to ASs on the same cascade port, the authentication profiles must be the same.

- The **authentication-profile** and **mac-limit maximum** *max-num* as well as **authentication-profile** and **traffic-limit inbound** { **arp** | **dhcp** } **cir** *cir-value* commands are mutually exclusive and cannot be configured together in a user access profile.
- If many users are connected to the port to which a user access profile is bound, the authentication configuration in the profile may need to take a certain period of time to complete.
- Before changing the authentication profile on the parent, run the **undo authentication-profile** command to delete the existing authentication profile and then run the **commit as** { **name** *as-name* | **all** } command to commit the configuration. You can then create a new authentication profile on the parent.
- After bidirectional flow control is configured in an authentication profile using the **authentication control-direction all** command, this authentication profile cannot be bound to a user access profile.
- In SVF of a version earlier than V200R019, access authentication is not supported for IPv6 users. In SVF of V200R019 or a later version, access authentication is supported for IPv6 users.
- In V200R019 and later versions, the **authentication ipv6-control enable** command configured in an authentication profile can be delivered to ASs. This command can take effect only in the following situations:
  - The parent is S6735-S, S6720-EI, or S6720S-EI, and ASs are S5720-LI, S5720S-LI, S5720I-SI, S5735-S, S5735S-S, S5735S-H, S5736-S, S6735-S, S6720-EI, S6720S-S, or S6720S-EI.
  - The parent is a modular switch and the parent's port to which the authentication profile is bound is not located on the ES0D0G24SA00, ES0D0G24CA00, LE0MG24CA, LE0MG24SA, LE1D2S04SEC0, LE1D2X32SEC0, LE1D2H02QEC0, or X series cards, and ASs are S5720-LI, S5720S-LI, S5720I-SI, S5735-S, S5735S-S, S5735S-H, S5736-S, S6735-S, S6720-EI, S6720S-S, or S6720S-EI.
- In V200R019 and later versions, the **authentication single-stack-control enable** command configured in an authentication profile can be delivered to ASs. This command can take effect only in the following situations:
  - The parent is S5531-H, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, or S6730-H, and ASs are S5531-H, S5531-S, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6730S-H, or S6730-H.
  - The parent is a modular switch and the parent's port to which the authentication profile is bound is located on the LE1D2S04SEC0, LE1D2X32SEC0, LE1D2H02QEC0, or X series cards, and ASs are S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6730S-H, or S6730-H.
- If an interface needs to be unbound from an authentication profile and there are many users on the interface, it takes a long time to unbind the interface from the authentication profile. To shorten the time, run the **authentication speed-limit max-num** command to increase the rate at which a specified AS sends user disassociation request messages.

Example

Bind an authentication profile to the user access profile.

```
<HUAWEI> system-view
[HUAWEI] mac-access-profile name 1
[HUAWEI-mac-access-profile-1] quit
[HUAWEI] authentication-profile name test
[HUAWEI-authen-profile-test] mac-access-profile 1
[HUAWEI-authen-profile-test] quit
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
[HUAWEI-um-user-access-profile_1] authentication-profile test
```

3.5.26 blacklist mac-address

Function

The **blacklist mac-address** command adds a specified MAC address to the blacklist.

The **undo blacklist mac-address** command deletes a MAC address from the blacklist.

By default, no MAC address is added to the blacklist. A maximum of 128 MAC addresses can be added to the blacklist.

NOTE

This command can only be executed on a parent switch.

Format

blacklist mac-address *mac-address1* [**to** *mac-address2*]

undo blacklist mac-address { *mac-address1* [**to** *mac-address2*] | **all** }

Parameters

Parameter	Description	Value
mac-address1 [**to** *mac-address2*]	Specifies the MAC address to be added to the blacklist.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.
all	Deletes all the MAC addresses in the blacklist.	-

Views

AS authentication view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an SVF system needs to authenticate an AS, the SVF system allows the AS to connect to if the MAC address of the AS is in the whitelist and disallows the AS to connect to if the MAC address is in the blacklist.

Precautions

- A MAC address cannot exist in both the whitelist and blacklist.
- By default, if the MAC address of an AS is neither in the whitelist nor in the blacklist, the AS fails the authentication. You can run the **confirm** { **all** | **mac-address** *mac-address* } command to allow all ASs or a specified AS to pass the authentication.
- If the MAC address of an AS that has connected to an SVF system is added to the blacklist, the AS restarts and exits from the SVF system.

Example

Add the MAC address 00e0-fc12-3456 to the blacklist.

```
<HUAWEI> system-view
[HUAWEI] as-auth
[HUAWEI-as-auth] blacklist mac-address 00e0-fc12-3456
```

3.5.27 broadcast-suppression (network enhanced profile view)

Function

The **broadcast-suppression** command configures broadcast traffic suppression in a network enhanced profile.

The **undo broadcast-suppression** command cancels broadcast traffic suppression in a network enhanced profile.

By default, broadcast traffic suppression is not configured in a network enhanced profile. By default, the percentage of broadcast traffic that can pass through an AS port is 50%.

NOTE

This command can only be executed on a parent switch.

Format

broadcast-suppression packets *packets-per-second*

undo broadcast-suppression

Parameters

Parameter	Description	Value
packets *packets-per-second*	Specifies the packet rate of an interface.	The value is an integer that ranges from 0 to 14881000, in packets per second (PPS). If the configured packet rate on the parent switch is larger than the maximum value on the AS port, the maximum value takes effect on the AS port.

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure broadcast traffic suppression in the profile. After the profile is bound to an AS port, broadcast traffic suppression is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 broadcast-suppression packets packets-per-second
#
```

To prevent broadcast storms, you can run the **broadcast-suppression** command to configure the maximum number of broadcast packets that can pass through a port. When the broadcast traffic rate reaches the maximum value, the system discards excess broadcast packets to control the traffic volume within a proper range.

Example

Configure broadcast traffic suppression in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] broadcast-suppression packets 148810
```

3.5.28 clear direct-command

Function

The **clear direct-command** command deletes commands to be directly delivered to an AS from the parent.

NOTE

This command can only be executed on a parent switch.

Format

clear direct-command [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID of a member device in an AS.	The value is an integer that ranges from 0 to 4.

Views

AS view

Default Level

3: Management level

Usage Guidelines

After you run the **direct-command** command to directly deliver commands to an AS, you can run the **clear direct-command** command to delete the commands from the parent.

You can delete directly delivered commands only when the AS is offline. Do not run the **clear direct-command** command when the parent is delivering the commands to an AS.

Example

Delete the commands to be directly delivered to AS1 from the parent.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] clear direct-command
```

3.5.29 commit as

Function

The **commit as** command delivers the service configuration to ASs.

NOTE

This command can only be executed on a parent switch.

Format

commit as { **name** *as-name* | **all** }

Parameters

Parameter	Description	Value
name *as-name*	Delivers the service configuration to an AS with a specified name.	The value must have an existing AS name.
all	Delivers the service configuration to all ASs.	-

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

After configuring or changing services (including service profiles and user authentication-free rules) on the parent, you need to run the **commit as** command to deliver the configuration to ASs to make the configuration take effect.

In versions earlier than V200R020C00, you do not need to configure an AS administrator before configuring an AS in centralized mode. However, in V200R020C00 and later versions, before configuring an AS in centralized mode, you have to configure an AS administrator and deliver it to the AS. Otherwise, the AS configuration will fail to be delivered. For details about how to configure an AS administrator, see Configuring Services for ASs Using an AS Administrator Profile.

Example

Deliver the service configuration to all ASs.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] commit as all
```

3.5.30 confirm

Function

The **confirm** command confirms that unauthenticated ASs pass the authentication.

NOTE

This command can only be executed on a parent switch.

Format

confirm { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Confirms that all ASs pass the authentication.	-
mac-address *mac-address*	Confirms that an AS with a specified MAC address passes the authentication.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Views

AS authentication view

Default Level

3: Management level

Usage Guidelines

When an AS needs to be authenticated before connecting to an SVF system, the AS fails the authentication if its MAC address is neither in the whitelist nor in the blacklist. You can run the **confirm** command to allow all ASs or a specified AS to pass the authentication.

You can run the **display as unauthorized record** command to check information about the ASs that fail the authentication.

Example

Confirm that the AS with the MAC address 00e0-fc12-3456 passes the authentication.

```
<HUAWEI> system-view
[HUAWEI] as-auth
[HUAWEI-as-auth] confirm mac-address 00e0-fc12-3456
```

3.5.31 description (Fabric-port view)

Function

The **description** command configures the description of a fabric port.

The **undo description** command deletes the description of a fabric port.

By default, no description is configured for a fabric port.

NOTE

This command can only be executed on a parent switch.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description.	The value is a string of 1 to 64 case-sensitive characters with spaces supported.

Views

Fabric-port view

Default Level

2: Configuration level

Usage Guidelines

To facilitate fabric port management and identification, you can configure descriptions for fabric ports. For example, you can describe the name of an AS that connects to a fabric port.

Example

Configure the description of a fabric port.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] interface fabric-port 1
[HUAWEI-um-fabric-port-1] description To_as1
```

3.5.32 description (port group view)

Function

The **description** command configures the description of a port group.

The **undo description** command deletes the description of a port group.

By default, a port group does not have a description.

NOTE

This command can only be executed on a parent switch.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description.	The value is a string of 1 to 15 case-sensitive characters with spaces supported.

Views

Port group view

Default Level

2: Configuration level

Usage Guidelines

To facilitate identification and management of terminals connected to a port group in the web system, configure the description of the port group.

Example

Configure the description of a specified port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] port-group name 1
[HUAWEI-um-portgroup-1] description switch
```

3.5.33 dhcp snooping enable (network enhanced profile view)

Function

The **dhcp snooping enable** command configures DHCP snooping in a network enhanced profile.

The **undo dhcp snooping enable** command cancels DHCP snooping in a network enhanced profile.

By default, DHCP snooping is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

dhcp snooping enable

undo dhcp snooping enable

Parameters

None

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure DHCP snooping in the profile. After the profile is bound to an AS port, DHCP snooping is automatically enabled on the AS and AS port. The following configuration is generated on the AS:

```
#
dhcp enable
#
dhcp snooping enable
#
interface GigabitEthernet0/0/1
 dhcp snooping enable
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration depends on the profile configuration.

You can run the **dhcp snooping enable** command to enable DHCP snooping on a port so as to improve DHCP security.

Precautions

Before running the **undo dhcp snooping enable** command, ensure that the network enhanced profile view is not configured with IPSG or DAI. To disable IPSG and DAI, run the **undo ip source check user-bind enable (network enhanced profile view)** and **undo arp anti-attack check user-bind enable (network enhanced profile view)** commands respectively.

The **dhcp snooping enable** command configured in the network enhanced profile can only configure a DHCP dynamic binding table but not a DHCP static binding table.

Example

Configure DHCP snooping in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] dhcp snooping enable
```

3.5.34 direct-command

Function

The **direct-command** command configures ASs on the parent. The parent directly delivers the configuration to the ASs, and you do not need to run the **commit as** command.

The **undo direct-command** command cancels the configuration for ASs on the parent.

The following table lists the service configurations that can be delivered using the **direct-command** command. If no configuration dependency and restriction are provided for a command, see the details in the command reference.

NOTE

This command can only be executed on a parent switch.

Format

direct-command view { **system** | **eth-trunk** *trunk-id* | *interface-type interface-number* | **stack-port** *member-id/port-id* } **command** *command-text*

undo direct-command view { **system** | **eth-trunk** *trunk-id* | *interface-type interface-number* | **stack-port** *member-id/port-id* } **command** *command-text*

Parameters

Parameter	Description	Value
view { **system** | **eth-trunk** *trunk-id* | *interface-type interface-number* | **stack-port** *member-id/port-id* }	Specifies the view in which a command is executed. - **system**: system view - *interface-type interface-number*: interface view - **stack-port** *member-id/port-id*: stack port view - **eth-trunk** *trunk-id*: Eth-Trunk interface view	-
command *command-text*	Specifies the command to be delivered to ASs.	The value is a string of 1 to 128 characters. This command does not support auto-completion of keywords by pressing Tab.

Views

AS view

Default Level

3: Management level

Usage Guidelines

- When you configure a directly delivered command on the parent, enter the complete and correct command instead of the abbreviated form. No info message is displayed for confirming your input.
- A directly delivered command supports the help and typeahead functions but not real-time check during input. The system checks the input only after you complete typing a command and press **Enter**. No detailed description is provided in help information. If you fail to configure a command for an AS, an info message is displayed.
- When you configure a directly delivered command, the AS to which the command is to be delivered must be online. If you need to specify a port or *slot-id* in a command, the corresponding member device must be available. If the AS is offline, run the **clear direct-command** command to delete the completed configuration on the parent.
- If a port has the configuration directly delivered using commands, the port cannot be configured as a member port of the Eth-Trunk to which a fabric port is bound. If a port has been configured as a member port of the Eth-Trunk to which a fabric port is bound, the configuration cannot be directly delivered to the port using commands.
- Directly delivering configuration using commands and delivering configuration using service profiles are mutually exclusive and cannot be performed simultaneously.
- In versions earlier than V200R019C00, a maximum of 4096 commands can be configured. In V200R019C00 and later versions, a maximum of 8192 commands can be configured.
- In versions earlier than V200R020C00, you do not need to configure an AS administrator before configuring an AS in centralized mode. However, in V200R020C00 and later versions, before configuring an AS in centralized mode, you have to configure an AS administrator and deliver it to the AS. Otherwise, the AS configuration will fail to be delivered. For details about how to configure an AS administrator, see Configuring Services for ASs Using an AS Administrator Profile.
- The following lists the commands that can be directly delivered to ASs. You can run the **undo direct-command view** { **system** | *interface-type interface-number* } **command** *command-text* command to cancel the configuration or restore default settings. The *command-text* parameter specifies the commands listed in the following table.

Service Category	Format	View	Function	Configuration Dependency and Restriction
Energy-saving management	**port-auto-sleep enable**	Interface view	Enables the port sleeping function on an electrical interface.	Currently, this command can be used on electrical interfaces (excluding MultiGE interfaces) and combo interfaces working as electrical interfaces.
PoE	**poe force-power**	Interface view	Enables forcible PoE power supply on an interface.	-
	poe legacy enable	Interface view	Enables an interface to check compatibility of PDs.	-
	poe priority { **critical** | **high** | **low** }	Interface view	Sets the power supply priority of a PoE interface.	-
	poe af-inrush enable slot *slot-id*	System view	Configures the IEEE 802.3at-compliant device to provide power in accordance with IEEE 802.3af.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
	poe high-inrush enable slot *slot-id*	System view	Configures a device to allow high inrush current during power-on.	-
	undo poe enable (supported in V200R011C10 and later versions)	Interface view	Disables the PoE function on an interface.	-
Ethernet interfaces	**undo negotiation auto**	Interface view	Configures an interface to work in non-auto negotiation mode. After you run the **undo direct-command** command, the interface works in auto negotiation mode.	- This command cannot be configured on combo interfaces. - Do not cancel the **undo negotiation auto** command when **speed** or **duplex** is specified.
	speed { **10** | **100** | **1000** | **2500** | **5000** | **10000** }	Interface view	Sets the rate in non-auto negotiation mode.	- This command cannot be configured on combo interfaces. - Ensure that the interface works in non-auto negotiation mode before configuring this command.

Service Category	Format	View	Function	Configuration Dependency and Restriction
	speed auto-negotiation	Interface view	Enables auto-negotiation on a GE optical interface.	- Support for this command varies depending on switch models. For details, see the **speed auto-negotiation** command in the *Command Reference - Interface Management Commands - Ethernet Interface Configuration Commands*. - Ensure that the interface works in auto-negotiation mode before configuring this command.

Service Category	Format	View	Function	Configuration Dependency and Restriction
	duplex { **full** | **half** }	Interface view	Sets the duplex mode for an electrical interface in non-auto negotiation mode.	● This command cannot be configured on combo interfaces. ● Ensure that the interface works in non-auto negotiation mode before configuring this command. ● When the working rate of a GE electrical interface is 1000 Mbit/s, the interface supports only the full duplex mode.
	loopback internal	Interface view	Configures a loopback detection mode on an interface.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
	description *description* (supported in V200R011C10 and later versions)	Interface view	Configures the description for an interface.	The description contains a maximum of 52 characters in V200R011C10, and the description contains a maximum of 116 characters in V200R012C00 and later versions.
Eth-Trunk interface	**description** *description* (supported in V200R019C00 and later versions)	Eth-Trunk interface view	Configures the description for an Eth-Trunk interface.	The description contains a maximum of 116 characters. The description can be configured for a service Eth-Trunk interface or an Eth-Trunk interface used in an SVF system to connect upstream and downstream devices. The description cannot be configured for Eth-Trunk0.

Service Category	Format	View	Function	Configuration Dependency and Restriction
Port bridge	**port bridge enable**	Interface view	Enables the bridging function on an interface.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
Port Security (supported in V200R019C00 and later versions)	**port-security max-mac-num** *max-number*	Interface view	Sets the maximum number of secure MAC addresses that can be learned on an interface.	● The **port-security max-mac-num** *max-number* command in direct configuration mode is mutually exclusive with the **mac-limit maximum** *max-num* command configured in a user access profile and cannot be both configured. ● Port security (and sticky MAC if needed) must be enabled in a network enhanced profile, and then run the **direct-command** command to deliver this command.

Service Category	Format	View	Function	Configuration Dependency and Restriction
	port-security mac-address sticky *mac-address* **vlan** *vlan-id*	Interface view	Configures a sticky MAC address entry.	Port security and sticky MAC must be enabled in a network enhanced profile, and then run the **direct-command** command to deliver this command.
	save sticky-mac configuration	System view	Saves the sticky MAC addresses on an AS to a file named unimng-xxxx.ztbl. *xxxx* in the file name represents the management MAC address of the AS.	-
Voice VLAN	**voice-vlan mac-address** *mac-address* **mask** *mask* (supported in V200R011C10 and later versions)	System view	Configures the OUI address of the voice VLAN.	-
LBDT	**loopback-detect enable**	Interface view	Enables loopback detection on an interface.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
	loopback-detect packet vlan *vlan-id*	Interface view	Enables loopback detection for a specified VLAN.	If you configure this command multiple times, loopback detection is enabled for multiple VLANs.

Service Category	Format	View	Function	Configuration Dependency and Restriction
ARP rate limiting	**arp speed-limit source-mac maximum** *maximum*	System view	Configures ARP rate limiting based on source MAC addresses.	● Only some models support this command. For details, see the **arp speed-limit source-mac** command in the *Command Reference - Security Commands - ARP Security Configuration Commands*. ● The value of **maximum** *maximum* ranges from 0 to 256. ● This function takes effect only for the ARP packets sent to the CPU.

Service Category	Format	View	Function	Configuration Dependency and Restriction
	arp speed-limit source-ip maximum *maximum*	System view	Configures ARP rate limiting based on source IP addresses.	- The value of **maximum** *maximum* ranges from 0 to 256. - This function takes effect only for the ARP packets sent to the CPU.
Stack	**port interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } **enable** (supported in V200R010 and later versions)	Stack interface view: **stack-port** *member-id/port-id*	Configures a service interface as a stack member port and adds it to a stack port.	Before restoring the stack member ports that are added to a stack port in direct configuration mode as common service interfaces, you do not need to run the **shutdown interface** command in the stack interface view.
	stack slot *slot-id* **priority** *priority* (supported in V200R010 and later versions)	System view	Sets a stack priority for a member switch in a stack.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
	stack slot *slot-id* **renumber** *new-slot-id* (supported in V200R011C10 and later versions)	System view	Changes the stack ID of a specified member switch in a stack. **NOTICE** If there are services running, delivering this command may cause service interruptions and configuration loss. Therefore, you are advised to deliver this command when an AS is unconfigured.	A stack ID cannot be changed in the following situations: - The switch is a standalone switch that does not join any stack. - The newly configured stack ID is an existing stack ID of a specified member switch in a stack. - Ports with the specified *slot-id* have been configured as member ports of an uplink fabric port. - Ports with the specified *slot-id* have been configured as member ports of a downlink

Service Category	Format	View	Function	Configuration Dependency and Restriction
				fabric port.

Service Category	Format	View	Function	Configuration Dependency and Restriction
User Access and Authentication (supported in V200R012C00 and later versions)	**access-user arp-detect vlan** *vlan-id* **ip-address** *ip-address* **mac-address** *mac-address*	System view	Sets the source IP address and source MAC address of offline detection packets in a VLAN.	- In other V200R012C00 versions except V200R012C00SPC710, this command can be configured only one. If you want to modify the configuration, delete the existing configuration and then perform the configuration again. - In V200R012C00SPC710 and V200R013C00, when **vlan**, **ip-address**, and **mac-address** are all different, multiple configurations of this command can be generated.

Service Category	Format	View	Function	Configuration Dependency and Restriction
				If any one of **vlan**, **ip-address**, and **mac-address** has been configured, delete the existing configuration before reconfiguring them. ● In V200R019 and later versions, multiple configurations of this command can be generated regardless of whether the VLAN, IP address, and MAC address are the same. You do not need to delete the existing configuration. If the newly configured VLAN is the same as the

Service Category	Format	View	Function	Configuration Dependency and Restriction
				existing one, the IP address and MAC address in the original configuration are replaced with the newly configured IP address and MAC address. If the newly configured VLAN is different from the existing one, a new configuration is generated.
	access-user arp-detect default ip-address *ip-address*	System view	Sets the default source IP address of offline detection packets.	-
	undo user-detect	System view	Disables the online user detection function.	-

Service Category	Format	View	Function	Configuration Dependency and Restriction
	authentication speed-limit max-num *max-num-value* **interval** *interval-value* (supported in V200R013C00 and later versions)	System view	Configures the rate limit for an access device to send user association and disassociation request messages.	-
	access-user arp-detect fallback ip-address *mask-length* (supported in V200R013C00 and later versions)	System view	Configures an IP address required for calculating the source address of offline detection packets.	If you run this command multiple times, only the latest configuration takes effect.
	access-user arp-detect delay *delay* (supported in V200R013C00 and later versions)	System view	Configures the delay for sending offline detection packets.	-
	static-user *start-ip-address* [*end-ip-address*] [**mac-address** *mac-address* | **vlan** *vlan-id*] (supported in V200R019C00 and later versions)	System view	Configures a static user.	If the IP address of a static user is set to an IP address range, any IP address in this address range cannot be modified or deleted.

Example

Configure the parent to deliver the **loopback-detect enable** command to GigabitEthernet0/0/1 on **as1** to enable loopback detection on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
```

```
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] direct-command view gigabitethernet 0/0/1 command loopback-detect enable
```

3.5.35 display as

Function

The **display as** command displays information about access switches (ASs).

NOTE

This command can only be executed on a parent switch.

Format

display as { **all** | **name** *as-name* | **mac-address** *mac-address* | **vpn-instance information** }

Parameters

Parameter	Description	Value
all	Displays information about all ASs.	-
name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.
mac-address *mac-address*	Specifies the MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.
vpn-instance information	Displays VPN instance information.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as** command to view information about ASs in an SVF system, including the AS device type, VPN instance information, and access status.

Example

Display information about all ASs.

```
<HUAWEI> display as all
Total: 1, Normal: 1, Fault: 0, Idle: 0, Version mismatch: 0
--------------------------------------------------------------------------------
No.  Type          MAC            IP              State       Name
--------------------------------------------------------------------------------
0    S5720-P-LI     00e0-fcbb-cc92 192.168.11.254  normal       as1
--------------------------------------------------------------------------------
```

Table 3-86 Description of the **display as all** command output

Item	Description
Total	Total number of ASs.
Normal	Number of ASs that are running normally.
Fault	Number of ASs in abnormal running status.
Idle	Number of ASs that have been configured but no gone online.
Version mismatch	Number of ASs of which the software versions do not match the software version of the parent.
No.	Sequence number.
Type	Device type of an AS.
MAC	Management MAC address of an AS.
IP	IP address of an AS.
State	Status of an AS: ● idle: The AS is in initial state. ● normal: The AS has gone online and connected to an SVF system. ● fault: The AS does not connect to an SVF system. ● version mismatch: The V, R, or C versions of the AS and parent are inconsistent.
Name	Name of an AS.

Display information about the AS **as1**.

```
<HUAWEI> display as name as1
-----------------------------------------------------------------------------

-------------------------------------------------------------------------------
```

Table 3-87 Description of the **display as name** command output

Item	Description
Management MAC	Management MAC address of an AS. In a Super Virtual Fabric (SVF) system, each AS has a unique management MAC address to identify itself. To set a management MAC address for an AS, run the **as access manage-mac** command. If no management MAC address is configured for an AS, the system MAC address of the AS is used as the management MAC address.
System MAC	System MAC address of an AS, which is the physical MAC address of this AS.
ESN	Sequence number of an AS.
Name	Name of an AS.
Model	Device model of an AS.
Device type	Device type of an AS.
State	Status of an AS: ● idle: The AS is in initial state. ● normal: The AS has gone online and connected to an SVF system. ● fault: The AS does not connect to an SVF system. ● version mismatch: The V, R, or C versions of the AS and parent are inconsistent.
Mode	Service configuration mode of an AS: ● centralized: indicates the centralized mode. ● independent: indicates the independent mode.
Slot	Stack ID of an AS in a stack.
AS group	AS group to which an AS belongs.

Item	Description
Port group	Port group to which an AS port belongs.

Display VPN instance information of ASs.

```
<HUAWEI> display as vpn-instance information

0    VPN1                              e-10005(1-1)
1    --                             t-10018(2-2)
2    VPN2                              s-10021(1-1)
3    --                             6-10023(2-1)
4    --                             11-t-16(x-s)
--------------------------------------------------------------------------------
```

Table 3-88 Description of the **display as vpn-instance information** command output

Item	Description
Total	Number of ASs.
No.	AS number.
VPN-Instance	VPN instance name.
AS Name	AS name.

3.5.36 display as access configuration

Function

The **display as access configuration** command displays the access configuration of ASs.

NOTE

Only the switches that function as ASs support this command.

Format

display as access configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as access configuration** command on an AS to check the access configuration of the AS.

Example

Display the access configuration of an AS.

```
<HUAWEI> display as access configuration
   AS mode                              : centralized
   Access interface                     : vlanif11
   Access controller configuration      : --
   Current connected access controller : 192.168.11.1(dynamic)
   Access management MAC                : xxxx-xxxx-xxxx
   Access system MAC                    : xxxx-xxxx-xxxx
   Current connected state              : normal
```

Table 3-89 Description of the **display as access configuration** command output

Item	Description
AS mode	AS mode: - disable: The device works in parent mode. To change the device working mode, run the **as-mode disable** command. - enable: The device works in AS mode, but it does not have the SVF function enabled using the **uni-mng** command. - centralized: The device works in AS mode and the service configuration mode is centralized mode. - independent: The device works in AS mode and the service configuration mode is independent mode.
Access interface	VLANIF interface for the management VLAN of an AS.
Access controller configuration	Parent IP address configured using the **as access controller ip-address** command. If this IP address is configured, the **Current connected access controller** field value contains configured.

Item	Description
Current connected access controller	IP address of the parent to which an AS is connected. If this field contains dynamic, the IP address is obtained through DHCP or in broadcast mode. If this field contains configured, the IP address is statically configured. If an AS does not go online, this field displays --.
Access management MAC	Configured management MAC address of an AS.
Access system MAC	System MAC address of an AS.
Current connected state	Connection status of an AS: ● idle: The AS is in initial state. ● normal: The AS has gone online and connected to an SVF system. ● fault: The AS does not connect to an SVF system. ● version mismatch: The V, R, or C versions of the AS and parent are inconsistent.

3.5.37 display as blacklist

Function

The **display as blacklist** command displays blacklist information of an AS.

NOTE

This command can only be executed on a parent switch.

Format

display as blacklist

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as blacklist** command to check blacklist information of an AS.

Example

Display blacklist information of an AS.

```
<HUAWEI> display as blacklist
-------------------------------------------------------------------------------
ID     MAC
-------------------------------------------------------------------------------
0      xxxx-xxxx-xxxx
-------------------------------------------------------------------------------
Total: 1
```

Table 3-90 Description of the **display as blacklist** command output

Item	Description
ID	ID of a blacklist.
MAC	MAC address added to the blacklist. To add a MAC address to a blacklist, run the **blacklist mac-address** command. If no MAC address is specified, no information is displayed.

3.5.38 display as run-info

Function

The **display as run-info** command displays running status information of an AS.

NOTE

This command can only be executed on a parent switch.

Format

display as { **name** *as-name* | **mac-address** *mac-address* } **run-info**

Parameters

Parameter	Description	Value
name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.

Parameter	Description	Value
mac-address *mac-address*	Specifies the MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as run-info** command to check running status information of an AS, including the AS access status, CPU usage, and memory usage.

Example

Display running status information of an AS.

```
<HUAWEI> display as name as1 run-info
Info: This operation may take a few seconds. Please wait...
-------------------------------------------------------------------------------
Software version     : Version 5.170 V200R023C00
Hardware version     : VER.A
Patch version        : --
Patch state          : running
IP address           : 192.168.1.154
IP mask              : 255.255.255.0
Gateway              : 192.168.1.1
VPN-Instance         : --
State                : normal
Online time          : 1 day, 18 hours, 40 minutes, 0 second

Memory usage         : 52%
Slot 0               : present
-------------------------------------------------------------------------------
```

Table 3-91 Description of the **display as run-info** command output

Item	Description
Software version	Software version running on an AS.
Hardware version	Hardware version running on an AS.
Patch version	Patch version. This field displays**--** when the patch package is not installed.

Item	Description
Patch state	Patch status. - Running: The patch is running. - not running: The patch is not running.
IP address	IP address of an AS.
IP mask	Subnet mask.
Gateway	Gateway of an AS.
VPN-Instance	Name of a VPN instance.
State	Status of an AS: - idle: The AS is in initial state. - normal: The AS has gone online and connected to an SVF system. - fault: The AS does not connect to an SVF system. - version mismatch: The V, R, or C versions of the AS and parent are inconsistent.
Online time	Online time of an AS.
CPU usage	CPU usage of an AS.
Memory usage	Memory usage of an AS.
Slot 0	Whether an AS member device is present: - present - absent

3.5.39 display as unauthorized record

Function

The **display as unauthorized record** command displays information about the ASs that fail the authentication.

NOTE

This command can only be executed on a parent switch.

Format

display as unauthorized record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as unauthorized record** command to check information about the ASs that fail the authentication.

Example

Display information about the ASs that fail the authentication.

```
<HUAWEI> display as unauthorized record
Unauthorized AS record:
-------------------------------------------------------------------------------
AS type        : S5720-SI
Host name      : host
AS MAC address : xxxx-xxxx-xxxx
AS IP address  : 192.168.1.253
Record time    : 2023-02-20 16:06:10 DST
-------------------------------------------------------------------------------
Total: 1
```

Table 3-92 Description of the **display as unauthorized record** command output

Item	Description
AS type	Device type of an AS.
Host name	Name of the AS.
AS MAC address	MAC address of the AS.
AS IP address	IP address of the AS.
Record time	Time when the AS is authenticated.

3.5.40 display as whitelist

Function

The **display as whitelist** command displays whitelist information of an AS.

NOTE

This command can only be executed on a parent switch.

Format

display as whitelist

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display as whitelist** command to check whitelist information of an AS.

Example

Display whitelist information of an AS.

```
<HUAWEI> display as whitelist
--------------------------------------------------------------------------------
ID     MAC
--------------------------------------------------------------------------------
0      00e0-fc07-8282
--------------------------------------------------------------------------------
Total: 1
```

Table 3-93 Description of the **display as whitelist** command output

Item	Description
ID	ID of a whitelist.
MAC	MAC address added to the whitelist.

3.5.41 display uni-mng as-discover packet statistics

Function

The **display uni-mng as-discover packet statistics** command displays AS Discovery packet statistics on a fabric port.

NOTE

This command can be used on the parent or an AS. After running this command, you can check AS Discovery packet statistics on a fabric port of the local device.

Format

display uni-mng as-discover packet statistics interface fabric-port *port-id*

Parameters

Parameter	Description	Value
interface fabric-port *port-id*	Specifies the number of a fabric port.	The value is an integer that ranges from 0 to 63 on an AS and the value range on the parent varies depending on the switch model: ● S12700/S12700E: 0 to 255 ● MCUD/SRUK/MFUX/MPUE/SRUE/SRUHA1/SRUHX1/SRUH: 0 to 255 ● Other switch models: 0 to 63

Views

All views

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng as-discover packet statistics** command to check AS Discovery packet statistics on a fabric port.

Example

Display AS Discovery packet statistics on a fabric port.

```
<HUAWEI> display uni-mng as-discover packet statistics interface fabric-port 1
The statistics of AS Discover packet on Fabric-port1:

PortName     Packet-type                  Receive        Send
-------------------------------------------------------------------------------
GE2/0/23     AS Discover Request            0              3
             AS Discover ACK              3              0
             AS Discover ParaSyn Req        0              3
             AS Discover ParaSyn ACK        3              0
             AS Discover HeartBeat Req      0              11238
             AS Discover HeartBeat ACK      11238          0
             AS Discover NAK              0              0
             AS Discover FabricCfg Req      0              0
             AS Discover FabricCfg ACK      0              0
             AS Discover NotifyOffline Req  0              0
             AS Discover NotifyOffline ACK  0              0
-------------------------------------------------------------------------------
```

Table 3-94 Description of the **display uni-mng as-discover packet statistics** command output

Item	Description
PortName	Name of a member port in a fabric port.
Packet-type	Packet type: - AS Discover Request: neighbor discovery request packet - AS Discover Request: neighbor discovery request packet - AS Discover ParaSyn Req: neighbor discovery parameter synchronization packet - AS Discover ParaSyn ACK: neighbor discovery parameter synchronization response packet - AS Discover HeartBeat Req: neighbor discovery heart packet - AS Discover HeartBeat ACK: neighbor discovery heart response packet - AS Discover NAK: neighbor discovery error packet - AS Discover FabricCfg Req: neighbor discovery AS fabric port configuration packet - AS Discover FabricCfg ACK: neighbor discovery AS fabric port configuration response packet - AS Discover NotifyOffline Req: request packet that notifies AS offline - AS Discover NotifyOffline ACK: response packet of the request that notifies AS offline
Receive	Statistics about received packets. Statistics about AS Discover HeartBeat Req and AS Discover HeartBeat ACK packets will be cleared and start from 0 after an active/standby switchover is performed on the device.

Item	Description
Send	Statistics about sent packets. Statistics about AS Discover HeartBeat Req and AS Discover HeartBeat ACK packets will be cleared and start from 0 after an active/standby switchover is performed on the device.

3.5.42 display uni-mng as-group

Function

The **display uni-mng as-group** command displays information about AS groups.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng as-group [**name** *group-name* | **verbose**]

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of an AS group.	The value must be an existing an AS group name.
verbose	Displays detailed information about an AS group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng as-group** command to check information about created AS groups.

Example

Display brief information about all AS groups.

```
<HUAWEI> display uni-mng as-group

-------------------------------------------------------------------------------
 Number                    AS-group Name
-------------------------------------------------------------------------------
 1                         asgroup
-------------------------------------------------------------------------------
```

Table 3-95 Description of the **display uni-mng as-group** command output

Item	Description
Number	Sequence number.
AS-group Name	AS group name.

Display detailed information about all AS groups.

```
<HUAWEI> display uni-mng as-group verbose

AS-group name: asgroup
-------------------------------------------------------------------------------
AS name list: (Total number = 1)
 as1
-------------------------------------------------------------------------------
AS-admin profile name: admin
-------------------------------------------------------------------------------
```

Table 3-96 Description of the **display uni-mng as-group verbose** command output

Item	Description
AS-group name	AS group name.
AS name list	List of ASs added to an AS group.
AS-admin profile name	Name of the bound AS administrator profile.

3.5.43 display uni-mng as index

Function

The **display uni-mng as index** command displays the index of an AS.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng as index

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng as index** command to check the index, management MAC address, and name of an AS.

Example

Display the index of an AS.

```
<HUAWEI> display uni-mng as index
Total number : 1
-------------------------------------------------------------------------------
Index     MAC-Current          MAC-Saved          Name
-------------------------------------------------------------------------------
1         00e0-fc12-3456       00e0-fc12-3456     as1
-------------------------------------------------------------------------------
```

Table 3-97 Description of the **display uni-mng as index** command output

Item	Description
Index	Index of an AS.
MAC-Current	Management MAC address.

Item	Description
MAC-Saved	MAC address saved in the flash memory. This field indicates the MAC address saved in the flash memory using the **save** command after an AS goes online or the **as name (uni-mng view)** command is configured. ● If this field displays --, the **save** command is not executed after an AS goes online or the **as name (uni-mng view)** command is configured. ● When **MAC-Current** and **MAC-Saved** are inconsistent, the **save** command is not executed after an AS is replaced or the **as name (uni-mng view)** command is configured.
Name	Name of an AS.

3.5.44 display uni-mng as interface brief

Function

The **display uni-mng as interface brief** command displays brief information about AS ports.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng as name *as-name* **interface brief**

Parameters

Parameter	Description	Value
name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.

Views

All views

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng as interface brief** command to check brief information about AS ports.

When an AS is offline or its version is inconsistent with the parent version, this command displays default attributes of ports on this AS.

Example

Display brief information about AS ports.

```
<HUAWEI> display uni-mng as name as1 interface brief
PHY: Physical
*down      : administratively down
*Stack Port: inactive stack port
-------------------------------------------------------------------------------
Interface                 Type            PHY      Online       MSTP state
-------------------------------------------------------------------------------
Eth-Trunk1                Fabric Port     up       present      forwarding
Eth-Trunk40               Service Port    down     present      discarding
GigabitEthernet0/0/1      Service Port    down     present      discarding
GigabitEthernet0/0/2      Service Port    up       present      forwarding
GigabitEthernet0/0/3      Service Port    down     present      discarding
GigabitEthernet0/0/4      Service Port    down     present      discarding
GigabitEthernet0/0/5      Service Port    down     present      discarding
GigabitEthernet0/0/6      Service Port    down     present      discarding
GigabitEthernet0/0/7      Service Port    down     present      discarding
GigabitEthernet0/0/8      Service Port    down     present      discarding
GigabitEthernet0/0/9      Service Port    down     present      discarding
GigabitEthernet0/0/10     Service Port    down     present      discarding
GigabitEthernet0/0/11     Service Port    down     present      discarding
GigabitEthernet0/0/12     Service Port    down     present      discarding
GigabitEthernet0/0/13     Service Port    down     present      discarding
GigabitEthernet0/0/14     Service Port    down     present      discarding
GigabitEthernet0/0/15     Service Port    down     present      discarding
GigabitEthernet0/0/16     Service Port    down     present      discarding
GigabitEthernet0/0/17     Service Port    down     present      discarding
GigabitEthernet0/0/18     Service Port    down     present      discarding
GigabitEthernet0/0/19     Service Port    down     present      discarding
GigabitEthernet0/0/20     Service Port    down     present      discarding
GigabitEthernet0/0/21     Service Port    down     present      discarding
GigabitEthernet0/0/22     Service Port    down     present      discarding
GigabitEthernet0/0/23     Service Port    down     present      discarding
GigabitEthernet0/0/24     Service Port    down     present      discarding
GigabitEthernet0/0/25     Fabric Port     down     present      discarding
GigabitEthernet0/0/26     Fabric Port     up       present      forwarding
GigabitEthernet0/0/27     Fabric Port     down     present      discarding
GigabitEthernet0/0/28     Fabric Port     up       present      discarding
-------------------------------------------------------------------------------
```

Table 3-98 Description of the **display uni-mng as interface brief** command output

Item	Description
Interface	Interface number.

Item	Description
Type	Interface type: ● Service Port: indicates a service port. ● Stack Port: indicates a physical stack member port. ● Fabric Port: indicates a member port of a fabric port. ● *Stack Port: indicates a stack member port that does not take effect.
PHY	Interface status: ● up: The interface is Up. ● down: The interface is Down. ● *down: The administrator shuts down the interface.
Online	Whether the card where the interface resides is present: ● present ● absent
MSTP state	STP forwarding status of the interface: ● disabled ● discarding ● learning ● forwarding ● --: The interface is absent or a physical stack member port. If the interface is an Eth-Trunk member port, this field displays the forwarding state of the Eth-Trunk.

3.5.45 display uni-mng as interface eth-trunk

Function

The **display uni-mng as interface eth-trunk** command displays information about an Eth-Trunk interface of an AS.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng as name *as-name* **interface eth-trunk** *eth-trunk-id*

Parameters

Parameter	Description	Value
name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.
eth-trunk-id	Specifies the ID of an Eth-Trunk.	The value range varies depending on the device.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After you use the **uni eth-trunk** command to create an Eth-Trunk on an AS, you can run the **display uni-mng as interface eth-trunk** command to view information including the Eth-Trunk working mode, member interface, and member interface status.

Example

Display information about Eth-Trunk 40 on AS as1.

```
<HUAWEI> display uni-mng as name as1 interface eth-trunk 40
Eth-Trunk40's state information is:
WorkingMode: NORMAL
Operate status: down
--------------------------------------------------------------------------------
PortName                Status
GigabitEthernet0/0/10     down
GigabitEthernet0/0/11     down
--------------------------------------------------------------------------------
The Number of Ports in Trunk : 2
The Number of UP Ports in Trunk : 0
```

Table 3-99 Description of the **display uni-mng as interface eth-trunk** command output

Item	Description
Eth-Trunk40's state information is	State information of Eth-Trunk 40.

Item	Description
WorkingMode	Working mode of the Eth-Trunk interface: ● NORMAL: manual mode ● LACP: LACP mode. To set the LACP mode, specify the **mode lacp** parameter when running the **uni eth-trunk** command to create an Eth-Trunk.
Operate status	Status of the Eth-Trunk interface: ● down: The interface is Down. ● up: The interface is Up.
PortName	Eth-Trunk member interface name. To add or delete an Eth-Trunk member interface, run the **port eth-trunk trunkmember** command.
Status	Eth-Trunk member interface status: ● down: The member interface is Down. ● up: The member interface is Up.
The Number of Ports in Trunk	Number of Eth-Trunk member interfaces.
The Number of UP Ports in Trunk	Number of Eth-Trunk member interfaces in Up state.

3.5.46 display uni-mng authen-user

Function

The **display uni-mng authen-user** command displays authenticated user information on an AS.

NOTE

This command can be used on the parent or an AS.

Format

display uni-mng authen-user [**as name** *as-name*]

Parameters

Parameter	Description	Value
as name *as-name*	Specifies the name of an AS. **NOTE** This parameter can be specified only when the command is run on the parent.	The value must be the name of an online AS.

Views

All views

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng authen-user** command to view authenticated user information on an AS.

Example

Display authenticated user information on the AS named **test1**.

```
<HUAWEI> display uni-mng authen-user as name test1
Total: 5
-------------------------------------------------------------------------------
MAC Address       VLAN  IP              Interface    AS Name
-------------------------------------------------------------------------------
xxxx-xxxx-xxx1    212   1.1.1.1         Ge1/0/1      test1
xxxx-xxxx-xxx2    212   1.1.1.2         Ge1/0/1      test1
xxxx-xxxx-xxx3    212   1.1.1.3         Ge1/0/1      test1
xxxx-xxxx-xxx4    212   1.1.1.4         Ge1/0/1      test1
xxxx-xxxx-xxx5    212   1.1.1.5         Ge1/0/1      test1
-------------------------------------------------------------------------------
```

Table 3-100 Description of the **display uni-mng authen-user** command output

Item	Description
Total	Total number of authenticated users on an AS.
MAC Address	MAC address of an authenticated user.
VLAN	VLAN that an authenticated user belongs to.
IP	IP address of an authenticated user. **NOTE** If this command is run on an AS, this field is displayed as **--**.

Item	Description
Interface	Interface to which an authenticated user is connected.
AS Name	Name of an AS.

3.5.47 display uni-mng commit-result

Function

The **display uni-mng commit-result** command displays the configuration delivery result.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng commit-result { **profile** | **free-rule** | **as-direct-config** }

Parameters

Parameter	Description	Value
profile	Displays the delivery result of the service profile configuration.	-
free-rule	Displays the delivery result of user authenticate-free rules.	-
as-direct-config	Displays the direct configuration recovery result after an AS goes online.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng commit-result** command to check the result of delivering the configuration to an AS, including the service profiles configured on the parent, user authentication-free rules, and configurations directly delivered to ASs. This command displays only the latest result but not historical information.

Example

Display the result of delivering the service profile configuration to an AS.

```
<HUAWEI> display uni-mng commit-result profile
Result of profile:
--------------------------------------------------------------------------------
 AS Name                        Commit Time              Commit/Execute Result
--------------------------------------------------------------------------------
 as1                        2014-09-16 14:38:03       Success/Success
--------------------------------------------------------------------------------
```

Table 3-101 Description of the **display uni-mng commit-result profile** command output

Item	Description
AS Name	Name of an AS.
Commit Time	Time when the configuration is delivered.
Commit/Execute Result	Commit Result indicates the configuration delivery result: ● Success: The configuration is delivered successfully. ● Failed: The configuration fails to be delivered. ● Committing: The configuration is being delivered. Execute Result indicates the execution result of the delivered configuration: ● Success: The configuration is executed successfully. ● Failed: The configuration fails to be executed. ● Executing: The configuration is being executed.

3.5.48 display uni-mng global

Function

The **display uni-mng global** command displays the global configuration of SVF.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng global

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng global** command to view the globally configured service functions of SVF.

Example

Display the global configuration of SVF.

```
<HUAWEI> display uni-mng global
Forward-mode : Centralized
Portal url encode : Disable
IGMP snooping VLAN : 10
Authorization VLAN : 23
Authentication configuration revert : Disabled
```

Table 3-102 Description of the **display uni-mng global** command output

Item	Description
Forward-mode	SVF forwarding mode: - Distributed: distributed forwarding. In distributed forwarding, local traffic of an AS can be forwarded from the AS, and traffic between ASs is sent to the parent for forwarding. - Centralized: centralized forwarding. In centralized forwarding mode, both traffic forwarded by the local AS and traffic forwarded between ASs are sent to the parent for forwarding.
Portal url encode	Whether URL encoding is enabled: - Disable: URL encoding is disabled. - Enable: URL encoding is enabled. To disable URL encoding, run the **portal url-encode disable** command.

Item	Description
IGMP snooping VLAN	Service VLAN in which IGMP snooping is enabled. To configure a service VLAN in which IGMP snooping is enabled, run the **as service-vlan igmp-snooping** command. If no service VLAN is configured, this field is not displayed.
Authorization VLAN	Create the service VLAN for ASs. To create the service VLAN, run **as service-vlan authorization** command.
Authentication configuration revert	Whether the function retaining the authentication configuration after an AS goes offline is enabled. To disable the function, run the **as authentication configuration revert disable** command.

3.5.49 display uni-mng indirect configuration

Function

The **display uni-mng indirect configuration** command displays the indirect connection configuration on ASs.

NOTE

This command can only be executed on an AS.

Format

display uni-mng indirect configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng indirect configuration** command on an AS to check the indirect connection configuration on the AS.

Example

Display the SVF indirect connection configuration on an AS.

```
<HUAWEI> display uni-mng indirect configuration
Uni-mng configuration information:
 Current uni-mng status      : disable
 Next uni-mng status         : enable
 Current management VLAN     : --
 Next management VLAN        : 100
 Current fabric-port members :
 Next fabric-port members    :
  GigabitEthernet0/0/9
```

Table 3-103 Description of the **display uni-mng indirect configuration** command output

Item	Description
Current uni-mng status	Current manually configured client mode.
Next uni-mng status	Next startup manually configured client mode. To configure the client mode and management VLAN, run the **uni-mng indirect mng-vlan** command.
Current management VLAN	Current management VLAN. To configure the client mode and management VLAN, run the **uni-mng indirect mng-vlan** command.
Next management VLAN	Next startup management VLAN.
Current fabric-port members	Current member port configuration in a fabric port. To configure member ports for a fabric port, run the **uni-mng indirect fabric-port** command.
Next fabric-port members	Next startup member port configuration in a fabric port.

3.5.50 display uni-mng execute-failed-record

Function

The **display uni-mng execute-failed-record** command displays execution failure records after the configuration is delivered to an AS.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng execute-failed-record { **profile** | **as-direct-config** } **as name** *as-name*

Parameters

Parameter	Description	Value
profile	Displays records of configurations delivered through profiles.	-
as-direct-config	Displays records of configurations directly delivered through commands.	-
as name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng execute-failed-record** command to check execution failure records after the configuration is delivered to an AS.

Example

Display execution failure records after the configuration is delivered to an AS.

```
<HUAWEI> display uni-mng execute-failed-record as-direct-config as name as1
Info: This operation may take a few seconds. Please wait....done.
--------------------------------------------------------------------------------
View name     : system
Command       : arp speed-limit source-mac maximum
1
Execute time  : 2015-01-19 15:09:23 DST
Failed reason : This device does not support this
command.
--------------------------------------------------------------------------------
```

Table 3-104 Description of the **display uni-mng execute-failed-record as-direct-config** command output

Item	Description
View name	View in which the configuration is executed.
Command	Command that failed to be executed.
Execute Time	Time the configuration is executed.
Failed reason	Cause of the execution failure.

3.5.51 display uni-mng interface fabric-port configuration

Function

The **display uni-mng interface fabric-port configuration** command displays the fabric port configuration.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng interface fabric-port configuration [**parent** | **as name** *as-name*]

Parameters

Parameter	Description	Value
parent	Display the parent-side fabric port configuration.	-
as name *as-name*	Display the AS-side fabric port configuration. If **parent** and *as-name* are not specified, the configurations of all the fabric ports in an SVF system are displayed.	The value must have an existing AS name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng interface fabric-port configuration** command to check the fabric port configuration.

Example

Display the fabric port configuration.

```
<HUAWEI> display uni-mng interface fabric-port configuration
Interface      Direction  Connect-type  Member-name
Location
-------------------------------------------------------------------------------
Fabric-port0   Down       Direct        Eth-Trunk0   Parent
Fabric-port1   Down       Direct        Eth-Trunk1   Parent
Fabric-port3   Down       Direct        Eth-Trunk3   Parent
Fabric-port5   Down       Direct        Eth-Trunk5   Parent
Fabric-port6   Down       Direct        Eth-Trunk6   Parent
Fabric-port7   Down       Direct        Eth-Trunk7   Parent
Fabric-port8   Down       Direct        Eth-Trunk8   Parent
Fabric-port9   Down       Indirect      Eth-Trunk9   Parent
Fabric-port10  Down       Indirect      Eth-Trunk10  Parent
Fabric-port11  Down       Direct        Eth-Trunk11  Parent
Fabric-port15  Down       Direct        Eth-Trunk15  Parent
-------------------------------------------------------------------------------
Total : 11
```

Table 3-105 Description of the **display uni-mng interface fabric-port configuration** command output

Item	Description
Interface	Fabric port name.
Direction	Direction of a fabric port. Down indicates downlink and Up indicates uplink.
Connect-type	Connection mode of a fabric port. Direct indicates the direct connection mode, whereas Indirect indicates the indirect connection mode (connection through an intermediate network).
Member-name	Eth-Trunk to which a fabric port is bound.
Location	Device where a fabric port resides.

3.5.52 display uni-mng interface fabric-port state

Function

The **display uni-mng interface fabric-port state** command displays the fabric port status.

NOTE

This command can be used on the parent or an AS. After running this command, you can check the fabric port status on the local device.

Format

display uni-mng interface fabric-port [*port-id*] **state**

Parameters

Parameter	Description	Value
port-id	Specifies the number of a fabric port. If this parameter is not specified, the status of all fabric ports is displayed.	The value is an integer and must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng interface fabric-port state** command to check the fabric port status.

- If an AS connects to the parent through an intermediate network, peer fabric port information cannot be obtained and displays --.
- If a fabric port is incorrectly connected, the system displays an error summary message to provide the cause of the error.

Example

Display the fabric port status on the parent.

```
<HUAWEI> display uni-mng interface fabric-port state
--------------------------------------------------------------------------------
Fabric-port name             : Fabric-port1
Fabric-port direction        : Down
Fabric-port member name      : Eth-Trunk1

Peer MAC                     : xxxx-xxxx-xxxx
Peer AS name                 : as1
Peer fabric-port member name : Eth-Trunk0

Physical member number       : 1
Local-port    Peer-port    State     Detail                    Exptime(s)
XGE6/0/3      XGE0/0/1     Connected None                            32
--------------------------------------------------------------------------------
```

Table 3-106 Description of the **display uni-mng interface fabric-port state** command output

Item	Description
Fabric-port name	Fabric port name.
Fabric-port direction	Direction of a fabric port. Down indicates downlink and Up indicates uplink.
Fabric-port member name	Eth-Trunk to which a fabric port is bound.
Peer MAC	MAC address of the peer device.
Peer AS name	Name of the peer device.
Peer fabric-port member name	Eth-Trunk to which the peer fabric port is bound.
Physical member number	Number of member ports in a fabric port.
Local-port	Local member port.
Peer-port	Peer member port.
State	Port connection status: ● Init: initialization state ● Config: negotiation state ● Error: negotiation error state ● Connected: connected state ● unknown: unknown state
Detail	Detailed information when the port connection state is Error. For error reasons and solutions, see **Table 3-107**.
Exptime(s)	Timeout period of link heartbeat packets, in seconds.

Table 3-107 Error reasons indicated by the **Detail** field and solutions

Detail Field	Meaning	Solution
Startup cfg file exists	The AS has a startup configuration file.	Clear the startup configuration file and restart the AS.

Detail Field	Meaning	Solution
Console input exists	Input exists on the console interface of an AS.	Restart the AS and do not log in to the console interface immediately after the AS is restarted.
VLAN for VCMP exists	The VLAN for VCMP exists on the AS.	Run the **reset vcmp** command on the AS to restart the AS.
Port not supported	The AS attempts to connect to the parent through an unsupported port.	Connect the AS to the parent through an uplink port or subcard port.
Fabric-port linked to multi-AS	Member ports of the same downlink fabric port connect to two ASs.	Member ports of a downlink fabric port can connect to only one AS, and different ASs must connect to different fabric ports.
Parent exists already	The AS connects to two parent switches.	Disconnect the AS from one parent switch.
Linked to multi fabric-port	The uplink port of the AS connects to multiple fabric ports of the parent.	Ensure that the AS connects to only one fabric port of the parent and disconnect the AS from other fabric ports.
Level-1 AS linked to level-1 AS	The downlink fabric port of a level-1 AS connects to another level-1 AS.	Disconnect the two level-1 ASs from each other.
Parent linked to level-2 AS	The parent directly connects to a level-2 AS.	Disconnect the parent from the level-2 AS.
Downstream fabric-port linked	A downlink fabric port of an AS connects to the parent.	Disconnect the fabric port of the AS from the parent.
No response received	The parent does not receive any response packet.	● Ensure that the parent is a Huawei switch that supports the SVF function. ● Ensure that the AS starts without configuration. ● Ensure that physical ports that connect the AS to the parent are of the same type.

Detail Field	Meaning	Solution
Failed to create Eth-Trunk	Failed to create an Eth-Trunk on an AS.	Disconnect the AS from the parent and then reconnect them.
Failed to bind trunk	Failed to add ports of an AS to an Eth-Trunk.	Disconnect the AS from the parent and then reconnect them.
Force Uni-mng mode	An AS has been configured to work in client mode.	On the parent, configure the indirect connection mode for the fabric port that connects to the AS. Alternative, run the **undo uni-mng enable** command on the AS and restart the AS to enable it exit from the client mode.
Parent linked to parent	The fabric port of the parent connects to another parent.	Disconnect the fabric port from the remote parent.
System is busy on AS	The system is busy on the AS.	Wait until the AS is idle.
Linked to AS with IPv4-hardware	When an S5700-10P-LI, S5700-10P-PWR-LI-AC, or S2750-EI functions as an AS, Layer 3 hardware forwarding for IPv4 packets has been enabled using the **assign forward-mode ipv4-hardware** command.	Disable Layer 3 hardware forwarding for IPv4 packets.
Configurations exist on port	Configurations exist on the port of an AS.	Delete the configurations of the port.
Invalid stack config exists	Downlink service port of AS is configured as a stack port.	Clear the stack configuration of the downlink service port.

3.5.53 display uni-mng port-group

Function

The **display uni-mng port-group** command displays information about port groups.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng port-group [**name** *group-name* | **verbose**]

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of a port group.	The value must be an existing a port group name.
verbose	Displays detailed information about a port group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng port-group** command to check information about created port groups.

Example

Display brief information about all port groups.

```
<HUAWEI> display uni-mng port-group

------------------------------------------------------------------------------
 Number              Port-group Name                Port-group Type
------------------------------------------------------------------------------
 1                group1                      connect to user
 2                ap_group1                     connect to AP
------------------------------------------------------------------------------
```

Table 3-108 Description of the **display uni-mng port-group** command output

Item	Description
Number	Sequence number.
Port-group Name	Port group name.

Item	Description
Port-group Type	Port group type: ● connect to user: port connected to a terminal user ● connect to AP: port connected to an AP

Display detailed information about all port groups.

```
<HUAWEI> display uni-mng port-group verbose

-------------------------------------------------------------------------------
Port-group name                  : ap
Port-group type                  : connect to AP

User-access profile              : --
-------------------------------------------------------------------------------
```

Table 3-109 Description of the **display uni-mng port-group verbose** command output

Item	Description
Port-group name	Port group name.
Port-group type	Port group type: ● connect to user: port connected to a terminal user ● connect to AP: port connected to an AP
Interface list	List of member ports added to a port group.
Network-basic profile	Name of the network basic profile bound to the port group. When no network basic profile is bound to the port group, this field displays --.

Item	Description
Network-enhanced profile	Name of the network enhanced profile bound to the port group. When no network enhanced profile is bound to the port group, this field displays --.
Network-qos profile	Name of the network QoS profile bound to the port group. When no network QoS profile is bound to the port group, this field displays --.
Traffic-policy profile	Name of the traffic policy profile bound to the port group. When no traffic policy profile is bound to the port group, this field displays --.
User-access profile	Name of the user access profile bound to the port group. When no user access profile is bound to the port group, this field displays --.

3.5.54 display uni-mng profile

Function

The **display uni-mng profile** command displays service profile information.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng profile [{ **as-admin** | **network-basic** | **network-enhanced** | **user-access** | **network-qos** | **traffic-policy** } [**name** *profile-name*]]

Parameters

Parameter	Description	Value
as-admin	Displays information about AS administrator profiles.	-
network-basic	Displays information about network basic profiles.	-
network-enhanced	Displays information about network enhanced profiles.	-

Parameter	Description	Value
user-access	Displays information about user access profiles.	-
network-qos	Displays information about network qos profiles.	-
traffic-policy	Displays information about traffic policy profiles.	-
name *profile-name*	Specifies the name of a service profile. If this parameter is specified, you can check information about services configured in a specified profile.	The profile must have an existing profile name.

------------------------------------------------------------------------------
```

Table 3-111 Description of the **display uni-mng profile network-basic name** command output

Item	Description
Profile name	Name of a service profile.
User-vlan	Default VLAN configured in a service profile. To configure a default VLAN, run the **user-vlan** command. By default, VLAN 1 is a default VLAN.
Voice-vlan	Voice VLAN configured in a service profile. To configure a voice VLAN, run the **voice-vlan** command. If no voice VLAN is configured, this field displays --.
Pass-vlan	Allowed VLAN configured in a service profile. To configure an allowed VLAN, run the **pass-vlan** command. By default, only VLAN 1 is allowed.

3.5.55 display uni-mng profile as

Function

The **display uni-mng profile as** command displays the configuration generated after an AS is bound to service profiles.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng profile as name *as-name* [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.
interface *interface-type interface-number*	Displays the configuration of a specified interface: ● *interface-type* specifies the interface type. The interface type can be a physical interface, an Eth-Trunk, or a fabric port. ● *interface-number* specifies the interface number. If this parameter is not specified, the configurations of all the service interfaces on an AS are displayed.	-

Views

Table 3-112 Description of the **display uni-mng profile as** command output

Item	Description
Global	Global AS configuration.
Centralized forward mode	Whether centralized forwarding is enabled: ● disable: Centralized forwarding is disabled, and distributed forwarding is used currently. ● enable: Centralized forwarding is enabled. To configure centralized forwarding, run the **forward-mode centralized** command. By default, distributed forwarding is used.

Item	Description
Portal url-encode	Whether URL encoding is enabled for an AS: ● disable: URL encoding is disabled for the AS. ● enable: URL encoding is enabled for the AS. To disable URL encoding for an AS, run the **portal url-encode disable** command. By default, URL encoding is enabled for an AS.
Igmp-vlan	VLAN in which IGMP Snooping is enabled. If no VLAN is configured, this field displays --. To configure the VLAN, run the **as service-vlan igmp-snooping** command.
Authorization-vlan	Service VLAN created on an AS. If no VLAN is configured, this field displays --. To configure the service VLAN, run the **as service-vlan authorization** command.
AS-group name	Name of the AS group to which an AS belongs.
Username	AS administrator user name. If no AS administrator user name is configured, this field displays --. AS administrator user name configured in the AS administrator profile bound to an AS group. To configure an AS administrator user name, run the **user password** command.
Privilege-level	User level. The value is 3 and cannot be changed.
Service-type	User access type. The value is terminal ssh and cannot be changed.
Bpdu-protection	BPDU protection status of an AS. If BPDU protection is not configured, this field displays --.
Ipv6	Whether IPv6 is enabled on an AS.
Acl number	ACL number created on an AS.

Item	Description
Traffic-limit outbound ARP(Kbps)	Outbound ARP packet rate limit of the uplink fabric port of an AS, in kbit/s. To set the outbound ARP packet rate limit, run the **traffic-limit outbound** command.
Traffic-limit outbound DHCP(Kbps)	Outbound DHCP packet rate limit of the uplink fabric port of an AS, in kbit/s. To set the outbound ARP packet rate limit, run the **traffic-limit outbound** command.
Interface GigabitEthernet0/0/1 Interface GigabitEthernet0/0/2 Interface fabric-port 0	Interface name.
Port-group name	Name of the port group to which an interface belongs. If an interface is not added to any port group, this field displays -- or disable.
User-vlan	Default VLAN. To configure a default VLAN, run the **user-vlan** command.
Voice-vlan	Voice VLAN. To configure a voice VLAN, run the **voice-vlan** command.
Pass-vlan	Allowed VLAN. To configure an allowed VLAN, run the **pass-vlan** command.
Priority-trust	Whether the priority trust function is enabled: ● disable: The priority trust function is disabled in a network enhanced profile. ● enable: The priority trust function is enabled in a network enhanced profile.

Item	Description
User-access-port	Whether the edge port function is enabled: ● disable: The edge port function is disabled in a network enhanced profile. ● enable: The edge port function is enabled in a network enhanced profile. To enable the edge port function, run the **user-access-port enable** command.
DHCP snooping	Whether DHCP snooping is enabled: ● disable: DHCP snooping is disabled in a network enhanced profile. ● enable: DHCP snooping is enabled in a network enhanced profile. To enable DHCP snooping, run the **dhcp snooping enable** command.
IP source check	Whether the IP packet check function is enabled: ● disable: IP packet check is disabled in a network enhanced profile. ● enable: IP packet check is enabled in a network enhanced profile. To enable IP packet check, run the **ip source check user-bind enable** command.
ARP anti-attack check	Whether the dynamic ARP inspection function is enabled: ● disable: The dynamic ARP inspection function is disabled in a network enhanced profile. ● enable: The dynamic ARP inspection function is enabled in a network enhanced profile. To enable the dynamic ARP inspection function, run the **arp anti-attack check user-bind enable** command.
Unicast-suppression(pps)	Rate limit for unknown unicast traffic, in pps. To set the rate limit for unknown unicast traffic, run the **unicast-suppression** command.

Item	Description
Multicast-suppression(pps)	Rate limit for multicast traffic, in pps. To set the rate limit for multicast traffic, run the **multicast-suppression** command.
Broadcast-suppression(pps)	Rate limit for broadcast traffic, in pps. To set the rate limit for broadcast traffic, run the **broadcast-suppression** command.
Rate-limit(Kbps)	Traffic rate limit, in kbit/s. To set the traffic rate limit, run the **rate-limit** command.
Port-security	Whether port security is enabled. To enable the port security function, run the **port-security enable** command.
Mac-address sticky	Whether the sticky MAC function is enabled on an interface. To enable the sticky MAC function on an interface, run the **port-security mac-address sticky** command.
Port-security aging-time	Aging time of secure dynamic MAC addresses on an interface. To set this parameter, run the **port-security aging-time** command.
Trust Flag	Packet priority mapping flag. To configure priority mapping, run the **trust dscp** command.
Scheduling Profile	Name of a network QoS profile.
Scheduling Mode	Queue scheduling mode. To configure the queue scheduling mode, run the **qos { pq | wrr | drr }** command.

Item	Description
Weight of Queue 0 Weight of Queue 1 Weight of Queue 2 Weight of Queue 3 Weight of Queue 4 Weight of Queue 5 Weight of Queue 6 Weight of Queue 7	Queue scheduling weight. To configure the queue scheduling weight, run the **qos queue** command.
Authentication	User authentication profile created using the **authentication-profile** command.
Authentication maximum user-num	Maximum number of access users configured in a user access profile. To set this parameter, run the **authentication access-user maximum** command.
MAC-limit	MAC address learning limit. To set the MAC address learning limit, run the **mac-limit** command.
Traffic-limit inbound ARP(Kbps)	Inbound ARP packet rate limit of an AS port, in kbit/s. To set the inbound ARP packet rate limit, run the **traffic-limit inbound** command.
Traffic-limit inbound DHCP(Kbps)	Inbound DHCP packet rate limit of an AS port, in kbit/s. To set the inbound ARP packet rate limit, run the **traffic-limit inbound** command.
Traffic policy profile	Name of the traffic policy profile bound to an AS.

3.5.56 display uni-mng topology configuration

Function

The **display uni-mng topology configuration** command displays the SVF network topology collection configuration.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng topology configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng topology configuration** command to check the SVF network topology collection configuration.

Example

Display the SVF network topology collection configuration.

```
<HUAWEI> display uni-mng topology configuration
Explore timer: 10 minutes
Last collection time: 10:03:58 UTC+00:00 2014/09/11
Total time for last collection: 9 ms
```

Table 3-113 Description of the **display uni-mng topology configuration** command output

Item	Description
Explore timer	Network topology collection interval. To set the network topology collection interval, run the **topology explore** command.
Last collection time	Last time the SVF network topology is collected.
Total time for last collection	Time taken to collect the SVF network topology.

3.5.57 display uni-mng topology information

Function

The **display uni-mng topology information** command displays SVF network topology information.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng topology information [**by-name**]

Parameters

Parameter	Description	Value
by-name	Displays SVF network topology information based on the device name. If this parameter is not specified, SVF network topology information is displayed based on the MAC address.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng topology information** command to check SVF network topology information.

Example

Display SVF network topology information.

```
<HUAWEI> display uni-mng topology information
The topology information of uni-mng network:
<-->: direct link        <??>: indirect link
T: Trunk ID                *: independent AS
------------------------------------------------------------------------------
 Local MAC       Hop  Local Port      T  ||  T   Peer Port      Peer MAC
------------------------------------------------------------------------------
 00e0-fc12-7890  0    GE6/1/0         11 <-->0   GE0/0/26       00e0-fc12-0008 *
 00e0-fc12-0008  1    GE0/0/2         -- <-->--  GE0/0/0        00e0-fc12-0005
------------------------------------------------------------------------------
Total items displayed : 2
```

Display SVF network topology information based on the device name.

```
<HUAWEI> display uni-mng topology information by-name
The topology information of uni-mng network:
<-->: direct link        <??>: indirect link
T: Trunk ID              *: independent AS
--------------------------------------------------------------------------------------------------------------
 Local Dev                        Hop  Local Port      T  ||  T   Peer Port      Peer Dev
--------------------------------------------------------------------------------------------------------------
 100-S1                           0    GE6/1/0         1  <-->0   GE0/0/26       as1 *
```

```
 as1                          1    GE0/0/2         -- <-->--  GE0/0/0       ap-1
------------------------------------------------------------------------------------------------------------------
Total items displayed : 2
```

Table 3-114 Description of the **display uni-mng topology information** command output

Item	Description
Local MAC	MAC address of the local device. If **by-name** is specified, this field displays **Local Dev**, indicating the device name.
Hop	Hierarchy of a device on the SVF network: ● 0: the parent ● 1: level-1 AS ● 2: level-2 AS
Local Port	Local physical port. When two devices are indirectly connected, port information cannot be displayed because ports are not indirectly connected.
T	ID of the Eth-Trunk to which a physical port belongs.
||	Whether two devices are directly connected: ● <-->: indicates that two devices are directly connected. ● <??>: indicates that two devices are indirectly connected. For example, two devices are connected through other networks.
Peer Port	Peer physical port. When two devices are indirectly connected, port information cannot be displayed because ports are not indirectly connected.
Peer MAC	MAC address of the peer device. If **by-name** is specified, this field displays **Peer Dev**, indicating the device name. If * is displayed, the AS is configured in the independent mode.
Local Dev	Local device name.

Item	Description
Peer Dev	Peer device name. If * is displayed, the AS is configured in the independent mode.

3.5.58 display uni-mng unauthen-user

Function

The **display uni-mng unauthen-user** command displays information about non-authenticated users on an AS.

NOTE

This command can be used on the parent or an AS.

Format

display uni-mng unauthen-user [**as name** *as-name* | **mac-address** *mac-address*]

Parameters

Parameter	Description	Value
as name *as-name*	Specifies the name of an AS. **NOTE** This parameter is supported only on the parent.	The value is a string of 1 to 31 case-insensitive characters without spaces.
mac-address *mac-address*	Specifies the MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view information about non-authenticated users on an AS, run the **display uni-mng unauthen-user** command.

Example

Display information about non-authenticated users on the AS **test1**.

```
<HUAWEI> display uni-mng unauthen-user as name test1
Total: 5
-------------------------------------------------------------------------------
MAC Address      VLAN  IP            Interface    AS Name
-------------------------------------------------------------------------------
xxxx-xxxx-xxx2   212   1.1.1.1       Ge1/0/1      test1
xxxx-xxxx-xxx3   212   1.1.1.2       Ge1/0/1      test1
xxxx-xxxx-xxx4   212   1.1.1.3       Ge1/0/1      test1
xxxx-xxxx-xxx5   212   1.1.1.4       Ge1/0/1      test1
xxxx-xxxx-xxx6   212   1.1.1.5       Ge1/0/1      test1
-------------------------------------------------------------------------------
```

Table 3-115 Description of the **display uni-mng unauthen-user** command output

Item	Description
Total	Number of non-authenticated users on an AS.
MAC Address	MAC address of a non-authenticated user.
VLAN	VLAN to which a non-authenticated user belongs.
IP	IP address of a non-authenticated user. **NOTE** When this command is run on the AS, this field is displayed as --.
Interface	Access interface of a non-authenticated user.
AS Name	Name of an AS.

3.5.59 display uni-mng unauthen-user offline-record

Function

The **display uni-mng unauthen-user offline-record** command displays offline records of non-authenticated users on an AS.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng unauthen-user offline-record [**as name** *as-name* | **mac-address** *mac-address*]

Parameters

Parameter	Description	Value
as name *as-name*	Specifies the name of an AS.	The value is a string of 1 to 31 case-insensitive characters without spaces.
mac-address *mac-address*	Specifies the MAC address of an AS.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view offline records of non-authenticated users on an AS, run the **display uni-mng unauthen-user offline-record** command.

Example

Display offline records of non-authenticated users on the AS **test1**.

```
<HUAWEI> display uni-mng unauthen-user offline-record as name test1
Total: 2
-------------------------------------------------------------------------------
 AS name               : test1
 User MAC              : 00e0-fc46-b67c
 User VLAN             : 212
 User access interface : Ge1/0/2
 User IP address       : 192.168.1.1
 User offline time     : 2016/01/21 04:59:43
 User offline reason   : As offline
-------------------------------------------------------------------------------
 AS name               : test1
 User MAC              : 00e0-fc46-b67d
 User VLAN             : 212
 User access interface : Ge1/0/3
 User IP address       : 192.168.1.2
 User offline time     : 2016/01/21 05:59:43
 User offline reason   : User offline
-------------------------------------------------------------------------------
```

Table 3-116 Description of the **display uni-mng unauthen-user offline-record** command output

Item	Description
Total	Number of offline records of non-authenticated users on an AS.
AS name	Name of an AS.
User MAC	MAC address of a non-authenticated user.
User VLAN	VLAN to which a non-authenticated user belongs.
User access interface	Access interface of a non-authenticated user.
User IP address	IP address of a non-authenticated user.
User offline time	Time when a non-authenticated user goes offline.
User offline reason	Reason that a non-authenticated user goes offline. ● User offline: The user goes offline. ● AS offline: The AS is offline.

3.5.60 display uni-mng upgrade-info

Function

The **display uni-mng upgrade-info** command displays AS version upgrade information.

NOTE

This command can only be executed on a parent switch.

Format

display uni-mng upgrade-info [**as name** *as-name* | **verbose**]

Parameters

Parameter	Description	Value
as name *as-name*	Specifies the name of an AS.	The value must have an existing AS name.

Parameter	Description	Value
verbose	Displays detailed version upgrade information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng upgrade-info** command to check AS version upgrade information.

Example

Display AS version upgrade information.

```
<HUAWEI> display uni-mng upgrade-info
The total number of AS is : 1
-------------------------------------------------------------------------------
 Name                          Method      Phase      Status      Result
-------------------------------------------------------------------------------
 as1                         --          --         NO-UPGRADE  --
-------------------------------------------------------------------------------
```

Table 3-117 Description of the **display uni-mng upgrade-info** command output

Item	Description
Name	Name of an AS.
Method	AS upgrade mode: ● --: The upgrade task is not started. ● ver-sync: The AS is automatically upgraded when going online. ● upgrade: The AS is manually upgraded after going online.

Item	Description
Phase	Upgrade phase: - --: The upgrade task is not started. - sys-file: The system is determining whether to download the system software or is downloading the system software from the parent. - patch-file: The system is determining whether to download the patch file or is downloading the patch file from the parent. - waiting: The AS is waiting for activation. - activating: The AS is being activated. - rebooting: The AS is restarting.
Status	Whether the AS is being upgraded: - NO-UPGRADE: The AS is not upgraded. - UPGRADING: The AS is being upgraded.
Result	Upgrade result: - --: The upgrade task is not started. - successful: The upgrade is successful. - failed: The upgrade fails.

Display detailed AS version upgrade information.

```
<HUAWEI> display uni-mng upgrade-info verbose
The total number of AS is : 1

-------------------------------------------------------------------------------
```

Table 3-118 Description of the **display uni-mng upgrade-info verbose** command output

Item	Description
AS name	Name of an AS.
Work status	Whether the AS is being upgraded: ● NO-UPGRADE: The AS is not upgraded. ● UPGRADING: The AS is being upgraded.
Startup system-software	Running system software.
Startup version	Current software version.
Startup patch	Running patch file. If this field displays --, no patch file is running.
Next startup system-software	System software that is configured for the next startup. If this field displays --, no system software is configured for the next startup.
Next startup patch	Patch package file that is configured for the next startup. If this field displays --, no patch package file is configured for the next startup.
Download system-software	Downloaded system software. If this field displays --, the upgrade task is not started.
Download version	Downloaded system software version. If this field displays --, the upgrade task is not started.

Item	Description
Download patch	Downloaded patch file. If this field displays --, the upgrade task is not started.
Activating file time	Activation time after the AS system software is downloaded. ● at **xxx**: The downloaded AS system software is activated at the specified time. ● delay **xxx**: The downloaded AS system software is activated after the specified delay time. ● immediately: The AS system software is activated immediately after being downloaded.
Activating file method	Mode in which the AS system software is activated: ● reload: The AS system software is activated by restarting the AS. ● default: The AS system software is activated without restarting the AS.
Method	AS upgrade mode: ● --: The upgrade task is not started. ● ver-sync: The AS is automatically upgraded when going online. ● upgrade: The AS is manually upgraded after going online.
Upgrading phase	Upgrade phase: ● --: The upgrade task is not started. ● sys-file: The system is determining whether to download the system software or is downloading the system software from the parent. ● patch-file: The system is determining whether to download the patch file or is downloading the patch file from the parent. ● waiting: The AS is waiting for activation. ● activating: The AS is being activated. ● rebooting: The AS is restarting.

Item	Description
Last operation result	Upgrade result: - --: The upgrade task is not started. - successful: The upgrade is successful. - failed: The upgrade fails.
Error reason	Upgrade failure reason.
Last operation time	Last time the AS is upgraded.

3.5.61 display uni-mng up-direction fabric-port

Function

The **display uni-mng up-direction fabric-port** command displays information about AS service ports added to an uplink fabric port.

NOTE

This command can only be executed on an AS.

Format

display uni-mng up-direction fabric-port

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display uni-mng up-direction fabric-port** command to check the current and next startup configurations of AS service ports added to an uplink fabric port.

Example

Display information about AS service ports added to an uplink fabric port.

```
<HUAWEI> display uni-mng up-direction fabric-port
Uni-mng up-direction fabric-port configuration:
```

```
Current fabric-port members :
GigabitEthernet0/0/1
GigabitEthernet0/0/2
GigabitEthernet0/0/3
GigabitEthernet0/0/4
Next fabric-port members    :
GigabitEthernet0/0/1
GigabitEthernet0/0/2
GigabitEthernet0/0/3
GigabitEthernet0/0/4
```

Table 3-119 Description of the **display uni-mng up-direction fabric-port** command output

Item	Description
Uni-mng up-direction fabric-port configuration	Configuration of an uplink fabric port.
Current fabric-port members	Effective member interfaces of the uplink fabric port.
Next fabric-port members	Effective member interfaces of the uplink fabric port after the device's next startup.

3.5.62 down-direction fabric-port

Function

The **down-direction fabric-port** command configures the fabric port that connects a level-1 AS to a level-2 AS.

The **undo down-direction fabric-port** command deletes the fabric port that connects a level-1 AS to a level-2 AS.

By default, no fabric port that connects a level-1 AS to a level-2 AS is configured.

NOTE

This command can only be executed on a parent switch.

Format

down-direction fabric-port *port-id* **member-group interface eth-trunk** *trunk-id*

undo down-direction fabric-port *port-id* **member-group**

Parameters

Parameter	Description	Value
port-id	Specifies the number of a fabric port.	The value is an integer and must be set according to the device configuration.
member-group interface	Specifies the Eth-Trunk to which a fabric port is bound.	-
eth-trunk *trunk-id*	Specifies the ID of an Eth-Trunk.	The value is an integer that ranges from 1 to 63. **NOTE** If an Eth-Trunk has been created and configured on an AS in independent mode, the **eth-trunk** *trunk-id* parameter cannot be the same as the existing Eth-Trunk ID of this AS. Otherwise, this command cannot be delivered.

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a level-1 AS needs to connect to a level-2 AS, you need to configure a fabric port on the level-1 AS to connect to the level-2 AS. A downlink port of a level-1 AS becomes Up only after the parent finishes delivering the configuration. A level-2 AS begins to go online only after the downlink port of the level-1 AS becomes Up.

Follow-up Procedure

Run the **port eth-trunk** *trunk-id* **trunkmember interface** *interface-type interface-number1* [**to** *interface-number2*] command to add member ports to the bound Eth-Trunk.

Example

Configure the fabric port that connects a level-1 AS to a level-2 AS.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] down-direction fabric-port 1 member-group interface eth-trunk 1
```

3.5.63 down-direction fabric-port connect independent-as

Function

The **down-direction fabric-port connect independent-as** command enables the independent mode on the fabric port that connects a level-1 AS to a level-2 AS.

The **undo down-direction fabric-port** command restores the default mode of the fabric port that connects a level-1 AS to a level-2 AS.

By default, the service configuration mode of the fabric port that connects a level-1 AS to a level-2 AS is centralized mode.

NOTE

This command can only be executed on a parent switch.

Format

down-direction fabric-port *port-id* **connect independent-as**

undo down-direction fabric-port *port-id* **connect**

Parameters

Parameter	Description	Value
port-id	Specifies the number of a fabric port.	The value is an integer and must be set according to the device configuration.

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In independent mode, you can log in to an AS to configure this AS using commands. After the independent mode is enabled on the fabric port that connects a level-1 AS to a level-2 AS, the level-2 AS can be configured independently.

Prerequisites

The fabric port used to connect a level-1 AS to a level-2 AS has been created using the **down-direction fabric-port** *port-id* **member-group interface eth-trunk** *trunk-id* command in the AS view.

Precautions

Before enabling the independent mode, run the **independent-as-admin** command in the uni-mng view to configure an administrator for AS login. If no administrator is created, you can only log in to an AS through a console port.

If service configurations have been delivered in centralized mode to a level-1 AS port before this port is changed to the independent mode, this port cannot be configured as a fabric port that connects to a level-2 AS. To do so, restore the level-1 AS to the centralized mode and cancel the service configurations of this port on the parent.

In independent mode, when an AS goes offline, traffic on the network attached to an AS port cannot be forwarded if the port has authentication configurations. To enable the traffic to be forwarded normally, manually delete the authentication configurations from the port.

Example

Enable the independent mode on the fabric port that connects a level-1 AS to a level-2 AS.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] down-direction fabric-port 1 member-group interface eth-trunk 1
[HUAWEI-um-as-as1] down-direction fabric-port 1 connect independent-as
```

3.5.64 forward-mode centralized

Function

The **forward-mode centralized** command sets the forwarding mode of an SVF system to centralized forwarding.

The **undo forward-mode** command restores the default forwarding mode of an SVF system.

By default, the forwarding mode of an SVF system is distributed forwarding.

NOTE

This command can only be executed on a parent switch.

Format

forward-mode centralized

undo forward-mode

Parameters

None

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An SVF system uses the distributed forwarding mode by default. You can change the forwarding mode to centralized mode.

- In centralized forwarding mode, traffic forwarded by the local AS and forwarded between ASs is sent to the parent for forwarding.
- In distributed forwarding mode, an AS directly forwards local traffic and the parent forwards traffic between ASs.

Precautions

- After changing the SVF forwarding mode, you must run the **commit as** { **name** *as-name* | **all** } command to commit the configuration so that the device can deliver it to ASs.
- In centralized forwarding mode, ports of the ASs connected to the same fabric port of the parent are isolated and so cannot communicate at Layer 2, and need to have proxy ARP in the corresponding VLAN configured using the **arp-proxy inner-sub-vlan-proxy enable** command to communicate at Layer 3.
- In centralized forwarding mode, after an AS goes offline, traffic of its attached network cannot be forwarded by the parent and will be interrupted.
- In distributed forwarding mode, after an AS goes offline, in versions earlier than V200R012C00, downlink ports of the AS are automatically error down. As a result, traffic of the AS attached network will be interrupted. In V200R012C00 and later versions, downlink ports of the AS will not be error down, and traffic of the AS attached network will be forwarded as usual.

Example

Set the SVF forwarding mode to centralized forwarding.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] forward-mode centralized
```

3.5.65 independent-as-admin

Function

The **independent-as-admin** command creates an administrator for AS login in independent mode.

The **undo independent-as-admin** command deletes the administrator for AS login in independent mode.

By default, no administrator is created for AS login in independent mode.

NOTE

This command can only be executed on a parent switch.

Format

independent-as-admin user *user-name* **password** *password*

undo independent-as-admin user

Parameters

Parameter	Description	Value

user *user-name*	Specifies a user name.	The value is a string of 1 to 64 characters. It cannot contain spaces, asterisk, double quotation mark and question mark.
		NOTE
		● During local authentication or authorization, run the **authentication-mode** { **local** | **local-case** } or **authorization-mode** { **local** | **local-case** } command to configure case sensitivity for user names. If the parameter is set to **local**, user names are case-insensitive. If the parameter is set to **local-case**, user names are case-sensitive.
		● Note the following when configuring case sensitivity for user names:
		  ● Only the user name is case-sensitive and the domain name is case-insensitive.
		  ● For user security purposes, you cannot configure multiple local users with the user names that differ only in uppercase or lowercase. For example, after configuring ABC, you cannot configure Abc or abc as the user name.
		  ● When a device is upgraded from V200R011C10 or an earlier version to a version later than V200R011C10, all local user names in the original configuration file are saved in lowercase. When a configuration file that is manually configured or generated using the third-party tool is used for configuration restoration, local user names that differ only in uppercase or lowercase are considered as one user name and the first one among these local user names is used.

Parameter	Description	Value
password *password*	Specifies the password.	The value is a string of case-sensitive characters without spaces. A password in plain text is a string of 8 to 128 characters. A password in cipher text is a string of 48 to 188 characters and cannot be generated using the irreversible algorithm. The password is displayed in cipher text in the configuration file regardless of whether the password is input in plain or cipher text. Do not set this password to the weak password preset by running the **load security weak-password-dictionary** command.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the AS service configuration mode is set to independent mode, you need to use this command to configure the administrator account used to log in to ASs. After the configuration is complete, the user name and password used for login are automatically configured on the AS. The following configuration is generated on the AS:

```
#
aaa
 local-user user-name password irreversible-cipher password
 local-user user-name privilege level 3
 local-user user-name service-type terminal ssh
#
```

After an AS user name and password are configured, you need to enter the correct user name and password when logging in to an AS through the console port. When you log in to an AS from the parent using the **attach as name** *as-name* command, you can log in to the AS without entering the user name or password.

Precautions

The user name and password configured using this command take effect after the configuration is generated on ASs. It takes about 5 minutes for the configuration to take effect after you run the command. Do not log in to an AS within this period; otherwise, the configuration may take effect after a longer period of time.

Example

Create an AS administrator user name and password in independent mode.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] independent-as-admin user test password YsHsjx_202206
```

3.5.66 interface fabric-port

Function

The **interface fabric-port** command creates a fabric port and displays the fabric port view.

The **undo interface fabric-port** command deletes a fabric port.

By default, no fabric port exists in the system.

NOTE

This command can only be executed on a parent switch.

Format

interface fabric-port *port-id*

undo interface fabric-port *port-id*

Parameters

Parameter	Description	Value
port-id	Specifies the number of a fabric port.	The value range on the parent varies depending on the switch model: • S12700/S12700E: 0 to 255 • MCUD/SRUK/MFUX/MPUE/SRUE/SRUHA1/SRUHX1/SRUH: 0 to 255 • Other switch models: 0 to 63

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

To set up an SVF system, create fabric ports on the parent switches to allow ASs to connect to the parent switches.

Example

Create a fabric port and enter the fabric port view.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] interface fabric-port 1
```

3.5.67 ip source check user-bind enable (network enhanced profile view)

Function

The **ip source check user-bind enable** command configures IP packet checking in a network enhanced profile.

The **undo ip source check user-bind enable** command cancels IP packet checking in a network enhanced profile.

By default, IP packet checking is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

ip source check user-bind enable

undo ip source check user-bind enable

Parameters

None

Views

Network enhanced profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a network enhanced profile, you can configure IP packet checking in the profile. After the profile is bound to the port of an AS, IP packet checking is automatically enabled on the port. The following configuration is generated on the AS port:

```
#
 ip source check user-bind enable
 ip source check user-bind alarm enable
#
```

When attackers steal authorized users' IP addresses or MAC addresses to send packets to access or attack networks, authorized users cannot obtain stable and secure network services. After configuring IP packet checking on a device, the device checks received IP packets against the binding table to prevent such attacks.

Prerequisites

DHCP snooping has been enabled in the network enhanced profile using the **dhcp snooping enable** command.

Precautions

When an AS is an S2750-EI, S5700-10P-LI, or S5700-10P-PWR-LI and works in Layer 3 hardware forwarding mode, the **ip source check user-bind enable** command does not take effect on the AS. Because an AS performs only Layer 2 forwarding in an SVF system, you are advised to run the **undo assign forward-mode** command to cancel the Layer 3 hardware forwarding mode and then connect the AS to the SVF system.

Example

Configure IP packet checking in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] dhcp snooping enable
[HUAWEI-um-net-enhanced-profile_1] ip source check user-bind enable
```

3.5.68 ipv6 (AS administrator profile view)

Function

The **ipv6** command enables IPv6 in an AS administrator profile.

The **undo ipv6** command disables IPv6 in an AS administrator profile.

By default, IPv6 is disabled in an AS administrator profile.

NOTE

This command can only be executed on a parent switch.

Format

ipv6

undo ipv6

Parameters

None

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

After creating an AS administrator profile, you can run the **ipv6** command to enable IPv6 for ASs in the profile. After an AS administrator profile is bound to an AS, the following configurations are generated globally on the AS:

```
#
ipv6
#
```

Example

Enable IPv6 in the AS administrator profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] ipv6
```

3.5.69 mac-address flapping action (network enhanced profile view)

Function

The **mac-address flapping action** command configures the action taken on an interface in case of MAC address flapping in a network enhanced profile.

The **undo mac-address flapping action** command deletes the action taken on an interface in case of MAC address flapping in a network enhanced profile.

By default, in a network enhanced profile, the system does not perform any action when detecting MAC address flapping on an interface.

NOTE

This command can only be executed on a parent switch.

Format

mac-address flapping action error-down

undo mac-address flapping action error-down

Parameters

Parameter	Description	Value
error-down	Configures the system to set an interface to the Error-Down state when detecting MAC address flapping on this interface.	-

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure the action taken on an interface when MAC address flapping occurs on the interface in the profile. After the profile is bound to an AS port, the configuration is automatically delivered to the AS port. The following configuration is generated on the AS:

```
#
interface GigabitEthernet0/0/1
 mac-address flapping action error-down
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration is determined by the profile configuration.

Example

Configure the system to set an interface to the Error-Down state when detecting MAC address flapping on this interface.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] mac-address flapping action error-down
```

3.5.70 mac-address trap notification (network enhanced profile view)

Function

The **mac-address trap notification** command configures the alarm function for MAC address learning and aging in a network enhanced profile.

The **undo mac-address trap notification** command deletes the alarm function of MAC address learning and aging in a network enhanced profile.

By default, the alarm function for MAC address learning and aging is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

mac-address trap notification all

undo mac-address trap notification

Parameters

Parameter	Description	Value
all	Indicates the alarm function for MAC address learning and aging.	-

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure the alarm function for MAC address learning and aging in the profile. After the profile is bound to an AS port, the configuration is automatically delivered to the AS port. The following configuration is generated on the AS:

```
#
interface GigabitEthernet0/0/1
 mac-address trap notification all
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration is determined by the profile configuration.

Example

Configure the alarm function for MAC address learning and aging.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] mac-address trap notification all
```

3.5.71 mac-limit (user access profile view)

Function

The **mac-limit** command configures MAC address learning limiting in a user access profile.

The **undo mac-limit** command cancels MAC address learning limiting in a user access profile.

By default, MAC address learning limiting is not configured in a user access profile.

NOTE

This command can only be executed on a parent switch.

Format

mac-limit maximum *max-num*

undo mac-limit

Parameters

Parameter	Description	Value
maximum *max-num*	Specifies the maximum number of MAC addresses that can be learned on an interface.	The value is an integer that ranges from 0 to 4096. The value 0 indicates that the maximum number of MAC addresses that can be learned is not limited.

Views

User access profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a user access profile, you can configure MAC address learning limiting in the profile. When the profile is bound an AS port, MAC address learning limiting is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 mac-limit maximum max-num
#
```

To control the number of access users and protect the MAC address table against attacks, you can limit the maximum number of MAC addresses that can be learned on an interface.

Precautions

The **mac-limit** and **authentication** commands are mutually exclusive and cannot be configured together in a user access profile.

Example

Configure MAC address learning limiting in a user access profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
[HUAWEI-um-user-access-profile_1] mac-limit maximum 1024
```

3.5.72 multicast-suppression (network enhanced profile view)

Function

The **multicast-suppression** command configures unknown multicast traffic suppression in a network enhanced profile.

The **undo multicast-suppression** command cancels unknown multicast traffic suppression in a network enhanced profile.

By default, unknown multicast traffic suppression is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

multicast-suppression packets *packets-per-second*

undo multicast-suppression

Parameters

Parameter	Description	Value
packets *packets-per-second*	Specifies the packet rate of an interface.	The value is an integer that ranges from 0 to 14881000, in packets per second (PPS). If the configured packet rate on the parent switch is larger than the maximum value on the AS port, the maximum value takes effect on the AS port.

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure unknown multicast traffic suppression in the profile. After the profile is bound to an AS port, unknown multicast traffic suppression is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 multicast-suppression packets packets-per-second
#
```

To prevent broadcast storms, you can run the **multicast-suppression** command to configure the maximum number of unknown multicast packets that can pass through a port. When the unknown multicast traffic rate reaches the maximum value, the system discards excess unknown multicast packets to control the traffic volume within a proper range.

Example

Configure unknown multicast traffic suppression in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] multicast-suppression packets 148810
```

3.5.73 network-basic-profile name

Function

The **network-basic-profile name** command creates a network basic profile.

The **undo network-basic-profile name** command deletes a network basic profile.

By default, no network basic profile is created.

NOTE

This command can only be executed on a parent switch.

Format

network-basic-profile name *profile-name*

undo network-basic-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network basic profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can configure basic user services in a network basic profile, including the default VLAN, allowed VLAN, and voice VLAN of a port.

Precautions

You can create a maximum of 256 network basic profiles in a version earlier than V200R011C10.

You can create a maximum of 512 network basic profiles in V200R011C10 and later versions.

Example

Create a network basic profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-basic-profile name profile_1
```

3.5.74 network-basic-profile (port group view)

Function

The **network-basic-profile** command binds a network basic profile to a port group.

The **undo network-basic-profile** command unbinds a network basic profile from a port group.

By default, no network basic profile is bound to a port group.

NOTE

This command can only be executed on a parent switch.

Format

network-basic-profile *profile-name*

undo network-basic-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network basic profile.	The value must have an existing network basic profile name.

Views

Port group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can bind a network basic profile to a port group to deliver the configurations in the profile to all the member ports in the port group.

Prerequisites

The network basic profile has been created.

Precautions

A port group can be bound to only one network basic profile.

Example

Bind a network basic profile to a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-basic-profile name profile_1
[HUAWEI-um-net-basic-profile_1] quit
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] network-basic-profile profile_1
```

3.5.75 network-enhanced-profile name

Function

The **network-enhanced-profile name** command creates a network enhanced profile.

The **undo network-enhanced-profile name** command deletes a network enhanced profile.

By default, no network enhanced profile is created.

NOTE

This command can only be executed on a parent switch.

Format

network-enhanced-profile name *profile-name*

undo network-enhanced-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network enhanced profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

3: Management level

Usage Guidelines

Usage Scenario

You can configure value-added services in a network enhanced profile, such as network security and QoS.

Precautions

- You can create a maximum of 16 network enhanced profiles.
- A network enhanced profile can be bound to only an AS port group but not an AP port group.

Example

Create a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
```

3.5.76 network-enhanced-profile (port group view)

Function

The **network-enhanced-profile** command binds a network enhanced profile to a port group.

The **undo network-enhanced-profile** command unbinds a network enhanced profile from a port group.

By default, no network enhanced profile is bound to a port group.

NOTE

This command can only be executed on a parent switch.

Format

network-enhanced-profile *profile-name*

undo network-enhanced-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network enhanced profile.	The value must have an existing network enhanced profile name.

- A network enhanced profile can be bound to only an AS port group but not an AP port group.
- A port group can be bound to only one network enhanced profile.

Example

Bind a network enhanced profile to a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] quit
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] network-enhanced-profile profile_1
```

3.5.77 network-qos-profile name

Function

The **network-qos-profile name** command creates a network QoS profile and displays the network QoS profile view.

The **undo network-qos-profile name** command deletes a network QoS profile.

By default, no network QoS profile is created.

NOTE

This command can only be executed on a parent switch.

Format

network-qos-profile name *profile-name*

undo network-qos-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network QoS profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A network QoS profile is used to configure QoS services for ASs on the parent, including the packet priority mapping mode, queue scheduling mode, and queue scheduling weight.

Precautions

- A maximum of 32 network QoS profiles can be created on the parent.
- A maximum of six network QoS profiles can be created on an AS.

Example

Create a network QoS profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-qos-profile name test
[HUAWEI-um-net-qos-test]
```

3.5.78 network-qos-profile (port group view)

Function

The **network-qos-profile** command binds a network QoS profile to a port group.

The **undo network-qos-profile** command unbinds a network QoS profile from a port group.

By default, no network QoS profile is bound to a port group.

NOTE

This command can only be executed on a parent switch.

Format

network-qos-profile *profile-name*

undo network-qos-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a network QoS profile.	The value must be an existing network QoS profile name.

Views

Port group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can bind a network QoS profile to a port group to deliver the configurations in the profile to all the member ports in the port group in a batch.

Prerequisites

The network QoS profile has been created before being bound to a port group.

Precautions

- A network QoS profile can be bound to only an AS port group but not an AP port group.
- A port group can be bound to only one network QoS profile.

Example

Bind a network QoS profile to a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-qos-profile name test
[HUAWEI-um-net-qos-test] trust dscp
[HUAWEI-um-net-qos-test] quit
```

```
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] network-qos-profile test
```

3.5.79 pass-vlan (network basic profile view)

Function

The **pass-vlan** command configures allowed VLANs in a network basic profile.

The **undo pass-vlan** command deletes allowed VLANs in a network basic profile.

By default, no allowed VLANs are configured in a network basic profile, and downlink ports of an AS allow packets from VLAN 1 to pass through.

NOTE

This command can only be executed on a parent switch.

Format

pass-vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo pass-vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies IDs of VLANs from which packets are allowed to pass through.	The value is an integer that ranges from 1 to 4094. The value cannot be the ID of an SVF management VLAN, a stack management VLAN, an ERPS control VLAN, an RRPP control VLAN, an SEP control VLAN, or a super VLAN.

Views

Network basic profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a network basic profile, you can configure allowed VLANs in the profile. After the profile is bound to an AS port, the port allows packets from these VLANs to pass through. The following configuration is generated on the AS port:

```
#
 port link-type hybrid
```

```
 port hybrid tagged vlan vlan-id1 to vlan-id2
#
```

Precautions

- The default VLAN, allowed VLANs, and voice VLAN in a network basic profile must be different.
- You can configure a maximum of 32 allowed VLANs in a network basic profile.

Example

Configured allowed VLANs in a network basic profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-basic-profile name profile_1
[HUAWEI-um-net-basic-profile_1] pass-vlan 10 to 12
```

3.5.80 patch delete as

Function

The **patch delete as** command deletes patches on a specified online AS.

NOTE

This command can only be executed on a parent switch.

Format

patch delete as { **all** | **name** *patch-name* | **name-include** *string* }

Parameters

Parameter	Description	Value
all	Indicates all online ASs.	-
name *patch-name*	Specifies the name of an AS.	The value is a string of 1 to 31 case-insensitive characters without spaces.
name-include *string*	Specifies the string contained in an AS name.	The value is a string of 1 to 31 case-insensitive characters without spaces.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If you find errors in the patches loaded to an AS, run this command to delete the patches to prevent system operation failures.

If non-incremental patches need to be loaded to an AS, you need to run the **patch delete as** command to delete the existing patches on the AS first. Otherwise, non-incremental patches will fail to be loaded.

Precautions

If the patch file to be loaded to an AS type has been specified using the **as type** command, patches on this AS type cannot be deleted.

Example

Delete the patches on as1.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] patch delete as name as1
Warning: This command will start to delete the patch of AS. Continue?[Y/N]:y
Info: This operation will take several seconds, please wait...
```

3.5.81 policy (traffic policy profile view)

Function

The **policy** command configures a traffic policy in a traffic policy profile.

The **undo policy** command deletes a traffic policy in a traffic policy profile.

By default, no traffic policy is configured in a traffic policy profile.

NOTE

This command can only be executed on a parent switch.

Format

policy *policy-name* **remark** { **8021p** { *8021p-value* | **inner-8021p** } | **cvlan-id** *cvlan-id* | **dscp** { *dscp-value* | *dscp-name* } | **ip-precedence** *ip-precedence* | **local-precedence** { *local-precedence-value* | *local-precedence-name* } [**green** | **yellow** | **red**] | **vlan-id** *vlan-id* | **flow-id** *flow-id* | **destination-mac** *mac-address* }* **if-match acl** *acl-number*

undo policy *policy-name*

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a traffic policy.	The value is a string of 1 to 64 case-sensitive characters without spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
remark	Specifies re-marking information.	-
8021p	Specifies the 802.1p priority of packets.	-
8021p-value	Specifies the 802.1p priority value of packets.	The value is an integer in the range from 0 to 7. A larger value indicates a higher priority.
inner-8021p	Inherits the 802.1p priority in the inner tag.	-
cvlan-id *cvlan-id*	Re-marks the inner VLAN tag in QinQ packets.	The value is an integer in the range from 1 to 4094.
dscp	Specifies the DSCP priority of packets.	-
dscp-value	Specifies the DSCP priority value of packets.	The value is an integer in the range from 0 to 63. A larger value indicates a higher priority.
dscp-name	Specifies the DSCP priority name of packets.	The value can be: **ef**, **af11**, **af12**, **af13**, **af21**, **af22**, **af23**, **af31**, **af32**, **af33**, **af41**, **af42**, **af43**, **cs1**, **cs2**, **cs3**, **cs4**, **cs5**, **cs6**, **cs7**, or **default**.
ip-precedence *ip-precedence*	Specifies the IP precedence.	The value is an integer in the range from 0 to 7. A larger value indicates a higher priority.
local-precedence	Specifies the local priority of packets.	-

Parameter	Description	Value
local-precedence-value	Specifies the local priority value.	The value is an integer in the range from 0 to 7. A larger value indicates a higher priority.
local-precedence-name	Specifies the local priority name.	The value can be: **af1**, **af2**, **af3**, **af4**, **be**, **cs6**, **cs7**, or **ef**.
green	Indicates that the packet color corresponding to the local priority is green.	-
yellow	Indicates that the packet color corresponding to the local priority is yellow.	-
red	Indicates that the packet color corresponding to the local priority is red.	-
vlan-id *vlan-id*	Re-marks a VLAN ID in packets.	The value is an integer in the range from 1 to 4094.
flow-id *flow-id*	Specifies the value of a flow ID.	The value is an integer in the range from 1 to 8.
destination-mac *mac-address*	Re-marks the destination MAC address in packets.	The value is in the format of H-H-H, in which H is a hexadecimal number of 1 to 4 digits.
if-match	Specifies an ACL rule for matching packets.	-
acl *acl-number*	Specifies an ACL rule number.	The value is an integer in the range from 3000 to 3900.

Views

Traffic policy profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a traffic policy profile, you can configure traffic behaviors and traffic classifiers in the profile. After the profile is bound to an AS port, the traffic behaviors and traffic classifiers are automatically configured on the port.

The following global configuration is generated on the AS:

```
#
traffic classifier classifier-name operator or
 if-match acl-number
#
traffic behavior behavior-name
 remark xxxx
#
```

The following configuration is generated on the AS port:

```
#
 traffic-policy profile-name inbound
#
```

Or:

```
#
 traffic-policy profile-name outbound
#
```

Precautions

- A maximum of 64 traffic policies can be created in a traffic policy profile.
- **remark 8021p** and **remark local-precedence** cannot be configured in the same traffic policy.
- **remark dsc** and **remark ip-precedence** cannot be configured in the same traffic policy.

Example

Configured allowed VLANs in a traffic policy profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] traffic-policy-profile name profile_1
[HUAWEI-um-traffic-policy-profile_1] policy a remark 8021p 2 if-match acl 3456
```

3.5.82 port connect independent-as

Function

The **port connect independent-as** command enables the independent mode on the fabric port that connects the parent to a level-1 AS.

The **undo port connect** command restores the default mode of the fabric port that connects the parent to a level-1 AS.

By default, the service configuration mode of the fabric port that connects the parent to a level-1 AS is centralized mode.

NOTE

This command can only be executed on a parent switch.

Format

port connect independent-as

undo port connect

Parameters

None

Views

Fabric-port view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In independent mode, you can log in to an AS to configure this AS using commands. After the independent mode is enabled on the fabric port that connects the parent to a level-1 AS, the level-1 AS can be configured independently.

Precautions

- Before enabling the independent mode, run the **independent-as-admin** command in the uni-mng view to configure an administrator for AS login.
- If the AS connected to a fabric port is online, running the **undo port connect** command on the fabric port for mode switching will cause the AS to automatically restart and register with the parent again. Switching from the centralized mode to the independent mode does not cause the AS to restart.
- During mode switching on a fabric port, the parent and AS exchange packets for multiple times. In this process, if faults occur, for example, link or device faults, mode switching may fail. An error message will be displayed on the parent, indicating that mode switching fails. Additionally, the AS may restart and then registers with the parent again. In this situation, run commands on the fabric port again to change the mode after the AS has registered with the parent.
- In independent mode, when an AS goes offline, traffic on the network attached to an AS port cannot be forwarded if the port has authentication configurations. To enable the traffic to be forwarded normally, manually delete the authentication configurations from the port.
- When the service configuration mode of an AS is independent mode, configuring the following commands on the Eth-Trunk bound to or on the member port of a fabric port connected to the AS may cause this AS to go offline.

Table 3-120 Commands that may cause an AS to go offline

Command
loopback internal

Command
traffic-policy
traffic-filter
speed
negotiation
port media-type
port split
training disable
wavelength-channel
undo port hybrid tagged vlan
undo port trunk allow-pass vlan
storm-control action
mac-address flapping action
port-security protect-action

- If the Eth-Trunk bound to a fabric port has other configurations in addition to the following **Table 2** and **Table 3**, you need to manually delete the other configurations before running the **undo port connect** command on this fabric port for mode switching. Otherwise, an error message will be displayed to indicate that mode switching fails.

Table 3-121 Commands that can not be manually deleted in an Eth-Trunk

Command
port link-type hybrid
port hybrid tagged vlan

Table 3-122 Commands that do not need to be manually deleted in an Eth-Trunk

Command
undo port hybrid vlan
stp root-protection
stp edged-port disable
loop-detection disable

Command
mode lacp
mad relay
trust 8021p
authentication-profile
authentication control-point

Example

Enable the independent mode on the fabric port that connects the parent to a level-1 AS.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] interface fabric-port 1
[HUAWEI-um-fabric-port-1] port connect independent-as
```

3.5.83 port connect-type indirect

Function

The **port connect-type indirect** command configures the indirect connection mode for a fabric port.

The **undo port connect-type** command restores the default connection mode for a fabric port.

The default connection mode of a fabric port is direct connection.

NOTE

This command can only be executed on a parent switch.

Format

port connect-type indirect

undo port connect-type

Parameters

None

Views

Fabric-port view

Default Level

3: Management level

Usage Guidelines

When the parent connects to an AS across a network, you need to run the **port connect-type indirect** command to configure the indirect connection mode for the fabric port that connects the parent to the AS.

Prerequisites

No Eth-Trunk is bound to the fabric port.

Follow-up Procedure

Run the **port member-group interface** command to bind an Eth-Trunk to the fabric port.

Example

Configure the indirect connection mode for a fabric port.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] interface fabric-port 1
[HUAWEI-um-fabric-port-1] port connect-type indirect
```

3.5.84 port-group name

Function

The **port-group name** command creates an AS port group.

The **port-group connect-ap name** command creates an AP port group.

The **undo port-group name** command deletes an AS port group.

The **undo port-group connect-ap name** command deletes an AP port group.

By default, no AS port group is created.

NOTE

This command can be executed only on a parent switch of models except the S6735-S, S6720-EI, S6720S-EI, S6720-SI, S6720S-SI, S6720S-S,S6730-S, or S6730S-S.

Format

port-group name *group-name*

port-group connect-ap name *group-name*

undo port-group name *group-name*

undo port-group connect-ap name *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a port group.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A port group is a set of AS ports. The purpose of a port group is to facilitate batch configuration of AS ports.

Port groups are classified into AS port groups and AP port groups.

- Ports in an AS port group are used to connect an AS to a user terminal. An AS port group can be bound to four types of service profiles (network basic profile, network enhanced profile, user access profile, traffic policy profile, and network qos profile), but only one profile of the same type can be bound.
- Ports in an AP port group are used to connect an AS to an AP. To connect an AP to an AS, you need to add the port that connects the AS to the AP to an AP port group. An AP port group can be bound to only a network basic profile, and only the **pass-vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command configured in the profile takes effect.

Follow-up Procedure

Run the **as name** *as-name* or **as name-include** *string* **interface all** command to add AS ports to a port group.

Precautions

- You can create a maximum of 256 AS port groups in a version earlier than V200R011C10.

  You can create a maximum of 512 AS port groups in V200R011C10 and later versions.
- You can create a maximum of 1 AP port group.

Example

Create a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] port-group name group_1
```

3.5.85 port eth-trunk trunkmember

Function

The **port eth-trunk trunkmember** command adds member ports to the Eth-Trunk.

The **undo port eth-trunk trunkmember** command deletes member ports from an Eth-Trunk.

By default, no member ports are added to the Eth-Trunk.

NOTE

This command can only be executed on a parent switch.

Format

port eth-trunk *trunk-id* **trunkmember interface** *interface-type interface-number1* [**to** *interface-number2*]

undo port eth-trunk *trunk-id* **trunkmember interface** *interface-type interface-number1* [**to** *interface-number2*]

Parameters

Parameter	Description	Value
trunk-id	Specifies the ID of an Eth-Trunk.	The value is an integer and the minimum value is 1. The maximum value varies according to the switch model. For a specific switch model, the maximum value is the same as that described in **interface eth-trunk**.
interface *interface-type interface-number1* [**to** *interface-number2*]	Specifies the type and number of the interface added to an Eth-Trunk: ● *interface-type* specifies the interface type. ● *interface-number1* specifies the first interface number. ● *interface-number2* specifies the last interface number.	-

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a downlink fabric port of a level-1 AS is configured using the **down-direction fabric-port** *port-id* **member-group interface eth-trunk** *trunk-id* command, you need to add member ports to the Eth-Trunk to which the fabric port is bound.

When an Eth-Trunk has been created for an AS using the **uni eth-trunk** command, you can run the **port eth-trunk trunkmember** command to add member ports to this Eth-Trunk.

Precautions

AS uplink ports can be used to connect to the parent or level-1 AS or set up a stack and be configured as downlink fabric ports to connect to other ASs.

On the S6720-EI and S6720S-EI, 40GE ports and 10GE ports split from 40GE ports cannot be configured as downlink fabric ports.

Example

Add member ports to the Eth-Trunk to which a fabric port is bound.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] down-direction fabric-port 1 member-group interface eth-trunk 1
[HUAWEI-um-as-as1] port eth-trunk 1 trunkmember interface gigabitethernet 0/0/16
```

Add member ports to the Eth-Trunk configured on the specified AS.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] uni eth-trunk 40
[HUAWEI-um-as-as1] port eth-trunk 40 trunkmember interface GigabitEthernet 0/0/10
```

3.5.86 port member-group interface

Function

The **port member-group interface** command binds a fabric port to an Eth-Trunk.

The **undo port member-group** command unbinds a fabric port from an Eth-Trunk.

By default, no fabric port is bound to an Eth-Trunk.

NOTE

This command can only be executed on a parent switch.

Format

port member-group interface eth-trunk *trunk-id*

undo port member-group

Parameters

Parameter	Description	Value
eth-trunk *trunk-id*	Specifies the ID of the Eth-Trunk to which a fabric port is bound.	The value is an integer that ranges from 0 to 127.

Views

Fabric-port view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a fabric port using the **interface fabric-port** *port-id* command, bind the fabric port to an Eth-Trunk.

Follow-up Procedure

Run the **eth-trunk** *trunk-id* command in the interface view to add interfaces to the bound Eth-Trunk.

Precautions

- After the **port connect independent-as** command is executed to enable the independent configuration mode, you need to run the **undo port connect** command to restore to the centralized configuration mode before unbinding a fabric port from an Eth-Trunk.
- A created Eth-Trunk cannot be bound to a fabric port. When a fabric port is bound to an Eth-Trunk, the system creates the Eth-Trunk.
- You can run the **interface eth-trunk** command to enter the view of the Eth-Trunk to which a fabric port is bound and configure services. Currently, the following commands can be executed in the view of the Eth-Trunk to which a fabric port is bound: **authentication open ucl-policy enable**, **mac-address multiport**, **quit**, and all display commands.
- If physical member interfaces have been added to the Eth-Trunk bound to a fabric port, the **undo port member-group** command cannot be used to unbind the fabric port from the Eth-Trunk.

- Running the **undo port member-group** command will delete the configuration in the Eth-Trunk interface view and delete the Eth-Trunk.
- When a fabric port is bound to an Eth-Trunk, the system creates the Eth-Trunk and performs some service configurations on the Eth-Trunk, for example, the **stp root-protection** and **mad relay** command configurations.

Example

Bind a fabric port to an Eth-Trunk.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] interface fabric-port 1
[HUAWEI-um-fabric-port-1] port member-group interface eth-trunk 11
```

3.5.87 port-security aging-time (network enhanced profile view)

Function

The **port-security aging-time** command sets the aging time of secure dynamic MAC addresses on an interface in a network enhanced profile.

The **undo port-security aging-time** command cancels the configuration.

By default, the aging time of secure dynamic MAC addresses is not configured in a network enhanced profile, that is, secure dynamic MAC addresses will not be aged out.

NOTE

This command can only be executed on a parent switch.

Format

port-security aging-time *time*

undo port-security aging-time

Parameters

Parameter	Description	Value
time	Specifies the aging time of secure dynamic MAC address entries.	The value is an integer ranging from 1 to 1440, in minutes.

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

Application scenario

After creating a network enhanced profile, you can set the aging time of secure dynamic MAC addresses in the profile. After the profile is bound to an AS port, the configuration is automatically delivered to the AS port. The following configuration is generated on the AS:

```
#
interface GigabitEthernet0/0/1
 port-security enable
 port-security aging-time 10
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration depends on the profile.

Prerequisites

Before setting the aging time of secure dynamic MAC addresses in a network enhanced profile, ensure that port security is enabled in the profile.

Example

Set the aging time of secure dynamic MAC addresses on an interface to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] port-security enable
[HUAWEI-um-net-enhanced-profile_1] port-security aging-time 10
```

3.5.88 port-security enable (network enhanced profile view)

Function

The **port-security enable** command enables port security in a network enhanced profile.

The **undo port-security enable** command disables port security in a network enhanced profile.

By default, port security is disabled in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

port-security enable

undo port-security enable

Parameters

None

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

Application scenario

After creating a network enhanced profile, you can enable port security in the profile. After the profile is bound to an AS port, the configuration is automatically delivered to the AS port. The following configuration is generated on the AS:

```
#
interface GigabitEthernet0/0/1
 port-security enable
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration depends on the profile.

Prerequisites

- If the **mac-limit** command is configured in the user access profile view on an AS port bound to a network enhanced profile, the port security function cannot be enabled on the AS port.
- The port security function cannot be disabled in a network enhanced profile if other port security configurations exist in the profile.

Example

Enable port security in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] port-security enable
```

3.5.89 port-security mac-address sticky (network enhanced profile view)

Function

The **port-security mac-address sticky** command enables the sticky MAC address function in a network enhanced profile.

The **undo port-security mac-address sticky** command disables the sticky MAC address function in a network enhanced profile.

By default, the sticky MAC address function is disabled in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

port-security mac-address sticky

undo port-security mac-address sticky

Parameters

None

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

Application scenario

After creating a network enhanced profile, you can enable the sticky MAC address function in the profile. After the profile is bound to an AS port, the configuration is automatically delivered to the AS port. The following configuration is generated on the AS:

```
#
interface GigabitEthernet0/0/1
 port-security enable
 port-security mac-address sticky
#
```

In the preceding configuration, GigabitEthernet0/0/1 is used for reference only. The actual configuration depends on the profile.

Prerequisites

Before enabling the sticky MAC address function in a network enhanced profile, ensure that port security has been enabled in the profile.

Example

Configure the system to set an interface to the Error-Down state when detecting MAC address flapping on the interface.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] port-security enable
[HUAWEI-um-net-enhanced-profile_1] port-security mac-address sticky
```

3.5.90 portal url-encode disable

Function

The **portal url-encode disable** command disables the URL encoding function of ASs.

The **undo portal url-encode disable** command enables the URL encoding function of ASs.

By default, the URL encoding function of AS is enabled.

NOTE

This command can only be executed on a parent switch.

Format

portal url-encode disable

undo portal url-encode disable

Parameters

None

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To improve web application security, data from untrustworthy sources must be encoded before being sent to clients. URL encoding is most commonly used in web applications. After URL encoding is enabled for ASs, special characters in redirect URLs are converted to secure formats, preventing clients from mistaking them for syntax signs or instructions and unexpectedly modifying the original syntax. In this way, cross-site scripting attacks and injection attacks are prevented. By default, URL encoding is enabled in ASs. This function can be disabled using the **portal url-encode disable** command.

Precautions

If the system software is upgraded from a version earlier than V200R009C00SPC500 to V200R009C00SPC500 or a later version, the switch automatically runs the **portal url-encode disable** command to disable URL encoding and decoding.

Example

Disable URL encoding.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] portal url-encode disable
```

3.5.91 qos { pq | wrr | drr } (network QoS profile view)

Function

The **qos** { **pq** | **wrr** | **drr** } command configures the queue scheduling mode for an AS port.

The **undo qos** { **pq** | **wrr** | **drr** } command restores the default queue scheduling mode of an AS port.

By default, no interface queue scheduling mode is configured in the network QoS profile view.

NOTE

This command can only be executed on a parent switch.

Format

qos { **pq** | **wrr** | **drr** }

undo qos { **pq** | **wrr** | **drr** }

Parameters

Parameter	Description	Value
pq	Indicates the PQ scheduling mode.	-
wrr	Indicates the WRR scheduling mode.	-
drr	Indicates the WDRR scheduling mode.	-

Views

Network QoS profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When congestion occurs on a network, configure the interface queue scheduling mode to balance between the delay and jitter of various service packets. In this way, packets of delay-sensitive services, such as voice and video services, can be processed preferentially. Among delay-insensitive services, such as the email service, the packets with the same priority are processed equally and the packets with different priorities are processed based on their weights.

In an SVF system, to change the queue scheduling mode of an AS port, run the **qos** { **pq** | **wrr** | **drr** } command in the network QoS profile view and then bind the profile to the AS port.

Precautions

If the queue scheduling weight has been configured using the **qos queue** command before the queue scheduling mode is configured, delete the configured queue scheduling weight first.

Example

Set the queue scheduling mode of an AS port to WDRR.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-qos-profile name test
[HUAWEI-um-net-qos-test] qos drr
```

3.5.92 qos queue (network QoS profile view)

Function

The **qos queue** command configures a queue scheduling weight for an AS.

The **undo qos queue** command restores the default queue scheduling weight of an AS.

By default, the queue scheduling weight is 1.

NOTE

This command can only be executed on a parent switch.

Format

qos queue *queue-index* { **drr** | **wrr** } **weight** *weight*

undo qos queue *queue-index* { **drr** | **wrr** }

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
drr	Specifies the WDRR scheduling weight.	-
wrr	Specifies the WRR scheduling weight.	-
weight *weight*	Specifies the scheduling weight.	The value is an integer that ranges from 0 to 127.

Views

Network QoS profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If congestion occurs during queue scheduling, to ensure that each queue can be scheduled, configure a scheduling weight for each queue so that the device schedules each queue based on the configured scheduling weights.

In an SVF system, to change the queue scheduling weight of an AS port, run the **qos queue** command in the network QoS profile view and then bind the profile to the AS port.

Prerequisites

The queue scheduling mode of an AS port has been set to WRR or WDRR using the **qos { pq | wrr | drr }** command.

Example

Set the WDRR scheduling weight of queue 4 in a network QoS profile to 6.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-qos-profile name test
[HUAWEI-um-net-qos-test] qos drr
[HUAWEI-um-net-qos-test] qos queue 4 drr weight 6
```

3.5.93 rate-limit (network enhanced profile view)

Function

The **rate-limit** command configures traffic rate limiting in a network enhanced profile.

The **undo rate-limit** command cancels traffic rate limiting in a network enhanced profile.

By default, traffic rate limiting is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

rate-limit *cir-value*

undo rate-limit

Parameters

Parameter	Description	Value
cir-value	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through.	The value is an integer that ranges from 64 to 1000000, in kbit/s. The packet rate range of an interface depends on the interface bandwidth,If the configured packet rate is larger than the maximum value, the maximum value takes effect.

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a network enhanced profile, you can configure traffic rate limiting in the profile. After the profile is bound to an AS port, traffic rate limiting is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 qos lr inbound cir cir-value cbs 125*cir-value
#
```

If user traffic is not limited, continuous burst data from numerous users can make the network congested. You can configure traffic rate limiting in inbound direction on an interface to limit traffic entering from the interface within a specified range.

Precautions

When an AS is an S2750-EI, S5700-10P-LI, or S5700-10P-PWR-LI switch and works in Layer 3 hardware forwarding mode, the **rate-limit** *cir-value* command does not take effect on the AS. Because an AS performs only Layer 2 forwarding in an SVF system, you are advised to run the **undo assign forward-mode** command to cancel the Layer 3 hardware forwarding mode and then connect the AS to the SVF system.

Example

Configure traffic rate limiting in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] rate-limit 100000
```

3.5.94 reboot uni-mng

Function

The **reboot uni-mng** command restarts an SVF system.

NOTE

This command can only be executed on a parent switch.

Format

reboot uni-mng

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When upgrading or troubleshooting an SVF system, you can restart the SVF system, including the parent and all ASs.

Precautions

- This command can be used only after the SVF function is enabled.
- The next startup software version of the AS must be V200R011C10 or later, and the next startup software version of the parent cannot be earlier than that of the AS.
- Before running this command to restart an SVF system, you must save the configuration of the parent. If an AS is configured in independent mode, you also need to save the configuration of the AS.

Example

Restart an SVF system.

```
<HUAWEI> reboot uni-mng
```

3.5.95 reset uni-mng as-discover packet statistics

Function

The **reset uni-mng as-discover packet statistics** command clears AS Discovery packet statistics on a fabric port.

NOTE

This command can be used on the parent or an AS. After running this command, you can clear AS Discovery packet statistics on a fabric port of the local device.

Format

reset uni-mng as-discover packet statistics interface fabric-port *port-id*

Parameters

Parameter	Description	Value
interface fabric-port *port-id*	Specifies the number of a fabric port.	The value is an integer that ranges from 0 to 63 on an AS and the value range on the parent varies depending on the switch model: • S12700/S12700E: 0 to 255 • MCUD/SRUK/MFUX/MPUE/SRUE/SRUHA1/SRUHX1/SRUH: 0 to 255 • Other switch models: 0 to 63

Views

User view

Default Level

3: Management level

Usage Guidelines

Before collecting statistics about AS Discovery packets on a fabric port, clear the existing statistics.

Example

Clear AS Discovery packet statistics on a fabric port.

```
<HUAWEI> reset uni-mng as-discover packet statistics interface fabric-port 1
```

3.5.96 shutdown interface

Function

The **shutdown interface** command disables an AS port.

The **undo shutdown interface** command enables an AS port.

By default, an interface is enabled.

NOTE

This command can only be executed on a parent switch.

Format

shutdown interface *interface-type interface-number*

undo shutdown interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the interface type and number. - *interface-type* specifies the interface type. The interface type cannot be an Eth-Trunk interface. - *interface-number* specifies the interface number.	-

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **shutdown interface** command to disable an AS port.

Precautions

Running this command can disable only an AS downlink port but not an AS uplink port. If an uplink port has been configured as a downlink fabric port, this port can be disabled.

If the version of an AS is inconsistent with that of the parent, the **shutdown interface** and **undo shutdown interface** commands do not take effect on the ports of this AS.

If an AS is configured in the independent mode, the **shutdown interface** and **undo shutdown interface** commands do not take effect on the ports of this AS.

Example

Disable an AS port.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] shutdown interface gigabitethernet 0/0/1
```

3.5.97 slot

Function

The **slot** command pre-configures a stack ID or changes the pre-configured device model.

The **undo slot** command deletes the pre-configured stack ID or changes the pre-configured device model.

By default, the pre-configured stack ID is 0.

NOTE

This command can only be executed on a parent switch.

Format

slot *slot-id1* **replace-model** *model-name*

undo slot *slot-id1* **replace-model**

slot *slot-id2* [**to** *slot-id3*] [**replace-model** *model-name*]

undo slot *slot-id2* [**to** *slot-id3*] [**replace-model**]

Parameters

Parameter	Description	Value
slot-id1	Specifies the pre-configured stack ID.	The value is 0.
slot-id2 [**to** *slot-id3*]	Specifies the pre-configured stack ID. *slot-id3* must be larger than *slot-id2*.	The value is an integer that ranging from 1 to 4.
replace-model *model-name*	Specifies the device model of which the stack ID needs to be pre-configured.	The value range depends on the device configuration.

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AS is a stack of multiple member switches, the system pre-configures only stack ID 0 by default. You can only pre-configure services for the member switch with stack ID 0. Before pre-configuring services for another member switch, pre-configure a stack ID for the member switch.

The pre-configured stack ID does not affect the actual stack ID. For example, the pre-configured stack ID is 0 (default value), but the actual stack IDs are 0 and 2. The actual stack IDs remain 0 and 2 except that no services are configured on the device with stack ID 2.

An AS can be a stack of the same device series but different device models. If the stack contains different device models, you need to specify the **replace-model** parameter to change the device model that is different from the other device models in the stack to the actual access device model. If you do not specify the device model of a specified member, by default, the device model of this member is consistent with the pre-configured AS type.

Precautions

If the AS does not support stacking, the **slot** *slot-id* command configuration takes effect on the parent only when slot 0 is configured as the stack ID.

Changing the device models of online devices in a stack is not allowed.

Example

Pre-configure a stack ID.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] slot 1 to 4
```

Change the device model of the switch with stack ID 2 in the AS **as1** to S5720-28X-SI-AC.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name as1
[HUAWEI-um-as-as1] slot 2 replace-model S5720-28X-SI-AC
```

3.5.98 stp bpdu-protection (AS administrator profile)

Function

The **stp bpdu-protection** command configures BPDU protection for ASs in an AS administrator profile.

The **undo stp bpdu-protection** command cancels BPDU protection of ASs in an AS administrator profile.

By default, BPDU protection is not configured for ASs in an AS administrator profile.

NOTE

This command can only be executed on a parent switch.

Format

stp bpdu-protection

undo stp bpdu-protection

Parameters

None

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

After creating an AS administrator profile, run the **stp bpdu-protection** command to configure BPDU protection for ASs in the profile. After the profile is bound to an AS, the following configuration is generated on the AS:

```
#
stp bpdu-protection
#
```

Example

Configure BPDU protection for ASs in an AS administrator profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] stp bpdu-protection
```

3.5.99 traffic-limit inbound (user access profile view)

Function

The **traffic-limit inbound** command configures the rate limit for incoming ARP and DHCP packets on an AS port.

The **undo traffic-limit inbound** command restores the default rate limit for incoming ARP and DHCP packets on an AS port.

By default, the forwarding rate of incoming ARP and DHCP packets on an AS port is not limited.

NOTE

This command can only be executed on a parent switch.

Format

traffic-limit inbound { **arp** | **dhcp** } **cir** *cir-value*

undo traffic-limit inbound { **arp** | **dhcp** }

Parameters

Parameter	Description	Value
arp	Specifies the ARP packet.	-
dhcp	Specifies the DHCP packet.	-
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed average rate of traffic that can pass through.	The value is an integer that ranges from 8 to 128, in kbit/s.

Views

User access profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a user access profile is created, you can configure the rate limit for incoming ARP and DHCP packets on an AS port. After the user access profile is bound to the AS port, the following configuration is generated on the AS port:

```
#
 traffic-limit inbound acl 4999 cir cir-value pir pir-value cbs cbs-value pbs pbs-value
 traffic-statistic inbound acl 4999
 traffic-limit inbound acl 3999 cir cir-value pir pir-value cbs cbs-value pbs pbs-value
 traffic-statistic inbound acl 3999
#
```

Precautions

- This command and the **authentication** command cannot be both run in the user access profile view.
- Do not run the **traffic-limit inbound dhcp** and **dhcp snooping enable (network enhanced profile view)** commands simultaneously on the same port; otherwise, the **traffic-limit inbound dhcp** command does not take

effect. On an AS of the S2750-EI, S5700-LI, S5700S-LI, S5720S-LI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5720I-SI, S5710-X-LI, S5735S-H, S5736-S, S6720S-S, or S600-E model, running the **dhcp snooping enable (network enhanced profile view)** command on any port may cause the **traffic-limit inbound dhcp** command unable to take effect on all ports. You are advised to shut down the attacked port after detecting DoS attacks.

- Do not run the **traffic-limit inbound arp** and **arp anti-attack check user-bind enable (network enhanced profile view)** commands simultaneously on the same port. Otherwise, the **traffic-limit inbound arp** command may not take effect. On an AS of the S2750-EI, S5700-LI, S5700S-LI, S5720S-LI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5720I-SI, S5710-X-LI, S5735S-H, S5736-S, S6720S-S, or S600-E model, running the **arp anti-attack check user-bind enable (network enhanced profile view)** command on any port may cause the **traffic-limit inbound arp** command unable to take effect on all ports. You are advised to shut down the attacked port after detecting DoS attacks.

Example

Set the rate limit for incoming ARP packets to 64 on an AS port.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
[HUAWEI-um-user-access-profile_1] traffic-limit inbound arp cir 64
```

3.5.100 traffic-limit outbound (AS administrator profile view)

Function

The **traffic-limit outbound** command configures the rate limit for outgoing ARP and DHCP packets on an AS uplink fabric port.

The **undo traffic-limit outbound** command restores the default rate limit for outgoing ARP and DHCP packets on an AS uplink fabric port.

By default, the rate limits for outgoing ARP packets and DHCP packets are 32 kbit/s and 128 kbit/s respectively on an AS uplink fabric port.

NOTE

This command can only be executed on a parent switch.

Format

traffic-limit outbound { **arp** | **dhcp** } **cir** *cir-value*

undo traffic-limit outbound { **arp** | **dhcp** }

Parameters

Parameter	Description	Value
arp	Specifies the ARP packet.	-
dhcp	Specifies the DHCP packet.	-
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed average rate of traffic that can pass through.	The value is an integer that ranges from 8 to 512, in kbit/s.

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After an AS administrator profile is created, you can configure the rate limit for outgoing ARP and DHCP packets on an AS uplink fabric port. After the AS goes online, the following configuration is generated in the AS Eth-Trunk 0 view and system view, regardless of whether the AS administrator profile is bound to the AS:

```
#
acl number 3999
 rule 5 permit udp destination-port eq bootps
#
acl number 4998
 rule 5 permit vlan-id management-vlan
acl number 4999
 rule 5 permit l2-protocol arp destination-mac ffff-ffff-ffff
 rule 10 permit l2-protocol arp
#
interface Eth-Trunk0
 traffic-filter outbound acl 4998
 traffic-statistic outbound acl 3999
 traffic-limit outbound acl 3999 cir cir-value pir pir-value cbs cbs-value pbs pbs-value
 traffic-statistic outbound acl 4999
 traffic-limit outbound acl 4999 cir cir-value pir pir-value cbs cbs-value pbs pbs-value
#
```

Example

Set the rate limit for outgoing ARP packets to 64 on an uplink fabric port.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] traffic-limit outbound arp cir 64
```

3.5.101 traffic-policy-profile (port group view)

Function

The **traffic-policy-profile** command binds a traffic policy profile to a port group.

The **undo traffic-policy-profile** command unbinds a traffic policy profile from a port group.

By default, no traffic policy profile is bound to a port group.

NOTE

This command can only be executed on a parent switch.

Format

traffic-policy-profile *profile-name* { **inbound** | **outbound** }

undo traffic-policy-profile { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a traffic policy profile.	The profile must have been created.
inbound	Applies a traffic policy profile to the inbound direction of an interface.	-
outbound	Applies a traffic policy profile to the outbound direction of an interface.	-

Views

Port group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can bind a traffic policy profile to a port group to deliver the configurations in the profile to all the member ports in the port group in a batch.

Prerequisites

The traffic policy profile has been created before being bound to a port group.

Precautions

- A traffic policy profile can be bound to only an AS port group but not an AP port group.
- A port group can be bound to only one traffic policy profile.

Example

Bind a traffic policy profile to a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] traffic-policy-profile name profile_1
[HUAWEI-um-traffic-policy-profile_1] quit
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] traffic-policy-profile profile_1 inbound
```

3.5.102 traffic-policy-profile name

Function

The **traffic-policy-profile name** command creates a traffic policy profile.

The **undo traffic-policy-profile name** command deletes a traffic policy profile.

By default, no traffic policy profile is configured.

NOTE

This command can only be executed on a parent switch.

Format

traffic-policy-profile name *profile-name*

undo traffic-policy-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a traffic policy profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A traffic policy profile is used to configure traffic policy functions for ASs, including the packet re-marking function.

Precautions

You can create at most 32 traffic policy profiles.

Example

Create a traffic policy profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] traffic-policy-profile name profile_1
```

3.5.103 trust dscp (network QoS profile view)

Function

The **trust dscp** command configures an AS to perform priority mapping on packets based on DSCP priorities.

The **undo trust dscp** command cancels configuring an AS to perform priority mapping on packets based on DSCP priorities.

By default, an AS performs priority mapping on packets based on 802.1p priorities.

NOTE

This command can only be executed on a parent switch.

Format

trust dscp

undo trust dscp

Parameters

None

Views

Network QoS profile view

Default Level

3: Management level

Usage Guidelines

By default, a device performs priority mapping on packets based on 802.1p priorities. If packets have the same 802.1p priority, the device cannot provide differentiated services to packets. To solve this problem, configure the device to perform priority mapping on packets based on DSCP priorities. After the **trust dscp** command is configured, the device searches for the priority mapping table based on DSCP priorities and assigns an internal priority to packets so that packets are placed in their corresponding queues.

In an SVF system, you can configure an AS to perform priority mapping on packets based on DSCP priorities by running the **trust dscp** command in the network QoS profile view and then binding the profile to an AS port.

Example

In a network QoS profile, configure an AS to perform priority mapping on packets based on DSCP priorities.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-qos-profile name test
[HUAWEI-um-net-qos-test] trust dscp
```

3.5.104 topology explore

Function

The **topology explore** command triggers SVF network topology collection immediately.

The **topology explore interval** command sets the interval for collecting SVF network topology information.

The **undo topology explore interval** command restores the default interval for collecting SVF network topology information.

By default, the interval for collecting SVF network topology information is 10 minutes.

NOTE

This command can only be executed on a parent switch.

Format

topology explore [**interval** *interval*]

undo topology explore interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for collecting SVF network topology information.	The value is an integer that ranges from 0 to 1440, in minutes. The value 0 indicates that SVF network topology information is not automatically collected.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

You can adjust the interval for collecting SVF network topology information based on SVF network stability. When the network topology is stable, you can increase the interval or disable periodic topology information collection. When the network topology is unstable, you can shorten the interval.

You can also run the **topology explore** command to trigger SVF network topology collection immediately.

Example

Set the SVF network topology collection interval to 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] topology explore interval 30
```

3.5.105 undo uni-mng enable

Function

The **undo uni-mng enable** command changes an AS from the client mode to the standalone mode.

NOTE

This command can only be executed on an AS. After this command is executed, the AS restarts.

Format

undo uni-mng enable

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can run the **undo uni-mng enable** command to change an AS from the client mode to the standalone mode.

Example

Change an AS from the client mode to the standalone mode.

```
<HUAWEI> undo uni-mng enable
```

3.5.106 uni eth-trunk

Function

The **uni eth-trunk** command creates an Eth-Trunk interface for an AS.

The **undo uni eth-trunk** command deletes an Eth-Trunk interface of an AS.

By default, no Eth-Trunk interface is created on an AS.

NOTE

This command can only be executed on the parent.

Format

uni eth-trunk *trunk-id* [**mode lacp**]

undo uni eth-trunk *trunk-id* [**mode lacp**]

Parameters

Parameter	Description	Value
trunk-id	Specifies the ID of an Eth-Trunk interface.	The value is an integer and the minimum value is 1. The maximum value varies according to the switch model. For a specific switch model, the maximum value is the same as that described in **interface eth-trunk**.
mode lacp	Sets the working mode of an Eth-Trunk interface to LACP mode. If this parameter is not specified, the working mode of an Eth-Trunk interface is manual mode.	-

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AP with two network interfaces connects to an SVF system through an AS or to improve access user bandwidth and reliability, you can create an Eth-Trunk interface for this AS.

Precautions

- An Eth-Trunk interface can be created for an AS only when this AS is in centralized mode.
- When an AS works in independent mode and its Eth-Trunk interface needs to be deleted, you need to run the **undo uni eth-trunk** *trunk-id* command in the AS view of the parent and log in to this AS to delete this Eth-Trunk interface.
- To delete an Eth-Trunk interface, ensure that it does not contain member interfaces.
- After an Eth-Trunk interface is created and its working mode is set to LACP, running the **uni eth-trunk** *trunk-id* command will not change the working mode of the Eth-Trunk interface. To change the working mode to manual mode, run the **undo uni eth-trunk** *trunk-id* **mode lacp** command.
- Running the **undo uni eth-trunk** *trunk-id* **mode lacp** command only changes the working mode of an Eth-Trunk interface and will not delete the Eth-Trunk interface. To delete an Eth-Trunk interface, run the **undo uni eth-trunk** *trunk-id* command.
- The Eth-Trunk interface of an AS and Eth-Trunk interfaces bound to fabric ports share the Eth-Trunk interface specifications.
- An Eth-Trunk interface contains a maximum of eight member interfaces.
- An Eth-Trunk interface cannot be created across ASs.

Follow-up Procedure

Run the **port eth-trunk trunkmember** command to add member interfaces to the Eth-Trunk interface.

Example

Create Eth-Trunk 2 in LACP mode for the AS **test**.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name test
[HUAWEI-um-as-test] uni eth-trunk 2 mode lacp
```

3.5.107 uni eth-trunk lacp timeout

Function

The **uni eth-trunk lacp timeout** command configures the LACP timeout time for an Eth-Trunk interface on an AS.

The **undo uni eth-trunk lacp timeout** command restores the default LACP timeout time of an Eth-Trunk interface on an AS.

By default, the LACP timeout time of an Eth-Trunk interface on an AS is 90 seconds.

NOTE

This command can only be executed on a parent switch.

Format

uni eth-trunk *trunk-id* **lacp timeout fast** [**user-defined** *user-defined-timeout*]

undo uni eth-trunk *trunk-id* **lacp timeout**

Parameters

Parameter	Description	Value
trunk-id	Specifies an Eth-Trunk ID.	The value must be an Eth-Trunk ID that has been created using the **uni eth-trunk** command.
fast	Sets the LACP timeout time of an Eth-Trunk interface to 3 seconds. In this situation, the interval at which the remote end sends LACP PDUs is 1 second.	-
user-defined *user-defined-timeout*	Indicates the user-defined LACP timeout time of an Eth-Trunk interface.	The value is an integer that ranges from 3 to 90, in seconds.

Views

AS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, if a member interface of the remote Eth-Trunk interface is faulty, it takes 90 seconds for the local Eth-Trunk interface to detect the remote member interface status change. This results in data traffic loss because the local interface continues to forward data traffic to the faulty remote member interface within 90 seconds. To enable the local interface to detect the remote member interface status change in a timely manner, run the **uni eth-trunk lacp timeout** command to reduce the LACP timeout time.

Prerequisites

The **uni eth-trunk lacp timeout** command can be configured only when the **uni eth-trunk** command has been configured to create an Eth-Trunk interface and set its working mode to LACP mode.

Precautions

The **uni eth-trunk lacp timeout** command is deleted when the **undo uni eth-trunk** command is configured to delete the Eth-Trunk interface.

Example

Set the LACP timeout time of Eth-Trunk 2 on the AS **test** to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as name test
[HUAWEI-um-as-test] uni eth-trunk 2 mode lacp
[HUAWEI-um-as-test] uni eth-trunk 2 lacp timeout fast
```

3.5.108 uni-mng

Function

The **uni-mng** command enables SVF or displays the uni-mng view.

The **undo uni-mng** command disables SVF.

By default, SVF is disabled.

NOTE

This command can only be executed on a parent switch.

Format

uni-mng

undo uni-mng

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When SVF is disabled, the **uni-mng** command enables SVF and displays the uni-mng view. When SVF has been enabled, this command displays the uni-mng view.

Prerequisites

- A source interface used to set up a CAPWAP link has been specified using the **capwap source interface vlanif** *vlan-id* command.
- The STP working mode must be STP or RSTP. If the current working mode is not STP or RSTP, run the **stp mode** { **rstp** | **stp** } command to set the STP working mode to STP or RSTP before enabling SVF. By default, the STP working mode is MSTP. You can run the **display stp** command to check the current STP working mode.
- The default STP/RSTP port path cost algorithm must be used. If the current port path cost algorithm is not the default one, run the **undo stp pathcost-standard** command to restore the default port path cost algorithm before enabling SVF. The default STP/RSTP port path cost algorithm is IEEE 802.1t (**dot1t**). You can run the **display stp** command to check the current port path cost algorithm.
- The default Eth-Trunk specifications are used. If the current Eth-Trunk specifications are not the default value on S5531-H, S5531-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S, S6735-S, S6720-EI, or S6720S-EI, run the **undo assign trunk** command to restore the default Eth-Trunk specifications before enabling SVF. You can run the **display trunk configuration** command to check the default and configured Eth-Trunk specifications.
- The NAC configuration mode must be the unified mode. If the current mode is not the unified mode, run the **authentication unified-mode** command to set the NAC configuration mode to unified mode. The default NAC configuration mode is unified mode. You can run the **display authentication mode** command to check the current NAC configuration mode.
- Remote authorization is not configured in the system. If remote authorization has been configured, run the **undo remote-authorize** command to disable remote authorization before enabling SVF. By default, remote authorization is not configured in the system. You can run the **display current-configuration** command to check whether remote authorization is configured.

Precautions

- When SVF is enabled on the parent, LLDP is automatically enabled on the parent if LLDP is disabled. When SVF is disabled on the parent, LLDP is not automatically disabled on the parent.

- When SVF is disabled on the parent, the STP priorities of ports change, and STP recalculates the port role and changes the interface status.
- After SVF is enabled on a switch used as the parent, the **stack timer mac-address switch-delay** value changes to 0 (not changing system MAC address) and cannot be changed. After SVF is disabled on this switch, this delay time is still 0, but you can manually change it.

Example

Enable SVF (default Eth-Trunk specifications and default NAC configuration mode).

```
<HUAWEI> system-view
[HUAWEI] vlan batch 11
[HUAWEI] interface Vlanif 11
[HUAWEI-Vlanif11] ip address 192.168.11.1 24
[HUAWEI-Vlanif11] quit
[HUAWEI] capwap source interface vlanif 11
[HUAWEI] stp mode stp
[HUAWEI] uni-mng
Warning: This operation will enable the uni-mng mode and disconnect all ASs. STP calculation may be
triggered and service traffic will be affected. Continue? [Y/N]:y
```

3.5.109 uni-mng indirect fabric-port

Function

The **uni-mng indirect fabric-port** command configures a member port for an uplink fabric port that connects an AS to the parent through a network.

The **undo uni-mng indirect fabric-port** command deletes a member port of an uplink fabric port that connects an AS to the parent through a network.

By default, no member port is configured for an uplink fabric port that connects an AS to the parent through a network.

NOTE

This command can only be executed on an AS.

Format

uni-mng indirect fabric-port member interface *interface-type interface-number*

undo uni-mng indirect fabric-port member interface *interface-type interface-number*

Parameters

Parameter	Description	Value
member interface *interface-type interface-number*	Specifies the type and number of member ports of a fabric port.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AS connects to the parent through a network, you must run the **uni-mng indirect fabric-port** command to configure a member port for an uplink fabric port of the AS. You can run this command multiple times to add multiple member ports to the fabric port.

Prerequisites

The **uni-mng indirect mng-vlan** command has been executed to configure the device to work in client mode and configure a management VLAN.

Precautions

- Only AS uplink ports or subcard ports can be added to an uplink fabric port. If you have to add AS downlink ports to uplink fabric ports, run the **uni-mng up-direction fabric-port member interface** *interface-type interface-number* [**to** *interface-number*] command.
- A maximum of eight member ports can be added to a fabric port.
- Ports used to set up a stack cannot be configured as member ports of a fabric port.
- The command that configures the stack ID is mutually exclusive with the command that configures a member port for a fabric port:
  - After the **stack slot** *slot-id* **renumber** *new-slot-id* command is executed in a specified slot, the port in the slot cannot be configured as a member port of a fabric port.
  - After a port in a slot is configured as a member port of a fabric port, the stack ID of the slot cannot be configured using the **stack slot** *slot-id* **renumber** *new-slot-id* command.
- You need to configure a member port of a fabric port according to the network configuration. A member port needs to be reconfigured if the stack ID changes because the stack changes, for example, the stacking function is disabled, or existing stack IDs conflict after member devices are added to the stack.

Example

Configure member ports for an uplink fabric port that connects an AS to the parent through a network.

```
<HUAWEI> uni-mng indirect fabric-port member interface gigabitethernet 0/0/27
<HUAWEI> uni-mng indirect fabric-port member interface gigabitethernet 0/0/28
```

3.5.110 uni-mng indirect mng-vlan

Function

The **uni-mng indirect mng-vlan** command configures a device to work in client mode and configures a management VLAN.

NOTE

This command can only be executed on an AS.

Format

uni-mng indirect mng-vlan *vlan-id*

Parameters

Parameter	Description	Value
vlan-id	Specifies a management VLAN. The VLAN must be consistent with the management VLAN configured on a parent.	The value is an integer that ranges from 2 to 4094. The VLAN cannot be the reserved VLAN (The default is VLAN 4093) of a stack.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an AS connects to the parent through a network, you must run the **uni-mng indirect mng-vlan** command to configure the AS to work in client mode and configures a management VLAN.

Precautions

- The VCMP role switching command is mutually exclusive with the command that configures a device to work in client mode. If the current device is not a silent switch in a VCMP domain, the device cannot be configured to work in client mode. You must run the **vcmp role silent** command in the system view to set the VCMP role of the device to silent. After a device is configured to work in client mode, the VCMP role switching command cannot be executed. That is, the device cannot change from the silent role to another role.
- After running the **uni-mng indirect mng-vlan** *vlan-id* command on the device in standalone mode, you must delete the configuration file of the device and restart the device to make the configuration take effect.

- If the device has been configured to work in client mode but has not gone online, you can run the **uni-mng indirect mng-vlan** *vlan-id* command multiple times to change the management VLAN, and the configuration takes effect immediately.
- If the device has been configured to work in client mode and has gone online, the **uni-mng indirect mng-vlan** *vlan-id* command cannot be executed.
- When an AS is an S5700-10P-LI, S5700-10P-PWR-LI-AC, or S2750-EI and Layer 3 hardware forwarding for IPv4 packets has been enabled using the **assign forward-mode ipv4-hardware** command in the system view, the management VLAN cannot be configured. To solve this problem, start the AS in standalone mode and run the **undo assign forward-mode** command in the system view to disable Layer 3 hardware forwarding for IPv4 packets.
- On the S5720-SI, S5735-S, S500, S5735S-S, S5720I-SI, S5735S-H, S5736-S, S6720S-S, or S600-E, the electrical port stack configuration on the front panel is mutually exclusive with the client mode configuration. If electrical ports on the front panel have been configured as stack physical member ports, no management VLAN cannot be configured. If a management VLAN has been configured, electrical ports on the front panel cannot be configured as stack physical member ports.
- If an AS is configured in the independent mode, its management VLAN cannot be configured using this command.
- The slot ID of an AS cannot be greater than or equal to 5. Otherwise, the management VLAN cannot be configured for the AS using the **uni-mng indirect mng-vlan** command.
- The command that changes a stack ID and the command that configures a management VLAN are mutually exclusive.
  - The management VLAN cannot be configured for an AS after the slot ID of the AS is changed using the **stack slot** *slot-id* **renumber** *new-slot-id* command.
  - The slot ID of an AS cannot be changed using the **stack slot** *slot-id* **renumber** *new-slot-id* command after a management VLAN is configured for the AS using the **uni-mng indirect mng-vlan** command.

Example

Configure the device to work in client mode and configure a management VLAN 100.

```
<HUAWEI> uni-mng indirect mng-vlan 100
```

3.5.111 uni-mng up-direction fabric-port

Function

The **uni-mng up-direction fabric-port** command configures AS service ports as an uplink fabric port's members.

The **undo uni-mng up-direction fabric-port** command cancels the configuration.

By default, AS service ports are not configured as members of uplink fabric ports.

NOTE

This command can only be executed on an AS.

Format

uni-mng up-direction fabric-port member interface *interface-type interface-number* [**to** *interface-number*]

undo uni-mng up-direction fabric-port member interface *interface-type interface-number* [**to** *interface-number*]

undo uni-mng up-direction fabric-port member all

Parameters

Parameter	Description	Value
member interface *interface-type interface-number*	Specifies the type and number of an AS service port to be configured as a member of an uplink fabric port.	-
all	Specifies all AS service ports.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure AS service ports as an uplink fabric port's members, run the **uni-mng up-direction fabric-port** command.

Precautions

- A maximum of eight interfaces can be configured as a fabric port's members on an AS.
- Stack ports cannot be configured as members of fabric ports. Similarly, fabric member ports cannot be configured as stack ports.
- After the **uni-mng up-direction fabric-port** command is run on an AS, you must restart the AS to make the configuration take effect. If the AS is a stack, you need to restart all stack members. If a configuration conflicting with this command exists on the parent, the AS may fail to go online.
- The command for configuring a stack ID and the command for configuring a fabric member port are mutually exclusive. Specifically:

  - If you have run the **stack slot** *slot-id* **renumber** *new-slot-id* command in a slot, you are not allowed to configure the service port of this slot as a member of an uplink fabric port.
  - If you have configured a service port of a slot as a member of an uplink fabric port, you are not allowed to run the **stack slot** *slot-id* **renumber** *new-slot-id* command to configure a stack ID in this slot.
- When configuring a service port as a member of a fabric port, pay attention to the stacking configuration. A member port needs to be reconfigured if stack IDs change because the stack changes, for example, the stacking function is disabled, or existing stack IDs conflict after member switches are added to the stack.
- If a downlink service interface of an AS is incorrectly configured as a stack port, other interfaces on the AS cannot be configured as uplink interfaces. In this case, delete the stack port configuration from the downlink service interface.

Example

Configure an AS service port as a member of an uplink fabric port.

```
<HUAWEI> uni-mng up-direction fabric-port member interface gigabitethernet 0/0/3
Warning: After a service port on an AS is configured as an uplink port, the AS needs to be restarted to
make the configuration take effect.
 If the parent has a configuration conflict with the AS, the AS may fail to go online. Continue? [Y/N]:y
```

3.5.112 unicast-suppression (network enhanced profile view)

Function

The **unicast-suppression** command configures unknown unicast traffic suppression in a network enhanced profile.

The **undo unicast-suppression** command cancels unknown unicast traffic suppression in a network enhanced profile.

By default, unknown unicast traffic suppression is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

unicast-suppression packets *packets-per-second*

undo unicast-suppression

Parameters

Parameter	Description	Value
packets *packets-per-second*	Specifies the packet rate of an interface.	The value is an integer that ranges from 0 to 14881000, in packets per second (PPS). If the configured packet rate on the parent switch is larger than the maximum value on the AS port, the maximum value takes effect on the AS port.

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure unknown unicast traffic suppression in the profile. After the profile is bound to an AS port, unknown unicast traffic suppression is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 unicast-suppression packets packets-per-second
#
```

To prevent broadcast storms, you can run the **unicast-suppression** command to configure the maximum number of unknown unicast packets that can pass through a port. When the unknown unicast traffic rate reaches the rate limit, the system discards excess unknown unicast packets to control the traffic volume within a proper range.

Example

Configure unknown unicast traffic suppression in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] unicast-suppression packets 148810
```

3.5.113 upgrade as

Function

The **upgrade as name** command upgrades an AS with a specified name.

The **upgrade as name-include** command upgrades ASs of which the name contains a specified string.

The **upgrade as type** command upgrades ASs of a specified type.

The **upgrade as all** command upgrades all ASs.

undo upgrade as command rolls back ASs to the previous version.

NOTE

This command can only be executed on a parent switch.

Format

upgrade as name *as-name* [**reload** [**at** *time*]]

upgrade as name-include *string* [**reload** [**at** *time*]]

upgrade as type *as-type* [**reload** [**at** *time*]]

upgrade as all [**reload** [**at** *time*]]

undo upgrade as { **all** | **name** *as-name* | **name-include** *string* | **type** *as-type* }

Parameters

Parameter	Description	Value
as-name	Upgrades an AS with a specified name.	The value must have an existing AS name.
string	Upgrades all the ASs of which the name contains a specified string.	The value is a string of 1 to 31 case-insensitive characters without spaces.
as-type	Upgrades ASs of a specified type.	The value is an enumerated type. You can enter a question mark (?) and select a value from the displayed value range.
reload	Configures an AS to restart after upgrade files are downloaded.	-
at *time*	Specifies the AS restart time. If **reload** is specified but *time* is not specified, an AS restarts immediately after loading files. If *time* is specified, the AS restarts at the specified time.	The value is a string of characters in the HH:MM format, where HH:MM indicates the hour and minute. HH ranges from 0 to 23, and MM ranges from 0 to 59.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **upgrade as** command to upgrade online ASs. You can upgrade one AS, ASs of a specified type, or all ASs.

After performing upgrade configuration on an AS, the patch and system software files for the next startup will be the specified ones. You can run the **undo upgrade as** command to cancel the configuration as long as the AS is not restarted. After this command is executed, the patch and system software files for the next startup are consistent with the currently running ones. If the patch has taken effect after upgrade configuration is performed, the patch cannot be rolled back to the previous version.

Precautions

- The patch and system software files used to upgrade ASs are specified in the **as type** command. If no system software file is not specified using the **as type** command, an AS automatically uses the system software of the same version as the parent during an upgrade. If the system software of the same version as the parent does not exist, the AS continues to use the previous system software.
- The **upgrade as** command cannot upgrade an AS if the software file name or patch file name specified in the **as type** command is the same as the current or next startup software file name or patch file name of the AS.
- The **upgrade as** command cannot upgrade an AS if the software file name specified in the **as type** command does not exist.
- When you upgrade an AS using the **upgrade as** command without specifying **reload**:
  - If you specify **patch** *patch* but not **system-software** *system-software* in the **as type** command, the patch file is activated online immediately.
  - If you specify both **patch** *patch* and **system-software** *system-software* in the **as type** command and the specified system software file version is the version running on the AS, the patch file is activated online immediately.
  - If you specify both **patch***patch* and **system-software***system-software* in the **as type** command and the specified system software file version is earlier or later than the version running on the AS, the specified system software file and patch file will be set as next startup files.

Example

Perform an in-service upgrade on an AS of the S5720-P-LI type.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] upgrade as type s5720-p-li reload
```

3.5.114 upgrade { local-ftp-server | local-sftp-server }

Function

The **upgrade** { **local-ftp-server** | **local-sftp-server** } command configures a local file server.

The **undo upgrade** { **local-ftp-server** | **local-sftp-server** } command deletes a local file server.

By default, no local file server is configured.

NOTE

This command can only be executed on a parent switch.

Format

upgrade { **local-ftp-server** | **local-sftp-server** } **username** *username* **password** *password*

undo upgrade { **local-ftp-server** | **local-sftp-server** }

Parameters

Parameter	Description	Value
local-ftp-server	Specifies the file server type as FTP server.	-
local-sftp-server	Specifies the file server type as SFTP server.	-

Parameter	Description	Value

username *username*	Specifies the user name for accessing the file server.	The value is a string of 1 to 64 characters. It cannot contain spaces, asterisk, double quotation mark and question mark.
		NOTE
		● During local authentication or authorization, run the **authentication-mode** { **local** | **local-case** } or **authorization-mode** { **local** | **local-case** } command to configure case sensitivity for user names. If the parameter is set to **local**, user names are case-insensitive. If the parameter is set to **local-case**, user names are case-sensitive.
		● Note the following when configuring case sensitivity for user names:
		  ● Only the user name is case-sensitive and the domain name is case-insensitive.
		  ● For user security purposes, you cannot configure multiple local users with the user names that differ only in uppercase or lowercase. For example, after configuring ABC, you cannot configure Abc or abc as the user name.
		  ● When a device is upgraded from V200R011C10 or an earlier version to a version later than V200R011C10, all local user names in the original configuration file are saved in lowercase. When a configuration file that is manually configured or generated using the third-party tool is used for configuration restoration, local user names that differ only in uppercase or lowercase are considered as one user name and the first one among these local user names is used.

password *password*	Specifies the password for accessing the file server.	The value is a string of case-sensitive characters without spaces. By default, the value is a string of 8 to 128 characters or 48 to 188 characters. You can enter a password in plain text or cipher text. The password is displayed in cipher text in the configuration file regardless of whether the password is input in plain or cipher text. ● The password in plain text is a string of 8 to 128 characters. ● The password in cipher text is a string of 48 to 188 characters. The password in cipher text cannot be generated using the irreversible algorithm.

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In an AS automatic upgrade or in-service AS batch upgrade, you need to download the version file or patch file from the parent. Before the upgrade, you need to configure the parent as an FTP/SFTP server. The AS then can work as a client to download files from the FTP/SFTP server.

Precautions

- The files used to upgrade an AS are often saved in the root directory unimng/ of the parent. These files can also be saved on an AS when the AS is upgraded or downgraded to the software version that is consistent with that of the parent.
- FTP has potential security risks, and so SFTP is recommended. If you want to use FTP, you are advised to configure ACLs to improve security. For details, see Configure the FTP ACL in "File Management" in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Basic Configuration*.
- When the file server is an FTP server, the parent automatically enables the FTP service and creates an FTP user. You only need to run the ftp server-source command to specify the source IP address of the FTP server.
- When the file server type is set to SFTP, the SFTP service is not automatically enabled and no SFTP user is created on the parent. You need to manually pre-configure SFTP on the parent.
- After the **upgrade** { **local-ftp-server** | **local-sftp-server** } command is executed, the same user name and password configuration is also generated in the AAA view. If you modify the configured local user information (the user password for example) in AAA view, the version management function does not take effect.
- If information about a user already exists in the AAA view, you cannot run this command to configure the same user name.
- Running this command multiple times to create new users will delete previous user information. Previous user information can be deleted only when the user level of the user running this command is higher or equal to the user level configured in the AAA view. Otherwise, the command does not take effect.
- If a remote authentication server is used for AAA authentication, the user name and password configured using this command must also be configured on the remote authentication server.
- If a remote authentication server is used for AAA authentication and the remote authentication server does not support FTP or SFTP, ASs will fail to be authenticated. In this case, run the **authentication-scheme** *authentication-scheme-name* command in the AAA view to create an authentication scheme and run the **authentication-mode local** command in the authentication scheme view to set the authentication mode to local authentication. Then, run the **domain** command in the AAA view to create a domain and run the **authentication-scheme** *authentication-scheme-name* command in the AAA

domain view to apply the created authentication scheme to the domain. ASs can be authenticated when they use the newly created domain for local authentication.

Example

Set the local file server type to FTP server.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] upgrade local-ftp-server username test password Pwd@12345
```

3.5.115 upload config

Function

The **upload config** command saves the AS configuration to the flash memory of an AS and uploads the configuration file of the AS to the parent.

NOTE

This command can only be executed on an AS.

Format

upload config

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In independent mode, after services are configured on an AS using commands, you can run the **upload config** command to save the service configuration and upload the configuration file to the parent.

Precautions

- After this command is executed, the AS configuration file uploaded to the parent will be saved to the **flash:/unimng/ind-cfg** directory or the **cfcard:/unimng/ind-cfg** directory on some parent switch models. If the file name format is unimng-xxxx-xxxx-xxxx.zip (xxxx-xxxx-xxxx indicates the management MAC address of an AS), and the service configuration mode of this AS is independent mode, it is not allowed to delete this configuration file.

- After the **upload config** command is executed, the AS configuration file may fail to be uploaded to the parent. The possible causes include insufficient storage space on the parent and a fault of the link between the AS and parent.
- To prevent services from being affected, it is recommended not to delete the configuration file saved on the AS.
- The AS configuration file saved on the parent can ensure configuration integrity for the AS. For example, after an AS goes online again or is replaced, the AS will compare its saved configuration file with that saved on the parent. If the two files are inconsistent, the configuration file saved on the parent will replace the configuration file saved on the AS and take effect after the AS restarts.

Example

Save the AS configuration to the flash memory of the AS and upload the configuration file of the AS to the parent.

```
<HUAWEI> upload config
```

3.5.116 user-access-port enable (network enhanced profile view)

Function

The **user-access-port enable** command configures the edge port function in a network enhanced profile.

The **undo user-access-port enable** command cancels the edge port function in a network enhanced profile.

By default, the edge port function is not configured in a network enhanced profile.

NOTE

This command can only be executed on a parent switch.

Format

user-access-port enable

undo user-access-port enable

Parameters

None

Views

Network enhanced profile view

Default Level

3: Management level

Usage Guidelines

After creating a network enhanced profile, you can configure the edge port function in the profile. After the profile is bound to an AS port, the port becomes an edge port. The following configuration is generated on the AS port:

```
#
 stp edged-port enable
#
```

Ports connected to a Layer 2 STP network do not need to participate in spanning tree calculation. If these ports participate in the calculation, the network topology convergence speed is affected and the status changes of these ports may cause network flapping. After these ports are configured as edge ports, they do not participate in spanning tree calculation. This configuration speeds up network topology convergence and enhances network stability.

Example

Enable the edge port function in a network enhanced profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-enhanced-profile name profile_1
[HUAWEI-um-net-enhanced-profile_1] user-access-port enable
```

3.5.117 user-access-profile name

Function

The **user-access-profile name** command creates a user access profile.

The **undo user-access-profile name** command deletes a user access profile.

By default, no user access profile is configured.

NOTE

This command can only be executed on a parent switch.

Format

user-access-profile name *profile-name*

undo user-access-profile name *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a user access profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain letters, digits, and underscores (_).

Views

uni-mng view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In a user access profile, you can configure authentication services for user access (for example, the authentication mode), MAC address learning limiting, and the rate limit for incoming ARP and DHCP packets on an AS port.

Precautions

You can create a maximum of 16 user access profiles.

Example

Create a user access profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
```

3.5.118 user-access-profile (port group view)

Function

The **user-access-profile** command binds a user access profile to a port group.

The **undo user-access-profile** command unbinds a user access profile from a port group.

By default, no user access profile is bound to a port group.

NOTE

This command can only be executed on a parent switch.

Format

user-access-profile *profile-name*

undo user-access-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a user access profile.	The value must have an existing user access profile name.

Views

Port group view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can bind a user access profile to a port group to deliver the configurations in the profile to all the member ports in the port group.

Prerequisites

The user access profile has been created.

Precautions

- A user access profile can be bound to only an AS port group but not an AP port group.
- A port group can be bound to only one user access profile.

Example

Bind a user access profile to a port group.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] user-access-profile name profile_1
[HUAWEI-um-user-access-profile_1] quit
[HUAWEI-um] port-group name group_1
[HUAWEI-um-portgroup-group_1] user-access-profile profile_1
```

3.5.119 user-vlan (network basic profile view)

Function

The **user-vlan** command configures the default VLAN in a network basic profile.

The **undo user-vlan** command deletes the default VLAN in a network basic profile.

By default, no default VLAN is configured in a network basic profile, and downlink ports of an AS use VLAN 1 as the default VLAN.

NOTE

This command can only be executed on a parent switch.

Format

user-vlan *vlan-id*

undo user-vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094. The value cannot be the ID of an SVF management VLAN, a stack management VLAN, an ERPS control VLAN, an RRPP control VLAN, an SEP control VLAN, or a super VLAN.

Views

Network basic profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a network basic profile, you can configure the default VLAN in the profile. After the profile is bound to an AS port, the default VLAN is automatically configured on the port. The following configuration is generated on the AS port:

```
#
 port link-type hybrid
 port hybrid pvid vlan vlan-id
 port hybrid tagged vlan 1
 port hybrid untagged vlan vlan-id
#
```

The **user-vlan** command can only configure the default VLAN for a port. To enable this port to allow packets of multiple VLANs to pass through, run the **pass-vlan** command in a network basic profile.

Precautions

The default VLAN, allowed VLANs, and voice VLAN in a network basic profile must be different.

Example

Configure the default VLAN in a network basic profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-basic-profile name profile_1
[HUAWEI-um-net-basic-profile_1] user-vlan 10
```

3.5.120 user password (AS administrator profile view)

Function

The **user password** command configures an AS administrator in an AS administrator profile.

The **undo user** command deletes an AS administrator in an AS administrator profile.

By default, no AS administrator is configured in an AS administrator profile.

NOTE

This command can only be executed on a parent switch.

Format

user *user-name* **password** *password*

undo user *user-name*

Parameters

Parameter	Description	Value

user-name	Specifies a user name.	The value is a string of 1 to 64 characters. It cannot contain spaces, asterisk, double quotation mark and question mark.
		NOTE
		- During local authentication or authorization, run the **authentication-mode** { **local** | **local-case** } or **authorization-mode** { **local** | **local-case** } command to configure case sensitivity for user names. If the parameter is set to **local**, user names are case-insensitive. If the parameter is set to **local-case**, user names are case-sensitive.
		- Note the following when configuring case sensitivity for user names:
		  - Only the user name is case-sensitive and the domain name is case-insensitive.
		  - For user security purposes, you cannot configure multiple local users with the user names that differ only in uppercase or lowercase. For example, after configuring ABC, you cannot configure Abc or abc as the user name.
		  - When a device is upgraded from V200R011C10 or an earlier version to a version later than V200R011C10, all local user names in the original configuration file are saved in lowercase. When a configuration file that is manually configured or generated using the third-party tool is used for configuration restoration, local user names that differ only in uppercase or lowercase are considered as one user name and the first one among these local user names is used.

Parameter	Description	Value
password	Specifies the password.	The value is a string of case-sensitive characters without spaces. By default, the value is a string of 8 to 128 characters or 48 to 188 characters. You can enter a password in plain text or cipher text. The password is displayed in cipher text in the configuration file regardless of whether the password is input in plain or cipher text. ● The password in plain text is a string of 8 to 128 characters. ● The password in cipher text is a string of 48 to 188 characters. The password in cipher text cannot be generated using the irreversible algorithm. Do not set this password to the weak password preset by running the **load security weak-password-dictionary** command.

Views

AS administrator profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating an AS administrator profile, you can configure an AS administrator in the profile, including the user name and password. After the profile is bound to an AS, the user name and password for login are automatically configured on the AS. The following configuration is generated on the AS:

```
#
aaa
 local-user user-name password irreversible-cipher password
 local-user user-name privilege level 3
 local-user user-name service-type terminal ssh
#
```

After an AS user name and password are configured, you need to enter the correct user name and password when logging in to an AS through the console port. When you log in to an AS from the parent using the **attach as name** *as-name* command, you can log in to the AS without entering the user name or password.

Precautions

In versions earlier than V200R020C00, when no AS user name and password are configured, you need to enter the default username and password when logging in to an AS through the console port. However, in V200R020C00 and later versions, there is no preset password for logging in to an AS through the console port, therefore, you must configure an AS user name and password before logging in to the AS through the console port.

The default username and password are available in *S Series Switches Default Usernames and Passwords* (**Enterprise Network** or **Carrier**). If you have not obtained the access permission of the document, see **Help** on the website to find out how to obtain it.

Example

Configure the user name and password for an AS administrator.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] as-admin-profile name profile_1
[HUAWEI-um-as-admin-profile_1] user test password YsHsjx_202206
```

3.5.121 voice-vlan (network basic profile view)

Function

The **voice-vlan** command configures a voice VLAN in a network basic profile.

The **undo voice-vlan** command deletes the voice VLAN in a network basic profile.

By default, no voice VLAN is configured in a network basic profile.

NOTE

This command can only be executed on a parent switch.

Format

voice-vlan *vlan-id* [**include-untagged**]

undo voice-vlan

Parameters

Parameter	Description	Value
vlan-id	Specifies a VLAN ID.	The value is an integer that ranges from 2 to 4094. The value cannot be the ID of an SVF management VLAN, a stack management VLAN, an ERPS control VLAN, an RRPP control VLAN, an SEP control VLAN, or a super VLAN.
include-untagged	Adds voice VLAN IDs to untagged packets.	-

Views

Network basic profile view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After creating a network basic profile, you can configure a voice VLAN in the profile. After the profile is bound to an AS port, the voice VLAN is automatically configured on the port. The following configuration is generated on the AS port:

- The **include-untagged** parameter is not specified:

```
#
 port link-type hybrid
 port hybrid tagged vlan vlan-id
 lldp tlv-enable med-tlv network-policy voice-vlan vlan vlan-id
 lldp compliance cdp txrx
#
```

- The **include-untagged** parameter is specified (S6735-S, S6720-EI, and S6720S-EI):

```
#
 port link-type hybrid
 port hybrid untagged vlan vlan-id
 voice-vlan vlan-id enable include-untagged include-tag0
 undo lldp tlv-enable med-tlv network-policy
#
```

- The **include-untagged** parameter is specified (except S6735-S, S6720-EI, and S6720S-EI):

```
#
 port link-type hybrid
 port hybrid untagged vlan vlan-id
 voice-vlan vlan-id enable include-untagged
 undo lldp tlv-enable med-tlv network-policy
#
```

Precautions

The default VLAN, allowed VLANs, and voice VLAN in a network basic profile must be different.

When configuring a voice VLAN on an AS port, ensure that IP phones connected to the AS port support LLDP and have LLDP enabled.

Example

Configure a voice VLAN in a network basic profile.

```
<HUAWEI> system-view
[HUAWEI] uni-mng
[HUAWEI-um] network-basic-profile name profile_1
[HUAWEI-um-net-basic-profile_1] voice-vlan 10
```

3.5.122 whitelist mac-address

Function

The **whitelist mac-address** command adds a specified MAC address to the whitelist.

The **undo whitelist mac-address** command deletes a MAC address from the whitelist.

By default, no MAC address is added to the whitelist. A maximum of 512 MAC addresses can be added to the whitelist.

NOTE

This command can only be executed on a parent switch.

Format

whitelist mac-address *mac-address1* [**to** *mac-address2*]

undo whitelist mac-address { *mac-address1* [**to** *mac-address2*] | **all** }

Parameters

Parameter	Description	Value
mac-address1 [**to** *mac-address2*]	Specifies MAC addresses to be added to a whitelist.	The value is in H-H-H format, where H is a hexadecimal number of 1 to 4 digits. The value cannot be all 0s, all Fs, or a multicast MAC address.
all	Deletes all the MAC addresses in a whitelist.	-

Views

AS authentication view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an SVF system needs to authenticate an AS, the SVF system allows the AS to connect to if the MAC address of the AS is in the whitelist and disallows the AS to connect to if the MAC address is in the blacklist.

Precautions

- A MAC address cannot exist in both the whitelist and blacklist.
- By default, if the MAC address of an AS is neither in the whitelist nor in the blacklist, the AS fails the authentication. You can run the **confirm** { **all** | **mac-address** *mac-address* } command to allow all ASs or a specified AS to pass the authentication.

Example

Add the MAC address xxxx-xxxx-xxxx to the whitelist.

```
<HUAWEI> system-view
[HUAWEI] as-auth
[HUAWEI-as-auth] whitelist mac-address xxxx-xxxx-xxxx
```

3.6 PoE Configuration Commands

3.6.1 Command Support

NOTE

Whether switches support PoE depends on the hardware. Non-PoE switches cannot be changed to PoE switches through software upgrades. A switch that meets any of the following conditions is a PoE switch:

- The device name contains PWR or PWH.
- The switch is released in V200R013C02 or later versions and provides new downlink interface types XUM, UM, P or U.

Only the following switch models support the PoE function:

S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5731-H, S5731-S, S5731S-S, S5732-H, S2730S-S, S5735-L1, S300, S5735-L, S5735-L-I, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-H, S5735S-S, S5735-S-I, S5736-S

3.6.2 display poe device

Function

The **display poe device** command displays information about the device supporting Power over Ethernet (PoE).

Format

display poe device

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before using the PoE function, run the **display poe device** command to check whether the device supports the PoE function. If the command output is displayed, the device supports the PoE function.

Example

Display information about the device supporting PoE.

```
<HUAWEI> display poe device
slot 0   : PoE
```

Table 3-123 Description of the display poe device command output

Item	Description
Slot 0	The device supports PoE.

3.6.3 display poe information

Function

The **display poe information** command displays PoE running information about the device.

Format

display poe information [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the PoE running information in a specified slot ID. If this parameter is not specified, the PoE information about all device is displayed.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays information including the maximum output power set by the user, current power consumption, peak power consumption, and power management mode.

Example

Display the PoE running information about the device. (The actual output information may differ from the following information.)

```
<HUAWEI> display poe information
PSE Information of slot 0:
    User Set Max Power(mW)     : 739200
    PoE Power Supply(mW)       : 369600
    Available Total Power(mW)  : 369600
    Total Power Consumption(mW): 0
    Power Peak Value(mW)       : 0
    Power-Management Mode      : auto
    Power High Inrush          : disable
<HUAWEI> display poe information
PSE Information of slot 0:
MCU 1:
    User Set Max Power(mW)     : 739200
    PoE Power Supply(mW)       : 369600
    Available Total Power(mW)  : 369600
    Total Power Consumption(mW): 0
    Power Peak Value(mW)       : 0
    Power-Management Mode      : auto
    Power High Inrush          : disable
MCU 2:
    User Set Max Power(mW)     : 739200
    PoE Power Supply(mW)       : 369600
    Available Total Power(mW)  : 369600
    Total Power Consumption(mW): 0
    Power Peak Value(mW)       : 0
    Power-Management Mode      : auto
    Power High Inrush          : disable
```

Table 3-124 Description of the **display poe information** command output

Item	Description
User Set Max Power(mW)	Maximum output power set by the user. To set the value, run the **poe max-power** command. When the value is not set using the command, this field displays the maximum output power that can be provided by the device.

Item	Description
PoE Power Supply(mW)	PoE total power supply, which is determined by the PoE power module configured on the device. **NOTE** On the S5720I-6X-PWH-SI-AC switch, the total available power includes the power of two 12 V DC outputs and one 24 V AC output. No command is available to view the 12 V DC and 24 V AC output power. On the S5720I-10X-PWH-SI-AC switch, the total available power includes the power of two 12 V DC outputs and one 24 V AC output. To view the DC output power, run the **display device dc-output information** command.
Available Total Power(mW)	Remaining available power
Total Power Consumption(mW)	Total output power.
Power Peak Value(mW)	Peak value of the output power.
Power-Management Mode	Power management mode, including auto and manual modes. To set the mode, run the **poe power-management** command.
Power High Inrush	State of power high inrush function, including enabled and disabled state. By default, the power high inrush function is in disabled state. To set the state, run the **poe high-inrush enable** command.

3.6.4 display poe power

Function

The **display poe power** command displays current power information on interfaces.

Format

display poe power [**slot** *slot-id* | **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the PoE power information in a specified slot ID. If this parameter is not specified, the PoE power information of all devices in a stack system or the PoE power information of the device in a non-stack system is displayed.	The value depends on the device configuration.
interface *interface-type interface-number*	Displays the PoE power information about a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If this parameter is not specified, the output power of all interfaces on the device is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display poe power** command displays information including the current actual power, maximum output power set for an interface, and class, reference power, and average power of PDs on the interface.

If this parameter is not specified, the output power of all interfaces on the device is displayed.

An interface provides 15400 mW power to PDs based on the power class 0 if non-standard PDs are connected to the interface or forcible power supply is configured on the interface of the switches except the S5720-16X-PWH-LI-AC, S5720-28X-

PWH-LI-AC, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, and S5732-H. If you run the **display poe power** command to check the interface power, the PD class is displayed as 0.

Example

Display the power information of interfaces on the device whose ID is 0.

```
<HUAWEI> display poe power slot 0
Codes: REFPW(Reference power), USMPW(User set max power),
       CURPW(Current power), PKPW(Peak power), AVGPW(Average power)

PortName             Class  REFPW(mW) USMPW(mW) CURPW(mW) PKPW(mW)  AVGPW(mW)
-------------------------------------------------------------------------------

GigabitEthernet0/0/20  -     -        15400     0         0         0
GigabitEthernet0/0/21  -     -        15400     0         0         0
GigabitEthernet0/0/22  -     -        15400     0         0         0
GigabitEthernet0/0/23  -     -        15400     0         0         0
GigabitEthernet0/0/24  -     -        15400     0         0         0
```

Table 3-125 Description of the display poe power slot command output

Item	Description
PortName	Name of an interface.
Class	Class of a PD on an interface. The system classifies PDs into nine classes, namely, class 0 to class 8, according to their maximum power. If no PD is connected to interface, "-" is displayed.
REFPW(mW)	Reference power of a PD. The system can identify the reference power of each PD. The value varies according to types of PDs.
USMPW(mW)	Maximum output power set for an interface. To set the value, run the **poe power** command.
CURPW(mW)	Current power of the PDs on an interface.

Item	Description
PKPW(mW)	Peak power of the PDs on an interface. The value is a statistical value, which equals the current maximum power consumption of the PDs on the interface.
AVGPW(mW)	Average power of the PDs on an interface. The value is a statistical value, which equals the average power consumption from the power-on of the interface till now.

Display the power of interface GigabitEthernet0/0/3.

```
<HUAWEI> display poe power interface gigabitethernet 0/0/3
PD power(mW)            : 3710
PD class                : 2
PD reference power(mW) : 7000
user set max power(mW) : 15400
PD peak power(mW)       : 3816
PD average power(mW)    : 3487
```

Table 3-126 Description of the display poe power interface command output

Item	Description
PD power(mW)	Output power of an interface.
PD class	Class of a PD on an interface. The system classifies PDs into nine classes, namely, class 0 to class 8, according to their maximum power.
PD reference power(mW)	Reference power of a PD. The system can identify the reference power of each PD. The value varies according to types of PDs.
user set max power(mW)	Maximum output power set for an interface. To set the value, run the **poe power** command.
PD peak power(mW)	Peak power of the PDs on an interface. The value is a statistical value, which equals the current maximum power consumption of the PDs on the interface.
PD average power(mW)	Average power of the PDs on an interface. The value is a statistical value, which equals the average power consumption from the power-on of the interface till now.

3.6.5 display poe power-state

Function

The **display poe power-state** command displays the PoE power supply status of a device.

Format

display poe power-state [**slot** *slot-id* | **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays the PoE power supply status of a specified slot ID. If the parameter is not specified, the PoE power supply status of all devices in a stack system or the PoE power supply status of a device in a non-stack system is displayed.	The value range depends on the device configuration.
interface *interface-type interface-number*	Displays the PoE power supply status of a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If this parameter is not specified, the PoE power supply status of all interfaces on the device is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display poe power-state** command displays information including whether an interface is enabled to check compatibility of non-standard PDs, power supply status on of an interface, class of PDs on an interface, power supply priority, and maximum output power of an interface.

Example

Display the PoE power supply status of GigabitEthernet 0/0/3.

```
<HUAWEI> display poe power-state interface gigabitethernet 0/0/3
Legacy detect           : disable
Power enable state      : enable
Power fast-on state     : -
Single-class state      : disable
Power-up mode           : at
Power-on delay(s)       : 0
PD power auto-neg state : enable
PD power-up mode        : at
PD support mode         : af at
Power ON/OFF            : on
Power status            : Powered
PD class                : 4
Reference power(mW)     : 30000
Power priority          : Low
Max power(mW)           : 30000
Current power(mW)       : 8910
Peak power(mW)          : 10725
Average power(mW)       : 8779
Current(mA)             : 162
Voltage(V)              : 55
```

Table 3-127 Description of the **display poe power-state interface** command output

Item	Description
Legacy detect	Whether an interface is enabled to check compatibility of non-standard PDs. To enable an interface to check compatibility of non-standard PDs, run the **poe legacy enable** command.
Power enable state	Whether PoE is enabled on an interface. To enable PoE on an interface, run the **poe enable** command.
Power fast-on state	Whether PoE fast power-on is enabled on an interface. To enable PoE fast power-on on an interface, run the **poe fast-on enable** command. If this field displays -, the device does not support the **poe fast-on enable** command.
Single-class state	Single-class power supply mode of an interface: ● disable: standard power supply mode ● enable: single-class power supply To set this parameter, run the **poe single-class enable** command.

Item	Description
Power-up mode	Power supply mode of an interface. To set the power supply mode for an interface, run the **poe { at-inrush | pre-bt-inrush | bt-inrush } enable** command. If this field displays -, this interface does not support this configuration.
Power-on delay(s)	Power supply delay of an interface, in seconds. The value 0 indicates that power supply is not delayed. To set the power supply delay, run the **poe power-on delay** command.
PD power auto-neg state	Whether power auto-negotiation is enabled for interfaces. To enable power auto-negotiation for interfaces, run the **poe power auto-neg enable** command. **NOTE** The S5731-H(except S5731-H48HB4XZ and S5731-H24HB4XZ), S5731-S, S5731S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5720-12TP-PWR-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28TP-PWR-LI-ACL, S5720-28P-PWR-LI-AC, S5720-52P-PWR-LI-AC, S5720-28X-PWR-LI-AC, S5720-28X-PWR-LI-ACF, S5720-52X-PWR-LI-AC, S5720-52X-PWR-LI-ACF, S5720S-12TP-PWR-LI-AC, S5720S-28TP-PWR-LI-ACL, S5720S-28P-PWR-LI-AC, S5720S-52P-PWR-LI-AC, S5720S-28X-PWR-LI-AC, and S5720S-52X-PWR-LI-AC support this field.
PD power-up mode	Current power supply standards of the PD connected to an interface: ● af: IEEE 802.3af ● at: IEEE 802.3at **NOTE** The S5731-H(except S5731-H48HB4XZ and S5731-H24HB4XZ), S5731-S, S5731S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5720-12TP-PWR-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28TP-PWR-LI-ACL, S5720-28P-PWR-LI-AC, S5720-52P-PWR-LI-AC, S5720-28X-PWR-LI-AC, S5720-28X-PWR-LI-ACF, S5720-52X-PWR-LI-AC, S5720-52X-PWR-LI-ACF, S5720S-12TP-PWR-LI-AC, S5720S-28TP-PWR-LI-ACL, S5720S-28P-PWR-LI-AC, S5720S-52P-PWR-LI-AC, S5720S-28X-PWR-LI-AC, and S5720S-52X-PWR-LI-AC support this field.

Item	Description
PD support mode	Power supply standards supported by the PD connected to an interface: ● af: IEEE 802.3af ● at: IEEE 802.3at ● af at: both IEEE 802.3af and 802.3at **NOTE** The S5731-H(except S5731-H48HB4XZ and S5731-H24HB4XZ), S5731-S, S5731S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5720-12TP-PWR-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28TP-PWR-LI-ACL, S5720-28P-PWR-LI-AC, S5720-52P-PWR-LI-AC, S5720-28X-PWR-LI-AC, S5720-28X-PWR-LI-ACF, S5720-52X-PWR-LI-AC, S5720-52X-PWR-LI-ACF, S5720S-12TP-PWR-LI-AC, S5720S-28TP-PWR-LI-ACL, S5720S-28P-PWR-LI-AC, S5720S-52P-PWR-LI-AC, S5720S-28X-PWR-LI-AC, and S5720S-52X-PWR-LI-AC support this field.
Power ON/OFF	Whether the interface is providing power: ● on: The interface is providing power. ● off: The interface is not providing power.

Item	Description
Power status	Power supply status of an interface: - Test mode: indicates the testing state. - Detecting: indicates the detection state. - Disabled: indicates that PoE is disabled on the interface. - Power-deny: indicates that the reference power is greater than the maximum output power of an interface. - Classification overcurrent: indicates that the current of the PD connected to the interface exceeds the threshold. - Unknown: indicates that the class of the PD is unknown. - Power overcurrent: indicates that the current of the PD connected to the interface exceeds the maximum current of the interface. - Power-on failed: indicates that the interface fails to provide power. - Power-ready: indicates that the interface is ready to provide power. - Powering: indicates that the PSE starts to power on the interface. - Powered: indicates that the interface is providing power. - Overloaded: indicates that the power is overloaded. - Time-range power-off: indicates that the interface is in the power-off time range. - Unstable voltage: indicates that the interface voltage is unstable. - Legacy disable: indicates that the PSE does not check the capability of PDs. - Class mismatch: indicates that the interface works in standard hierarchical power supply mode.
PD class	Class of a PD connected to an interface. The system classifies PDs into nine classes, namely, class 0 to class 8, according to their maximum power.
Reference power(mW)	Reference power of an interface. The system can identify the maximum power of a PD, classify the PD into a certain level, and define the reference power of each level.

Item	Description
Power priority	Power supply priority of an interface: ● Critical: indicates the highest priority. ● High: indicates the second highest priority. ● Low: indicates the lowest priority. To set the priority, run the **poe priority** command.
Max power(mW)	Maximum output power of an interface. A maximum output power of 15400 mW indicates that the device complies with IEEE 802.3af. A maximum output power of 30000 mW indicates that the device complies with IEEE 802.3at. To set the value, run the **poe power** command.
Current power(mW)	Current output power of an interface.
Peak power(mW)	Peak output power of an interface.
Average power(mW)	Average output power of an interface.
Current(mA)	Output current of an interface.
Voltage(V)	Output voltage of an interface.

Display the PoE power supply status of the device.

```
<HUAWEI> display poe power-state slot 0
PORTNAME            POWERON/OFF  ENABLED  FAST-ON  PRIORITY STATUS
-------------------------------------------------------------------------------
GigabitEthernet0/0/1     off     enable   disable  Low      Detecting
GigabitEthernet0/0/2     off     enable   disable  Low      Detecting
GigabitEthernet0/0/3     off     enable   disable  Low      Detecting
GigabitEthernet0/0/4     off     enable   disable  Low      Detecting
GigabitEthernet0/0/5     off     enable   disable  Low      Detecting
GigabitEthernet0/0/6     off     enable   disable  Low      Detecting
GigabitEthernet0/0/7     off     enable   disable  Low      Detecting
GigabitEthernet0/0/8     off     enable   disable  Low      Detecting
GigabitEthernet0/0/9     off     enable   disable  Low      Detecting
GigabitEthernet0/0/10    off     enable   disable  Low      Detecting
GigabitEthernet0/0/11    off     enable   disable  Low      Detecting
GigabitEthernet0/0/12    off     enable   disable  Low      Legacy disable
```

Table 3-128 Description of the display poe power-state slot command output

Item	Description
PORTNAME	Name of an interface.
POWERON/OFF	Whether the interface is providing power: ● On: The interface is providing power. ● Off: The interface is not providing power.

Item	Description
ENABLED	Whether PoE is enabled on an interface. To enable PoE on an interface, run the **poe enable** command.
FAST-ON	Whether PoE fast power-on is enabled on an interface. To enable PoE fast power-on on an interface, run the **poe fast-on enable** command.
PRIORITY	Power supply priority of an interface: ● Critical: indicates the highest priority. ● High: indicates the second highest priority. ● Low: indicates the lowest priority. To set the priority, run the **poe priority** command.

Item	Description
STATUS	Power supply status of an interface: - Test mode: indicates the testing state. - Detecting: indicates the detection state. - Disabled: indicates that PoE is disabled on the interface. - Power-deny: indicates that the reference power is greater than the maximum output power of an interface. - Classification overcurrent: indicates that the current of the PD connected to the interface exceeds the threshold. - Unknown: indicates that the class of the PD is unknown. - Power overcurrent: indicates that the current of the PD connected to the interface exceeds the maximum current of the interface. - Power-on failed: indicates that the interface fails to provide power. - Power-ready: indicates that the interface is ready to provide power. - Powering: indicates that the PSE starts to power on the interface. - Powered: indicates that the interface is providing power. - Overloaded: indicates that the power is overloaded. - Time-range power-off: indicates that the interface is in the power-off time range. - Unstable voltage: indicates that the interface voltage is unstable. - Legacy disable: indicates that the PSE does not check the capability of PDs. - Class mismatch: indicates that the interface works in standard hierarchical power supply mode.

3.6.6 display poe-power

Function

The **display poe-power** command displays information about the PoE power supply.

Format

display poe-power [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display poe-power** displays information including the available total PoE power, percentage of the reserved power, power alarm threshold, and PoE power module.

If the stack ID is not specified, information about the PoE power supply of all the stack devices is displayed.

Example

Display information about the PoE power supply of a switch (except S5720I-28X-PWH-SI-AC).

```
<HUAWEI> display poe-power
Slot 0
Total Available PoE Power(mW)  : 246400
Reserved PoE Power Percent     : 20 %
PoE Power Threshold Percent    : 90 %
    PoE Power 1
    Power Value(mW)            : 123200
    Type                       : PSA250-A2
    Supported Mode             : Redundancy, Balance
    PoE Power 2
    Power Value(mW)            : 123200
    Type                       : PSA250-A2
    Supported Mode             : Redundancy, Balance

Slot 1
Total Available PoE Power(mW) : 492800
Reserved PoE Power Percent    : 20 %
PoE Power Threshold Percent   : 90 %
    PoE Power 1
    Power Value(mW)            : 123200
    Type                       : PSA250-A2
    Supported Mode             : Redundancy, Balance
    PoE Power 2
    Power Value(mW)            : 369600
    Type                       : PSA500-A1
    Supported Mode             : Redundancy, Balance

Slot 2
Total Available PoE Power(mW) : 739200
Reserved PoE Power Percent    : 20 %
PoE Power Threshold Percent   : 90 %
```

```
    PoE Power 1
    Power Value(mW)           : 369600
    Type                      : PSA500-A1
    Supported Mode            : Redundancy, Balance
    PoE Power 2
    Power Value(mW)           : 369600
    Type                      : PSA500-A1
    Supported Mode            : Redundancy, Balance
```

Display information about the PoE power supply of S5720I-28X-PWH-SI-AC.

```
<HUAWEI> display poe-power
Slot 0
Total Available PoE Power(mW) : 369600
Power backup-mode             : 2+0
MCU 1:
Reserved PoE Power Percent    : 20 %
PoE Power Threshold Percent   : 90 %
MCU 2:
Reserved PoE Power Percent    : 20 %
PoE Power Threshold Percent   : 90 %

    PoE Power 1
    Power Value(mW)           : 369600
    PoE Power 2
    Power Value(mW)           : -
```

Table 3-129 Description of the display poe-power command output

Item	Description
Total Available PoE Power(mW)	Total power that can be provided for PDs.
Power backup-mode	PoE power supply backup mode: ● 2+0: high power mode ● 1+1: backup mode
MCU 1/MCU 2	MCU ID.
PoE Power 1/PoE Power 2	PoE Power ID.
Reserved PoE Power Percent	Percentage of the reserved power to the total power. To set the percentage, run the **poe power-reserved** command.
PoE Power Threshold Percent	Alarm threshold of the power consumption percentage. To set the threshold, run the **poe power-threshold** command.
Power Value(mW)	Power of a PoE power supply.

Item	Description
Type	Type of a PoE power supply. The value can be: ● PSA250-A1: 250 W non-current-balance power supply ● PSA250-A2: 250 W current balance power supply ● PSA500-A1: 500 W current balance power supply ● PAC1000S56-CB: 1000W AC power supply ● PAC1000S56-DB: 1000W AC power supply ● PDC1000S56-CB: 1000W DC power supply ● PAC600S56-CB: 600W AC & 240V DC power module ● PAC600S56-EB: 600W AC & 240V DC power module ● PAC1000S56-EB: 1000W AC & 240V DC power module ● PDC1000S56-EB: 1000W DC power module
Supported Mode	Supported PoE power supply mode. The value can be: ● Redundancy: redundancy backup mode ● Balance: current balance mode

3.6.7 poe af-inrush enable

Function

The **poe af-inrush enable** command configures the power supply standards of interfaces as 802.3af.

The **undo poe af-inrush enable** command restores the power supply standards of interfaces to the default value.

By default, interfaces on the devices supporting PoE++ comply with 802.3bt, the other interfaces comply with 802.3at.

Format

poe af-inrush enable

undo poe af-inrush enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Switches that comply with 802.3at or 802.3bt cannot power some non-standard PDs that do not support inrush current. To power these PDs, configure the power supply standards of interfaces as 802.3af.

Precautions

- The **poe af-inrush enable** command applies to the scenario where some non-standard PDs cannot be powered on. After this command is executed, some PDs requiring high current may be unable to be powered on.
- After running the **poe af-inrush enable** command, remove non-standard PDs and then install them so that they can be powered on.
- On the S5720-16X-PWH-LI-AC, S5720-28X-PWH-LI-AC, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, and S5732-H, the **poe af-inrush enable** and **poe single-class enable** commands are mutually exclusive and cannot be configured on the same interface.
- In an upgrade to V200R011C10 or later, if the **poe af-inrush enable** command is configured in the system view before the upgrade, the **poe af-inrush enable** command configuration is automatically generated on all interfaces after the upgrade.

Example

Configures the power supply standards of interfaces as 802.3af.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe af-inrush enable
Warning: This operation will cause PD to be powered off. Continue?[Y/N]:y
```

3.6.8 poe anti-interference frequency

Function

The **poe anti-interference frequency** command configures the PoE anti-interference frequency of the device.

The **undo poe anti-interference frequency** command restores the default configuration.

By default, the PoE anti-interference frequency of a device is 50 Hz.

NOTE

PoE models in the S5720-LI, S5720S-LI, and S5720I-SI series do not support this command. PoE models in other series support this command.

Format

poe anti-interference frequency { **50** | **60** }

undo poe anti-interference frequency

Parameters

Parameter	Description	Value
50	Sets the anti-interference frequency to 50 Hz.	-
60	Sets the anti-interference frequency to 60 Hz.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The mains frequency varies in different countries and regions. Some are 60 Hz and some are 50 Hz. When a device provide PoE power supply, incorrect grounding may occur. As a result, industrial frequency interference is coupled to network cables, resulting in abnormal PoE detection classification. You can run the **poe anti-interference frequency** command to modify the PoE anti-interference frequency on the device to make that become the same as the mains frequency, reducing the impact of the mains frequency on PoE detection.

Example

Set the PoE anti-interference frequency of a device to 60 Hz.

```
<HUAWEI> system-view
[HUAWEI] poe anti-interference frequency 60
```

3.6.9 poe { at-inrush | pre-bt-inrush | bt-inrush } enable

Function

The **poe { at-inrush | pre-bt-inrush | bt-inrush } enable** command changes the power supply mode of interfaces supporting the PoE++ mode.

The **undo poe { at-inrush | pre-bt-inrush | bt-inrush } enable** command restores the default power supply mode of PoE interfaces.

By default, interfaces supporting the PoE++ mode on devices provide power in PoE ++ mode. That is, the power supply mode is **bt-inrush**, interfaces not supporting the PoE++ mode on devices provide power in **at-inrush** mode.

NOTE

Only the MultiGE interface of an S5720-28X-PWH-LI-AC, the first 12 electrical interfaces of an S5720-16X-PWH-LI-AC, the first 8 electrical interfaces of an S5720I-28X-PWH-SI-AC, and electrical interfaces of the S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-PWH-SI-DC, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5731-H, S5731S-H, S5731-S, S5731S-S, and S5732-H support this command.

Format

poe { **at-inrush** | **pre-bt-inrush** | **bt-inrush** } **enable**

undo poe { **at-inrush** | **pre-bt-inrush** | **bt-inrush** } **enable**

Parameters

Parameter	Description	Value
at-inrush	Sets the power supply mode to PoE+.	-
pre-bt-inrush	Sets the power supply mode to PoE++ compatible. That is, except that the PoE power is 60000 mW, interfaces comply with 802.3at. **NOTE** The S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5731-H, S5731S-H, S5731-S, and S5731S-S do not support the **pre-bt-inrush**.	-
bt-inrush	Sets the power supply mode to PoE++. **NOTE** The S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5731-H, S5731S-H, S5731-S, and S5731S-S do not support the **bt-inrush**.	-

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To power the PDs requiring the standard power supply mode, run the **poe at-inrush enable** command. This command changes the power supply mode of the PoE interface to the PoE+ mode. If most of the parameters supported by the PDs requiring high power comply with 802.3at, run the **poe pre-bt-inrush enable** command to change the power supply mode of these interfaces to PoE++ compatible.

Precautions

- When the **poe bt-inrush enable** command is configured after the **poe af-inrush enable** command is configured in the interface, the **poe af-inrush enable** command configuration is automatically overwritten.
- The **poe { pre-bt-inrush | bt-inrush } enable** and **poe single-class enable** commands are mutually exclusive and cannot be configured on the same interface.
- Changing the power supply mode of a PoE interface will power off the PD connected to this PoE interface.
- After the power supply mode of an interface is set to **bt-inrush**, forcible PoE power supply and PD compatibility check configured on this interface using the **poe force-power** and **poe legacy enable** commands respectively do not take effect on this interface.
- After the power supply mode of an interface is set to **bt-inrush**, and the interface detects that it connects to a non-standard PD, confirm whether this interface is connected to a PD. If so, run the **poe pre-bt-inrush enable** command and the **poe legacy enable** or **poe force-power** command to provide power to this PD.

Example

Set the power supply mode of GE0/0/1 to PoE+.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe at-inrush enable
Warning: This operation will cause the PD to be powered off. Continue?[Y/N]:y
```

Set the power supply mode of GE0/0/1 to PoE++ compatible.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe pre-bt-inrush enable
Warning: This operation will cause the PD to be powered off. Continue?[Y/N]:y
```

3.6.10 poe enable

Function

The **poe enable** command enables the PoE function on an interface.

The **undo poe enable** command disables the PoE function on an interface.

By default, the PoE function is enabled on an interface.

Format

poe enable

undo poe enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

Before providing power for the PD connected to an interface, ensure that the PoE function has been enabled on the interface. If the PoE function is not enabled on the interface, run the **poe enable** command to enable the PoE function on the interface.

In automatic mode, PD power-on and power-off on interfaces are determined by the PoE power and interface power priority. When the PoE power is sufficient, the device does not power off the PD connected to any interface. To stop providing power for a PD, run the **undo poe enable** command on the interface to which the PD is connected.

Precautions

The device only supports PoE power supply on downlink interfaces and does not support PoE power supply on uplink interfaces.

Example

Disable the PoE function on GigabitEthernet0/0/3.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/3
[HUAWEI-GigabitEthernet0/0/3] undo poe enable
```

3.6.11 poe fast-on enable

Function

The **poe fast-on enable** command enables fast power-on for a PoE interface.

The **undo poe fast-on enable** command disables fast power-on for a PoE interface.

By default, fast power-on is disabled on a PoE interface.

NOTE

Only the S5720-28X-PWH-LI-AC, S5720-16X-PWH-LI-AC, S5720I-12X-PWH-SI-DC, S5735S-H, S5736-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5731-H, S5731S-H, S5731-S, S5731S-S, and S5732-H support this command.

Format

poe fast-on enable

undo poe fast-on enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a PoE switch is powered off and then restarts, interfaces on this device can be powered on again only after a certain period. As a result, PDs connected to these interfaces are powered off within this period. To shorten the time during which the PDs are powered off, you can run the **poe fast-on enable** command on the PoE switch. After the PoE switch is powered off and then restarts, PoE interfaces can rapidly resume power supply to PDs.

Precautions

- This command takes effect only during cold startup of the device.
- The **poe fast-on enable** command does not generate any configuration but always takes effect after being executed until the **undo poe fast-on enable** command is executed. To determine whether the fast power-on configuration takes effect, run the **display poe power-state** command to check the **fast-on** field.

Example

Enable fast power-on for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe fast-on enable
Warning: This configuration takes effect only after a cold restart. Continue?[Y/N]:y
Warning: Ensure that the power required by the connected PD does not exceed the rated PoE power
provided by the device. Otherwie, the device may not start normally. Continue?[Y/N]:y
```

Disable fast power-on for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo poe fast-on enable
Warning: This configuration takes effect only after a cold restart. Continue?[Y/N]:y
```

3.6.12 poe force-power

Function

The **poe force-power** command enables forcible powering on a PoE interface.

The **undo poe force-power** command disables forcible powering on a PoE interface.

By default, forcible powering is disabled on a PoE interface.

Format

poe force-power

undo poe force-power

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the power of the system is sufficient, you can run the **poe force-power** command on the interface connected to PDs when the PSE cannot detect the PDs.

Precautions

After the power supply mode of an interface is set to PoE++ using the **poe bt-inrush enable** command, the **poe force-power** command does not take effect on this interface.

The **poe force-power** command and the **poe legacy enable** command are mutually exclusive. When configured on the same interface, the later configured command takes effect and the earlier configured command is cleared.

If the interface connects to a non-PD device, configuring forcible powering on the interface may damage the non-PD device. Exercise caution when using the **poe force-power** command. After forcible powering is configured on a PoE switch, you must delete the forcible powering configuration from the switch if you need to remove the switch from the current networking environment and deploy it in a new networking environment.

Example

Enable forcible powering on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe force-power
Warning: Is there a valid PD connected to this interface? Yes or No?[Y/N]:y
```

3.6.13 poe group management enable

Function

The **poe group management enable** command enables a PoE device's group management of PDs.

The **undo poe group management enable** command disables a PoE device's group management of PDs.

By default, a PoE device's group management of PDs is disabled.

NOTE

Among PoE models, the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5731-H, S5731-S, S5731-S24UN4X2Q, S5731-S8UM16UN2Q, S5731S-S24UN4X2Q-A, S5731S-S8UM16UN2Q-A, S5736-S24UM4XC, and S5731S-S do not support this command.

Format

poe group management enable

undo poe group management enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Powering on some PDs may affect other PDs, causing other PDs unable to be detected by a PoE device. After group management of PDs is enabled, a PoE device can detect PDs on a per-group basis and power on these PDs in a batch.

Precautions

- To support a PoE device's group management of PDs, every four interfaces on the left are added to one group. For example, interfaces numbered 1 to 4 or numbered 5 to 8 can be added to one group, but interfaces numbered 2 to 5 cannot. That is, the number of the last interface in each group must be the multiple of 4. If the **poe group management enable** command is configured on any interface in a group, this command is also delivered to the other three interfaces in the same group.

- After group management of PDs is configured on an interface, the other interfaces in the same group use the same power supply priority as this interface and this priority is lower than that of other interfaces that are not added to any group. If some interfaces have this group management function configured, the PoE interface power supply priority configured using the **poe priority** command does not take effect on these interfaces.

Example

Enable group management of PDs on PoE interfaces GE0/0/1 through GE0/0/4.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe group management enable
Info: 'Poe group management enable' will be executed on interface GigabitEthernet0/0/1 to
GigabitEthernet0/0/4. Continue?[Y/N]: y
```

3.6.14 poe high-inrush enable

Function

The **poe high-inrush enable** command configures an interface to allow generation of the high pulse current during power-on.

The **undo poe high-inrush enable** command configures an interface not to allow generation of the high pulse current during power-on.

By default, interfaces do not allow generation of the high pulse current during power-on.

Format

poe high-inrush enable [**slot** *slot-id*]

undo poe high-inrush enable [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

High inrush current is generated when a non-standard PD is powered on. In this case, the PSE cuts off the power of the PD to protect itself. If the PSE is required to provide power for the PD, the PSE must allow high inrush current. The high inrush current may damage device components.

Example

Enable the device to allow generation of the high pulse current during power-on.

```
<HUAWEI> system-view
[HUAWEI] poe high-inrush enable
```

3.6.15 poe { power-off | power-on } interface

Function

The **poe** { **power-off** | **power-on** } **interface** command manually powers on or powers off the PD of an interface.

NOTE

Among PoE models, the S5720-16X-PWH-LI-AC, S5720-28X-PWH-LI-AC, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, and S5732-H do not support this command.

Format

poe { **power-off** | **power-on** } **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
power-off	Powers off an interface.	-
power-on	Powers on an interface.	-
interface-type interface-number	Specifies the type and number of the interface that needs to be powered on or powered off manually.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

By default, a PoE device works in automatic power management mode. After a PD is connected to a PoE device, the PoE device automatically provides power for the PD.

After you run the **poe power-management** command to configure the power management mode of a PoE device to manual, the PoE device does not automatically provide power for PDs when PDs are connected to the PoE device. You need to run the **poe power-on interface** command to manually power on the interfaces of the PoE device. Check whether the interface is powered on based on the Power ON/OFF field in the **display poe power-state** command.

Precautions

When the available power of the device is insufficient and the device cannot provide power for a new PD, the **poe power-on interface** command is invalid.

Pre-configuration Tasks

Before powering on or powering off an interface, ensure that:

- The power management mode has been in manual mode through running the **poe power-management** command.
- PDs have been connected to the interface.
- The PoE function of the interface has been enabled.
- The classification of the PDs connected to the interface has finished and the PDs have been ready for being powered on.

Example

Manually power on PDs connected to GigabitEthernet 0/0/1.

```
<HUAWEI> system-view
[HUAWEI] poe power-management manual
[HUAWEI] poe power-on interface gigabitethernet 0/0/1
```

3.6.16 poe legacy enable

Function

The **poe legacy enable** command enables the power sourcing equipment (PSE) to check the compatibility of power devices (PDs).

The **undo poe legacy enable** command disables the PSE from checking the compatibility of PDs.

By default, the PSE does not check the capability of PDs.

Format

poe legacy enable

undo poe legacy enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the switch is enabled to check the compatibility of PDs, the switch can detect and provide power to the PDs that do not comply with the 802.3af or 802.3at standard or the standard PDs that are detected as non-standard PDs because of the external environment. If compatibility check is disabled, the switch cannot provide power to the non-standard PDs.

After interfaces are enabled to check the compatibility of PDs, the interfaces can provide power to both standard and non-standard PDs. This configuration does not affect the power supply of standard PDs. That is, the interfaces can still provide power to standard PDs after the **poe legacy enable** command is configured.

Precautions

After the power supply mode of an interface is set to PoE++ using the **poe bt-inrush enable** command, the **poe legacy enable** command does not take effect on this interface.

The **poe force-power** command and the **poe legacy enable** command are mutually exclusive. When configured on the same interface, the later configured command takes effect and the earlier configured command is cleared.

If the interface is connected to a non-PD device, enabling PD compatibility check may damage this non-PD device. Exercise caution when you use this command. After enabling PD compatibility check on a PoE switch, you need to manually disable this function if you need to remove the switch from the current networking environment and deploy it in a new networking environment.

Example

Enable GigabitEthernet0/0/1 to check the compatibility of the PD.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe legacy enable
```

3.6.17 poe lldp-proxy

Function

The **poe lldp-proxy** command configures a 10GE optical port as a proxy for a MultiGE electrical port to perform LLDP negotiation.

The **undo poe lldp-proxy** command restores the default configuration.

By default, a 10GE optical port does not act as a proxy for a MultiGE electrical port to perform LLDP negotiation.

NOTE

Only the S5732-H48XUM2CC supports this command.

Format

poe lldp-proxy interface multige *interface-number*

undo poe lldp-proxy

Parameters

Parameter	Description	Value
interface multige *interface-number*	Specifies the number of a MultiGE electrical port.	It must be a MultiGE electrical port on the panel of an S5732-H48XUM2CC switch.

Views

XGE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hybrid optical/electrical cables integrate optical fibers and electrical cables and are used to connect S5732-H48XUM2CC switches to APs. Hybrid optical/electrical cables are often used in the following scenarios:

- One end of the RJ45 cable in a hybrid optical/electrical cable is connected to a MultiGE electrical port of a switch, and the other end is connected to the RJ45 power receiving port of an AP. The RJ45 cable is used only for the switch to provide PoE power supply for the AP and does not transmit data.
- One end of the optical fiber in a hybrid optical/electrical cable is connected to a 10GE optical port on a switch, and the other end is connected to an uplink

10GE optical port on an AP. The optical fiber is used for data transmission between the switch and AP.

Since the MultiGE electrical port connected to a hybrid optical/electrical cable stays in the **down** state, to use LLDP to negotiate the power supply capability, you must run the **poe lldp-proxy** command to configure the 10GE optical port on the switch connected to the hybrid optical/electrical cable as a proxy for the MultiGE electrical port to perform LLDP negotiation.

Precautions

- LLDP must be enabled on the 10GE optical port connected to a hybrid optical/electrical cable. This function is enabled by default.
- If an AP requires PoE++ power supply, run the **poe legacy enable** command on the 10GE optical port connected to a hybrid optical/electrical cable to enable compatibility check.

Example

Configure the 10GE 0/0/1 optical port as a proxy for the MultiGE 0/0/1 electrical port to perform LLDP negotiation.

```
<HUAWEI> system-view
[HUAWEI] interface XGigabitEthernet 0/0/1
[HUAWEI-XGigabitEthernet0/0/1] poe lldp-proxy interface MultiGE 0/0/1
```

3.6.18 poe max-power

Function

The **poe max-power** command sets the maximum output power of the device.

The **undo poe max-power** command restores the default maximum output power of the device.

By default, the maximum output power of a device is the power actually provided by the device. Therefore, the configured maximum output power must be lower than or equal to the total power of PoE power modules. On the S5720I-12X-PWH-SI-DC, the default maximum output power is 220000 mW, and the supported maximum output power is 240000 mW. On the S5720I-10X-PWH-SI-AC, the default maximum output power is 175000 mW. When the 110 V voltage is input, the maximum output power is 175000 mW. When the input voltage is 220 V, the maximum output power is 200000 mW.

Format

poe max-power *max-power* [**slot** *slot-id* [**mcu** *mcu-id*]]

undo poe max-power *max-power* **slot** *slot-id*

undo poe max-power [**slot** *slot-id* [**mcu** *mcu-id*]]

NOTE

Only the S5720I-28X-PWH-SI-AC supports the **mcu** *mcu-id* parameter.

Parameters

Parameter	Description	Value
max-power	Specifies the maximum output power.	The value is an integer that ranges from 15400 to 2880000, in mW.
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
mcu *mcu-id*	Specifies an MCU ID.	The value is 1 or 2.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a stack, if no stack ID is added to the **poe max-power** command, this command sets the maximum output power of all stack member switches.

Precautions

- If the configured maximum output power is lower than the total power required by PDs, lower-priority PDs will be powered off or cannot be powered on manually.
- The configured maximum output power of the device must be lower than the remaining PoE power of the device. Otherwise, the configuration does not take effect.

Example

Set the maximum output power of the device with the ID 0 to 45000 mW.

```
<HUAWEI> system-view
[HUAWEI] poe max-power 45000 slot 0
```

3.6.19 poe power

Function

The **poe power** command sets the maximum output power of an interface.

The **undo poe power** command restores the default maximum output power of an interface.

This default value varies depending on interfaces of switches:

- The electrical interface of an S5731-S24UN4X2Q, S5731-S8UM16UN2Q, S5731S-S24UN4X2Q-A, S5731S-S8UM16UN2Q-A, S5736-S24UM4XC, S5736-S24U4XC, S5736-S48U4XC, S5735S-H24U4XC-A, or S5735S-H48U4XC-A: 90000 mW
- The MultiGE interface of an S5720-28X-PWH-LI-AC: 60000 mW; Other electrical interface of an S5720-28X-PWH-LI-AC: 30000 mW
- First 8 electrical interfaces of an S5720I-28X-PWH-SI-AC: 60000 mW; last 16 electrical interfaces of an S5720I-28X-PWH-SI-AC: 30000 mW
- The electrical interface of an S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-PWH-SI-DC, S5720-16X-PWH-LI-AC, or S5732-H: 60000 mW
- The electrical interface of other PoE devices: 30000 mW

Format

poe power *port-max-power*

undo poe power

Parameters

Parameter	Description	Value
port-max-power	Specifies the maximum output power of an interface.	The value is an integer, in mW. - For a electrical interface of S5731-S24UN4X2Q, S5731-S8UM16UN2Q, S5731S-S24UN4X2Q-A, S5731S-S8UM16UN2Q-A, S5736-S24UM4XC, S5736-S24U4XC, S5736-S48U4XC, S5735S-H24U4XC-A, or S5735S-H48U4XC-A, the value ranges from 0 to 90000. - For a MultiGE interface of S5720-28X-PWH-LI-AC, the value ranges from 0 to 60000. For other an electrical interface of S5720-28X-PWH-LI-AC, the value ranges from 0 to 30000. - For the first 8 electrical interfaces of an S5720I-28X-PWH-SI-AC, the value ranges from 0 to 60000. For the last 16 electrical interfaces of an S5720I-28X-PWH-SI-AC, the value ranges from 0 to 30000. - For an electrical interface of S5720I-6X-PWH-SI-AC, S5720I-10X-PWH-SI-AC, S5720I-12X-PWH-SI-DC, S5720-16X-PWH-LI-AC, S5732-H, or the value ranges from 0 to 60000.

Parameter	Description	Value
		- For electrical interfaces of other PoE devices, the value ranges from 0 to 30000.

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

The PD negotiation power may be different from the power required by some non-standard PDs or PDs that cannot be classified. You can run the **poe power** command to set the maximum output power of the interface, which prevents power overload for PDs and saves energy.

Prerequisites

The PoE function has been enabled on the interface using the **poe enable** command.

Example

Set the maximum output power on GigabitEthernet0/0/1 to 15400 mW.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe power 15400
```

3.6.20 poe power auto-neg enable

Function

The **poe power auto-neg enable** command enables power auto-negotiation for interfaces.

The **undo poe power auto-neg enable** command disables power auto-negotiation for interfaces.

By default, power auto-negotiation is disabled for interfaces.

NOTE

Among PoE models, only the S5731-H(except S5731-H48HB4XZ and S5731-H24HB4XZ), S5731-S, S5731S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5720-12TP-PWR-LI-AC, S5720-28TP-PWR-LI-AC, S5720-28TP-PWR-LI-ACL, S5720-28P-PWR-LI-AC, S5720-52P-PWR-LI-AC, S5720-28X-PWR-LI-AC, S5720-28X-PWR-LI-ACF, S5720-52X-PWR-LI-AC, S5720-52X-PWR-LI-ACF, S5720S-12TP-PWR-LI-AC, S5720S-28TP-PWR-LI-ACL, S5720S-28P-PWR-LI-AC, S5720S-52P-PWR-LI-AC, S5720S-28X-PWR-LI-AC, and S5720S-52X-PWR-LI-AC support this command.

Format

poe power auto-neg enable

undo poe power auto-neg enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch supplies power to the APs connected to interfaces in compliance with IEEE 802.3at (the maximum output power is 30 W). Some APs support both IEEE 802.3at and 802.3af. The switch can supply power to these APs in accordance with IEEE 802.3af (the maximum output power is 15.4 W). When the APs connected to the switch support both IEEE 802.3at and 802.3af, enable power auto-negotiation on the interfaces connected to these APs. When the total available power of the switch is less than 30 W and the switch detects that the current power supply standards of an AP are IEEE 802.3at, the switch can send an LLDP packet to the AP to enable the AP to set its power supply standards to IEEE 802.3af. Power auto-negotiation changes only the power supply standards of APs but not the interfaces to which the APs are connected.

Enabling power auto-negotiation on interfaces will change the power supply standards of the APs connected to the interfaces, reduce the power consumption of the APs, and enable the switch to supply power to more APs when the rated output power of the switch is fixed.

Precautions

- The **poe power auto-neg enable** command is mutually exclusive with the **lldp dot3-tlv power 802.1ab force** and **lldp dot3-tlv power 802.3at** commands and cannot be configured together.
- When the total available power of the switch is less than 30 W, the power supply standards of all the APs connected to the interfaces that have power

auto-negotiation enabled will be set to IEEE 802.3af. When the total available power of the switch is more than the larger value of 60 W and reserved power, the power supply standards of the APs connected to the interfaces will be restored to IEEE 802.3at based on the power supply priority configured on the interfaces. That is, the power supply standards of the AP connected to the interface with a higher priority are restored to IEEE 802.3at. If the power supply priority of these interfaces is the same, the power supply standards of the AP connected to the interface with a smaller interface number are restored to IEEE 802.3at first.

- Disabling power auto-negotiation on an interface will restore the power supply standards of the AP connected to the interface to IEEE 802.3at. This operation will power off the APs connected to some interfaces if the total power of the switch is insufficient.

Example

Enable power auto-negotiation on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe power auto-neg enable
Warning: This operation will enable PoE power auto-negotiation of the port, which will change the power-
up mode of the PD connected to the port from AT to AF in case of insufficient power. Continue?[Y/N]:y
```

3.6.21 poe power-management

Function

The **poe power-management** command sets the power management mode of the device.

The **undo poe power-management** command restores the default power management mode of the device.

By default, the device uses the automatic power management mode.

NOTE

Among PoE models, the S5720-16X-PWH-LI-AC, S5720-28X-PWH-LI-AC, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, and S5732-H do not support this command.

Format

poe power-management { **auto** | **manual** } [**slot** *slot-id*]

undo poe power-management { **auto** | **manual** } **slot** *slot-id*

undo poe power-management [**slot** *slot-id*]

Parameters

Parameter	Description	Value
auto	Specifies the power management mode to automatic mode.	-
manual	Specifies the power management mode to manual mode.	-
slot *slot-id*	Specifies the slot ID.	The value range depends on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

In automatic power management mode, the device first provides power for the interfaces with higher priority and powers off the interfaces of lower priority when the power is insufficient. When the power is sufficient, all interfaces connected to PDs are powered on. To stop providing power for some interfaces, run the **undo poe enable** command to disable the PoE function on the interfaces. If the PoE function is enabled and disabled frequently, faults may occur on the interfaces. To prevent the faults, you can set the power management mode to manual mode. In manual mode, the power-on and power-off of an interface are controlled manually and not affected by the interface power priority.

Precautions

- If all the interfaces are of the same priority, the power supply priority of the interface with a smaller interface number is higher in automatic mode.
- You can view the power management mode by running the **display poe information** command.

Follow-up Procedures

After setting the power management mode to manual, you need to run the **poe { power-off | power-on } interface** command to manually power on or off the PDs connected to interfaces of the device. If the device restarts after being powered off, you need to run the **power-on** command on the interfaces again to power on the PDs connected to the interfaces. If the device restarts without being powered off, you do not need to run the **power-on** command on the interfaces again to power on the PDs.

Example

Set the power management mode of a device to automatic mode.

```
<HUAWEI> system-view
[HUAWEI] poe power-management auto slot 0
```

3.6.22 poe power-off time-range

Function

The **poe power-off time-range** command makes a configured PoE power-off time range effective on an interface.

The **undo poe power-off time-range** command cancels the configuration.

By default, a device is not configured with PoE power-off time range.

Format

poe power-off time-range *time-range-name*

undo poe power-off time-range

Parameters

Parameter	Description	Value
time-range-name	Specifies a name for a PoE power-off time range.	The value is a string of 1 to 32 case-sensitive characters and must begin with a letter. In addition, the word all cannot be specified as a time range name.

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **poe power-off time-range** command makes a PoE power-off time range set in the system view effective on an interface. If the current time is within the specified time range, the PD connected to the interface cannot be powered on.

The **undo poe power-off time-range** command cancels the configuration. The time range does not take effect on the PD connected to the interface; however, the configuration of the time range is still saved.

Pre-configuration Tasks

Before running the **poe power-off time-range** command, you must ensure a PoE power-off time range has been configured through running the **time-range** command in the system view.

Example

Configure a PoE power-off time range from 10:00 to 11:00 for PDs connected to GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] time-range PoE 10:00 to 11:00 daily
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe power-off time-range PoE
```

3.6.23 poe power-on delay

Function

The **poe power-on delay** command sets the PoE power supply delay on an interface.

The **undo poe power-on delay** command restores the default PoE power supply delay on an interface.

By default, the PoE power supply delay is 0. That is, the PoE power supply is not delayed.

Format

poe power-on delay *delay-time*

undo poe power-on delay

Parameters

Parameter	Description	Value
delay-time	Specifies the PoE power supply delay.	The value is an integer that ranges from 1 to 60, in seconds.

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maintain current of the used PD is insufficient at the power-on moment, so the PoE switch considers that the PD has been disconnected and powers it off.

IEEE standards require that a PD must maintain a current value of more than 10 mA for at least 75 ms in each 325 ms duration. Otherwise, the PoE switch considers that the PD has left and powers off the PD.

To enable the PoE switch to power these non-standard PDs, set the PoE power supply delay on the appropriate interfaces of the switch so that the switch detects the maintain power of the PDs after the specified delay.

Precautions

After the PoE power supply delay is configured on an interface, do not replace the PD connected to this interface within the delay. Otherwise, the new PD cannot work properly.

Example

Set the PoE power supply delay to 5 seconds on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe power-on delay 5
```

3.6.24 poe power-reserved

Function

The **poe power-reserved** command sets the percentage of the reserved PoE power against the total PoE power.

The **undo poe power-reserved** command restores the default percentage of the reserved PoE power against the total PoE power.

By default, the percentage of the reserved PoE power against the total PoE power is 20%.

Format

poe power-reserved *power-reserved* [**slot** *slot-id* [**mcu** *mcu-id*]]

undo poe power-reserved *power-reserved* **slot** *slot-id*

undo poe power-reserved [**slot** *slot-id* [**mcu** *mcu-id*]]

NOTE

Only the S5720I-28X-PWH-SI-AC supports the **mcu** *mcu-id* parameter.

Parameters

Parameter	Description	Value
power-reserved	Specifies the percentage of the reserved PoE power against the total PoE power.	The value is an integer that ranges from 0 to 100, in percentage. The default value is 20.

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
mcu *mcu-id*	Specifies an MCU ID.	The value is 1 or 2.

2: Configuration level

Usage Guidelines

Usage Scenarios

The device can dynamically allocate power to each interface according to the power consumption of each interface. The power consumption of a PD keeps changing when the PD is running. The system periodically calculates the total power consumption of all the PDs. If the total power consumption exceeds the upper threshold of the device, the system powers off the PDs on the interfaces of low priority. If interfaces have the same priority, the system powers off the PD on the interface with a larger port number.

Sometimes, however, the power consumption increases sharply and the available power of the system cannot support the burst increase of power. At this time, the system has not calculated and found that the total power consumption exceeded the upper threshold; therefore, the system does not cut off power low-priority interfaces in time. As a result, the PoE power supply is shut down for overload protection, and all PDs are powered off.

This problem can be solved by running the **poe power-reserved** command to set proper reserved power. When there is a burst increase in power consumption, the reserved power can support the system running. Then the system has time to power off interfaces of low priority to ensure stable running of other PDs.

Precautions

- The reserved power should not be set greater than 20%. If the reserved PoE power is greater than 20% of the total PoE power, the power capacity of the device is affected.
- To set the maximum output power of a device, run the **poe max-power** command. In this case, the device calculates the reserved power based on the set maximum output power. If the maximum output power is not set, the available PoE power is the power provided by the PoE power module.

Example

Set the percentage of reserved PoE power to the total PoE power to 30%.

```
<HUAWEI> system-view
[HUAWEI] poe power-reserved 30
Warning: The power for new PDs connected to slot 0 may be insufficient after this operation is performed.
Continue?[Y/N]:y
```

3.6.25 poe power-threshold

Function

The **poe power-threshold** command sets the alarm threshold of the PoE power consumption percentage.

The **undo poe power-threshold** command restores the default alarm threshold of the PoE power consumption percentage.

By default, the alarm threshold is 90%. That is, an alarm is generated when the consumed power accounts for 90% of the total power.

Format

poe power-threshold *threshold-value* [**slot** *slot-id* [**mcu** *mcu-id*]]

undo poe power-threshold *threshold-value* **slot** *slot-id*

undo poe power-threshold [**slot** *slot-id* [**mcu** *mcu-id*]]

NOTE

Only the S5720I-28X-PWH-SI-AC supports the **mcu** *mcu-id* parameter.

Parameters

Parameter	Description	Value
threshold-value	Specifies the alarm threshold of the PoE power consumption percentage. When the power consumption reaches this value, a PoE power alarm is generated.	The value is an integer that ranges from 0 to 100, in percentage. The default value is 90.
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
mcu *mcu-id*	MCU ID	The value is an integer ranging from 1 to 2.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **poe power-threshold** command sets the alarm threshold of the PoE power consumption percentage. If the total PoE power is 369.6 W and the alarm threshold is 90%, an alarm is generated when the power consumption is greater than 332.64 W. When the power consumption falls below 332.64 W, the alarm is cleared.

Example

Set the alarm threshold of the PoE power consumption percentage to 80%.

```
<HUAWEI> system-view
[HUAWEI] poe power-threshold 80
```

3.6.26 poe priority

Function

The **poe priority** command sets the power priority of a PoE interface.

The **undo poe priority** command restores the default power priority of a PoE interface.

By default, the power supply priority of an interface is **low**.

Format

poe priority { **critical** | **high** | **low** }

undo poe priority

Parameters

Parameter	Description	Value
critical	Indicates the highest priority.	-
high	Indicates the second highest priority.	-
low	Indicates the lowest priority.	-

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

When the output power of a device is insufficient, the device in automatic power management mode provides power for the interfaces of the higher power supply priorities first and cuts off power of the interfaces of the lower power supply priorities. PoE switches provide power to PDs connected to the interfaces in the sequence in which PDs are connected to them.

Example

Set the power supply priority of GigabitEthernet0/0/1 to critical.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe priority critical
```

3.6.27 poe-power backup-mode

Function

The **poe-power backup-mode** command sets the PoE power supply mode to the backup mode.

The **undo poe-power backup-mode** command restores the PoE power supply mode to the high-power mode.

By default, the PoE power supply mode is the high-power mode.

NOTE

Only the S5720I-28X-PWH-SI-AC supports this command.

Format

poe-power backup-mode *backup-mode* [**slot** *slot-id*]

undo poe-power backup-mode [**slot** *slot-id*]

Parameters

Description	Description	Value
backup-mode	Specifies the backup mode of PoE power supplies.	The value can only be 1.

Description	Description	Value
slot *slot-id*	Specifies a slot ID. If this parameter is not specified in Stack, only the PoE power supply mode of the master switch is modified.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The S5720I-28X-PWH-SI-AC has two built-in power modules, which support two PoE power supply modes:

- High-power mode (default): When two power modules are used, they provide 369.6 W PoE power for the first 8 electrical ports and last 16 electrical ports respectively, and the system provides 739.2 W PoE power. If one of the two power modules is faulty, the first 8 electrical interfaces provide power normally, but the PDs connected to the last 16 electrical ports are powered off and the PoE function becomes unavailable on the last 16 electrical ports. When only one power module is used, only the first 8 electrical interfaces can provide PoE power.
- PoE backup mode: The PoE power supply mode can be manually set to the backup mode using the **poe-power backup-mode** command. The backup mode provides 1+1 redundancy. In backup mode, the system provides 369.6 W PoE power, regardless of whether one or two power modules are used. The 369.6 W PoE power is shared by 24 electrical ports. Setting the PoE power supply mode to the backup mode can improve system stability.

Precautions

Changing the PoE power supply mode will power off the PDs connected to all ports.

Example

Set the PoE power supply mode to the backup mode.

```
<HUAWEI> system-view
[HUAWEI] poe-power backup-mode 1
```

3.6.28 poe single-class enable

Function

The **poe single-class enable** command configures the single-class power supply mode for an interface.

The **undo poe single-class enable** command restores the standard hierarchical power supply mode for an interface.

By default, an interface works in standard hierarchical power supply mode.

NOTE

Format

poe single-class enable

undo poe single-class enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a PoE interface works in standard hierarchical power supply mode. If PoE interfaces provide power to non-standard PDs in standard hierarchical power supply mode, these PDs cannot initiate power requests using LLDP or CDP and can only obtain a low power. As a result, these PDs cannot work normally. To address this issue, run the **poe single-class enable** command to configure the single-class power supply mode for PoE interfaces. These non-standard PDs can then initiate power requests and obtain the standard power supply to work normally.

Precautions

- If a standard PD is connected to the interface, this PD may be unable to work normally after the **poe single-class enable** command is run.
- On the S5720-16X-PWH-LI-AC, S5720-28X-PWH-LI-AC, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-S, and S5732-H, the **poe af-inrush enable** and **poe single-class enable** commands are mutually exclusive and cannot be configured on the same interface.

Example

Configure the single-class power supply mode for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] poe single-class enable
```

3.6.29 reset poe slot

Function

The **reset poe slot** command resets the PoE chip in a specified slot.

NOTE

Only the S5720-LI, S5731-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S-I, S500, and S5735-S support this command.

Format

reset poe { **all chips** | **chip** *chip-id* } **slot** *slot-id*

Parameters

Parameter	Description	Value
all chips	Specifies all PoE chips.	-
chip *chip-id*	Specifies a chip ID.	The value must be set according to the device configuration.
slot-id	Specifies a slot ID.	The value must be set according to the device configuration.

Views

All views

Default Level

3: Management level

Usage Guidelines

If one or multiple PoE chips of a PSE are suspended, the port connected to a PD cannot detect the suspension and fails power the PD. In this case, you can run the **reset poe** { **all chips** | **chip** *chip-id* } **slot** *slot-id* command to reset the PoE chip.

Example

Reset PoE chip 0 in slot 1.

```
<HUAWEI> reset poe chip 0 slot 1
Warning: This command will cause power cycling for the PD connected to port 1,2,3,4. Continue? [Y/N]:y
```

3.7 Monitoring Interface Configuration Commands

3.7.1 Command Support

Only the following switch models support monitoring interfaces:

S5720I-SI (excluding the S5720I-6X-PWH-SI-AC and S5720I-10X-PWH-SI-AC), S5735-S-I

3.7.2 display monitor input

Function

The **display monitor input** command displays the status of an input line connected to a monitoring interface.

NOTE

Only the S5735-S-I supports this command.

Format

display monitor input { *line-id* | **all** } [**slot** *slot-id*]

Parameters

Parameter	Description	Value
line-id	Displays the status of the specified input line.	The value is an integer that ranges from 1 to 2.
all	Displays the status of all input lines.	-
slot *slot-id*	Specifies the stack ID if stacking is configured.	The value is determined based on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display monitor input** command to check the status of an input line connected to a monitoring interface, including the name, the normal level, and the current status of the input line, and whether the monitoring function is enabled.

Example

Display the current status of all input lines.

```
<HUAWEI> display monitor input all

--------------------------------------------------------------------------
LineID  LineName                   Enable  NormalStatus  CurrentStatus
--------------------------------------------------------------------------
1       Input1                     enable  low-level     abnormal
2       Input2                     enable  high-level    normal
--------------------------------------------------------------------------
```

Table 3-130 Description of the display monitor input command output

Item	Description
LineID	ID of the input line connected to a monitoring interface.
LineName	Name of the input line connected to a monitoring interface. To set the name, run the **monitor input** command.
Enable	Whether an input line connected to a monitoring interface is enabled. To set the parameter, run the **monitor input enable** command.
NormalStatus	Normal level of an input line connected to a monitoring interface: ● low-level: The normal level is low level. ● high-level: The normal level is high level. To set the normal level, run the **monitor input** command.
CurrentStatus	Current status of an input line connected to a monitoring interface: ● normal: The input line is in normal state. ● abnormal: The input line is abnormal state.

3.7.3 display monitor output

Function

The **display monitor output** command displays the status of an output line connected to a monitoring interface.

NOTE

Only the S5735-S-I supports this command.

Format

display monitor output { *line-id* | **all** }

Parameters

Parameter	Description	Value
line-id	Displays the status of a specified output line.	The value is 1.
all	Displays the status of all output lines.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **monitor output enable** or **undo monitor output enable** command, you can run the **display monitor output** command to check the status of an output line connected to a monitoring interface, including line ID, the initial status of the monitoring function on the output line, and the current status of the monitoring function on the output line. If the initial status of the monitoring function on the output line is the same as the current status, the maintenance compartment door is closed. If they are inconsistent, the maintenance compartment door is opened.

Example

Display the status of all output lines.

```
<HUAWEI> display monitor output all
----------------------------------
LineID  Config  Current Keeptime(s)
----------------------------------
1       enable  enable  3
----------------------------------
```

Table 3-131 Description of the **display monitor output** command output

Item	Description
LineID	ID of the output line connected to a monitoring interface.

Item	Description
Config	Initial status of the monitoring function on the output line. - enable: The **monitor output enable** command is run. - disable: The **undo monitor output enable** command is run.
Current	Current status of the monitoring function on the output line. If the value of this field is the same as that of **Config**, the maintenance compartment door is closed. If they are inconsistent, the maintenance compartment door is opened.
Keeptime(s)	Hold time of the signals indicating the maintenance compartment door is open or closed when the monitoring function on the output line connecting to a monitoring interface is enabled. The unit is second.

3.7.4 monitor input

Function

The **monitor input** command configures the name and normal level of the input lines connected to a monitoring interface.

The **undo monitor input** command restores the name and normal level of the input lines connected to a monitoring interface to default value.

By default, the name of a monitored input line is **Input1** or **Input2**. The normal level is **low-level**.

NOTE

Only the S5735-S-I supports this command.

Format

monitor input *line-id* **name** *line-name* **normal-state** { **low-level** | **high-level** } [**slot** *slot-id*]

undo monitor input *line-id* [**slot** *slot-id*]

Parameters

Parameter	Description	Value
line-id	Specifies the ID of an input line.	The value is an integer that ranges from 1 to 2.
name *line-name*	Specifies the name of an input line.	The name is a string of 1 to 31 case-sensitive characters without spaces.
normal-state { **low-level** | **high-level** }	Specifies the normal level of input lines connected to a monitoring interface. ● **low-level**: indicates that the normal level is low level. ● **high-level**: indicates that the normal level is high level.	-
slot *slot-id*	Specifies the stack ID if stacking is configured.	The value is determined based on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run the **monitor input** command to configure the name and normal level of the input lines connected to a monitoring interface. When the level of the input line changes, the device generates an alarm.

Example

Configure the name of input line 1 as line1 and normal level as **high-level**.

```
<HUAWEI> system-view
[HUAWEI] monitor input 1 name line1 normal-state high-level
```

3.7.5 monitor input enable

Function

The **monitor input enable** command enables the monitoring function on an input line.

The undo monitor input enable command disables the monitoring function on an input line.

By default, the monitoring function on an input line is disabled.

NOTE

Only the S5735-S-I supports this command.

Format

monitor input *line-id* **enable** [**slot** *slot-id*]

undo monitor input *line-id* **enable** [**slot** *slot-id*]

Parameters

Parameter	Description	Value
line-id	Specifies the ID of an input line.	The value is an integer that ranges from 1 to 2.
slot *slot-id*	Specifies the stack ID if stacking is configured.	The value is determined based on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You can run the **monitor input enable** command to enable the monitoring function on an input line so that you can monitor the application environment of the device.

Example

Enable the monitoring function on input line 1.

```
<HUAWEI> system-view
[HUAWEI] monitor input 1 enable
```

3.7.6 monitor output enable

Function

The **monitor output enable** command configures the initial status of the monitoring function on an output line connected to a monitoring interface to enabled.

The **undo monitor output enable** command configures the initial status of the monitoring function on an output line connected to a monitoring interface to disabled.

By default, the initial status of the monitoring function on an output line is not configured.

NOTE

Only the S5735-S-I supports this command.

Format

monitor output *line-id* **enable slot** *slot-id*

undo monitor output *line-id* **enable slot** *slot-id*

Parameters

Parameter	Description	Value
line-id	Specifies the ID of an output line.	The value is 1.
slot *slot-id*	Specifies the slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After the **monitor output enable** command is run, the initial status of the monitoring function on an output line (DOUT status for short) is configured to enabled. If the maintenance compartment door is opened, the DOUT status changes to disabled. If the maintenance compartment door is closed, the DOUT status changes to enabled. You can monitor whether the maintenance compartment door is opened based on the DOUT status.

Similarly, after the **undo monitor output enable** command is run, the initial DOUT status is configured to disabled. If the maintenance compartment door is opened, the DOUT status changes to enabled. If the maintenance compartment door is closed, the DOUT status changes to disabled.

Example

Configure the initial status of the monitoring function on output line 1 to enabled.

```
<HUAWEI> system-view
[HUAWEI] monitor output 1 enable slot 0
```

3.7.7 monitor output keeptime

Function

The **monitor output keeptime** command sets the hold time of the signals indicating the maintenance compartment door on a device is open or closed when the monitoring function on the output line connecting to a monitoring interface is enabled.

The **undo monitor output keeptime** command restores the default setting.

By default, the hold time of the signals indicating the maintenance compartment door on a device is open or closed is 3 seconds.

NOTE

Only the S5735-S-I supports this command.

Format

monitor output keeptime *time* **slot** *slot-id*

undo monitor output keeptime slot *slot-id*

Parameters

Parameter	Description	Value
time	Specifies the hold time.	The value is an integer ranging from 1 to 3600, in seconds.
slot *slot-id*	Specifies the slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, the hold time of the signals indicating the maintenance compartment door on a device is open or closed is three seconds. That is, a camera keeps monitoring the device maintenance compartment door for 3 seconds and then turns to another direction. You can run the **monitor output keeptime** command to change the hold time based on the actual situation of the camera.

Example

Set the hold time to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] monitor output keeptime 10 slot 0
```

3.8 OPS Configuration Commands

3.8.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.8.2 assistant scheduler suspend

Function

The **assistant scheduler suspend** command disables the OPS maintenance assistant function.

The **undo assistant scheduler suspend** command enables the OPS maintenance assistant function.

By default, the OPS maintenance assistant function is enabled.

Format

assistant scheduler suspend

undo assistant scheduler suspend

Parameters

None

Views

OPS view

Default Level

3: Management level

Usage Guidelines

If the OPS maintenance assistant function is no longer needed, the **assistant scheduler suspend** command applies to the following scenarios:

- Before deleting configured Python script assistants one by one, you can run this command to disable the OPS maintenance assistant function to prevent the assistants from running.

- During system maintenance, you can run this command to disable the OPS maintenance assistant function temporarily.

After you run the **assistant scheduler suspend** command to disable the OPS maintenance assistant function, none of Python script assistants will run again.

Example

Disable the OPS maintenance assistant function.

```
<HUAWEI> system-view
[HUAWEI] ops
[HUAWEI-ops] assistant scheduler suspend
```

3.8.3 display ops assistant

Function

The **display ops assistant** command displays information about Python script assistants.

Format

display ops assistant { **current** [**verbose**] | **history** } [**name** *assistant-name*]

Parameters

Parameter	Description	Value
current	Displays brief information about the current status of Python script assistants.	-
verbose	Displays detailed information about the current status of Python script assistants.	-
history	Displays historical operation records of Python script assistants.	-
name *assistant-name*	Specifies the name of a Python script assistant, namely, a Python script name for a script assistant.	The value must be the name of a script file for which the script assistant has been configured.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can use this command to check the current status and historical operation record of a Python script assistant, including the Python script assistant name, running status, and execution result. The command can display a maximum of 100 latest Python script assistant records.

Example

Display brief information about the current status of Python script assistants.

```
<HUAWEI> display ops assistant current
-----------------------------------------------------
Assistant                   State         Condition
-----------------------------------------------------
subscribe_cli_sync_1.py       ready          cli
user-correlat-10.py          ready         multi
-----------------------------------------------------
```

Table 3-132 Description of the **display ops assistant current** command output

Item	Description
Assistant	Name of a Python script assistant.
State	Current status of the Python script assistant. • ready: The Python script assistant is waiting to be triggered. • pending: The Python script assistant is waiting to run. • waiting: A resident script is waiting to be triggered the second time. • running: The Python script assistant is running. • shutdown: The Python script assistant stops. • suspend: The OPS maintenance assistant function is disabled.

Item	Description
Condition	Triggering condition for a Python script assistant. ● cli: command line event ● device: stack status change event ● iclog: log event ● ifm: interface statistics collection event event ● lldp: LLDP neighbor change event ● multi: complex event ● timer: timer event ● trap: trap event ● URM: routing event

Table 3-133 Description of the **display ops assistant current verbose** command output

Item	Description
Assistant information	Information about a Python script assistant.
Name	Name of a Python script assistant.
State	Current status of a Python script assistant. - ready: The Python script assistant is waiting to be triggered. - pending: The Python script assistant is waiting to run. - waiting: A resident script is waiting to be triggered the second time. - running: The Python script assistant is running. - shutdown: The Python script assistant stops. - suspend: The OPS maintenance assistant function is disabled.
Running statistics	Detailed running information about a Python script assistant.
Running times	Number of running times.
Queue size/(free)	Number of buffered Python script assistants. If the number of buffered Python script assistants reaches the maximum value, excessive assistants will be discarded.
Skip for queue full	Number of tasks discarded because the queue is full.
Skip for delay	Number of tasks discarded within the delay.
Skip for suppression	Number of times the triggering of the assistant is suppressed.
Condition information	Condition information about a Python script assistant. The **Condition information** field is displayed only for a complex event script.
Condition tag	Condition name.
Condition type	Type of triggering condition. The value is **multi**.

Item	Description
Threshold	Maximum number of times that tasks are executed. The default value is 1.
Period (s)	Detection period, in seconds. The default value is 30.
Hits in period	Number of times the triggering condition is met in the detection period.
Correlate expression	Condition combination mode.
Trigger control	Trigger control.
Delay (s)	Delay in triggering a working task. The default value is 0 seconds.
Suppress max	Maximum number of times working tasks are triggered within the delay. The default value is 0, indicating that working tasks will not be suppressed.

Display historical operation records of Python script assistants.

```
<HUAWEI> display ops assistant history
Assistant history information
  Name                          :subscribe_cli_sync_1.py
  Running information
    Trigger condition             :cli
    Trigger event name            :cli1
    Trigger time                  :2017-03-25 19:48:51
    Execute start time            :2017-03-25 19:48:51
    Execute end time              :2017-03-25 19:48:53
    Execute result                :normal
```

Table 3-134 Description of the **display ops assistant history** command output

Item	Description
Assistant history information	Historical information about a Python script assistant.
Name	Name of a Python script assistant.
Running information	Running information about a Python script assistant.

Item	Description
Trigger condition	Triggering condition for a Python script assistant. ● cli: command line event ● device: stack status change event ● iclog: log event ● ifm: interface statistics collection event event ● lldp: LLDP neighbor change event ● multi: complex event ● timer: timer event ● trap: trap event ● URM: routing event
Trigger event name	Trigger event name for a Python script assistant.
Trigger time	Triggering time of a Python script assistant.
Execute start time	Execution time of a Python script assistant.
Execute end time	End time of a Python script assistant.
Execute result	Execution result of a Python script assistant. ● normal: The script assistant ends normally. ● abnormal: An exception occurs in the script. ● userCancel: A user stops the script. ● duplicate: The script file name conflicts with the database file name. ● os: The system kills the script process due to a script exception.

3.8.4 display ops environment

Function

The **display ops environment** command displays information about user-defined environment variables.

Format

display ops environment

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display ops environment** command to check information about user-defined environment variables after user-defined environment variables are configured using the **environment** command.

Example

Display user-defined environment variables.

```
<HUAWEI> display ops environment
No.  Name                          Value
1    user                          admin
```

Table 3-135 Description of the **display ops environment** command output

Item	Description
No.	User-defined environment variable number. The value ranges from 1 to 100.
Name	Name of a user-defined environment variable. To configure this parameter, run the **environment** command.
Value	Value of a user-defined environment variable. To configure this parameter, run the **environment** command.

3.8.5 display ops error

Function

The **display ops error** command displays script execution errors.

Format

display ops error [**name** *assistant-name*]

Parameters

Parameter	Description	Value
name *assistant-name*	Specifies the name of a Python script assistant, namely, a Python script name for a script assistant.	The value must be the name of a script file for which the script assistant has been configured.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to view execution errors of all scripts or a specified script. According to the errors in the command output, you can modify the script.

Example

Display execution errors of all scripts.

```
<HUAWEI> display ops error
--------------------------------------------------------------------------------
test12.py:
Traceback (most recent call last):
  File ".lib/frame.py", line 114, in <module>
    ret = m.ops_execute(ops)
  File "flash:$_user/test12.py", line 7, in ops_execute
    status, err_context = ops.context.save(varName, value)
NameError: global name 'varName' is not defined

--------------------------------------------------------------------------------
test13.py:
Traceback (most recent call last):
  File ".lib/frame.py", line 114, in <module>
    ret = m.ops_execute(ops)
  File "flash:$_user/test13.py", line 6, in ops_execute
    status, err_log = ops.syslog("Syslog: Hello, World..", ops.CRITICAL, "syslog
")
```

```
AttributeError: 'module' object has no attribute 'syslog'

--------------------------------------------------------------------------------
```

Table 3-136 Description of the **display ops error** command output

Item	Description
test12.py	Python script file name.
Traceback (most recent call last)	Last call error.
File ".lib/frame.py", line 114, in <module>	Stack where an error occurs.
File "flash:$_user/test12.py", line 7, in ops_execute	Information about location where an error occurs, including the Python script name, number of line, and phase when the error occurs.
status, err_context = ops.context.save(varName, value)	Invalid contents.
NameError	A variable error. The system is attempting to access a variable that is not declared.
AttributeError	An attribute error. The system is attempting to access an unknown object attribute.

3.8.6 display ops system-script

Function

The **display ops system-script** command displays system built-in OPS scripts.

Format

display ops system-script

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When associating OIDS with OPS, you need to use OPS scripts to subscribe to OIDS events. The device provides built-in OPS scripts, which removing the need to make scripts or download scripts from websites and import the scripts to the device. To view system built-in OPS scripts, run the **display ops system-script** command.

Precautions

The system built-in OPS scripts are not installed by default.

Example

Display system built-in OPS scripts.

```
<HUAWEI> display ops system-script
ScriptName                  Description
------------------------------------------------------------------------------
oids.py                       The OIDS sample script describes the subscriptio
                            n process. The execution result of the script ha
                            s been recorded to OIDS. You can refer to this s
                            cript to implement the OIDS script process.
```

Table 3-137 Description of the **display ops system-script** command output

Item	Description
ScriptName	Name of a script.
Description	Description of the script.

3.8.7 environment

Function

The **environment** command configures a user-defined environment variable.

The **undo environment** command deletes a user-defined environment variable.

By default, no user-defined environment variable is configured.

Format

environment *variable-name variable-value*

undo environment *variable-name*

Parameters

Parameter	Description	Value
variable-name	Specifies the name of a user-defined environment variable.	The value is a string of 1 to 31 case-sensitive characters without spaces. It starts with a letter and contains only letters, digits, and underscores (_).
variable-value	Specifies the value of a user-defined environment variable.	The value is a string of 1 to 64 case-sensitive characters without spaces. If the string is enclosed in double quotation marks (""), the string can contain spaces.

Views

OPS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

An environment variable consists of a name and a value. In a Python script, you can input an environment variable name in the location where a parameter needs to be input to indicate that an environment variable value needs to be referenced. When the system is running a Python script, it replaces an environment variable name with an environment variable value. To change the value, you can directly change it on the device without having to change and install the Python script. You can define and use user-defined environment variables to simplify the configuration and improve flexibility and feasibility of the Python script.

Precautions

If *variable-name* is specified multiple times, the system will prompt that the configured user-defined environment variable already exists. You can choose whether to overwrite the existing variable value. After overwriting the existing variable value, you need to run the **undo script-assistant python** command to delete the Python script assistant that uses the environment variable and then run the **script-assistant python** command to re-configure the Python script assistant.

A maximum of 100 environment variables can be configured on the device.

To check configured user-defined environment variables, run the **display ops environment** command.

Example

Set the value of the user-defined environment variable **user** to **admin**.

```
<HUAWEI> system-view
[HUAWEI] ops
[HUAWEI-ops] environment user admin
```

3.8.8 ops

Function

The **ops** command displays the OPS view.

Format

ops

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

You can configure the Python script assistant in the OPS view.

Example

Display the OPS view.

```
<HUAWEI> system-view
[HUAWEI] ops
[HUAWEI-ops]
```

3.8.9 ops abort

Function

The **ops abort** command stops all OPS Python scripts.

Format

ops abort

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If commands cannot be entered on the switch due to OPS Python script exceptions, run the **ops abort** command to stop all OPS Python scripts to make the switch work properly.

Prerequisites

Running the **ops abort** command on the master switch will not be captured by the CLI event subscription API (ops.cli.subscribe), but running this command on the standby switch will be captured by this API.

Follow-up Procedure

To restore the OPS function, perform the following operations:

1. Run the **system-view** command to enter the system view.
2. Run the **ops** command to enter the OPS view.
3. Run the **undo script-assistant python** *script-name* command to delete the assistant of the abnormal Python script.
4. Run the **return** command to return to the user view.
5. Run the **ops uninstall file** *script-name* command to uninstall the abnormal Python script.
6. Run the **system-view** command to enter the system view.
7. Run the **ops** command to enter the OPS view.
8. Run the **undo assistant scheduler suspend** command to enable the OPS assistant to restore the OPS function.

Example

Stop all OPS Python scripts.

```
<HUAWEI> ops abort
```

3.8.10 ops install file

Function

The **ops install file** command installs a Python script.

Format

ops install file *file-name* [**destination** *directory*]

Parameters

Parameter	Description	Value
file-name	Specifies the directory and file name of the Python script to be installed. ● To install a Python script stored in the root directory of the device, you can directly specify the file name of the script. ● To install a Python script that is stored a non-root directory, you need to specify both the directory and file name of the script.	The value is a string of 4 to 64 case-insensitive characters. Spaces and special characters |, ;, &, $, >, <, `, \, !, \n, and \0 are not allowed. The file name extension of a Python script file is .py.

Parameter	Description	Value
		NOTE *file-name* cannot be set to the name of a built-in Python script file, including ConfigParser.py, copy_reg.py, locale.py, sre.py, Queue.py, decimal.py, macurl2path.py, sre_compile.py, StringIO.py, dis.py, modulefinder.py, sre_constants.py, UserDict.py, dummy_thread.py, ntpath.py, sre_parse.py, UserList.py, dummy_threading.py, nturl2path.py, stat.py, UserString.py, filecmp.py, numbers.py, string.py, __future__.py, fileinput.py, opcode.py, stringold.py, _abcoll.py, fnmatch.py, os.py, struct.py, _pyio.py, formatter.py, os2emxpath.py, subprocess.py, _strptime.py, fractions.py, pickle.py, sysconfig.py, _threading_local.py, functools.py, pkgutil.py, textwrap.py, _weakrefset.py, genericpath.py, platform.py, threading.py, abc.py, getopt.py, posixpath.py, token.py, argparse.py, getpass.py, pprint.py, tokenize.py, atexit.py, gettext.py, re.py, trace.py, base64.py, glob.py, repr.py, traceback.py, bisect.py, heapq.py, runpy.py, types.py, calendar.py, imputil.py, sched.py, user.py, codecs.py, inspect.py, sets.py, warnings.py, collections.py, io.py, shutil.py, weakref.py, contextlib.py, keyword.py, site.py, xmllib.py, copy.py, linecache.py, socket.py, _cli.py, _device.py, _frame.py, _route.py, _timer.py, _common.py, _environment.py, _iclog.py, _snmp.py, _trap.py, _context.py, _farg.py, _lldp.py, _terminal.py, and ops.py.

Parameter	Description	Value
destination *directory*	Specifies the installation directory of a script.	The value is a string of 1 to 64 case-insensitive characters without any spaces. If this parameter is not specified, the script will be installed in $_user. If this parameter is specified, the script will be installed in $_user/*directory*. If the directory name does not exist, a directory will be created. **NOTE** The total length of *file-name* and the installation directory of the script cannot exceed 118. The total length refers to the storage path + $_user + directory name + file name. The installation directory of the script cannot be huawei_pys. The depth of the path specified by *directory* cannot exceed three levels.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

OPS allows you to run the scripts you make. A script can be executed after the script assistant is configured. Before configuring a script assistant, install the script.

To check information about the scripts installed in $_user, run the **dir (user view)** command.

Precautions

- Before installing a script, upload the script to the root directory of flash: on the device.

- Ensure that the device has sufficient storage space when the script is installed. Otherwise, the script fails to be installed.
- If the specified installation directory does not exist, a directory will be created. A maximum of seven levels of subdirectories can be created in $_user.
- The name of the script to be installed cannot be the same as an existing directory name on the device. After scripts are installed successfully, you cannot create a directory whose name is the same as that of an installed script.
- To install scripts in $_user, you can only run the **ops install file** command. The scripts installed in this directory will be automatically backed up to the standby switch when a stack is configured.
- To modify a script that has been installed, run the **ops uninstall file** command to uninstall the script and the **delete (user view)** command to delete the script file. After modifying the script, upload and reinstalling the script file.
- It is recommended that the total size of files installed in $_user be smaller than 100 MB. If the total size of files exceeds 100 MB, performance of data synchronization between the active and standby cards may deteriorate.

Example

Install the script file config.py in the flash: root directory to the default flash:/$_user.

```
<HUAWEI> ops install file config.py
```

Install the script file config.py in the flash: root directory to the specified flash:/$_user/user.

```
<HUAWEI> ops install file config.py destination user
```

Install the script file config.py in the flash:/admin directory to the default flash:/$_user.

```
<HUAWEI> ops install file admin/config.py
```

3.8.11 ops uninstall file

Function

The **ops uninstall file** command uninstalls a Python script.

Format

ops uninstall file *file-name*

Parameters

Parameter	Description	Value
file-name	Specifies the name of the script file to be uninstalled.	The value must be the name of a script file that has been installed. If a script in a specified installation directory *directory*/*file-name* needs to be deleted, *directory* specifies the installation directory of the script. **NOTE** The total length of *file-name* and the installation directory of the script cannot exceed 118. The total length refers to the storage path + $_user + directory name + file name.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can uninstall unnecessary scripts to release storage space on a device. If an installed script needs to be updated, uninstall it first, and reinstall it after the update.

Precautions

This command cannot uninstall a script for which a script assistant has been configured. To uninstall the script, delete the script assistant first.

If the script for which a script assistant has configured invokes another script, the called script can be uninstalled using this command. Therefore, it is recommended that you use one script to implement required functions.

Example

Uninstall the script file config.py in the default directory flash:/$_user.

```
<HUAWEI> ops uninstall file config.py
```

Uninstall the script file config.py in the specified directory flash:/$_user/user.

```
<HUAWEI> ops uninstall file user/config.py
```

3.8.12 script-assistant python

Function

The **script-assistant python** command configures a Python script assistant.

The **undo script-assistant python** command deletes a Python script assistant.

By default, no Python script assistant is configured.

Format

script-assistant python *script-name*

undo script-assistant python *script-name*

Parameters

Parameter	Description	Value
script-name	Specifies the name of a Python script assistant, namely, a Python script name for a script assistant.	The value must be the name of a script file that has been installed.

Parameter	Description	Value
		NOTE *script-name* cannot be set to the file name of a built-in Python script, including ConfigParser.py, copy_reg.py, locale.py, sre.py, Queue.py, decimal.py, macurl2path.py, sre_compile.py, StringIO.py, dis.py, modulefinder.py, sre_constants.py, UserDict.py, dummy_thread.py, ntpath.py, sre_parse.py, UserList.py, dummy_threading.py, nturl2path.py, stat.py, UserString.py, filecmp.py, numbers.py, string.py, __future__.py, fileinput.py, opcode.py, stringold.py, _abcoll.py, fnmatch.py, os.py, struct.py, _pyio.py, formatter.py, os2emxpath.py, subprocess.py, _strptime.py, fractions.py, pickle.py, sysconfig.py, _threading_local.py, functools.py, pkgutil.py, textwrap.py, _weakrefset.py, genericpath.py, platform.py, threading.py, abc.py, getopt.py, posixpath.py, token.py, argparse.py, getpass.py, pprint.py, tokenize.py, atexit.py, gettext.py, re.py, trace.py, base64.py, glob.py, repr.py, traceback.py, bisect.py, heapq.py, runpy.py, types.py, calendar.py, imputil.py, sched.py, user.py, codecs.py, inspect.py, sets.py, warnings.py, collections.py, io.py, shutil.py, weakref.py, contextlib.py, keyword.py, site.py, xmllib.py, copy.py, linecache.py, socket.py, _cli.py, _device.py, _frame.py, _route.py, _timer.py, _common.py, _environment.py, _iclog.py, _snmp.py, _trap.py, _context.py, _farg.py, _lldp.py, _terminal.py, and ops.py.

Views

OPS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

As networks are developing rapidly, existing network devices provide only limited functions and predefined services, failing to meet the requirements for diversified services. You can run the script using OPS to implement customized functions.

The device supports a built-in Python script interpreter. You can run the **script-assistant python** command to run a Python script and register the events defined in the script.

Prerequisites

The script has been uploaded to the device and installed using the **ops install file** command in the user view.

Precautions

Only one assistant can be configured for a Python script. A maximum of 100 Python script assistants can be configured on the device.

The system does not check correctness of the Python script.

If you run the **undo script-assistant python** command to uninstall the script assistant, the corresponding Python script will be terminated.

Example

Configure a script assistant for the script config.py.

```
<HUAWEI> ops install file config.py
<HUAWEI> system-view
[HUAWEI] ops
[HUAWEI-ops] script-assistant python config.py
```

3.8.13 shutdown script-assistant

Function

The **shutdown script-assistant** command stops a Python script assistant.

The **undo shutdown script-assistant** command starts a Python script assistant.

By default, the Python script assistant is started.

Format

shutdown script-assistant *script-name*

undo shutdown script-assistant *script-name*

Parameters

Parameter	Description	Value
script-name	Specifies the name of a Python script assistant, namely, a Python script name for a script assistant.	The value must be the name of a script file for which the script assistant has been configured.

Views

OPS view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To prevent a Python script of an assistant from running, run the **shutdown script-assistant** command to stop the Python script assistant.

Precautions

Stopping a running assistant interrupts the task of the assistant. Exercise caution when you perform this operation.

Example

Stop a script assistant for the script config.py.

```
<HUAWEI> system-view
[HUAWEI] ops
[HUAWEI-ops] shutdown script-assistant config.py
Info: Succeeded in stopping script assistant config.py.
```

3.9 Energy-saving Configuration Commands

3.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.9.2 als enable

Function

The **als enable** command enables ALS on an interface.

The **undo als enable** command disables ALS on an interface.

By default, ALS is disabled on an interface.

Format

als enable

undo als enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

The constraints on ALS are as follows:

- Only optical interfaces support ALS. Electrical interfaces and combo interface do not support ALS.
- When optical interfaces transmit services unidirectionally, they do not support ALS.
- When the copper cable, copper module, or GPON optical module is used on the optical port, the ALS function is not supported. In addition, after the copper cable or GPON optical module is inserted, all the ALS-related commands configured on this interface are cleared.
- When you run the display elabel command to view electronic label information of a port and the command output shows that the component vendor is FCBN410QB1C10-HW, this port does not support ALS.

Example

Enable ALS on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] als enable
```

3.9.3 als restart

Function

The **als restart** command manually restarts the laser of an interface.

Format

als restart

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to manually restart the laser of an optical module. After the optical link recovers, the laser is started after a certain interval if the restart mode is automatic restart. To start the laser immediately after the optical link recovers, set the restart mode of the laser to manual restart and run the **als restart** command. If this command is not executed, the laser automatically sends a pulse after receiving a pulse from the remote end.

Prerequisites

ALS has been enabled on the interface using the **als enable** command and the restart mode of the laser has been set to manual restart mode using the **als restart mode manual** command.

Precautions

This command cannot be executed on an interface if the interface has been added to an interface protection group and is in **Protect** state.

Example

Restart lasers on GigabitEthernet0/0/1 manually.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] als enable
[HUAWEI-GigabitEthernet0/0/1] als restart mode manual
[HUAWEI-GigabitEthernet0/0/1] als restart
```

3.9.4 als restart mode manual

Function

The **als restart mode manual** command sets the mode of restarting the laser of the optical module to manual.

The **undo als restart mode manual** command restores the mode of restarting the laser of the optical module to automatic.

By default, a laser works in automatic restart mode.

Format

als restart mode manual

undo als restart mode manual

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

The laser of an optical module works in automatic restart mode or manual restart mode.

- In automatic restart mode, the laser sends pulses at the interval set using the **als restart pulse-interval** command to detect whether the link is recovered. The pulse width is set through the **als restart pulse-width** command.
- In manual restart mode, you must manually start the laser using the **als restart** command so that the laser can send a pulse. The ALS pulse width is set using the **als restart pulse-width** command.

If the fiber link recovery is detected in time, you can use the manual restart mode so that the laser can send pulses immediately. Therefore, data communication can be recovered rapidly.

Example

Configure lasers on GigabitEthernet0/0/1 to work in manual restart mode.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] als restart mode manual
```

3.9.5 als restart pulse-interval

Function

The **als restart pulse-interval** command sets the ALS pulse interval for the laser of an optical module.

The **undo als restart pulse-interval** command restores the default ALS pulse interval of the laser of an optical module.

By default, the ALS pulse interval of the laser is 100s.

Format

als restart pulse-interval *pulse-interval*

undo als restart pulse-interval

Parameters

Parameter	Description	Value
pulse-interval	Specifies the ALS pulse interval of the laser.	The value is an integer that ranges from 100 to 20000, in seconds.

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

In automatic restart mode, the ALS pulse interval affects the frequency of detecting the LOS on the interface. A long ALS pulse interval is beneficial for energy saving, but the fiber link recovery cannot be detected in a timely manner. In contrary, a short ALS pulse interval wastes power but the fiber link recovery can be detected immediately.

Example

Set the ALS pulse interval of lasers on GigabitEthernet0/0/1 to 150s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] als restart pulse-interval 150
```

3.9.6 als restart pulse-width

Function

The **als restart pulse-width** command sets the ALS pulse width for the laser of an optical module.

The **undo als restart pulse-width** command restores the default ALS pulse width for the laser of an optical module.

By default, the ALS pulse width of the laser is 2s.

Format

als restart pulse-width *pulse-width*

undo als restart pulse-width

Parameters

Parameter	Description	Value
pulse-width	Specifies the ALS pulse width of the laser.	The value is an integer that ranges from 2 to 200, in seconds.

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

The ALS pulse width refers to the period between rising edges of pulses. A short ALS pulse width is beneficial for energy saving, but the fiber link recovery cannot be detected immediately. In contrary, a long ALS pulse width consumes more power but the fiber link recovery can be detected immediately.

Example

Set the ALS pulse width on GigabitEthernet0/0/1 to 3s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] als restart pulse-width 3
```

3.9.7 display als configuration

Function

The **display als configuration** command displays ALS configuration.

Format

display als configuration slot *slot-id*

display als configuration interface *interface-type interface-number*

Parameters

Parameter	Description	Value
slot *slot-id*	Displays ALS configuration in a slot with a specified slot ID.	The value depends on the device configuration.
interface *interface-type interface-number*	Displays ALS configuration on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an optical interface connects to a high-speed cable, this command does not have command output.

Example

Display ALS configuration on GigabitEthernet0/0/1.

```
<HUAWEI> display als configuration interface gigabitethernet 0/0/1
-------------------------------------------------------------------------------
Interface              ALS        Laser      Restart    Interval(s)   Width(s)
                       Status     Status     Mode
-------------------------------------------------------------------------------
GigabitEthernet0/0/1   Disable    On         Auto       100           2
-------------------------------------------------------------------------------
```

Table 3-138 Description of the **display als configuration** command output

Item	Description
Interface	Interface type and number.

Item	Description
ALS Status	Whether ALS is enabled. - Enable: ALS is enabled. - Disable: ALS is disabled. ALS is enabled using the **als enable** command.
Laser Status	Status of the laser on the interface. The value can be: - Off: The laser is shut down. - On: The laser is turned on. - --: No optical module is present on the interface.
Restart Mode	ALS restart mode. - Auto: automatic restart mode. - Manual: manual restart mode. The ALS restart mode is set to manual using the **als restart mode manual** command.
Interval(s)	ALS pulse interval, expressed in seconds. The ALS pulse interval is set using the **als restart pulse-interval** command.
Width(s)	ALS pulse width, expressed in seconds. The ALS pulse width is set using the **als restart pulse-width** command.

3.9.8 display power manage cycle

Function

The **display power manage cycle** command displays the interval for updating power consumption data.

Format

display power manage cycle

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The average power consumption of a device is the average power consumption within a period of time. You can use the **display power manage cycle** command to view the interval for calculating the average power consumption.

Example

Display the interval for updating power consumption data.

```
<HUAWEI> display power manage cycle
 3 : 1 hour
```

Table 3-139 Description of the display power manage cycle command output

Item	Description
3 (1 hour)	The interval for updating power consumption data is 1 hour. You can set the interval to the following values: • 1 : 15 minutes • 2 : 30 minutes • 3 : 1 hour • 4 : 1 day • 5 : 1 week • 6 : 1 month (30 days) To set the interval for updating power consumption data, use the **set power manage cycle** command.

3.9.9 display power manage mode

Function

The **display power manage mode** command displays the energy-saving mode of the device.

Format

display power manage mode

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display power manage mode** command to check the currently configured energy-saving mode of the device.

Example

Display the energy-saving mode of the device.

```
<HUAWEI> display power manage mode
2 (Standard mode)
```

Table 3-140 Description of the display power manage mode command output

Item	Description
2 (Standard mode)	Standard energy-saving mode. The device supports the following energy-saving modes: ● 1. User-defined mode: user-defined energy-saving mode. ● 2. Standard mode: standard energy-saving mode ● 3. Basic mode: basic energy-saving mode ● 4. Deep mode: depth energy-saving mode ● 5. Standby mode. **NOTE** The device does not support the user-defined mode. Only the S5720-16X-PWH-LI supports the standby mode. You can set the energy-saving mode using the **set power manage mode** command.

3.9.10 display power manage power-information

Function

The **display power manage power-information** command displays the power consumption information of a device.

Format

display power manage power-information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display power manage power-information** command enables you to check the system power consumption information, including the accumulative power consumption, average power, real-time power, rated power, and power threshold of the device.

Example

Display the system power consumption information.

```
<HUAWEI> display power manage power-information
The information of net element power:
 --------------------------------------------------
 The total power consumption (Joule) : 3702200060
 The average power consumption (mW)  : 67050
 The current power consumption (mW)  : 65750
 The inbound interface power (mW)    : 81750
 The rated power (mW)                : 229000
 The threshold of power (mW)         : 600000
 The typical power (mW)              : 126000
 --------------------------------------------------
```

Table 3-141 Description of the display power manage power-information command output

Item	Description
The information of net element power	System power consumption information.

Item	Description
The total power consumption (Joule)	Accumulative power consumption, in Joule. This field displays NA for PoE-incapable models, including the SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I. This field displays NA when the device uses the PDC180S12-CR, PDC260S12-DL, PAC60S12-AR or PAC150S12-R power module of which power information cannot be obtained. **NOTE** The accumulative power consumption is stored in the device memory and will not be lost when the device is powered off. When the device is running, power consumption is accumulated once every 15 minutes. The accumulated power consumption and accumulative power consumption in the memory are added and recorded in the memory once every 24 hours. If there is no accumulative power consumption in the memory, this field displays 0. If the device is powered off within 24 hours after starting, the power consumption accumulated within 24 hours is not added to the accumulative power consumption in the memory.
The average power consumption (mW)	The average power consumption of a device is the average power consumption within a period of time, including the PoE power, in mW. This field displays NA for PoE-incapable models, including the SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I. This field displays NA when the device uses the PDC180S12-CR, PDC260S12-DL, PAC60S12-AR or PAC150S12-R power module of which power information cannot be obtained.
The current power consumption (mW)	The output power of the system, including the PoE power, in mW. This field displays NA for PoE-incapable models, including the SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I. This field displays NA when the device uses the PDC180S12-CR, PDC260S12-DL, PAC60S12-AR or PAC150S12-R power module of which power information cannot be obtained.

Item	Description
The inbound interface power (mW)	The input power of the system, including the PoE power, in mW. This field displays NA for PoE-incapable models, including the SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I. This field displays NA when the device uses the PDC180S12-CR, PDC260S12-DL, PAC60S12-AR or PAC150S12-R power module of which power information cannot be obtained.
The rated power (mW)	Rated power of the system, excluding the PoE power, in mW. For a stack, the value of this parameter indicates the maximum power consumption of the stack.
The threshold of power (mW)	Power threshold of the power supply unit, in mW. The value is the rated power of the power supply unit used on the device. ● When there are two power supply units on the device, they work in redundancy mode to supply power to the system. The supplied power is not the accumulated power of the two power supply units. When the rated power of both power supply units can be obtained, this field displays the smaller rated power. If the rated power of one power supply unit cannot be obtained, this field displays the obtained rated power. If the rated power of both power supply units cannot be obtained, this field displays the system rated power. ● If a built-in power supply is used, the value is the rated power of the system.
The typical power (mW)	Power of the device when 30% of the line rate is used, excluding the PoE power. The unit is mW.

3.9.11 display power manage sleep configuration

Function

The **display power manage sleep configuration** command displays device dormancy information.

NOTE

Only the S500, S5735-S, S5735-S-I, S5735S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735S-H, and S5736-S series switches support the sleep mode.

Format

display power manage sleep configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display power manage sleep configuration** command shows device dormancy information, including the time range, period during which the awakening port status is detected continuously, awakening mode, and non-awakening ports.

Example

Display the device dormancy configuration.

```
<HUAWEI> display power manage sleep configuration
The device sleep function status: enable
The device sleep time-range: night-time
----------------------------------------------
Current time is 16:19:45 5-14-2012 Monday

Time-range: night-time ( Inactive )
20:00 to 00:00 working-day
00:00 to 08:00 working-day
----------------------------------------------
The awaken port state check interval (minutes): 20(default)
The configuration of non-awaken port:
----------------------------------------------
 GigabitEthernet0/0/1     GigabitEthernet0/0/2
 GigabitEthernet0/0/3     GigabitEthernet0/0/4
 GigabitEthernet0/0/5     GigabitEthernet0/0/6
 GigabitEthernet0/0/7     GigabitEthernet0/0/8
 GigabitEthernet0/0/9     GigabitEthernet0/0/10
----------------------------------------------
```

Table 3-142 Description of the display power manage sleep configuration command output

Item	Description
The device sleep function status	Device dormancy mode. - disable: The device dormancy function is disabled. That is, the device energy-saving mode configured using the **set power manage mode** command is not 4. - enable: The device dormancy function is enabled. That is, the device energy-saving mode configured using the **set power manage mode** command is 4.
The device sleep time-range	Dormancy time range name. If no dormancy time range is specified, the whole day takes effect by default. To set a dormancy time range, run the **sleep time-range** command.
Time-range	Dormancy time range. - If the field value contains (Inactive), the current time is not within the dormancy time range. - If the field value contains (Active), the current time is within the dormancy time range.
The awaken port state check interval (minutes)	Period during which the awakening port status is detected continuously. To set the period, run the **set power manage interval** command.
The configuration of non-awaken port	Configured non-awakening ports. To configure non-awakening ports, run the **set power manage non-awaken-port** command.

3.9.12 energy-efficient-ethernet enable

Function

The **energy-efficient-ethernet enable** command enables the Energy Efficient Ethernet (EEE) function on an electrical interface.

The **undo energy-efficient-ethernet enable** command disables the EEE function on an electrical interface.

By default, EEE is disabled on an electrical interface.

Format

energy-efficient-ethernet enable

undo energy-efficient-ethernet enable

Parameters

None

Views

GE interface view, port group view, MultiGE interface view, XGE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The system provides power for each interface. Even though an interface is idle, it consumes the same power as working interfaces. The **energy-efficient-ethernet enable** command enables the system to reduce the power on an interface when the interface is idle and restore the power when the interface starts to transmit data. This reduces system power consumption.

Prerequisites

If an electrical interface works in non-auto negotiation mode, run the **negotiation auto** command to enable auto-negotiation.

Precautions

- The EEE function can be configured only on electrical interfaces (including combo electrical interfaces). Optical interfaces do not support the EEE function.
- If an electrical interface works at 10 Mbit/s after auto-negotiation, the EEE function does not take effect.
- The S5731-H, S5731-S (except S5731-S32ST4X-A, S5731-S32ST4X-D, S5731-S24N4X2Q-A, S5731-S24UN4X2Q, S5731-S8UM16UN2Q, and S5731-S32ST4X), S5731S-H, S5731S-S (except S5731S-S32ST4X-A, S5731S-S24N4X2Q-A1, S5731S-S24UN4X2Q-A, S5731S-S8UM16UN2Q-A, and S5731S-S32ST4X-A1), S6735-S, S6720-EI, and S6720S-EI do not support the EEE function.
- For the S5732-H48XUM2CC, S5732-H24UM2CC and S5732-H48UM2CC, MultiGE interfaces working at 2.5 Gbit/s or 5 Gbit/s do not support the EEE function.
- Enabling or disabling EEE on an interface will trigger re-negotiation. During the negotiation, the interface may change to Down state, which causes short service interruption. Therefore, determine whether the operation is allowed before you run this command.
- If auto-negotiation is disabled on an interface, the EEE configuration is automatically deleted.

Example

Enable the EEE function on electrical interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] energy-efficient-ethernet enable
```

3.9.13 port-auto-sleep enable

Function

The **port-auto-sleep enable** command enables the port dormancy function on an Ethernet electrical port to save energy.

The **undo port-auto-sleep enable** command disables the port dormancy function on an Ethernet electrical port.

By default, the port dormancy function is disabled on an Ethernet electrical port.

Format

port-auto-sleep enable

undo port-auto-sleep enable

Parameters

None

Views

Interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

The **port-auto-sleep enable** command enables electrical port dormancy. If this function is enabled on a port, the port enters the energy-saving mode when no carrier wave signals are transmitted on the port. When carrier wave signals are transmitted on the port, the port exits the energy-saving mode. Port sleep does not affect functioning of the port.

NOTE

Currently, this command can be used on electrical interfaces (excluding MultiGE interfaces) and combo interfaces working as electrical interfaces.

The port sleeping function is enabled by default on the ES5D21X08T00 electrical sub-card supported by the S5731-H, and S5731S-H, and cannot be disabled.

Example

Enable the port dormancy function on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-auto-sleep enable
```

3.9.14 set power manage cycle

Function

The **set power manage cycle** command sets the interval for updating power consumption data.

The **undo set power manage cycle** command restores the default interval for updating power consumption data.

By default, the interval for updating power consumption data is 1 hour.

Format

set power manage cycle *cycle-id*

undo set power manage cycle

Parameters

Parameter	Description	Value
cycle-id	Sets the interval for updating power consumption data.	The value is an integer that ranges from 1 to 6. • 1: 15 minutes • 2: 30 minutes • 3: 1 hour • 4: 1 day • 5: 1 week • 6: 30 days

Views

System view

Default Level

3: Management level

Usage Guidelines

The average power consumption of a device is the average power consumption within a period of time. You can use the **set power manage cycle** command to set the interval for calculating the average power consumption. To obtain real-time power consumption, set a short interval.

Example

Set the interval for updating power consumption data to 15 minutes.

```
<HUAWEI> system-view
[HUAWEI] set power manage cycle 1
```

3.9.15 set power manage interval

Function

The **set power manage interval** command sets the period during which the awakening port status is probed continuously.

The **undo set power manage interval** command restores the default period during which the awakening port status is probed continuously.

By default, the period is 20 minutes.

NOTE

Only the S500, S5735-S, S5735-S-I, S5735S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735S-H, and S5736-S series switches support the sleep mode.

Format

set power manage interval *interval-time*

undo set power manage interval

Parameters

Parameter	Description	Value
interval-time	Specifies the period during which the awakening port status is probed continuously.	The value is an integer ranging from 5 to 60, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

When the device does not enter the dormancy state in the specified time range, the device continuously probes the status of all awakening ports. The device enters the dormancy state when the device does not probe any awakening port in Up state within the default 20 minutes. Otherwise, the device continues to probe the awakening ports status.

If no time range is applied to the device, the device probes the status of all awakening ports all round the clock. By default, the device enters the dormancy state when the device does not probe any awakening port in Up state within 20 minutes.

NOTE

In a stack, the **set power manage interval** command cannot set the period during which the awakening port status is detected continuously. However, you can use the **undo set power manage interval** command to delete the configuration in standalone mode.

Example

Set the period during which the awakening port status is probed continuously to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] set power manage interval 10
[HUAWEI] quit
<HUAWEI> save
```

3.9.16 set power manage mode

Function

The **set power manage mode** command sets the energy-saving mode of the device.

The **undo set power manage mode** command restores the default energy-saving mode of the device.

By default, the standard energy-saving mode is used.

Format

set power manage mode *mode-id*

undo set power manage mode

Parameters

Parameter	Description	Value
mode-id	Specifies the energy-saving mode of the device.	The value is an integer that ranges from 1 to 5: • 1: indicates the user-defined energy-saving mode. This mode is not supported currently. • 2: indicates the standard energy-saving mode. • 3: indicates the basic energy-saving mode. • 4: indicates the deep energy-saving mode. • 5: indicates the standby energy-saving mode. **NOTE** Only the S5720-16X-PWH-LI supports the standby energy-saving mode.

Views

System view

Default Level

3: Management level

Usage Guidelines

The **set power manage mode** command sets the energy-saving mode of the device.

The device can run in the following energy-saving modes:

- Standard mode

  Factory mode and default power saving mode.
- Basic mode

  Components not in use are shut down or switched to the sleep mode when no services are configured or users are not online.
- Deep mode

  Power consumption is dynamically adjusted for running services, and components not in use are shut down or switched to the sleep mode according to service requirements.
- Standby mode

  The device enters the low power consumption mode when it does not need to provide PoE power to PDs and shuts down all the interfaces except GE0/0/13 and GE0/0/14.

NOTE

- The ALS, EEE, and port dormancy functions are disabled in standard mode by default. However, the port dormancy function is enabled by default on the ES5D21X08T00 electrical sub-card supported by the S5731-H, and S5731S-H, and cannot be disabled.
- The ALS, EEE, and port dormancy functions are enabled by default in basic or deep mode.
- The deep mode adds the device dormancy function based on functions of the basic mode.
- Only the S5720-16X-PWH-LI supports the standby mode. The interfaces that have been shut down in standby mode cannot be enabled manually using a command. To enable these interfaces manually, ensure that the switch exits the standby mode.
- Before entering the standby mode, the system forcibly saves the configuration to the configuration file that is being used by the device.
- The configuration restoration function is not configured in the standby mode. That is, after the device restarts, the currently configured standby mode of an interface is automatically restored to the default standard mode.
- On the S5720-16X-PWH-LI XGE0/0/1 and XGE0/0/2, installing optical modules and configuring the standby mode are mutually exclusive. That is, the two interfaces cannot have the standby mode configured after they have optical modules installed. When they work in standby mode, installing optical modules into them will restore them to the default standard mode or may even restart the device.
- The minimum interval between configuring and disabling the standby mode is 15s.
- The standby mode cannot be configured in a stack.
- When the device is switched from the basic or deep mode to the standby mode, disabling the EEE function may cause interface flapping. Similarly, when the device is switched from the standby mode to the basic or deep mode, enabling the EEE function may cause interface flapping.

After the energy-saving mode is set to basic or deep mode, loopback test on interfaces is disabled. Therefore, before performing a loopback test, set the energy-saving mode to standard mode.

Example

Set the energy-saving mode of the device to basic mode.

```
<HUAWEI> system-view
[HUAWEI] set power manage mode 3
Warning: Performance of ALS, EEE, Auto sleep will be enabled, and the EEE function may lead to port
flapping. Continue?[Y/N]:y
Info: It will take a few seconds. Please wait...
```

3.9.17 set power manage non-awaken-port

Function

The **set power manage non-awaken-port** command configures a port as a non-awakening port.

The **undo set power manage non-awaken-port** command restores a non-awakening port to be an awakening port.

By default, all ports are awakening ports.

NOTE

Only the S500, S5735-S, S5735-S-I, S5735S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735S-H, and S5736-S series switches support the sleep mode.

Format

set power manage non-awaken-port interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

undo set power manage non-awaken-port interface { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10>

Parameters

Parameter	Description	Value
interface { *interface-type interface-number1* [**to** *interface-type interface-number2*]	Specifies the type and number of an interface: ● *interface-type* specifies the type of the interface. ● *interface-number1* specifies the number of the first interface. ● *interface-number2* specifies the number of the second interface.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

You can use the **set power manage non-awaken-port** command to configure some ports as non-awakening ports so that these ports do not affect device dormancy and awakening. This is because device dormancy and awakening depend on the awakening port status.

NOTE

In a stack, the **set power manage non-awaken-port** command cannot configure a port as a non-awakening port. However, you can use the **undo set power manage non-awaken-port** command to delete the configuration in standalone mode.

Example

Configure interfaces GigabitEthernet0/0/1 to GigabitEthernet0/0/5 as non-awakening interfaces.

```
<HUAWEI> system-view
[HUAWEI] set power manage non-awaken-port interface gigabitethernet 0/0/1 to gigabitethernet
0/0/5
Info: Succeeded in setting the configuration.
[HUAWEI] quit
<HUAWEI> save
```

3.9.18 sleep time-range

Function

The **sleep time-range** command applies a time range to the device in dormancy state.

The **undo sleep time-range** command deletes the time range.

By default, no time range is applied to the device.

NOTE

Only the S500, S5735-S, S5735-S-I, S5735S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735S-H, and S5736-S series switches support the sleep mode.

Format

sleep time-range *timerange-name*

undo sleep time-range *timerange-name*

Parameters

Parameter	Description	Value
timerange-name	Specifies the name of a time range that applies to the device.	The value is a string of 1 to 32 case-sensitive characters without spaces and must start with an uppercase or lowercase.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

A device on an enterprise network is not used at certain time. You can apply a time range to the device in dormancy mode to save power. When dormancy conditions are met, the device automatically enters the dormancy state during the time range. When the time range expires, the device is awakened.

When an awakening interface detects a user, the device in dormancy mode is awakened. User services on the device are not affected.

The device enters the sleeping mode when the following conditions are met:

- The device works in deep mode. By default, the standard energy-saving mode is used.
- A time range applies to the device in sleeping mode.
- During the period for continuously detecting awakening port status, the terminals (switches or PCs) connected to awakening ports are shut down.

  NOTE

  If the terminal is a PC, the device can enter the dormancy state only when the PC is shut down and its network adapter is powered off (this can be set in the power management module of BIOS).

The device is awakened when either of the following conditions is met:

- A user logs in to the device through the serial port and presses Ctrl+W.
- The terminals (switches or PCs) connected to awakening ports are started up.
- The sleeping time range expires (if a time range is configured).
- A user presses the mode switching button.

Prerequisites

- The energy-saving mode of the device has been set to deep mode using the **set power manage mode** command.
- A time range has been specified using the **time-range** command.

NOTE

In a stack, the **sleep time-range** command cannot apply a time range to the device in dormancy state. However, you can use the **undo sleep time-range** command to delete the configuration in standalone mode.

Example

Apply the time range 1:00 to 6:00 am to the device.

```
<HUAWEI> system-view
[HUAWEI] set power manage mode 4
[HUAWEI] time-range test 1:00 to 6:00 daily
[HUAWEI] sleep time-range test
[HUAWEI] quit
<HUAWEI> save
```

3.10 Information Center Configuration Commands

3.10.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.10.2 display buffer

Function

The **display buffer** command displays statistics about logs cached in the buffer.

Format

display buffer [*feature-name* [*buffer-name*]]

Parameters

Parameter	Description	Value
feature-name	Specifies the name of the buffer dedicated to caching logs of a specific feature.	-
buffer-name	Specifies the name of the buffer.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

On the device, service modules generate logs and control the log volume. The information center processes the received logs.

When the number of logs that are generated within a specified period (T) exceeds the threshold, the service module, with the buffer mechanism, saves extra logs to the buffer and does not send them to the information center.

You can run the **display buffer** command to view statistics about log information in the buffer.

Example

Display statistics about logs cached in the buffer on the service module **L2IF**.

```
<HUAWEI> display buffer L2IF
Feature name : L2IF
Buffer number : 1
Buffer name : CALLBACKFAIL
  Buffer ID                    : 35
```

```
Max length of message        : 256
Max number of message        : 5
Time threshold(s)            : 3600
Store lastest message number : 0
Total receive number         : 76
Total process number         : 5
Max rate record              : 0 / 3600(s)
Max rate timestamp           : 0-00-00 00:00:00
```

Table 3-143 Description of the **display buffer** command output

Item	Description
Feature name	Feature name.
Buffer number	Buffer number.
Buffer name	Buffer name.
Buffer ID	Buffer ID.
Max length of message	Maximum length of a message.
Max number of message	Maximum number of messages.
Time threshold(s)	Time threshold.
Store lastest message number	Number of messages saved to non-volatile memory.
Total receive number	Total receive number
Total process number	Total process number
Max rate record	Maximum rate record.
Max rate timestamp	Maximum rate timestamp.

3.10.3 display channel

Function

The **display channel** command displays the channel configuration.

Format

display channel [*channel-number* | *channel-name*]

Parameters

Parameter	Description	Value
channel-number	Specifies the number of a channel.	The value is an integer that ranges from 0 to 9. That is, the system has 10 channels. Channels 0 to 5 have default names and the six channels map to six different output directions. **Table 3-144** shows the relationship between channels and output directions.
channel-name	Specifies the name of a channel.	The value is a string of 1 to 30 case-insensitive characters. The value consists of letters or numbers and must start with a letter.

Table 3-144 Relationship between channel and output directions

Channel Number	Default Channel Name	Output Direction	Description
0	console	console	Console that can receive logs, traps, and debugging messages.
1	monitor	monitor	VTY terminal that can receive logs, traps, and debugging messages, which facilitates remote maintenance.
2	loghost	loghost	Log host that can receive logs, traps, and debugging messages. By default, information is saved on the log host in file format for easy reference.
3	trapbuffer	trapbuffer	Trap buffer that can receive traps.
4	logbuffer	logbuffer	Log buffer that can receive logs.
5	snmpagent	snmpagent	SNMP agent that can receive traps.
6	channel6	Unspecified	Reserved. You can specify to which destination this channel can output information.
7	channel7	Unspecified	Reserved. You can specify to which destination this channel can output information.
8	channel8	Unspecified	Reserved. You can specify to which destination this channel can output information.

Channel Number	Default Channel Name	Output Direction	Description
9	channel9	Unspecified	Reserved. You can specify to which destination this channel can output information.

Views

3: Management level

Usage Guidelines

The **display channel** command displays the channel configuration.

When using this command, note the following points:

- When *channel-number* or *channel-name* is specified, the **display channel** command displays the specified channel that information passes through and information severity.
- When *channel-number* or *channel-name* is not specified, the **display channel** command displays all the channels that information passes through and information severity.

Example

Display the configuration of channel 0.

```
<HUAWEI> display channel 0
channel number:0, channel name:console
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      warning       Y      debugging     Y      debugging
```

Display the configuration of all channels.

```
<HUAWEI> display channel
channel number:0, channel name:console
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      warning       Y      debugging     Y      debugging

channel number:1, channel name:monitor
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      warning       Y      debugging     Y      debugging

channel number:2, channel name:loghost
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      informational Y      debugging     N      debugging

channel number:3, channel name:trapbuffer
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  N      informational Y      debugging     N      debugging
```

```
channel number:4, channel name:logbuffer
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      warning       N      debugging     N      debugging

channel number:5, channel name:snmpagent
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  N      debugging     Y      debugging     N      debugging

channel number:6, channel name:channel6
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      debugging     Y      debugging     N      debugging

channel number:7, channel name:channel7
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      debugging     Y      debugging     N      debugging

channel number:8, channel name:channel8
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      debugging     Y      debugging     N      debugging

channel number:9, channel name:channel9
MODU_ID  NAME     ENABLE LOG_LEVEL     ENABLE TRAP_LEVEL    ENABLE DEBUG_LEVEL
ffff0000 default  Y      debugging     Y      debugging     N      debugging
```

Table 3-145 Description of the display channel command output

Item	Description
channel number	Channel number, which ranges from 0 to 9.
channel name	Channel name. **Table 3-144** lists default channel names. To set the channel name, run the **info-center channel name** command.
MODU_ID	Module ID. The default value is ffff0000.
NAME	Module name. The default value is **default**. To set the module name, run the **info-center source channel** command.
ENABLE	Whether logs/traps/debugging messages are allowed to pass through a channel: ● Y ● N To specify the channel, run the **info-center source channel** command.

Item	Description
LOG_LEVEL/ TRAP_LEVEL/ DEBUG_LEVEL	Lowest severity of output logs/traps/debugging messages. The following severities are listed in descending order of priority: ● emergencies ● alert ● critical ● error ● warning ● notification ● informational ● debugging To set the lowest severity of output logs, run the **info-center source channel** command.

3.10.4 display debugging

Function

The **display debugging** command displays debugging messages allowed to be sent by the device.

Format

display debugging [**interface** *interface-type interface-number*] [*module-name*]

display debugging interface all

display debugging slot *slot-id* **vcpu** *vcpu-index*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vcpu** *vcpu-index* parameter.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the interface type and number.	-
all	Display debugging information on all interfaces.	-

Parameter	Description	Value
module-name	Displays debugging messages sent by a specified module such as the DHCP module. If this parameter is not specified, all debugging messages allowed to be sent are displayed.	Enumerated type. The value depends on the registered module.
slot *slot-id*	Specifies a slot ID.	The value is an integer, and the value range depends on the device configuration.
vcpu *vcpu-index*	Specifies the virtual CPU number.	Specify the *vcpu-index* parameter based on the hardware configuration.

Views

All views

3: Management level

Usage Guidelines

Usage Scenario

Using the **display debugging** command, you can display the enabled debugging. If no parameters are specified, the **display debugging** command displays global debugging information.

Debugging affects device performance. The **display debugging** command displays debugging messages allowed to be sent by the Switch.

Prerequisites

By default, sending debugging messages is prohibited. The debugging of a specified module has been enabled.

Example

Display debugging messages allowed to be sent by the Switch.

```
<HUAWEI> debugging acl4 all
<HUAWEI> display debugging
ACL4 event debugging switch is on
ACL4 packet debugging switch is on
```

Table 3-146 Description of the **display debugging** command output

Item	Description
ACL4 event debugging switch is on	Event debugging is enabled for the ACL4 module.
ACL4 packet debugging switch is on	Packet debugging is enabled for the ACL4 module.

3.10.5 display info-center

Function

The **display info-center** command displays the output configuration of the information center.

Format

display info-center

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display info-center** command to display all information recorded in the information center.

When a module is specified, you can view all information about the module recorded in the information center.

Example

Display output configuration of the information center.

```
<HUAWEI> display info-center
Information Center:enabled
Log host:
        10.1.1.1, channel number 2, channel name loghost,
language English , host facility local7
Console:
```

```
        channel number : 0, channel name : console
Monitor:
        channel number : 1, channel name : monitor
SNMP Agent:
        channel number : 5, channel name : snmpagent
Log buffer:
        enabled,max buffer size 1024, current buffer size 512,
current messages 512, channel number : 4, channel name : logbuffer
dropped messages 0, overwritten messages 53
Trap buffer:
        enabled,max buffer size 1024, current buffer size 256,
current messages 256, channel number:3, channel name:trapbuffer
dropped messages 0, overwritten messages 6229
Information timestamp setting:
        log - date, trap - date, debug - date millisecond

 Sent messages = 270090, Received messages = 281030

 IO Reg messages = 2 IO Sent messages = 10940
```

Table 3-147 Description of the display info-center command output

Item	Description
Information Center	Information center status: ● enabled ● disabled To enable the information center, run the **info-center enable** command.
Log host	Log host configuration.
10.1.1.1	Log host IP address. To set the log host IP address, run the **info-center loghost** command.
channel number	Number of a channel used to output information. To set the number of a channel used to output information, run the **info-center channel** command.
channel name	Name of a channel used to output information. To set the name of a channel used to output information, run the **info-center channel name** command.
language	Language mode in which information is output to a log host. To set the language mode in which information is output to a log host, run the **info-center loghost** command.
host facility	Logging tool. To configure the logging tool, run the **info-center loghost** command.
Console	Console configuration.
Monitor	Remote terminal configuration.
SNMP Agent	SNMP agent configuration.

Item	Description
Log buffer	Log buffer configuration.
enabled	Whether the Switch is enabled to send logs/traps to the log/trap buffer. - enabled - disabled To enable the Switch to send logs/traps to the log/trap buffer, run the **info-center logbuffer** or **info-center trapbuffer** command.
max buffer size	Maximum number of logs/traps in the log/trap buffer.
current buffer size	Maximum number of logs/traps in the current log/trap buffer. To set the maximum number of logs/traps in the current log/trap buffer, run the **info-center logbuffer size** or **info-center trapbuffer size** command.
current messages	Number of messages recorded in the log/trap buffer.
dropped messages	Number of messages discarded by the log/trap buffer.
overwritten messages	Number of overwritten messages in the log/trap buffer.
Trap buffer	Trap buffer configuration.
Information timestamp setting	Timestamp format of logs, traps, and debugging messages: - boot: indicates that the timestamp is expressed in the format of relative time, a period of time since system start. - date: indicates the current system date and time. It is expressed in mm dd yyyy hh:mm:ss format. - short-date: indicates the short date. This timestamp differs from **date** is that the year is not displayed. - format-date: indicates that the timestamp is expressed in YYYY-MM-DD hh:mm:ss format. - none: indicates that the output information does not contain the timestamp. To configure the timestamp format, run the **info-center timestamp** command.
Sent messages	Number of sent messages output by information center modules.
Received messages	Number of messages sent to information center modules.
IO Reg messages	Number of receive messages by switch.
IO Sent messages	Number of sent messages by switch.

3.10.6 display info-center filter-id

Function

The **display info-center filter-id** command displays information filtered by the information center.

Format

display info-center filter-id [*id* | **bymodule-alias** *modname alias*]

Parameters

Parameter	Description	Value
id	Displays filtered information with the specified ID.	The value is in hexadecimal notation and is a string of 8 digits. The value can contain 0-9, a-f, and A-F.
bymodule-alias *modname alias*	Displays filtered information with the specified module name and mnemonic symbol. ● *modname*: specifies the module name. ● *alias* specifies the mnemonic symbol.	Enumerated type. Set the value according to the device configuration.

Views

All views

Default Level

3: Management level

Usage Guidelines

ID identifies each function module for log registration. An ID filter list is the aggregation of the shielded IDs.

If *id* or **bymodule-alias** is not specified, all information is filtered.

If you do not want to output a specific log to the log file or log buffer, you can find the ID of the log in the data dictionary and run the **info-center filter-id** command to inject the ID into the filter list. Then, you can run the **display info-center filter-id** command to check whether the ID has become the one to be filtered.

Example

Display all the IDs in the filter list.

```
<HUAWEI> display info-center filter-id
ID              : 0x40394017
Module          : SHELL
Alias           : CMDRECORD
Content         : Recorded command information. (Task=[string], Ip=[string], VpnName=[STRING],
User=[string], AthenticationMethod="[STRING]",
Command="[string]")
Filtered Number : 2

ID              : 0x40394018
Module          : SHELL
Alias           : DISPLAY_CMDRECORD
Content         : Recorded display command information. (Task=[string], Ip=[string], VpnName=[string],
User=[string], AuthenticationMethod="[string]",
Command="[string]")
Filtered Number : 1
```

Table 3-148 Description of the display info-center filter-id command output

Item	Description
ID	Identifier to which each log corresponds. To configure the Switch to filter a log or trap with a specified ID, run the **info-center filter-id** *id* command.
Module	Module name. To configure the Switch to filter a log or trap with a specified module name or alias name, run the **info-center filter-id bymodule-alias** *modname alias* command.
Alias	Alias name. To configure the Switch to filter a log or trap with a specified module name or alias name, run the **info-center filter-id bymodule-alias** *modname alias* command.
Content	Log message to which each log ID corresponds.
Filtered Number	Number of times that the log to which the log ID corresponds is filtered.

3.10.7 display info-center rate-limit record

Function

The **display info-center rate-limit record** command displays the suppression of the log processing rate in the information center.

Format

display info-center rate-limit record

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display info-center rate-limit record** command to check suppression information of the log processing rate. Then you can determine whether service logs are suppressed because there are many logs.

Example

Display the suppression of the log processing rate in the information center.

```
<HUAWEI> display info-center rate-limit record
Record No.1
 InfoID                : 417d5000
 Module                  : 6OVER4
 Alias                 : DESTFAIL
 Rate limit threshold : 50
 Total receive number : 1872
 Total drop number    : 922
 Total send number    : 950
 Begin timestamp      : 2009-12-21 11:41:28
```

Table 3-149 Description of the **display info-center rate-limit record** command output

Item	Description
InfoID	Log ID.
Module	Log module name.
Alias	Log mnemonic name.
Rate limit threshold	Maximum number of logs set for the information center to process every second.
Total receive number	Total number of logs that are generated during the latest suppression period.
Total drop number	Total number of logs that are discarded during the latest suppression period.

Item	Description
Total send number	Total number of logs that the information center process during the latest suppression period.
Begin timestamp	Timestamp signifying when the suppression function is enabled for the last time.

3.10.8 display info-center rate-limit threshold

Function

The **display info-center rate-limit threshold** command displays the threshold of the log processing rate (maximum number of logs that the information center can process every second). The threshold information includes the default threshold contained in the released version, the default threshold for the specified log ID, and the threshold set through the command lines after the system startup.

Format

display info-center rate-limit threshold

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display info-center rate-limit threshold** command to check the log processing rate threshold of each module and then adjust the threshold based on service requirements.

Example

Display the threshold of the log processing rate set for the information center.

```
<HUAWEI> display info-center rate-limit threshold
Rate limit threshold(per second):
 Module           Alias                            Default  Config
 default                                        30       30
 IPC            IPCFRGTOOLARGE                       5        5
 IPC            IPCDUMPMEM                          5        5
 IPC            ALLOCINDEXERR                       5        5
 IPC            DRVNOTSTABLE                        2        2
```

```
IPC          NOTIMODFALNOREASM                2        2
IPC          SYNRPCGETSMFAL                5        5
IPC          SYNRPCMODUNREG                  5        5
IPC          SYNRPCRETNULL                5        5
IPC          MODULENOTREG                  5        5
IPC          SENDRETURN                5        5
IPC          GETMTUFAL                5        5
IPC          ALLOCIPCFRGFAL                5        5
IPC          RECVINVALIDMSG                5        5
IPC          RCVNOTIQUEERR                5        5
IPC          NOTIFYQUEERR                5        5
IPC          SENDFINISHRETURN                5        5
IPC          RECVINVALIDMSGTYPE                5        5
SOURCE          UMSGGETSRCOBJFAL                1        1
```

Table 3-150 Description of the **display info-center rate-limit threshold** command output

Item	Description
Module	Log module name.
Alias	Log mnemonic name.
Default	The default threshold of the log processing rate.
Config	The threshold of the log processing rate set for the information center.

3.10.9 display info-center session log status

Function

The **display info-center session log status** command displays the status of the user session logging function.

Format

display info-center session log status

Parameters

None

Views

All views

Level

3: Management level

Usage Guidelines

If no session log file is generated in a VTY window, you can run the **display info-center session log status** command to view the status of the user session logging function and status of the online user session logging function.

Example

Display the status of the user session logging function.

```
<HUAWEI> display info-center session log status
Info-center Session Log Status:
-------------------------------
Global Status: On
-------------------------------
User-Interface    Status
VTY 0             Off
VTY 1             On
VTY 2             On
VTY 3             On
CON 0              On
```

Table 3-151 Description of the **display info-center session log status** command output

Item	Description
Info-center Session Log Status	Status of the user session logging function.
Global Status	Status of the user session logging function: ● On: Recording session logs is enabled. ● Off: Recording session logs is disabled. This function can be configured using the **info-center session log disable** command in the system view.
User-Interface	User UI identifier: ● VTY/CON: indicates the user type. ● 0/1/2/3: indicates online users.
Status	Status of the online user session logging function: ● On: The function is enabled. ● Off: The function is disabled. The online user session logging function is disabled after the **info-center session log disable** command is executed to disable the user session logging function. The online user session logging function is enabled after the **undo info-center session log disable** command is executed to enable the user session logging function.

3.10.10 display info-center statistics

Function

The **display info-center statistics** command displays statistics on the information center.

Format

display info-center statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run the **display info-center statistics** command to view statistics on the information center, including logs, traps, and debugging messages of each module.

Example

Display statistics on the information center.

```
<HUAWEI> display info-center statistics
Information statistics data:
ModuleID    ModuleName       LogSend   LogDrop   DiagSend  DiagDrop  TrapSend
TrapDrop  DebugSend DebugDrop
0x417d0000  6OVER4           0         0         0         0         0
0         0         0
0x41470000  AAA              0         0         0         0         0
0         0         0
0x406c0000  ACL              0         0         0         0         0
0         0         0
0x40ef0000  ACL6             0         0         0         0         0
0         0         0
0xff060000  ACLE             1         0         0         0         0
0         0         0
0xff380000  ADA_BFD          0         0         0         0         0
0         0         0
0x40e70000  ADDR             0         0         0         0         0
0         0         0
0xff2f0000  ADP_RRPP         0         0         114       18        0
0         0         0
0xff950000  ADPIPV4          0         0         253       393       0
0         0         0
  ---- More ----
```

Table 3-152 Description of the display info-center statistics command output

Item	Description
ModuleID	Registered ID of the module.
ModuleName	Name of the module that generates logs.
LogSend	Number of sent logs.
LogDrop	Number of discarded logs.
DiagSend	Number of sent diagnostic messages.
DiagDrop	Number of discarded diagnostic messages.
TrapSend	Number of sent traps.
TrapDrop	Number of discarded traps.
DebugSend	Number of sent debugging messages.
DebugDrop	Number of discarded debugging messages.

3.10.11 display logbuffer

Function

The **display logbuffer** command displays information recorded in the log buffer.

Format

display logbuffer [**size** *size* | **slot** *slot-id* | **module** *module-name* | **security** | **level** { *severity* | *level* }] *

display logbuffer summary [**level** *severity* | **slot** *slot-id*] *

display logbuffer order by module

Parameters

Parameter	Description	Value
size *size*	Displays the specified number of logs recently generated in the log buffer.	The value is an integer that ranges from 1 to 1024.
module *module-name*	Displays logs of a specified module in the log buffer.	Enumerated type. The value depends on the registered module.

Parameter	Description	Value
security	Specifies the security logs.	-
slot *slot-id*	Displays logs in a specified slot.	The value must be set according to the device configuration.
level { *severity* | *level* }	Displays logs of specified severity name or ID. - *severity* specifies the severity ID. - *level* specifies the severity name.	The value of *severity* is an integer that ranges from 0 to 7. - 0: Emergencies - 1: Alert - 2: Critical - 3: Error - 4: Warning - 5: Notification - 6: Informational - 7: Debugging The value of *level* is the enumerated type: - emergencies - alert - critical - error - warning - notification - informational - debugging
summary	Displays the summary of logs in the log buffer.	-

Parameter	Description	Value
order by module	Displays logs in the order of the modules to which they belong to. **NOTE** ● Logs in the log buffer are classified and displayed by the modules they belong to. ● Modules are displayed by the time that the module's first log is generated in the log buffer in descending order. ● Logs in each module are displayed by the time they are generated in descending order.	-

Usage Guidelines

The **display logbuffer** command displays the information of recent logs. If the actual number of logs is smaller than the value specified by *size*, the system displays logs of the actual number.

Example

Display all the logs in the log buffer.

```
<HUAWEI> display logbuffer
Logging buffer configuration and contents : enabled
Allowed max buffer size : 1024
Actual buffer size : 512
Channel number : 4 , Channel name : logbuffer
Dropped messages : 0
Overwritten messages : 0
Current messages : 43

Table 3-153 Description of the display logbuffer command output

Item	Description
Logging buffer configuration and contents	Whether the device is enabled to output logs to the log buffer: ● enabled ● disabled To configure the device to output logs to the log buffer, run the **info-center logbuffer** command.
Allowed max buffer size	Maximum size of the log buffer.
Actual buffer size	Actual size of the log buffer. To set the log buffer size, run the **info-center logbuffer size** command.
Channel number	Number of the channel used to send logs to the log buffer. To configure the number of a channel used to send logs to the log buffer, run the **info-center channel** command.
Channel name	Name of the channel used to send logs to the log buffer. To configure the name of a channel used to send logs to the log buffer, run the **info-center channel name** command.
Dropped messages	Number of dropped messages.
Overwritten messages	Number of overwritten messages.
Current messages	Number of current messages.

Display the summary of information in the log buffer.

```
<HUAWEI> display logbuffer summary
     SLOT EMERG ALERT  CRIT ERROR  WARN NOTIF  INFO DEBUG
        0     0     0     0    36   476     0     0     0
```

Table 3-154 Description of the display logbuffer summary command output

Item	Description
SLOT	ID of the slot where logs are generated.
EMERG	Number of logs of emergency.
ALERT	Number of logs of alert.
CRIT	Number of logs of critical.
ERROR	Number of logs of error.
WARN	Number of logs of warning.
NOTIF	Number of logs of notification.
INFO	Number of logs of informational.
DEBUG	Number of logs of debugging.

3.10.12 display logfile

Function

The **display logfile** command displays information about a log file.

Format

display logfile *file-name* [*offset* | **hex**] *

Parameters

Parameter	Description	Value
file-name	Specifies the log file name, which can contain the drive and path.	The value is a string of case-insensitive characters, spaces not supported. If the parameter value does not contain any path, it is a string of 1 to 64 bytes. Otherwise, it is a string of 1 to 160 bytes.
offset	Displays the log file with the specified offset or byte.	The value is an integer that ranges from 0 to 2147483647.

Parameter	Description	Value
hex	Displays the log file in hexadecimal notation. If the parameter is not specified, the log file is displayed in text format.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

When encountering problems, you can query log information to know about what happened during device operation. This is helpful for fault location.

The file name is generated automatically by the system. The file name extension of the log file is *.log or *.dblg. When the current log file size reaches the specified upper limit, the system compresses the file into a *.log.zip or *.dblg.zip file.

You can view the *.log files or *.log.zip files. When viewing a *.log.zip file, you can press **Ctrl+C** to abort command execution.

When viewing the *.log.zip file, it is recommended that the length of the file name (including the driver and path) not exceed 62 bytes. Otherwise, the content of the file may fail to be viewed.

If the files you filter based on the pipe character are large and no qualified log file is displayed, the command fails to display any output for a long period of time until the command execution finishes.

For details about the log format, see "Log Message Format Description" in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Log Reference - Introduction*.

Example

Display log information saved in the log file in a specified path.

```
<HUAWEI> display logfile logfile/log.log
###################################################################
#     This logfile is generated at slot 0
###################################################################

3.10.13 display log restrain all

Function

The **display log restrain all** command displays all log suppression configurations.

Format

display log restrain all

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

To check configurations of the log suppression function, run this command.

Example

Display all log suppression configurations.

```
<HUAWEI> display log restrain all
Log restrain                     : enable
Check interval in seconds        : 60
The maximum number of a log per minute : 200

---------------------------------------------------------------------
Description                  InfoId               MaxCount
---------------------------------------------------------------------
```

```
RecordCommand(*)              40394017              NotLimit
RecordCommandResult(*)           40394025              NotLimit
```

Table 3-155 Description of the **display log restrain all** command output

Item	Description
Log restrain	Whether log suppression is enabled.
Check interval in seconds	Statistical period, in seconds.
The maximum number of a log per minute	Maximum number of logs that can be generated every minute.
Description	Description.
InfoId	Log ID.
MaxCount	Maximum number of logs with a specific log ID that can be generated per minutes.

3.10.14 display log restrain statistics

Function

The **display log restrain statistics** command displays all log suppression statistics.

Format

display log restrain statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

To view all log suppression statistics, run this command.

Example

Display all log suppression statistics.

```
<HUAWEI> display log restrain statistics
Total number of logs                   : 56477
```

```
Average number of logs per minute      : 6
Maximum number of logs per minute      : 1796
Minimum number of logs per minute      : 0
Number of log types in the last minute : 0

-------------------------------------------------------------------
InfoId                         TotalDiscard           MaxCount
-------------------------------------------------------------------
ff51502a                         29                   229
ffd35005                         124                   324
```

Table 3-156 Description of the **display log restrain statistics** command output

Item	Description
Total number of logs	Total number of logs.
Average number of logs per minute	Average number of logs generated per minute.
Maximum number of logs per minute	Maximum number of logs generated per minute.
Minimum number of logs per minute	Minimum number of logs generated per minute.
Number of log types in the last minute	Number of types of the logs generated in the last minute.
InfoId	Log ID.
TotalDiscard	Total number of discarded logs.
MaxCount	Maximum number of logs with a specific log ID generated per minutes.

3.10.15 display trapbuffer

Function

The **display trapbuffer** command displays information recorded in the trap buffer.

Format

display trapbuffer [**size** *value* | **slot** *slot-id* | **module** *module-name* | **level** { *severity* | *level* }] *

display trapbuffer order by module

Parameters

Parameter	Description	Value
size *value*	Displays the specified number of traps recently generated in the trap buffer. If this parameter is not specified, all traps are displayed.	The value is an integer that ranges from 1 to 1024.
module *module-name*	Displays traps of a specified module in the trap buffer.	Enumerated type. The value depends on the registered module.
slot *slot-id*	Displays traps in a specified slot.	The value must be set according to the device configuration.
level { *severity* | *level* }	Displays traps of specified severity name or ID. • *severity* specifies the severity ID. • *level* specifies the severity name.	The value of *severity* is an integer that ranges from 0 to 7. • 0: Emergencies • 1: Alert • 2: Critical • 3: Error • 4: Warning • 5: Notification • 6: Informational • 7: Debugging The value of *level* is the enumerated type: • emergencies • alert • critical • error • warning • notification • informational • debugging

Parameter	Description	Value
order by module	Displays alarms in the order of the modules they belong to. **NOTE** - Alarms in the alarm buffer are classified and displayed by the modules they belong to. - Modules are displayed by the time that the module's first alarm is generated in the alarm buffer in descending order. - Alarms in each module are displayed by the time they are generated in descending order.	-

Table 3-157 Description of the display trapbuffer command output

Item	Description
Trapping buffer configuration and contents	Whether the device is enabled to output traps to the trap buffer: ● enabled ● disabled To enable the device to output traps to the trap buffer, run the **info-center trapbuffer** command.

Item	Description
Allowed max buffer size	Maximum size of the trap buffer.
Actual buffer size	Actual size of the trap buffer. To set the size of the trap buffer, run the **info-center trapbuffer size** command.
Channel number	Number of the channel used to send traps to the trap buffer. To set the channel number, run the **info-center channel** command.
Channel name	Name of the channel used to send traps to the trap buffer. To set the channel name, run the **info-center channel name** command.
Dropped messages	Number of dropped messages.
Overwritten messages	Number of overwritten messages.
Current messages	Number of current messages.

3.10.16 info-center channel

Function

The **info-center channel** command configures channels for outputting information in various directions.

The **undo info-center channel** command restores the default settings.

By default, the system outputs information in various directions through channels listed in the table below.

Table 3-158 Default association between the channel number, channel name, and output direction of information channels

Channel Number	Channel Name	Output Direction
0	console	Console
1	monitor	User terminal
2	loghost	Log host
3	trapbuffer	Trap buffer
4	logbuffer	Log buffer

Channel Number	Channel Name	Output Direction
5	snmpagent	SNMP agent
6	channel6	Unspecified
7	channel7	Unspecified
8	channel8	Unspecified
9	channel9	Log file

Format

info-center { **console** | **logbuffer** | **logfile** | **monitor** | **snmp** | **trapbuffer** } **channel** { *channel-number* | *channel-name* }

undo info-center { { **console** | **monitor** | **snmp** | **logfile** } **channel** | { **logbuffer** | **trapbuffer** } **channel** [*channel-number* | *channel-name*] }

Parameters

Parameter	Description	Value
console	Specifies the channel used to output information to the console.	-
logbuffer	Specifies the channel used to output information to the log buffer.	-
logfile	Specifies the channel used to output information to the log file.	-
monitor	Specifies the channel used to output information to the user terminal.	-
snmp	Specifies the channel used to output information to the SNMP agent.	-
trapbuffer	Specifies the channel used to output information to the trap buffer.	-
channel-number	Specifies the channel number.	The value is an integer ranging from 0 to 9.
channel-name	Specifies the name of a channel, which can be the default channel name or a user-defined name.	The value is a string of 1 to 30 case-insensitive characters. The value consists of letters or numbers and must start with a letter.

Views

System view

Default Level

3: Management level

Usage Guidelines

You can run the **info-center channel** command in the following scenarios: The same information is sent to different directions. For example, the log file and log host record the same content or the trap buffer and the SNMP agent record the same content.

NOTE

The channels should not have the same name.

For details on how to configure a channel for outputting information to a log host, see **info-center loghost**.

The **info-center channel** command takes effect only after the information center function has been enabled using the **info-center enable** command.

Example

Configure the channel used to output information to a console.

```
<HUAWEI> system-view
[HUAWEI] info-center console channel console
```

Configure the channel used to output information to the log buffer.

```
<HUAWEI> system-view
[HUAWEI] info-center logbuffer channel logbuffer
```

Configure the channel used to output information to the user terminal.

```
<HUAWEI> system-view
[HUAWEI] info-center monitor channel monitor
```

Configure the channel used to output information to an SNMP agent.

```
<HUAWEI> system-view
[HUAWEI] info-center snmp channel 5
```

Configure the channel used to output information to the trap buffer.

```
<HUAWEI> system-view
[HUAWEI] info-center trapbuffer channel trapbuffer
```

3.10.17 info-center channel name

Function

The **info-center channel name** command names a channel with a specified number.

The **undo info-center channel** command restores the default channel name.

The following lists default channel names.

Table 3-159 Default channel names

Channel Number	Default Channel Name
0	console
1	monitor
2	loghost
3	trapbuffer
4	logbuffer
5	snmpagent
6	channel6
7	channel7
8	channel8
9	channel9

Format

info-center channel *channel-number* **name** *channel-name*

undo info-center channel *channel-number*

Parameters

Parameter	Description	Value
channel-number	Specifies the number of a channel.	The value is an integer that ranges from 0 to 9. That is, the system has 10 channels.
channel-name	Specifies the name of a channel.	The value is a string of 1 to 30 case-insensitive characters. The value consists of letters or numbers and must start with a letter.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can rename channels, which facilitates memorization and usage.

Precautions

Channel names must be unique. It is recommended that channel names represent channel functions.

Example

Name channel 0 execconsole.

```
<HUAWEI> system-view
[HUAWEI] info-center channel 0 name execconsole
```

3.10.18 info-center enable

Function

The **info-center enable** command enables the information center.

The **undo info-center enable** command disables the information center.

The **info-center disable** command disables the information center.

By default, the information center is enabled.

Format

info-center enable

undo info-center enable

info-center disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

During device running, the information center records device operation. The system outputs system information to destinations such as the log host and the console only after the information center is enabled. Network administrators can store and query output information to monitor device running and locate faults.

Precautions

After the **undo info-center enable** or **info-center disable** command is executed, only logfile, logbuffer, and user session record logs, the other channel no longer records logs.

Follow-up Procedure

Configure a rule for outputting information to the terminal or remote server.

Example

Enable the information center.

```
<HUAWEI> system-view
[HUAWEI] info-center enable
Info: Information center is enabled.
```

3.10.19 info-center filter-id

Function

The **info-center filter-id** command configures the Switch to filter a specified log or trap.

The **undo info-center filter-id** command disables the Switch from filtering a specified log or trap.

By default, no log or trap is filtered.

Format

info-center filter-id { *id* | **bymodule-alias** *modname alias* } &<1-50>

info-center filter-id { *id* | **bymodule-alias** *modname alias* } [**bytime** *interval* | **bynumber** *number*]

undo info-center filter-id all

undo info-center filter-id { *id* | **bymodule-alias** *modname alias* } &<1-50>

undo info-center filter-id { *id* | **bymodule-alias** *modname alias* } [**bytime** *interval* | **bynumber** *number*]

Parameters

Parameter	Description	Value
id	Specifies the ID of the log or trap to be filtered. **NOTE** This parameter indicates the ID of a log. If this parameter fails to be configured, the log specified by this ID does not exist.	The value is in hexadecimal notation and contains 8 digits. The value contains 0-9, a-f, and A-F.
bymodule-alias *modname alias*	Specifies the module name and alias name corresponding to the log or trap to be filtered.	Enumerated type. Set the value according to the device configuration.

Parameter	Description	Value
all	Filters all logs or traps.	-
bytime *interval*	Specifies the interval at which logs are sent.	The value is an integer that ranges from 1 to 86400, in seconds.
bynumber *number*	Specifies the number of logs that are discarded between two received logs.	The value is an integer that ranges from 1 to 1000.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If some logs or traps are unnecessary, configure the Switch not to output the logs and traps. When the filtering function is enabled, the information center does not send the traps with a specified ID that satisfy the filtering condition to any channel. As a result, the trap buffer, console, terminal, or SNMP agent cannot receive the traps with the specified ID.

Precautions

- Currently, the Switch can filter traps with a maximum of 50 IDs. If there are more than 50 log IDs, the system displays a message indicating that the filtering table is full. To configure the filtering function, run the **undo info-center filter-id** { *id* | **bymodule-alias** *modname alias* } &<1-50> [**bytime** *interval* | **bynumber** *number*], or the **undo info-center filter-id all** command to delete original IDs and reconfigure the log ID.
- When both the **bytime** *interval* and **bynumber** *number* parameters are not specified, all the logs with the specified ID will be discarded.
- When the **bytime** *interval* parameter is specified, the interval for sending two allowed logs must be at least the configured time.
- When the **bynumber** *number* parameter is specified, the configured number of logs between two allowed logs must be discarded.
- To add multiple IDs at a time, use a space to separate every two IDs. The result of adding each ID is displayed.
- You cannot add the same ID or alias name repeatedly.
- When you add an unregistered or nonexistent ID or alias name, the system displays a message indicating that the system fails to filter the log or trap with the specified ID or alias name.

- During a software upgrade, if the information filtering function is configured in the old version, but the new version does not support the specified log module and alias, the information filtering configuration of the specified log module and alias will be automatically cleared after the upgrade.
- You are advised to use the module name and alias to filter specified log information. The *id* parameter can be obtained by running the **display info-center register-info** [**module** *module-name*] **log** command in the diagnostic view, and the *modname* and *alias* parameters can be obtained through the command association function.

Example

Filter information by module names and alias names.

```
<HUAWEI> system-view
[HUAWEI] info-center filter-id bymodule-alias CMD CMD_PRI_REARRG
```

Cancel filtering for all logs.

```
<HUAWEI> system-view
[HUAWEI] undo info-center filter-id all
```

Filter the log with the ID of 40394017.

```
<HUAWEI> system-view
[HUAWEI] info-center filter-id 40394017
```

3.10.20 info-center local log-counter disable

Function

The **info-center local log-counter disable** command disables the local log from carrying the sequence number.

The **undo info-center local log-counter disable** command enables the local log to carry the sequence number.

By default, the local log carries the sequence number.

Format

info-center local log-counter disable

undo info-center local log-counter disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the device keeps running for a long time, a large number of logs may be generated.

- You can run the **info-center local log-counter disable** command to disable logs sent to the log buffer, log file, console, or terminal from carrying the sequence number, and run the **undo info-centerlocal log-counter disable** command to enable these logs to carry the sequence number.
- You can run the **undo info-center local log-counter disable** command to enable logs to carry the incremental sequence number, checking whether all logs have been sent to the log buffer, log file, console, or terminal.

NOTE

- Logs sent to the console log file, or terminal are counted separately and therefore carry different sequence numbers in ascending order. The sequence number of the earliest log is 0.
- Logs sent to the log buffer carry sequence numbers in descending order. The sequence number of the latest log is 0.

Example

Disable local logs from carrying the sequence number.

```
<HUAWEI> system-view
[HUAWEI] info-center local log-counter disable
```

Enable local logs to carry the sequence number.

```
<HUAWEI> system-view
[HUAWEI] undo info-center local log-counter disable
```

3.10.21 info-center logbuffer

Function

The **info-center logbuffer** command enables the Switch to send logs to the log buffer.

The **undo info-center logbuffer** command disables the Switch from sending logs to the log buffer.

By default, the Switch is enabled to send logs to the log buffer.

Format

info-center logbuffer

undo info-center logbuffer

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

To log in to a device and check the faults or problems during operation, run the **info-center logbuffer** command to enable the function to output logs to the log buffer. Then, you can view log information in the log buffer.

By configuring the size of the log buffer using the **info-center logbuffer size** *buffersize* command, you can view information about specified logs.

By configuring the number or name of a channel through which a device sends logs to the log buffer using the **info-center logbuffer channel** { *channel-number* | *channel-name* } command, you can send log information through a specified channel to the log buffer.

Example

Enable the Switch to send logs to the log buffer.

```
<HUAWEI> system-view
[HUAWEI] info-center logbuffer
```

3.10.22 info-center logbuffer size

Function

The **info-center logbuffer size** command sets the maximum number of logs in the log buffer.

The **undo info-center logbuffer size** command restores the default maximum number of logs in the log buffer.

By default, a log buffer can store a maximum of 512 logs.

Format

info-center logbuffer size *logbuffer-size*

undo info-center logbuffer size [*logbuffer-size*]

Parameters

Parameter	Description	Value
logbuffer-size	Specifies the maximum number of logs in the log buffer.	The value is an integer that ranges from 0 to 1024. If *logbuffer-size* is 0, logs are not displayed.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the number of logs in the log buffer reaches the maximum value, new logs will replace the existing logs that were placed earlier in the log buffer until all the new logs are stored.

Precautions

When you run the **info-center logbuffer size** command multiple times, only the latest configuration takes effect.

The **info-center logbuffer size** command takes effect only after the information center function has been enabled using the **info-center enable** command.

Example

Set the maximum number of logs in the log buffer to 50.

```
<HUAWEI> system-view
[HUAWEI] info-center logbuffer size 50
```

3.10.23 info-center logfile size

Function

The **info-center logfile size** command sets the log file size.

The **undo info-center logfile size** command restores the default log file size.

By default, the log file size is 8 MB.

Format

info-center logfile size *size*

undo info-center logfile size

Parameters

Parameter	Description	Value
size	Specifies the log file size.	The value is an integer that is 4, 8, 16, or 32, in MB. The default value is 8 MB.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure the Switch to export information to a log file, run the **info-center logfile size** command to set the log file size.

Precautions

If you configure the device to export information to a log file, exported information is saved in the **log.log** or **log.dblg** file. When the **log.log** or **log.dblg** file exceeds the specified size, the system compresses the file in to a zip package and names the compressed file *date time*.log.zip or *date time*.dblg.zip.

The **info-center logfile size** command takes effect only after the information center function has been enabled using the **info-center enable** command.

Example

Set the log file size to 32 MB.

```
<HUAWEI> system-view
[HUAWEI] info-center logfile size 32
```

3.10.24 info-center loghost

Function

The **info-center loghost** command configures the device to output information to a log host.

The **undo info-center loghost** command disables the device from outputting information to a log host.

By default, no information is output to the log host.

Format

info-center loghost *ip-address* [**channel** { *channel-number* | *channel-name* } | **facility** *local-number* | **language** *language-name* | { **vpn-instance** *vpn-instance-name* | **public-net** } | **local-time** | **log-counter** { **disable** | **enable** } | **port** *port* | **security-log** | **operation-log** | { **source-ip** *source-ip-address* } | **transport** { **udp** | **tcp ssl-policy** *policy-name* [**verify-dns-name** *verify-dns-name*] }] *

info-center loghost ipv6 *ipv6-address* [**channel** { *channel-number* | *channel-name* } | **facility** *local-number* | **language** *language-name* | **local-time** | **log-counter** { **disable** | **enable** } | **port** *port* | **security-log** | **operation-log** | **transport** { **udp** | **tcp ssl-policy** *policy-name* [**verify-dns-name** *verify-dns-name*] }] *

undo info-center loghost *ip-address* [**vpn-instance** *vpn-instance-name*]

undo info-center loghost ipv6 *ipv6-address*

info-center loghost domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**channel** { *channel-number* | *channel-name* } | **facility** *local-number* | **language** *language-name* | **log-counter** { **disable** | **enable** } | **local-time** | **port** *port* | **security-log** | **operation-log** | **transport** { **udp** | **tcp ssl-policy** *policy-name* [**verify-dns-name** *verify-dns-name*] }] *

undo info-center loghost domain *domain-name* [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ip-address	Specifies the IPv4 address of the log host.	The value is in dotted decimal notation.
channel { *channel-number* | *channel-name* }	Specifies the channel used to send information to a log host. ● *channel-number*: specifies the number of a channel. ● *channel-name*: specifies the name of a channel. The name can be the default or user-defined channel name.	The value of *channel-number* is an integer that ranges from 0 to 9. The value of *channel-name* is a string of 1 to 30 case-insensitive characters. The value consists of letters or numbers and must start with a letter.
facility *local-number*	Specifies a syslog server facility that is used to identify the log information source. You can use this parameter to plan a local value for the log information of a specified device, so that the syslog server can handle received log information based on the parameter.	The value ranges from local0 to local7. The default value is local7.
language *language-name*	Displays the language in which logs are recorded.	Currently, the value can only be English.

Parameter	Description	Value
vpn-instance *vpn-instance-name*	VPN instance.	The value must be an existing VPN instance name. **NOTE** _public_ cannot be specified as a VPN instance name.If the VPN instance is not created, the command does not take effect.
public-net	Indicates that the log host is connected in the public network.	-
local-time	Indicates the local time when logs are sent to the log host.	-
log-counter { **disable** | **enable** }	Disables or enables the log counter function.	-
port *port*	Specifies the port number of a log host.	The value is an integer that ranges from 1 to 65535. By default, when the transport mode is UDP, the port number of the log host is 514; when the transport mode is TCP, the port number of the log host is 6514.
security-log	Configures a device to send security logs to a specified log host.	-
operation-log	Configures a device to send operation logs to a specified log host.	-
source-ip *source-ip-address*	Specifies the source IP address used to send information to the log host.	The value is in dotted decimal notation.
transport	Indicates the information transport mode.	-

Parameter	Description	Value
udp	Indicates the UDP transport mode. **NOTE** The default transport mode is UDP if no transport mode is specified.	-
tcp	Indicates the TCP transport mode. **NOTE** The default transport mode is UDP if no transport mode is specified.	-
ssl-policy *policy-name*	Specifies a Secure Sockets Layer (SSL) policy in the TCP transport mode. This parameter is recommended to improve log transmission security.	The value is a string of 1 to 23 case-insensitive characters without spaces.
verify-dns-name *verify-dns-name*	Verify DNS identifier name.	The value is a string of 1 to 255 case-insensitive characters without spaces.
ipv6 *ipv6-address*	Specifies the IPv6 address of the log host.	The value is a 32-digit hexadecimal number.
domain *domain-name*	Specifies a DNS domain name of a log host.	The value is a string of 1 to 255 case-sensitive characters, spaces not supported.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To query information generated on the Switch deployed remotely, configure the Switch to export information to a log host so that you can view device information on the log host. Run the **info-center loghost** command to configure the Switch to export information to a log host.

To configure the Switch to output information to different log hosts using different channels, specify the channels used to send information to the log hosts. For example, you can configure the Switch to output information to log hosts at 192.168.0.1 and 192.168.0.2 using channels 7 and 8 respectively.

Precautions

The Switch can output information to eight log hosts including IPv4 and IPv6 hosts to implement backup among log hosts.

To transfer logs to the log hosts using TCP and encrypt logs using SSL, create an SSL policy first.

If the **set net-manager vpn-instance** command is run to configure the NMS to manage network elements through a VPN instance, either of the following situations occurs.

- If **vpn-instance** is configured, the system accesses the log host in the VPN instance.
- If **public-net** is configured, the system accesses the log host on the public network.

If the **transport tcp ssl-policy** *policy-name* parameters are specified to enable logs to be transmitted in TCP mode through SSL encryption, perform the following operations:

- Run the **ssl-policy** *policy-name* command to configure an SSL policy and enter the SSL policy view.
- Run the **trusted-ca load** command to load trusted-CA files (**cacert** and **rootcert** files) of the SSL client.
- On the log server, load trusted-CA files (**serverkey** and **servercert** files) of the SSL server.
- Run the **display tcp status** command to check that the TCP connection status of port 6514 is **Established**.

Example

Configure a device to use channel 6 to output information to the log host at 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] info-center loghost 10.1.1.1 channel channel6
```

Configure the source IP address used to send information to the log host is Loopback1.

```
<HUAWEI> system-view
[HUAWEI] info-center  loghost source LoopBack1
```

Configure the Switch to send information to the log host at FC00:0:0:3001::1/64.

```
<HUAWEI> system-view
[HUAWEI] info-center loghost ipv6 fc00:0:0:3001::1
```

Configure the Switch to send information to the host with the IPv4 address 192.168.2.2 and VPN instance name **vpn1**.

```
<HUAWEI> system-view
[HUAWEI] info-center loghost 192.168.2.2 vpn-instance vpn1
```

Configure a device to send information to a log host with the domain name set to **www.test.com**.

```
<HUAWEI> system-view
[HUAWEI] info-center loghost domain www.test.com
```

Configure a device to send information to the log host at 192.168.2.2 in TCP mode, using the SSL policy **YsHsjx_202206** that has been created in the system.

```
<HUAWEI> system-view
[HUAWEI] ssl policy YsHsjx_202206
[HUAWEI-ssl-policy-ftps_der] trusted-ca load pem-ca 1_cacert_pem_rsa.pem
[HUAWEI-ssl-policy-ftps_der] trusted-ca load pem-ca 1_rootcert_pem_rsa.pem
[HUAWEI-ssl-policy-ftps_der] quit
```

3.10.25 info-center loghost source

Function

The **info-center loghost source** command configures the source interface used by the Switch to send information to a log host.

The **undo info-center loghost source** command restores the default source interface used by the Switch to send information to a log host.

By default, the source interface for a device to send logs to a log host is the actual interface that sends the logs.

Format

info-center loghost source *interface-type interface-number*

undo info-center loghost source

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If multiple devices send log messages to the same log host, you can identify the devices by setting different source interfaces so as to index the received log messages.

The source interface specified in the **info-center loghost source** command for a device to send logs to a log host is not necessarily the actual interface that sends the logs, but the IP address of the specified source interface is carried in logs.

Prerequisites

There is a reachable route between the source interface and the log host.

Example

Specify Loopback0 IP address as the source interface address to send information to a log host.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 0
[HUAWEI-LoopBack0] ip address 10.1.1.1 255.255.255.0
[HUAWEI-LoopBack0] quit
[HUAWEI] info-center loghost source loopback 0
```

3.10.26 info-center loghost source-port

Function

The **info-center loghost source-port** command configures a source interface through which the device sends information to the log host.

The **undo info-center loghost source-port** command restores the default source interface through which the device sends information to the log host.

By default, the source interface number is 38514.

Format

info-center loghost source-port *source-port*

undo info-center loghost source-port

Parameters

Parameter	Description	Value
source-port	Specifies the number of the source interface through which the device sends information to the log host.	The value is an integer ranging from 1025 to 65535.

Views

System view

Default Level

3: Management level

Usage Guidelines

If the device uses the default source interface to send information to the log host, attackers may keep accessing this interface. As a result, the log host cannot send information. To improve system security, you can run the **info-center loghost source-port** *source-port* command to change the source interface through which the device sends information to the log host so that attackers cannot obtain the new source interface.

Example

Change the number of the source interface through which the device sends information to the log host to 1026.

```
<HUAWEI> system-view
[HUAWEI] info-center loghost source-port 1026
```

3.10.27 info-center max-logfile-number

Function

The **info-center max-logfile-number** command sets the maximum number of log files to be saved.

The **undo info-center max-logfile-number** command restores the default maximum number of log files to be saved.

By default, a maximum of 500 log files can be stored on the S5732-H, S6730-H, S6730-S, S6730S-S, and S6730S-H, and a maximum of 200 log files can be stored on other models.

Format

info-center max-logfile-number *filenumbers*

undo info-center max-logfile-number

Parameters

Parameter	Description	Value
filenumbers	Specifies the maximum number of log files that can be saved.	The value is an integer that ranges from 3 to 500.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If too many log files are saved on the Switch, many disk space resources are occupied. To view log files generated recently, run the **info-center max-logfile-number** command to set the maximum number of log files that can be saved.

Precautions

If the number of log files generated on the Switch exceeds the limit, the system deletes the oldest log file so that the number of log files is not larger than the maximum value.

NOTICE

If the number of saved log files is greater than the default value, more system resources are consumed. The default value is recommended. Excess log files can be deleted automatically. When the system deletes excess log files, high CPU usage may last for a short period.

Example

Set the maximum number of log files to be saved to 100.

```
<HUAWEI> system-view
[HUAWEI] info-center max-logfile-number 100
```

3.10.28 info-center rate-limit except

Function

The **info-center rate-limit except** command cancels the log processing rate limit for logs.

The **undo info-center rate-limit except** command deletes the preceding configuration.

Format

info-center rate-limit except { **byinfoid** *infoID* | **bymodule-alias** *modname alias* }

undo info-center rate-limit except { **byinfoid** *infoID* | **bymodule-alias** *modname alias* }

Parameters

Parameter	Description	Value
byinfoid *infoID*	Specifies the log ID in hexadecimal notation.	The value is a 32-digit hexadecimal number in the format XXXXXXXX. It ranges from 0 to fffffff.
bymodule-alias *modname*	Specifies the log module name.	The value is a string of 1 to 24 case-insensitive characters without spaces.

Parameter	Description	Value
alias	Specifies the log mnemonic name.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

System view

3: Management level

Usage Guidelines

When too many logs will never be generated under a specified ID, you can run the **info-center rate-limit except** command to avoid the impact of the suppression of the log processing rate. After this command is run, the configured log processing rate limit will not be effective for logs with the specified ID or module name.

During a software upgrade, if the function that prevents logs from being suppressed by the information center is configured in the old version, but the new version does not support the specified log module and alias, the function configuration of the specified log module and alias will be automatically cleared after the upgrade.

Example

Prevent logs specified by the module name and mnemonic from being suppressed by the information center.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit except bymodule-alias AAA AUTHEN_ERR_EVENT
```

Prevent logs specified by the log ID from being suppressed by the information center.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit except byinfoid ff011015
```

Prevent logs with a specified log ID from being suppressed by the information center.

```
<HUAWEI> system-view
[HUAWEI] undo info-center rate-limit except bymodule-alias AAA AUTHEN_ERR_EVENT
```

3.10.29 info-center rate-limit global-threshold

Function

The **info-center rate-limit global-threshold** command sets the total number of logs that the information center can process every second.

The **undo info-center rate-limit global-threshold** command restores the default value.

By default, the information center processes a maximum of 400 logs in every second.

Format

info-center rate-limit global-threshold *value*

undo info-center rate-limit global-threshold

Parameters

Parameter	Description	Value
value	Specifies the maximum number of logs that the information center can process every second.	The value is an integer that ranges from 100 to 1000.

Views

System view

Default Level

3: Management level

Usage Guidelines

You can run the **info-center rate-limit global-threshold** command to adjust the processing capability of the information center. If the number of logs to be processed exceeds the processing capability of the information center, the extra logs are discarded.

NOTE

- If the threshold is too low, some logs may be discarded.
- If the threshold is too high, the information center cannot identify the log ID under which too many logs are generated. The number of logs to be processed depends on the current processing capacity of the information center.

Example

Set the number of logs that the information center can process every second to 300.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit global-threshold 300
```

3.10.30 info-center rate-limit monitor-period

Function

The **info-center rate-limit monitor-period** command sets the monitoring period for the information center to suppress the log processing rate.

The **undo info-center rate-limit monitor-period** command restores the default value.

By default, the monitoring period is 3 seconds.

Format

info-center rate-limit monitor-period *value*

undo info-center rate-limit monitor-period

Parameters

Parameter	Description	Value
value	Specifies the monitoring period for the information center to suppress the log processing rate.	The value is an integer ranging from 1 to 60, in seconds.

Views

System view

Default Level

3: Management level

Usage Guidelines

In the monitoring period specified by *value*, if the rate of sending a single log every second exceeds the threshold configured using the **info-center rate-limit threshold** command, the information center will limit the log processing rate. In this situation, the information center discards logs exceeding the threshold.

In the monitoring period that is five times *value*, if the number of a single type of logs that are sent every second is smaller than the threshold configured using the **info-center rate-limit threshold** command, the information center does not limit the log processing rate.

Example

Set the monitoring period for the information center to suppress the log processing rate to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit monitor-period 5
```

3.10.31 info-center rate-limit threshold

Function

The **info-center rate-limit threshold** command sets the maximum number of logs with the same log ID that the information center can process every second.

The **undo info-center rate-limit threshold** command restores the default setting.

By default, the information center processes a maximum of 30 logs with the same log ID in every second.

Format

info-center rate-limit threshold *value* [**byinfoid** *infoID* | **bymodule-alias** *modname alias*]

undo info-center rate-limit threshold [*value*] [**byinfoid** *infoID* | **bymodule-alias** *modname alias*]

Parameters

Parameter	Description	Value
value	Specifies the maximum number of logs with the same log ID that the information center can process every second.	The value is an integer that ranges from 1 to 500.
byinfoid *infoID*	Specifies the log ID.	The value is a 32-digit hexadecimal number in the format XXXXXXXX. It ranges from 0 to ffffffff.
bymodule-alias *modname*	Specifies the log of the module name.	The value is a string of 1 to 24 case-insensitive characters without spaces.
alias	Specifies the log of the mnemonic name.	The value is a string of 1 to 64 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

You can run the **info-center rate-limit threshold** command to set the maximum number of logs with the same log ID that the information center can process every second. The information center monitors the number of logs that are generated every second under the same log ID. When the number of logs that are generated every second under the same log ID exceeds the threshold in the monitoring period, the information center decides that too many logs are generated and suppresses its log processing rate by processing only the conforming traffic (logs within the threshold) and discarding the non-conforming traffic (logs exceeding the threshold). When the number of logs that are generated every second under the same log ID falls below the threshold and remains below the threshold for five monitoring periods, the information center removes the suppression.

By default, the information center processes a maximum of 30 logs with the same log ID in every second. In certain application scenarios, by default, the information center needs to process more than 50 logs with the same log ID in every second. You can set thresholds for logs with different log IDs. Generally, the default threshold is recommended.

- If the threshold is too low, some logs may be discarded.
- If the threshold is too high, the information center cannot identify the log ID under which too many logs are generated.

NOTE

- If the threshold *value1* specified by the parameter **byinfoid** *infoID* or **bymodule-alias** *modname alias* differs from the threshold *value0* specified globally, *value1* takes effect.
- During a software upgrade, if the threshold is configured in the old version, but the new version does not support the specified log module and alias, the threshold configuration of the specified log module and alias will be automatically cleared after the upgrade.

Example

Set the maximum number of logs that the information center can process every second to 60.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit threshold 60
```

Set the maximum number of logs identified by the same module name and mnemonic that the information center can process every second to 30.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit threshold 30 bymodule-alias AAA AUTHEN_ERR_EVENT
```

Set the maximum number of logs with the same log ID that the information center can process every second to 20.

```
<HUAWEI> system-view
[HUAWEI] info-center rate-limit threshold 20 byinfoid ff011015
```

Restore the maximum number of logs that the information center can process every second to the default value.

```
<HUAWEI> system-view
[HUAWEI] undo info-center rate-limit threshold
```

Cancel the restriction on the maximum number of logs with a specified log ID that the information center can process every second.

```
<HUAWEI> system-view
[HUAWEI] undo info-center rate-limit threshold bymodule-alias AAA AUTHEN_ERR_EVENT
```

3.10.32 info-center session log disable

Function

The **info-center session log disable** command disables the user session logging function.

The **undo info-center session log disable** command enables the user session logging function.

By default, the user session logging function is enabled.

Format

info-center session log disable

undo info-center session log disable

Parameters

None

Views

System view

Level

3: Management level

Usage Guidelines

Usage Scenario

The user session logging function saves the user input, device screen output, and time when the device executes the commands entered by users to a session log file. If the device becomes faulty or services become abnormal, you can obtain the user operation records from the saved session log file for fault location.

A session log file is generated in each VTY window and named cli_channel name.log, for example: **cli_vty1.log**. The generated session log files are stored in the sessionlog directory. The file size cannot exceed 1 MB.

If the number of session log files exceed the maximum value 20 (cannot be changed), the system compresses the files into .zip files. The compressed file is named cli_slot ID_timestamp_channel name_host name.log.zip, for example: **cli_11_20171129081148_vty1_huawei.log.zip**.

If the remaining device space is less than 30 MB, the system deletes the earliest log files until the remaining device space is more than 30 MB.

Precautions

Using the **undo info-center enable** or **info-center disable** command disables the information center will not affect the user session logging function. This function can only be enabled or disabled using the **undo info-center session log disable** or **info-center session log disable** command.

Example

Disable the user session logging function.

```
<HUAWEI> system-view
[HUAWEI] info-center session log disable
```

3.10.33 info-center source channel

Function

The **info-center source channel** command configures a rule for outputting information to a channel.

The **undo info-center source channel** command deletes the rules for outputting information to a channel.

The following lists the default rule for outputting information to a channel.

Table 3-160 Default rule for outputting information to a channel

Output Channel	Module Enabled to Output Information	Log		Trap		Debugging Message	
		Status	Lowest Output Severity	Status	Lowest Output Severity	Status	Lowest Output Severity
0 (console)	default	on	warning	on	debugging	on	debugging
1 (remote terminal)	default	on	warning	on	debugging	on	debugging
2 (log host)	default	on	informational	on	debugging	off	debugging
3 (trap buffer)	default	off	informational	on	debugging	off	debugging
4 (log buffer)	default	on	warning	off	debugging	off	debugging
5 (SNMP agent)	default	Not supported	Not supported	on	debugging	Not supported	Not supported
6 (channel 6)	default	on	debugging	on	debugging	off	debugging
7 (channel 7)	default	on	debugging	on	debugging	off	debugging
8 (channel 8)	default	on	debugging	on	debugging	off	debugging
9 (channel 9)	default	on	debugging	on	debugging	off	debugging

Format

info-center source { *module-name* | **default** } **channel** { *channel-number* | *channel-name* } [**log** { **state** { **off** | **on** } | **level** *severity* } * | **trap** { **state** { **off** | **on** } | **level** *severity* } * | **debug** { **state** { **off** | **on** } | **level** *severity* } *] *

undo info-center source { *module-name* | **default** } **channel** { *channel-number* | *channel-name* }

Parameters

Parameter	Description	Value
module-name	Specifies the module name.	Enumerated type. The value depends on the registered module.
default	Indicates the default module.	-
channel-number	Specifies the number of a channel.	The value is an integer that ranges from 0 to 9.
channel-name	Specifies the name of a channel.	The value is a string of 1 to 30 case-insensitive characters. The value consists of letters or numbers and must start with a letter.
log { **state** { **off** | **on** } }	Specifies the log status. - **off**: Logs are not sent. - **on**: Logs are sent. **NOTE** This field does not take effect for diagnostic logs.	-

Parameter	Description	Value
log { **level** *severity* }	Specifies the lowest severity of output logs. **NOTE** This field does not take effect for diagnostic logs.	Logs are classified into eight severities. The following severities are listed in descending order of priority: - emergencies - alert - critical - error - warning - notification - informational - debugging
trap { **state** { **off** | **on** } }	Specifies the trap status: - **off**: Traps are not sent. - **on**: Traps are sent.	-
trap { **level** *severity* }	Specifies the lowest severity of output traps.	Traps are classified into eight severities. The following severities are listed in descending order of priority: - emergencies - alert - critical - error - warning - notification - informational - debugging
debug { **state** { **off** | **on** } }	Specifies the debugging message status. - **off**: Debugging messages are not sent. - **on**: Debugging messages are sent.	-

Parameter	Description	Value
debug { **level** *severity* }	Specifies the lowest severity of output debugging messages.	Debugs are classified into eight severities. The following severities are listed in descending order of priority: - emergencies - alert - critical - error - warning - notification - informational - debugging

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To collect and query information generated on the Switch, define severities for various types of information that is output to different channels. You can run the **info-center source channel** command to configure a rule for outputting information to a channel.

The following lists information severities.

Table 3-161 Information severities

Value	Severity	Description
0	emergencies	A fault causes the device to fail to run normally unless it is restarted. For example, the device is restarted because of program exceptions or a memory error is detected.
1	alert	A fault needs to be rectified immediately. For example, memory usage of the system reaches the upper limit.

Value	Severity	Description
2	critical	A fault needs to be analyzed and processed. For example, the memory usage falls below the lower threshold; temperature falls below the alarm threshold; BFD detects that a device is unreachable or detects locally generated error messages.
3	error	An improper operation is performed or exceptions occur during service processing. The fault does not affect services but needs to be analyzed. For example, users enter incorrect commands or passwords; error protocol packets are received from other devices.
4	warning	Some events or operations may affect device running or cause service processing faults, which requires full attention. For example, a routing process is disabled; BFD detects packet loss; error protocol packets are detected.
5	notification	A key operation is performed to keep the device running normally. For example, the **shutdown** command is run; a neighbor is discovered; protocol status changes.
6	informational	A normal operation is performed. For example, a **display** command is run.
7	debugging	A normal operation is performed, which requires no attention.

Precautions

Each information channel has a default record with the module name **default**. The default configuration for logs, traps, and debugging messages in different channels may differ.

If a module generates a large number of logs, traps, or debugging messages in a short time, use the following methods to suppress this information:

- Specify **level** *severity* to adjust the channel level. Information with lower severity will be filtered.
- Specify **state off** to disable information sent by a specified module.

NOTICE

After the lowest severity of output information is specified, information lower than the severity will be filtered.

Example

Enable the device to send debugging messages of the CFM module through the log host channel, and set the lowest severity of output debugging messages to warning.

```
<HUAWEI> system-view
[HUAWEI] info-center source CFM channel loghost debug level warning
```

3.10.34 info-center statistic-suppress enable

Function

The **info-center statistic-suppress enable** command enables suppression of statistics about consecutive repeated logs.

The **undo info-center statistic-suppress enable** command disables suppression of statistics about consecutive repeated logs.

The **info-center statistic-suppress disable** command disables suppression of statistics about consecutive repeated logs.

By default, suppression of statistics about consecutive repeated logs is enabled.

Format

info-center statistic-suppress enable

undo info-center statistic-suppress enable

info-center statistic-suppress disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In the system, service modules generate logs and control the volume of generated logs. The information center processes the received logs.

A large number of repeated logs are generated in a short time in some scenarios, for example, when ARP and VRRP are enabled. This wastes both the storage space and CPU resources. Generally, users do not want to view the repeated logs. You can run the **info-center statistic-suppress enable** command to suppress statistics on consecutive repeated logs so that the system can still record other logs.

NOTE

Logs that are generated consecutively and with the identical log ID and parameters can be regarded as repeatedly generated logs.

Precautions

Statistics about repeatedly generated logs are first output at the 30th seconds from the time the first log is output, and then statistics about repeatedly generated logs are output at the 120th seconds. After being output two times, statistics about repeatedly generated logs are output every 600 seconds.

By default, once receiving a log, the information center outputs the log. If the information center receives repeatedly generated logs within a period, it outputs the number of these logs and will output logs only when it receives a new log (a log with a different log ID). For example, a module sends logs to the information center in the sequence of A1(T1) A2(T2) A3(T2) B1(T3) B2(T4) B3(T4) C1(T5) C2(T6) A4(T7) B4(T8) B5(T8) B5(T8) B7(T9) A5(T9) B8(T10) D1(T11) A6(T11) A7(T12) A8(T12) A9(T13) A10(T14) A11(T15) A12(T16) A13(T17) A14(T18) B9(T18). A1 to A14 are the same; B1 to B9 are the same; C1, C2 and D1 are different from others; T1 to T18 are sequence numbers. The log information output by the information center is as follows:

```
T1:A1
T3(1): last message repeated 2 times
T3:B1
T5: last message repeated 2 times
T5:C1
T6:C2
T7:A4
T8:B4
T9(1): last message repeated 3 times
T9:A5
T10:B8
T11:D1
T11:A6
T13(2): last message repeated 3 times
T18(2): last message repeated 5 times
T18:B9
```

Logs of the service module received by the information center show that:

- Statistics about repeatedly generated logs are output when either of the following conditions is met:
  - The next log is a different log, as shown in **(1)**.
  - The time period (every 30 seconds, 120 seconds, and 600 seconds) for outputting log statistics expires, as shown in **(2)**.
- Each time the statistics are output, the service module clears the count and starts counting again. For example, during the period from T11 to T18, log A is generated 9 times.
- The information center outputs logs in the same sequence the logs are generated, making the trace of information and scenario easy.

NOTE

Logs with the sequence being A B A B A B A B are alternate logs; therefore, the **info-center statistic-suppress enable** command is unable to suppression the statistics about these logs.

Example

Disable suppression of statistics about consecutive repeated logs.

```
<HUAWEI> system-view
[HUAWEI] undo info-center statistic-suppress enable
```

3.10.35 info-center timestamp

Function

The **info-center timestamp** command sets the timestamp format of logs, traps, and debugging messages.

The **undo info-center timestamp** command restores the default timestamp format of logs, traps, and debugging messages.

By default, the **date** timestamp is used in traps, logs and debugging messages. Debugging messages are accurate to milliseconds, and traps and logs are accurate to seconds.

Format

info-center timestamp { **debugging** | **log** | **trap** } { { **date** | **format-date** | **short-date** } [**precision-time** { **second** | **tenth-second** | **millisecond** }] | **boot** } [**without-timezone**]

undo info-center timestamp { **debugging** | **trap** | **log** }

Parameters

Parameter	Description	Value
debugging	Indicates debugging messages.	-
log	Indicates logs.	-
trap	Indicates traps.	-
boot	Indicates that the timestamp is expressed in the format of relative time, a period of time since the start of the system. The format is xxxxxx.yyyyyy. xxxxxx is the higher order 32 bits of the milliseconds elapsed since the start of the system; yyyyyy is the lower order 32 bits of the milliseconds elapsed since the start of the system.	-
date	Specifies the current date and time. It is expressed in mm dd yyyy hh:mm:ss format.	-
short-date	Indicates the short date. This timestamp differs from **date** is that the year is not displayed.	-
format-date	Indicates that the timestamp is expressed in YYYY-MM-DD hh:mm:ss format.	-
precision-time	Specifies the precision.	-

Parameter	Description	Value
second	Indicates that the precision is accurate to seconds.	-
tenth-second	Indicates that the precision is accurate to 0.1 second.	-
millisecond	Indicates that the precision is accurate to milliseconds.	-
without-timezone	Specifies a timestamp to filter timezone information. **NOTE** If **without-timezone** is configured for logs, traps, or debug information, the log, trap, or debugging information sent to the log host does not carry time zone or DST information.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

The **info-center timestamp** command sets the timestamp format of logs, traps, and debugging messages.

The following describes the timestamp in **date** format.

Table 3-162 Description of fields of the timestamp in **date** format

Field	Description	Value
mm	Month	The value can be Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, or Dec.
dd	Date	1-31. If the date is smaller than 10, add a space in front of the date, For example, " 7".
yyyy	Year	4 digits
hh:mm:ss	Local time	hh ranges from 00 to 23, and mm or ss ranges from 00 to 59.

When the precision of the timestamp is accurate to 0.1 second or milliseconds, the system adds identifiers to the logs generated at the same time based on the sequence.

Prerequisites

The information center has been enabled by using the **info-center enable** command.

Example

Set the timestamp format of traps to **boot**.

```
<HUAWEI> system-view
[HUAWEI] info-center timestamp trap boot
```

Set the timestamp precision of logs, traps, and debugging messages.

```
<HUAWEI> system-view
[HUAWEI] info-center timestamp log date precision-time millisecond
[HUAWEI] info-center timestamp debugging date precision-time tenth-second
[HUAWEI] info-center timestamp trap date precision-time millisecond
```

3.10.36 info-center trapbuffer

Function

The **info-center trapbuffer** command enables the Switch to send traps to the trap buffer.

The **undo info-center trapbuffer** command disables the Switch from sending traps to the trap buffer.

By default, the Switch is enabled to send traps to the trap buffer.

Format

info-center trapbuffer

undo info-center trapbuffer

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

To view traps in the trap buffer, run the **info-center trapbuffer** command to enable the Switch to send traps to the trap buffer.

The **info-center trapbuffer** command takes effect only after the information center function has been enabled using the **info-center enable** command.

Example

Enable the Switch to send traps to the trap buffer.

```
<HUAWEI> system-view
[HUAWEI] info-center trapbuffer
```

3.10.37 info-center trapbuffer size

Function

The **info-center trapbuffer size** command sets the maximum number of traps in the trap buffer.

The **undo info-center trapbuffer size** command restores the default maximum number of traps in the trap buffer.

By default, a trap buffer allows a maximum of 256 traps.

Format

info-center trapbuffer size *trapbuffer-size*

undo info-center trapbuffer size [*trapbuffer-size*]

Parameters

Parameter	Description	Value
trapbuffer-size	Specifies the maximum number of traps in the trap buffer.	The value is an integer that ranges from 0 to 1024. If *trapbuffer-size* is 0, traps are not displayed.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **info-center trapbuffer size** command sets the maximum number of traps in the trap buffer.

Prerequisites

The Switch has been enabled to output traps to the trap buffer by using the **info-center trapbuffer** command.

Precautions

When you run the **info-center trapbuffer size** command multiple times, only the latest configuration takes effect.

If a small value of *trapbuffer-size* is used, some traps may be not displayed. If a large value of *trapbuffer-size* is used, repeated traps may be displayed. The default value of *trapbuffer-size* is recommended.

Example

Set the maximum number of traps in the trap buffer to 30.

```
<HUAWEI> system-view
[HUAWEI] info-center trapbuffer size 30
```

3.10.38 log restrain disable

Function

The **log restrain disable** command disables log restrainion.

The **undo log restrain disable** command enables log restrainion.

By default, log restrainion is enabled.

Format

log restrain disable

undo log restrain disable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

When a large number of logs are generated, device resources are wasted, affecting system performance. To prevent this problem, enable log restrainion.

Example

Disable log restrainion.

```
<HUAWEI> system-view
[HUAWEI] log restrain disable
```

3.10.39 log restrain threshold

Function

The **log restrain threshold** command sets the maximum number of logs that can be generated per minute.

The **undo log restrain threshold** command restores the default setting.

By default, a maximum of 200 logs can be generated per minute.

Format

log restrain threshold *threshold-value* [**infoid** *infoid-value* **description** *description-str*]

undo log restrain threshold [**infoid** *infoid-value*]

Parameters

Parameter	Description	Value
threshold-value	Specifies the maximum number of logs that can be generated per minute.	The value is an integer that ranges from 10 to 50000.
infoid *infoid-value*	Specifies a log ID. If this parameter is specified, *threshold-value* specifies the maximum number of logs with the specified ID that can be generated per minute. If this parameter is not specified, *threshold-value* specifies the maximum number of logs that can be generated globally on the device per minute.	The value is a 32-digit hexadecimal number in the format XXXXXXXX. It ranges from 0 to ffffffff.
description *description-str*	Specifies the description of the log with the sepecified ID.	The value is a string of 1 to 32 case-insensitive characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

After log restrainion is enabled, if the number of logs generated per minute exceeds the specified threshold, excess logs are discarded.

You can run the **display log restrain all** command to check the configuration of the log suppression function. If the value of **MaxCount** in the command output is **NotLimit**, the log of the corresponding ID is not suppressed.

Example

Set the maximum number of logs that can be generated globally on the device per minute to 100.

```
<HUAWEI> system-view
[HUAWEI] log restrain threshold 100
```

3.10.40 reset info-center statistics

Function

The **reset info-center statistics** command clears statistics on each module.

Format

reset info-center statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To re-collect statistics on each module, run the **reset info-center statistics** command to clear all historical statistics.

Precautions

The cleared statistics cannot be restored. Exercise caution when you run the **reset info-center statistics** command.

Example

Clear statistics on each module.

```
<HUAWEI> reset info-center statistics
```

3.10.41 reset logbuffer

Function

The **reset logbuffer** command clears logs in the log buffer.

Format

reset logbuffer

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To record logs in the log buffer again, run the **reset logbuffer** command to clear all the information in the log buffer.

Precautions

Statistics cannot be restored after being cleared. Exercise caution when you run the **reset logbuffer** command.

Example

Clear information in the log buffer.

```
<HUAWEI> reset logbuffer
Warning: This command will reset the log buffer. Logs in the buffer will be lost. Continue? [Y/N]:y
```

3.10.42 reset log restrain statistics

Function

The **reset log restrain statistics** command clears all log suppression statistics.

Format

reset log restrain statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

To clear all log suppression statistics, run this command.

Example

Clear all log suppression statistics.

```
<HUAWEI> reset log restrain statistics
```

3.10.43 reset trapbuffer

Function

The **reset trapbuffer** command clears Trap information in the trap buffer.

Format

reset trapbuffer

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To record traps in the trap buffer again, run the **reset trapbuffer** command to clear all the information in the trap buffer.

Precautions

Statistics cannot be restored after being cleared. Exercise caution when you run the **reset trapbuffer** command.

Example

Clear information in the trap buffer.

```
<HUAWEI> reset trapbuffer
```

3.10.44 save logfile

Function

The **save logfile** command saves logs in the user log file buffer to a user log file.

Format

save logfile

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The system periodically saves log information in the user log buffer to a user log file. If the log buffer becomes full within the log saving interval, the system immediately saves logs to the user log file. To view the current logs, run the **save logfile** command to save the logs to the user log file.

When you run this command, the device obtains or uses some personal data of users, such as the STA MAC address. Delete the personal data immediately after the command is executed to ensure user data security.

Example

Save logs in the user log file buffer to the user log file.

```
<HUAWEI> save logfile
Info: Save logfile successfully.
```

3.10.45 save logfile all

Function

The **save logfile all** command saves the logs in the user log buffer area and diagnostic log buffer area to the user log file and diagnostic log file, respectively.

Format

save logfile all

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The logs in the user log buffer area and diagnostic log buffer area are periodically saved to the user log file and diagnostic log file, respectively. The log saving interval varies with the product. To save the logs in the user log buffer area and diagnostic log buffer area to the user log file and diagnostic log file, respectively, run the **save logfile all** command.

A user log file is saved in a log directory (for example, the **log** or **logfile** directory) and named in the **log.log** format.

A diagnostic log file is saved in a log directory (for example, the **log** or **logfile** directory) and named in the **log.dblg** format.

Example

Save the logs in the user log buffer area and diagnostic log buffer area to the user log file and diagnostic log file, respectively.

```
<HUAWEI> save logfile all
Info: Save logfile successfully.
Info: Save diagnostic logfile successfully.
```

3.10.46 terminal debugging

Function

The **terminal debugging** command enables debugging message display on the user terminal.

The **undo terminal debugging** command disables debugging message display on the user terminal.

By default, debugging message display is disabled on the user terminal.

Format

terminal debugging

undo terminal debugging

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **terminal debugging** command to enable debugging message display on the user terminal to view system debugging message and locate faults.

Prerequisites

The **terminal monitor** command has been executed to enable display of logs, traps, and debugging message output on the user terminal.

Example

Enable debugging message display on the user terminal.

```
<HUAWEI> terminal debugging
Info: Current terminal debugging is on.
```

3.10.47 terminal echo synchronous

Function

The **terminal echo synchronous** command enables a terminal to display debugging, log, or trap information synchronously.

The **undo terminal echo synchronous** command disables a terminal from displaying debugging, log, or trap information synchronously.

By default, a terminal displays debugging, log, and trap information asynchronously.

Format

terminal echo synchronous [**level** { *severity* | **all** } | **size** *size-number*] *

undo terminal echo synchronous

Parameters

Parameter	Description	Value
level *severity*	Specifies an information severity.	The value is an integer ranging from 0 to 7. The default value is **0**. The information center classifies information into the following severities: - 0: emergency - 1: alert - 2: critical - 3: error - 4: warning - 5: notice - 6: informational - 7: debug A smaller value indicates a higher severity. The information with a severity higher than a specified severity is displayed asynchronously.
all	Displays information of all severities.	-
size *size-number*	Specifies the total number of debugging, log, and trap records.	The value is an integer ranging from 1 to 1024. The default value is **512**.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a device generates debugging, log, or trap information, the information queues in the device process and is sent to a terminal sequentially. This output is called a synchronous output.

A synchronous output provides effectively organized output information, improving user experience. In asynchronous output mode, multiple types of information interlaces, which brings poor readability. An asynchronous output allows you to promptly obtain debugging and diagnosis information and therefore applies to debugging and diagnosis scenarios.

You can run the **terminal echo synchronous** command to enable a synchronous output on a terminal, facilitating subsequent operations.

- When you enter a command, the entered command content is displayed after debugging, log, or trap information is displayed. This function is enabled by default. After a synchronous output is disabled, this function is still supported.
- When no command is entered, the command prompt is displayed after debugging, log, or trap information is displayed. This function is enabled by default. After a synchronous output is disabled, this function is still supported.
- When a command is being run, no debugging, log, or trap information is displayed. After the command is run, debugging, log, or trap information is displayed.
- When you enter **Y** for the message "Are you sure to continue?[Y/N]," the **[Y/N]:** prompt is displayed after debugging, log, or trap information is displayed.
- When you enter the More phase, the **More** prompt is displayed after debugging, log, or trap information is displayed.
- If you run a command, for example, for decompressing or saving a file, the terminal does not display output information until the operation is complete. This process ensures monitoring continuity.

Prerequisites

- Terminal display has been enabled using the **terminal monitor** command.
- The terminal has been enabled to display debugging, log, or trap information using the **terminal debugging**, **terminal logging**, or **terminal trapping** command.

Example

Enable a terminal to display debugging information synchronously.

```
<HUAWEI> terminal monitor
Info: Current terminal monitor is on.
<HUAWEI> terminal debugging
Info: Current terminal debugging is on.
<HUAWEI> terminal echo synchronous
Info: Current terminal synchronization is on.
<HUAWEI> save
The current configuration will be written to the device.
Are you sure to continue?[Y/N]:

```

3.10.48 terminal logging

Function

The **terminal logging** command enables log display on the user terminal.

The **undo terminal logging** command disables log display on the user terminal.

By default, log display is enabled on the user terminal.

Format

terminal logging

undo terminal logging

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To view logs on a terminal, run the **terminal logging** command to enable log display on the user terminal.

Prerequisites

The **terminal monitor** command has been executed to enable display of logs, traps, and debugging message output on the user terminal.

Example

Disable log display on the user terminal.

```
<HUAWEI> undo terminal logging
Info: Current terminal logging is off.
```

3.10.49 terminal monitor

Function

The **terminal monitor** command enables display of logs, traps, and debugging message output by the information center on the user terminal.

The **undo terminal monitor** command disables display of logs, traps, and debugging message output by the information center on the user terminal.

By default, console display is enabled and terminal display is disabled.

Format

terminal monitor

undo terminal monitor

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Prerequisites

The information center has been enabled by using the **info-center enable** command.

Follow-up Procedure

Run the **terminal debugging**/**undo terminal debugging**, **terminal logging**/**undo terminal logging**, **terminal trapping**/**undo terminal trapping**/ command to enable or disable terminal debugging message, log, or trap display.

Precautions

Logs, traps, and debugging message are sent to the current terminal only when the **terminal monitor** command is used.

Running the **undo terminal monitor** command is equivalent to running the **undo terminal debugging**, **undo terminal logging**, **undo terminal trapping** command.

Example

Disable display of logs, traps, and debugging message output by the information center on the user terminal.

```
<HUAWEI> undo terminal monitor
Info: Current terminal monitor is off.
```

3.10.50 terminal session-log disable

Function

The **terminal session-log disable** command disables the session logging function for an online user.

The **undo terminal session-log disable** command enables the session logging function for an online user.

By default, the session logging function for an online user is enabled.

Format

terminal session-log disable

undo terminal session-log disable

Parameters

None

Views

User view

Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The session logging function for an online user stores the user input, device output, and time when the device executes user-issued commands to a session log file.

Prerequisites

The session logging function has been enabled globally.

Example

Enable the session logging function for an online user.

```
<HUAWEI> undo terminal session-log disable
```

3.10.51 terminal trapping

Function

The **terminal trapping** command enables trap display on the user terminal.

The **undo terminal trapping** command disables trap display on the user terminal.

By default, trap display is enabled on the user terminal.

Format

terminal trapping

undo terminal trapping

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To view traps on a terminal, run the **terminal trapping** command to enable trap display on the user terminal.

Prerequisites

The **terminal monitor** command has been executed to enable display of logs, traps, and debugging message output on the user terminal.

Example

Disable trap display on the user terminal.

```
<HUAWEI> undo terminal trapping
Info: Current terminal trapping is off.
```

3.11 Fault Management Commands

3.11.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.11.2 alarm (system view)

Function

Using the **alarm** command, you can enter the alarm view.

Format

alarm

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

After running the **alarm** command to enter the alarm view, you can configuration alarm management functions.

Example

Enter the alarm view.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm]
```

3.11.3 alarm-name severity

Function

The **alarm-name severity** command sets the severity for an alarm.

The **undo alarm-name severity** command restores the default setting.

By default, each alarm has a default severity.

Format

alarm-name *alarm-name* **severity** *severity*

undo alarm-name *alarm-name* **severity**

Parameters

Parameter	Description	Value
alarm-name	Specifies the registered alarm name.	The value is a string and varies according to the registered device type. To view registered alarm information, run the **display alarm information** command.

Parameter	Description	Value
severity *severity*	Specifies the alarm severity.	The value is of enumerated type. Alarms are classified into the following severities: • **critical**: indicates that a fault affecting services has occurred and it must be rectified immediately. • **major**: indicates that services are being affected and related measures need to be taken urgently. • **minor**: indicates that a fault occurs but does not affect services. To avoid more serious faults that affect services, related measures must be taken. • **warning**: indicates that a potential or impending service-affecting fault is detected before any significant effect has been felt. Take corrective actions to diagnose and rectify the fault. • **indeterminate**: indicates that the alarm severity cannot be determined. • **cleared**: indicates one or more previous alarm conditions have been cleared.

Views

Alarm view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **alarm-name severity** command to raise or lower the level of an alarm based on the severity and emergency of the alarm. However, the level of a clear alarm cannot be changed unless during the configuration restoration period. You can configure filtering conditions to allow the NMS to receive only alarms of specified alarm severity.

Precautions

The default severity of each alarm is different. To view the default severity of an alarm, run the **undo alarm-name severity** and **display alarm information** commands in sequence.

Example

Set the severity of the hwSysSlaveHDError alarm to warning.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] alarm-name hwSysSlaveHDError severity warning
```

3.11.4 clear alarm active

Function

The **clear alarm active** command clears active alarms.

Format

clear alarm active { **all** | **sequence-number** *sequence-number* }

Parameters

Parameter	Description	Value
all	Clears all active alarms.	-
sequence-number *sequence-number*	Specifies the sequence number of an active alarm.	The value is an integer ranging from 1 to 2147483647.

Views

Alarm view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting statistics on alarms generated on the device again, run the **clear alarm active** to clear active alarms.

Precautions

After the **clear alarm active** command is used, all active alarms on the device are deleted and cannot be restored.

Example

Clear all active alarms on the device.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] clear alarm active all
```

3.11.5 clear alarm manual-clear

Function

The **clear alarm manual-clear** command clears the active alarms that are not reported repeatedly so that these active alarms can be reported again.

Format

clear alarm manual-clear { **all** | **sequence-number** *sequence-number* }

Parameters

Parameter	Description	Value
all	Specifies all the active alarms that are not reported repeatedly.	-
sequence-number *sequence-number*	Specifies the sequence number of the active alarm that is not reported repeatedly. You can run **display alarm manual-clear** get the sequence number of the active alarm.	The value is an integer that ranges from 1 to 2147483647.

Views

Alarm management view

Default Level

3: Management level

Usage Guidelines

After the **mask manual-clear alarm** command is executed to prevent manually cleared active alarms from being reported repeatedly and then the **clear alarm**

active command or MIB table hwAlarmActiveTable is used to manually clear active alarms, active alarms will not be reported repeatedly. To view the active alarms that are not reported repeatedly, run the **clear alarm manual-clear** command.

To ensure that the active alarms that are not reported repeatedly can be reported again, run the **clear alarm manual-clear** command. After the **clear alarm manual-clear** command is executed, running the **display alarm manual-clear** command does not display corresponding alarm information.

Example

Clear the active alarms that are not reported repeatedly.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] clear alarm manual-clear all
```

3.11.6 clear event all

Function

The **clear event all** command clears events on the device.

Format

clear event all

Parameters

None

Views

Event view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting statistics on events generated on the device again, run the **clear event all** to clear events.

Precautions

NOTICE

The **clear event all** command clears events on the device and cleared events cannot be restored.

Example

Clear events on the device.

```
<HUAWEI> system-view
[HUAWEI] event
[HUAWEI-event] clear event all
```

3.11.7 clear record device-alarm

Function

The **clear record device-alarm** command clears hardware alarms.

Format

clear record device-alarm [**all** | **slot** *slot-id*]

Parameters

Parameter	Description	Value
all	Clears all hardware alarms of the device.	-
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

When current hardware alarms are not required on the device, use the **clear record** command to clear the hardware alarms of the device.

Example

Clear all hardware alarms of the device.

```
<HUAWEI> clear record device-alarm all
```

3.11.8 delay-suppression enable

Function

The **delay-suppression enable** command enables delayed alarm or event reporting.

The **undo delay-suppression enable** command disables delayed alarm or event reporting.

By default, delayed reporting is enabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

delay-suppression enable

undo delay-suppression enable

Parameters

None

Views

Alarm view or event view

Default Level

3: Management level

Usage Guidelines

In the event that an alarm or an event is repeatedly generated, you can enable delayed reporting to prevent a large number of repeated alarms or events from being reported to the NMS. You can choose to enable or disable delayed reporting:

- Run the **delay-suppression enable** command to enable delayed reporting.
- Run the **undo delay-suppression enable** command to disable delayed reporting.

Run the **delay-suppression enable** command in the alarm view to enable delayed alarm reporting. Run the **delay-suppression enable** command in the event view to enable delayed event reporting.

Example

Enable delayed alarm reporting.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] delay-suppression enable
```

3.11.9 display alarm active

Function

The **display alarm active** command displays active alarms on the device.

Format

display alarm active

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display alarm active** command to view active alarms on the device to locate faults.

Example

Display active alarms on the device.

```
<HUAWEI> display alarm active
A/B/C/D/E/F/G/H/I/J
A=Sequence, B=RootKindFlag(Independent|RootCause|
nonRootCause)
C=Generating time, D=Clearing time
E=ID, F=Name, G=Level, H=State
I=Description information for locating(Para info, Reason
info)
J=RootCause alarm sequence(Only for nonRootCause
alarm)

  92/Independent/2019-08-09 10:44:58/-/0x502001/linkDown/Critical/Start/OID 1.3.6.1.6.3.1.1.5.3 Interface
58 turned into DOWN state.
(AdminStatus=1,OperStatus=2,InterfaceName=40GE0/0/5)
```

Table 3-163 Description of the display alarm active command output

Item	Description
A/B/C/D/E/F/G/H/I/J	Alarm display format
A=Sequence	Sequence number
B=RootKindFlag(Independent|RootCause|nonRootCause)	Flag indicating a root-cause alarm or a non-root-cause alarm: ● Independent: indicates an alarm for which alarm correlation analysis is not performed. ● RootCause: indicates a root-cause alarm. ● nonRootCause: indicates a non-root-cause alarm.

Item	Description
C=Generating time	Time when an alarm is generated
D=Clearing time	Time when an alarm is cleared
E=ID	Alarm ID
F=Name	Alarm name
G=Level	Alarm severity level You can run the **alarm-name severity** command to set this parameter.
H=State	Alarm status: ● Start ● End
I=Description information for locating(Para info, Reason info)	Alarm description including alarm parameters and causes for triggering alarms
J=RootCause alarm sequence(Only for nonRootCause alarm)	Sequence number of the root-cause alarm (for non-root-cause alarms only)

3.11.10 display alarm history

Function

The **display alarm history** command displays historical alarms on the device.

Format

display alarm history

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display alarm history** command to view the alarms that are cleared or generated on the device. The **display alarm history** command displays a maximum of 300 alarm history records.

Example

Display historical alarms on the device.

```
<HUAWEI> display alarm history
A/B/C/D/E/F/G/H/I/J
A=Sequence, B=RootKindFlag(Independent|RootCause|nonRootCause)
C=Generating time, D=Clearing time
E=ID, F=Name, G=Level, H=State
I=Description information for locating(Para info, Reason info)
J=RootCause alarm sequence(Only for nonRootCause alarm)

  3/Independent/2010-07-14 09:40:20-08:00/2010-07-14 09:40:23-08:00/0x502001/linkDown/
Critical/End/OID 1.3.6.1.6.3.1.1.5.3 Interface 5 turned into DOWN state.
```

Table 3-164 Description of the display alarm history command output

Item	Description
A/B/C/D/E/F/G/H/I/J	Alarm display format
A=Sequence	Sequence number
B=RootKindFlag(Independent|RootCause|nonRootCause)	Flag indicating a root-cause alarm or a non-root-cause alarm: ● Independent: indicates an alarm for which alarm correlation analysis is not performed. ● RootCause: indicates a root-cause alarm. ● nonRootCause: indicates a non-root-cause alarm.
C=Generating time	Time when an alarm is generated
D=Clearing time	Time when an alarm is cleared
E=ID	E=ID
F=Name	Alarm ID
G=Level	Alarm severity level You can run the **alarm-name severity** command to set this parameter.

Item	Description
H=State	Alarm status: - Start - End
I=Description information for locating(Para info, Reason info)	Alarm description including alarm parameters and causes for triggering alarms
J=RootCause alarm sequence(Only for nonRootCause alarm)	Sequence number of the root-cause alarm

3.11.11 display alarm information

Function

The **display alarm information** command displays alarm configurations.

Format

display alarm information [**name** *alarm-name*]

Parameters

Parameter	Description	Value
name *alarm-name*	Displays the configuration of a specified alarm. If this parameter is not set, configurations of all alarms are displayed.	The value is a string and varies according to the registered device type.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view alarm configurations on the device, run the **display alarm information** command.

If no alarm name is specified, information about all alarms in the system will be displayed.

In addition, to change the severity level of an alarm, you can run the **alarm-name** *alarm-name* **severity** *severity* command.

Example

Display the configuration of the alarm named linkUp.

```
<HUAWEI> display alarm information name linkUp
**********************************
  AlarmName: linkUp
  AlarmType: Resume Alarm
  AlarmLevel: Cleared
  Suppress Period: NA
  CauseAlarmName: linkDown
  Match VB Name: ifIndex
**********************************
```

Table 3-165 Description of the display alarm information command output

Item	Description
AlarmName	Name of an alarm.
AlarmType	Alarm type: ● Alarm: indicates a fault occurs. ● Resume Alarm: indicates a fault is rectified.
AlarmLevel	Alarm severity. To set this parameter, run the **alarm-name severity** command.
Suppress Period	Alarm reporting delay. To set this parameter, run the **suppression alarm-name** command. If this field displays **NA**, this alarm does not support the delayed alarm reporting function.
CauseAlarmName	Name of the root-cause alarm. Name of the root-cause alarm, namely, paired alarm name.
Match VB Name	Matching content of paired alarms.

3.11.12 display alarm manual-clear

Function

The **display alarm manual-clear** command displays the alarms that are not reported repeatedly after being cleared.

Format

display alarm manual-clear

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the **mask manual-clear alarm** command is executed to prevent manually cleared active alarms from being reported repeatedly and then the **clear alarm active** command or MIB table hwAlarmActiveTable is used to manually clear active alarms, you can run the **display alarm manual-clear** command to view the active alarms that are not reported repeatedly after being cleared.

Example

Display the alarms that are not reported repeatedly after being cleared.

```
<HUAWEI> display alarm manual-clear
A/B/C/D/E/F/G/H/I/J
A=Sequence, B=RootKindFlag(Independent|RootCause|nonRootCause)

, RelativeResource="", ReasonDescription="Because of get offline message, the en
tity of SLOT1 changed to offline state")
```

Table 3-166 Description of the **display alarm manual-clear** command output

Item	Description
A/B/C/D/E/F/G/H/I/J	Alarm display format
A=Sequence	Alarm sequence number.

Item	Description
B=RootKindFlag(Independent| RootCause| nonRootCause)	Flag indicating a root-cause alarm or a non-root-cause alarm: - Independent: indicates an alarm for which alarm correlation analysis is not performed. - RootCause: indicates a root-cause alarm. - nonRootCause: indicates a non-root-cause alarm.
C=Generating time	Time when an alarm is generated.
D=Clearing time	Time when an alarm is cleared.
E=ID	Alarm ID.
F=Name	Alarm name.
G=Level	Alarm severity. To set this parameter, run the **alarm-name severity** command.
H=State	Alarm status: - Start - End
I=Description information for locating(Para info, Reason info)	Alarm description.
J=RootCause alarm sequence(Only for nonRootCause alarm)	Sequence number of a root-cause alarm (for non-root-cause alarms only)

3.11.13 display alarm urgent

Function

Using the **display alarm urgent** command, you can view hardware alarms on the device.

Format

display alarm urgent [**slot** *slot-id* | **time** *interval*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.
time *interval*	Displays hardware alarms generated in the last period of time. *interval* specifies the period.	The value is an integer that ranges from 1 to 10000, in minutes.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the command to view hardware alarms, including alarms about the abnormality of the temperature, the fan, and the chip.

If no parameter is specified, the command displays all the hardware alarms.

Example

Display hardware alarms of the device.

```
<HUAWEI> display alarm urgent
 Alarm:

Alarm                 Slot      Date        Time(DST)      Location
-------------------------------------------------------------------------
Temp normal             1         2000/04/09  04:52:47      Slot 1
Temp low              1         2000/04/09  04:52:14      Slot 1
Temp normal             1         2000/04/09  04:39:05      Slot 1
Temp high             1         2000/04/09  04:37:23      Slot 1
Temp normal             2         2000/04/10  07:13:16      Slot 2
Temp high             2         2000/04/10  07:11:22      Slot 2
```

Table 3-167 Description of the display alarm urgent command output

Item	Description
Alarm	Details about an alarm. - Fan pulled out: A fan module is removed. - Fan plugged in: A fan module is installed. - Fan abnormal: A fan module is not working properly. - Fan normal: A fan module is working properly. - Fan unmatched: A fan module does not match the device model. - Fan matched: A fan module matches the device model. - Power pulled out: A power module is removed. - Power plugged in: A power module is installed. - Power abnormal: A power module is not working properly. - Power normal: A power module is working properly. - PWR Input Vol Low: A power module is in an input power outage or undervoltage condition. - PWR Input Vol Low Resume: A power module recovers from an input power outage or undervoltage condition. - Built-in power Off: A built-in power module does not provide power. - Built-in power On: A built-in power module provides power normally. - Temp high: The temperature is too high. - Temp low: The temperature is too low. - Temp normal: The temperature returns to the normal range. - Temp chip abnormal: A temperature sensor is faulty. - Temp chip normal: A temperature sensor recovers from a failure. - storage abnormal: The storage utilization exceeded 85%.
Slot	Slot ID of the device where alarms are generated.
Date	Date when alarms are generated.
Time(DST)	Time when alarms are generated.
Location	Position where alarms are generated.

3.11.14 display event

Function

The **display event** command displays events on the device.

Format

display event

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To obtain the contents of events in the system, you can run the display event command.

Example

Display events on the device.

```
<HUAWEI> display event
A/B/C/D/E/F/G/H/I/J
A=Sequence, B=RootKindFlag(Independent|RootCause|nonRootCause)
C=Generating time, D=Clearing time
E=ID, F=Name, G=Level, H=State
I=Description information for locating(Para info, Reason info)

cords is 4095.
```

Table 3-168 Description of the display event command output

Item	Description
A/B/C/D/E/F/G/H/I/J	Event display format
A=Sequence	Sequence number of an event

Item	Description
B=RootKindFlag(Independent| RootCause| nonRootCause)	Flag indicating a root-cause alarm or a non-root-cause alarm (The value of this field is **Independent** for any event.)
C=Generating time	Time when the event is generated
D=Clearing time	Time when the event is cleared (for non-root-cause alarms only)
E=ID	Event ID
F=Name	Event name
G=Level	Event level
H=State	Event status: ● Start ● End
I=Description information for locating(Para info, Reason info)	Description of an event, including parameters of the event and the reason why the event was triggered.
J=RootCause alarm sequence(Only for nonRootCause alarm)	This parameter is valid only for alarms.

3.11.15 display event information

Function

The **display event information** command displays event configurations.

Format

display event information [**name** *event-name*]

Parameters

Parameter	Description	Value
name *event-name*	Displays the configuration of a specified event. If this parameter is not set, configurations of all events are displayed.	The value is a string and varies according to the registered device type.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view event configurations on the device, run the **display event information** command.

If no event name is specified, information about all events in the system will be displayed.

Example

Display registration information about the hwCfgManEventlog event.

```
<HUAWEI> display event information name hwCfgManEventlog
***********************************
  EventName: hwCfgManEventlog
  EventType: Critical Event
  EventLevel: Warning
  Suppress Period: NA
  Match VB Name: hwCfgLogSrcCmd hwCfgLogSrcData hwCfgLogDesData
***********************************
```

Table 3-169 Description of the display event information command output

Item	Description
EventName	Event name.
EventType	Event type.
EventLevel	Event level, which cannot be configured.
Suppress Period	Event report delay period. To set this parameter, run the **suppression event-name** command. If this field displays **NA**, this event does not support the delayed event reporting function.
Match VB Name	Matching content of repeated events.

3.11.16 event

Function

Using the **event** command, you can enter the event view.

Format

event

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

After running the **event** command to enter the event view, you can configure event management functions.

Example

Enter the event view.

```
<HUAWEI> system-view
[HUAWEI] event
[HUAWEI-event]
```

3.11.17 mask manual-clear alarm

Function

The **mask manual-clear alarm** command prevents manually cleared active alarms from being reported repeatedly.

The **undo mask manual-clear alarm** command restores the default configuration.

By default, active alarms are reported repeatedly after being manually cleared.

Format

mask manual-clear alarm

undo mask manual-clear alarm

Parameters

None

Views

Alarm management view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, after the **clear alarm active** command or MIB table hwAlarmActiveTable is used to manually clear active alarms, active alarms are reported repeatedly when being generated again. To prevent manually cleared active alarms from being reported repeatedly, run the **mask manual-clear alarm** command.

After the **mask manual-clear alarm** command is executed and then the **clear alarm active** command or MIB table hwAlarmActiveTable is used, cleared active alarms will not be reported repeatedly before clear alarms of active alarms are reported. To view all the active alarms that are not reported repeatedly, run the **display alarm manual-clear** command.

Precautions

Before the **mask manual-clear alarm** command is executed, the active alarms manually cleared using the **clear alarm active** command or MIB table hwAlarmActiveTable will be reported repeatedly.

Example

Prevent manually cleared active alarms from being reported repeatedly.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] mask manual-clear alarm
```

3.11.18 reset alarm urgent

Function

The **reset alarm urgent** command clears all alarm messages.

Format

reset alarm urgent slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

You can run the **reset alarm urgent** command to clear all alarm messages. Confirm the action before you run this command.

Example

Clear all alarm messages of the device that slot id is 0.

```
<HUAWEI> system-view
[HUAWEI] reset alarm urgent slot 0
```

3.11.19 set alarm resend interval

Function

The **set alarm resend interval** command set the alarm reporting interval.

The **undo set alarm resend interval** command restores the default alarm reporting interval.

By default, the alarm interval is 10 minutes.

Format

set alarm resend interval *interval-value*

undo set alarm resend interval

Parameters

Parameter	Description	Value
interval-value	Specifies the alarm interval.	The value is an integer that ranges from 0 to 65535, in minutes.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **set alarm resend interval** command sets the interval at which alarms are generated. If the periodic alarm reporting function is not required, set the interval to 0.

Precautions

If the alarm reporting interval is set to 0, the system does not report alarms periodically.

Example

Set the alarm reporting interval to 4 minutes.

```
<HUAWEI> system-view
[HUAWEI] set alarm resend interval 4
```

3.11.20 suppression alarm-name

Function

The **suppression alarm-name** command modifies a delay period after which a generated alarm is reported.

The **undo suppression alarm-name** command restores the configured delay period after which a generated alarm is reported.

By default, the system defines a delay period after which a generated alarm is reported. To view this default delay period, run the **undo suppression alarm-name** command and then the **display alarm information** command. If the **Suppress Period** field displays NA for an alarm, this alarm does not support the delayed alarm reporting function.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

suppression alarm-name *alarm-name* { **cause-period** *cause-seconds* | **clear-period** *clear-seconds* }

undo suppression alarm-name *alarm-name* { **cause-period** | **clear-period** }

Parameters

Parameter	Description	Value
alarm-name	Specifies the name of an alarm for which the delay period is set.	The value cannot be the alarm name of which the **Suppress Period** field in the **display alarm information** command output displays NA.
cause-period *cause-seconds*	Specifies the period after which a generated alarm is reported.	The value is an integer ranging from 0 to 600, in seconds. If the value is set to 0s, the alarm management module sends the alarm to the NMS without any delay.
clear-period *clear-seconds*	Specifies the period after which a generated clear alarm is reported.	The value is an integer ranging from 0 to 600, in seconds. If the value is set to 0s, the alarm management module sends the alarm to the NMS without any delay.

Views

Alarm view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a certain alarm is repeatedly generated, you can enable delayed alarm reporting and set a period after which the alarm is reported to prevent the alarm from being reported during this period.

After the period is set for a certain alarm:

- If no clear alarm is generated during the period, the alarm is not reported to the NMS until the period expires.
- If a clear alarm is generated during this period, the alarm and its clear alarm are both deleted from the alarm queue and will not be reported to the NMS.

If the delay period is too short, alarm reporting is not efficiently delayed. If the delay period is too long, alarm reporting is postponed and the time when the fault occurs cannot be correctly obtained. For most alarms, the default delay period is recommended. For common alarms, such as alarms about hardware and environment, delayed alarm reporting is not recommended.

The value of **cause-period** *cause-seconds* is irrelevant to the value of **clear-period** *clear-seconds*. The delay in reporting an alarm and the delay in reporting a clear alarm can be configured separately.

Prerequisites

Before running the **suppression alarm-name** command, ensure that delayed alarm reporting has been enabled using the **delay-suppression enable** command.

Precautions

- If the delay period is changed when an alarm is being sent, the changed delay period takes effect on the next alarm to be sent.
- If *alarm-name* specifies an alarm, you can configure only **cause-period** *cause-seconds*. If it specifies a clear alarm, you can configured only **clear-period** *clear-seconds*.

Example

Set the hwsysmasterhderror alarm to be reported 5s after it is generated.

```
<HUAWEI> system-view
[HUAWEI] alarm
[HUAWEI-alarm] delay-suppression enable
[HUAWEI-alarm] suppression alarm-name hwsysmasterhderror cause-period 5
```

3.11.21 suppression event-name

Function

The **suppression event-name** command modifies a delay period after which a generated event is reported.

The **undo suppression event-name** command restores the configured delay period after which a generated event is reported.

By default, the system defines a delay period after which a generated event is reported. To view this default delay period, run the **undo suppression event-name** command and then the **display event information** command. If the **Suppress Period** field displays NA for an alarm, this alarm does not support the delayed alarm reporting function.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

suppression event-name *event-name* **period** *seconds*

undo suppression event-name *event-name* **period**

Parameters

Parameter	Description	Value
event-name	Specifies the name of an event for which the delay period is set.	The value cannot be the event name of which the **Suppress Period** field in the **display event information** command output displays NA.
period *seconds*	Specifies the period after which a generated event is reported.	The value is an integer ranging from 0 to 600, in seconds. If the value is set to 0s, the alarm management module sends the event to the NMS without any delay.

Views

Event view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In the case where a certain event is repeatedly generated, you can enable delayed event reporting and set a period after which a generated event is reported.

After the delay period is set for a certain event, if an event is generated several times during the delay period, the system reports only the first one to the NMS when the delay period expires and discards the following ones.

Prerequisites

Before running the **suppression event-name** command, ensure that delayed alarm reporting has been enabled using the **delay-suppression enable** command.

Precautions

If the delay period is changed when an event is being sent, the changed delay period takes effect on the next event to be sent.

Example

Set the delay period to 5s after which a generated hwFlhSyncFailNotification event is reported.

```
<HUAWEI> system-view
[HUAWEI] event
[HUAWEI-event] delay-suppression enable
[HUAWEI-event] suppression event-name hwFlhSyncFailNotification period 5
```

3.12 SAID Configuration Commands

3.12.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.12.2 display said-node brief

Function

The **display said-node brief** command displays brief information about SAID nodes.

Format

display said-node { **all** | *said-name* } **brief** [**slot** *slot-id*]

Parameters

Parameter	Description	Value
all	Indicates all SAID nodes.	-
said-name	Specifies an SAID node.	The value depends on the device configuration.
slot *slot-id*	Specifies a slot ID. If no slot ID is specified, this command displays brief information about SAID nodes on the active MPU.	The value depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display said-node brief** command to view brief information about all supported SAID nodes for fault location.

Example

Display brief information about the SAID node named **mac** in slot 2.

```
<HUAWEI> display said-node mac brief slot 2
------------------------------------------------------------------------------------------
Node  Node            Type    Cycle  Enable   Active      Inactive Reason
ID    Name                    (s)    Status   Status
------------------------------------------------------------------------------------------
2     mac             Restore 1      Enable   Active      -
------------------------------------------------------------------------------------------
```

Table 3-170 Description of the **display said-node brief** command output

Item	Description
Node ID	ID of an SAID node.
Node Name	Name of the SAID node.
Type	Type of the SAID node: ● Detect: diagnostic node ● Restore: self-healing node
Cycle(s)	Detection period of the SAID node, in seconds.
Enable Status	Whether the SAID node is enabled: ● Enable: The SAID node is enabled. ● Disable: The SAID node is disabled.
Active Status	Running status of the SAID node: ● Active: The SAID node is running. ● Inactive: The SAID node is not running.
Inactive Reason	Whether the SAID node is activated: ● -: The SAID node is enabled and activated. ● Node disabled: The SAID node is not activated.

3.12.3 set said-node disable

Function

The **set said-node disable** command disables SAID nodes.

The **undo set said-node disable** command enables SAID nodes.

By default, all SAID nodes are enabled.

Format

set said-node { **all** | *said-name* &<1-6> } **disable**

undo set said-node { **all** | *said-name* &<1-6> } **disable**

Parameters

Parameter	Description	Value
all	Indicates all SAID nodes.	-
said-name	Specifies an SAID node.	The value depends on the device configuration. A maximum of six SAID nodes can be configured at a time. If you need to configure more than six SAID nodes, run the **set said-node disable** command multiple times.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The System of Active Immunization and Diagnosis (SAID) is an intelligent fault diagnosis system that automatically diagnoses and rectifies some faults by simulating human operations in troubleshooting. The SAID system has multiple SAID nodes, which detect, diagnose, and rectify faults of multiple modules. However, if a node processes a large number of services, the processing efficiency of other nodes is affected. In this case, run this command disable this node.

Currently, the switch supports the following SAID nodes listed in **Table 3-171**.

Table 3-171 Supported SAID nodes

Node Name	Node Type
FLASH-WRITE	Diagnostic node
MAC	Self-healing node
STG	Self-healing node

Node Name	Node Type
PORT	Self-healing node
VLAN	Self-healing node
SE-REG **NOTE** Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S support this node.	Self-healing node
SE-TABLE **NOTE** Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S support this node.	Self-healing node
CONFD-MEMORY	Self-healing node
PING	Diagnostic node After this node is enabled, the device periodically sends ICMP ping packets.

Precautions

If some cards do not support a specific SAID node and no cards that support this SAID node are installed on the device, the device displays a message, indicating that the device does not support this SAID node.

Example

Disable the SAID nodes **mac** and **stg**.

```
<HUAWEI> system-view
[HUAWEI] set said-node mac stg disable
```

Disable all SAID nodes.

```
<HUAWEI> system-view
[HUAWEI] set said-node all disable
```

3.13 NTP Configuration Commands

3.13.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

3.13.2 display ntp-service event clock-unsync

Function

The **display ntp-service event clock-unsync** command displays the last 10 clock unsynchronization reasons.

Format

display ntp-service event clock-unsync

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ntp-service event clock-unsync** command to view information about the last 10 clock unsynchronization reasons in the current system.

Example

Display the last 10 clock unsynchronization reasons.

```
<HUAWEI> display ntp-service event clock-unsync
 1. Clock source   :  10.1.1.1(vrf1)
    Session type   :  client, configured
    Unsync reason  :  Peer reachability lost
    Unsync time    :  2012-07-30 12:24:44+00:00

 2. Clock source   :  10.2.1.1(vrf2)
    Session type   :  bdcast client (Interface: GE0/0/1), dynamic
    Unsync reason  :  Authentication failure
    Unsync time    :  2011-06-15 11:24:44+00:0
```

Display the clock unsynchronization reasons.

Table 3-172 Description of the **display ntp-service event clock-unsync** command output

Item	Description
Clock source	Indicates the IP address of the server clock.

Item	Description
Session type	Indicates the session type of the server clock.
Unsync reason	Indicates the unsynchronization reasons.
Unsync time	Indicates the unsynchronization time.

3.13.3 display ntp-service sessions

Function

The **display ntp-service sessions** command displays all session information maintained by NTP on the local end.

Format

display ntp-service sessions [**verbose**]

Parameters

Parameter	Description	Value
verbose	Displays detailed information about an NTP session. If **verbose** is not specified, only summary information about the NTP session is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To monitor or locate faults on NTP sessions, run the **display ntp-service sessions** command to obtain status information about NTP sessions so that the fault can be located efficiently.

Precautions

- If **verbose** is not specified, summary information about NTP sessions is displayed.

- If **verbose** is specified, detailed information about NTP sessions is displayed.

Example

Display NTP session information of the local device.

```
<HUAWEI> display ntp-service sessions
 clock source: 224.0.1.1
 clock stratum: 1
 clock status: configured, insane, valid, unsynced
 reference clock ID: LOCAL(0)
 reach: 0
 current poll: 64
 now: 9
 offset: 0.0000 ms
 delay: 0.00 ms
 disper: 0.00 ms
```

Table 3-173 Description of the display ntp-service sessions command output

Item	Description
clock source	Address of the clock source.
clock stratum	Stratum of the clock source. The clock stratum determines the precision of the clock, and its value ranges from 1 to 16. The higher the stratum value, the lower the clock precision. The value 1 indicates the highest precision, and the value 16 indicates the lowest precision. The clock with stratum 16 is in the unsynchronized status, and cannot be used as a reference clock.

Item	Description
clock status	Status of a clock, where - configured: indicates that the session is set up by a configuration command. - master: indicates that the clock source corresponding to the session is the primary clock source of the current system. - selected: indicates that the clock source corresponding to the session passes the clock selecting algorithm. - candidate: indicates that the clock source corresponding to the session is a candidate clock source. - sane: indicates that the clock source corresponding to the session passes the saneness test. - insane: indicates that the clock source corresponding to the session does not pass the saneness test. - valid: indicates that the clock source corresponding to the session is valid. The clock source corresponding to the session passes the test, is in a synchronized status and is of an effective stratum. The root delay and the root dispersion are within the normal range. - invalid: indicates that the clock source corresponding to the session is invalid. - unsynced: indicates that the clock source corresponding to the session is not yet synchronized or the stratum is invalid.
reference clock ID	When the local system has been synchronized to a remote NTP server or a clock source, the address of the remote server or the identifier of the clock source is displayed.
reach	Reachability count of the clock source. The value 0 indicates that the clock source is unreachable.
current poll	Poll interval of NTP packets. The interval for sending two successive NTP packets, in seconds. To set the poll interval, run the **ntp-service discard min-interval** command.
now	Interval between the last synchronization and the current time.
offset	Offset to the superior clock source.
delay	Delay to the superior clock source.
disper	Dispersion to the superior clock source.

Display detailed information about NTP sessions on the local device.

```
<HUAWEI> display ntp-service sessions verbose
 clock source: 172.16.12.1
 clock stratum: 1
 clock status: configured, insane, valid, unsynced
 reference clock ID: LOCAL(0)
 local mode: client, local poll: 64, current poll: 64
 peer mode: server, peer poll: 64, now: 21
 offset: -3.2385 ms,delay: 26.97 ms,  disper: 14.85 ms
 root delay: 0.00 ms, root disper: 10.94 ms
 reach: 255, sync dist: 0.058, sync state: 4
 precision: 2^18, version: 3, peer interface: wildcard
 reftime: 10:01:38.546 UTC Sep 5 2005(C6C69602.8C00DA1A)
 orgtime: 10:01:43.463 UTC Sep 5 2005(C6C69607.76ACC921)
 rcvtime: 10:01:43.480 UTC Sep 5 2005(C6C69607.7AF4ADBC)
 xmttime: 10:01:43.452 UTC Sep 5 2005(C6C69607.73F1E8E6)
 filter delay :  0.03   0.02   0.03   0.02   0.02   0.02   0.04   0.02
 filter offset:  0.00  -0.01   0.00   0.01   0.00   0.00   0.00   0.00
 filter disper:  0.03   0.02   0.00   0.11   0.09   0.08   0.06   0.05
 reference clock status: normal
```

Table 3-174 Description of the display ntp-service sessions verbose command output

Item	Description
clock source	Address of the clock source.
clock stratum	NTP stratum on which the local system is located.

Item	Description
clock status	Status of a clock, where ● configured: indicates that the session is set up by a configuration command. ● master: indicates that the clock source corresponding to the session is the primary clock source of the current system. ● selected: indicates that the clock source corresponding to the session passes the clock selecting algorithm. ● candidate: indicates that the clock source corresponding to the session is a candidate clock source. ● sane: indicates that the clock source corresponding to the session passes the saneness test. ● insane: indicates that the clock source corresponding to the session does not pass the saneness test. ● valid: indicates that the clock source corresponding to the session is valid. The clock source corresponding to the session passes the test, is in a synchronized status and is of an effective stratum. The root delay and the root dispersion are within the normal range. ● invalid: indicates that the clock source corresponding to the session is invalid. ● unsynced: indicates that the clock source corresponding to the session is not yet synchronized or the stratum is invalid.
reference clock ID	When the local system has been synchronized to a remote NTP server or a clock source, the address of the remote server or the identifier of the clock source is displayed. When the server is located on a certain VPN, the name of the VPN instance is displayed.
local mode	Local system mode.
peer mode	Peer system mode.
local poll	Local polling mode.
peer poll	Peer polling mode.
offset	Offset to the superior clock source.
delay	Delay to the superior clock source.
disper	Dispersion to the superior clock source.

Item	Description
root delay	Total system delay between the local end and the master reference clock. The default value is 0. If the value of root delay or root disper is large, clock synchronization may fail. A larger value indicates that the packet takes a longer time to reach the local device from the master reference clock. Therefore, the local device cannot determine whether the time in the packet is correct.
root disper	System dispersion of the local end to the master reference clock. The default value is 0. If the value of root delay or root disper is large, clock synchronization may fail. A larger value indicates that the packet takes a longer time to reach the local device from the master reference clock. Therefore, the local device cannot determine whether the time in the packet is correct.
reach	Reachability mark, indicating the reachability to the clock source.
sync dist	Synchronization distance to the superior clock source. This parameter evaluates and describes the clock source, and NTP chooses the clock source with the shortest synchronization distance.
sync state	Synchronization state: ● 0: The clock has never been synchronized. ● 1: Frequency information is obtained from configuration information. ● 2: The clock is set. ● 3: The clock is set, but the frequency is not yet determined. ● 4: The clock is synchronized. ● 5: An error is found.
precision	Precision of a peer clock.
version	NTP version.
peer interface	Peer interface.
reftime	Reference timestamp.
orgtime	Time when an NTP packet is sent for the last time.
rcvtime	Time when an NTP packet is received for the last time.
xmttime	Time when an NTP packet is forwarded for the last time.
filter delay	Filter delays of the 8 packets received for the last time.

Item	Description
filter offset	Filter offsets of the 8 packets received for the last time.
filter disper	Filter dispersions of the 8 packets received for the last time.
reference clock status	The status of the reference clock, including: ● normal: indicates that the peer clock is reachable. ● abnormal: indicates that the peer clock is unreachable.

3.13.4 display ntp-service statistics packet

Function

The **display ntp-service statistics packet** command displays statistics on NTP packets.

Format

display ntp-service statistics packet [**ipv6** | **peer** [*ip-address* [**vpn-instance** *vpn-instance-name*] | **ipv6** [*ipv6-address* [**vpn-instance** *vpn-instance-name*]]]]

Parameters

Parameter	Description	Value
ipv6	Displays statistics about global IPv6 NTP packets.	-
peer	Displays statistics on an NTP symmetric peer.	-
ip-address	Specifies the IP address of an NTP symmetric peer.	-
vpn-instance *vpn-instance-name*	Specifies a VPN instance related to an NTP symmetric peer.	The value must be an existing VPN instance name.
ipv6	Displays the packet statistics on IPv6 peers.	-
ipv6-address	Displays the NTP packet statistics on the specified IPv6 peer.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ntp-service statistics packet** command output includes the following information, and can help you to debug NTP packets.

- Number of packets sent and received by an interface
- Number of packets failing authentication
- Number of dropped packets
- Reason for dropping an NTP packet last time

Example

Display the statistics on NTP packets.

```
<HUAWEI> display ntp-service statistics packet
 NTP IPv4 Packet Statistical Information
 ---------------------------------------
 Sent                          : 100
    Send failures                : 10
 Received                      : 1000
    Processed                  : 800
    Dropped                    : 200
       Validity test failures      : 50

Table 3-175 Description of the **display ntp-service statistics packet** command output

Item	Description
NTP IPv4 Packet Statistical Information	Statistics on IPv4 NTP packets.
Sent	Number of packets sent.
Send failures	Number of failures in sending packets.
Received	Number of received packets.
Processed	Number of processed packets.
Dropped	Number of dropped packets.

Item	Description
Validity test failures	Number of packets dropped because the packets fail to pass the validity test.
Authentication failures	Number of packets dropped because the packets fail to pass the authentication.
Invalid packets	Number of packets dropped because the packets are invalid.
Access denied	Number of packets dropped for lack of access control authority.
Rate-limited	Number of packets dropped due to rate limit.
Processing delay	Number of packets dropped because processing of the packets is delayed.
