When multiple IS-IS topology instances are deployed on a network, the **spf-priority** command can be used to set a priority for the SPF calculation in each IS-IS topology instance.

If a higher priority is set for a topology, routes of the topology instance are converged first, ensuring that important services are running properly.

Example

Set the priority of SPF calculation in an IPv4 base topology to 30.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] spf-priority 30
```

7.6.107 spf-slice-size

Function

The **spf-slice-size** command sets the maximum duration for IS-IS route calculation.

The **undo spf-slice-size** command restores the default setting.

By default, IS-IS route calculation lasts for a maximum of 2 ms at a time.

Format

spf-slice-size *duration-time*

undo spf-slice-size

Parameters

Parameter	Description	Value
duration-time	Specifies the maximum duration for IS-IS route calculation.	The value is an integer that ranges from 1 to 5000, in milliseconds. The default value is 2.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

When a routing table contains a large number of routes, run the **spf-slice-size** command to specify the maximum duration of SPF calculation to prevent route calculation from using system resources for a long period.

Example

Set the maximum duration of IS-IS route calculation to 50 ms.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] spf-slice-size 50
```

7.6.108 summary (IS-IS)

Function

The **summary** command configures IS-IS to generate summarized routes.

The **undo summary** command disables IS-IS from generating summarized routes.

By default, IS-IS does not generate summarized routes.

Format

summary *ip-address mask* [**avoid-feedback** | **generate_null0_route** | **tag** *tag* | [**level-1** | **level-1-2** | **level-2**]] *

undo summary *ip-address mask* [**level-1** | **level-1-2** | **level-2**]

Parameters

Parameter	Description	Value
ip-address	Specifies the IPv4 address of a summarized route.	The value is in dotted decimal notation.
mask	Specifies the mask of the IP address of a summarized route.	The value is in dotted decimal notation.
avoid-feedback	Prevents summarized routes from being learned through SPF calculation.	-
generate_null0_route	Generates null0 routes to prevent routing loops.	-
tag *tag*	Assigns administrative tags to advertised routes.	The value is an integer that ranges from 1 to 4294967295.
level-1	Summarizes only the routes imported into Level-1 areas. If no level is specified, Level-2 is used by default.	-
level-1-2	Summarizes the routes imported into Level-1 areas and the backbone network. If no level is specified, Level-2 is used by default.	-
level-2	Summarizes only the routes imported into the backbone network. If no level is specified, Level-2 is used by default.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Route summarization on a large-scale IS-IS network efficiently reduces routing entries. This minimizes system resource consumption and maintains system performance.

If a link frequently alternates between Up and Down, the links not involved in the route summarization will not be affected. Therefore, route summarization prevents route flapping on the network and improves network stability.

Precautions

Configuring route summarization does not affect the routing table of the local device because each specific route is still displayed in the routing table. Route summarization reduces the flooding of LSPs. Routing tables of other devices that receive the LSP from the local device contain only one summarized routes but not specific routes. Specific routes are still displayed in the routing table of the device directly connected to the summarized network segment.

Both IS-IS routes and routes imported from other protocols can be summarized. The lowest cost among that of the routes that are summarized is used as the cost of the summarized route.

Example

Generate a summarized route with destination subnet 202.0.0.0/8.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] summary 10.0.0.0 255.0.0.0
```

7.6.109 suppress-flapping peer disable (IS-IS)

Function

The **suppress-flapping peer disable** command disables IS-IS neighbor relationship flapping suppression globally.

The **undo suppress-flapping peer disable** command enables IS-IS neighbor relationship flapping suppression globally.

By default, IS-IS neighbor relationship flapping suppression is enabled globally.

Format

suppress-flapping peer disable

undo suppress-flapping peer disable

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

If an interface carrying IS-IS services alternates between Up and Down, IS-IS neighbor relationship flapping occurs on the interface. During the flapping, IS-IS reestablishes the neighbor relationship and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, IS-IS services, and other IS-IS-dependent services, such as LDP and BGP. IS-IS neighbor relationship flapping suppression can address this problem by delaying IS-IS neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

By default, IS-IS neighbor relationship flapping suppression is enabled globally. To disable this function globally, run the **suppress-flapping peer disable** command.

Example

Disable neighbor relationship flapping suppression globally.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] suppress-flapping peer disable
```

7.6.110 timer lsp-generation

Function

The **timer lsp-generation** command configures an intelligent timer for generating LSPs.

The **undo timer lsp-generation** command cancels the intelligent timer for generating LSPs.

By default, no intelligent timer is configured to generate LSPs.

Format

timer lsp-generation *max-interval* [*init-interval* [*incr-interval*]] [**level-1** | **level-2**]

undo timer lsp-generation [*max-interval* [*init-interval* [*incr-interval*]]] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
max-interval	Specifies the maximum delay in generating LSPs with the same LSP ID.	The value is an integer that ranges from 1 to 120, in seconds. The default value is 2.
init-interval	Specifies the initial delay in generating LSPs.	The value is an integer that ranges from 1 to 60000, in milliseconds. By default, this delay is not used.
incr-interval	Specifies the incremental delay in generating two LSPs with the same LSP ID.	The value is an integer that ranges from 1 to 60000, in milliseconds. By default, this delay is not used.
level-1	Specifies the delay in generating Level-1 LSPs. If no level is specified, the delay in generating Level-1 and Level-2 LSPs is set.	-
level-2	Specifies the delay in generating Level-2 LSPs. If no level is specified, the delay in generating Level-1 and Level-2 LSPs is set.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IS-IS network, if the local routing information changes, a device needs to generate a new LSP to notify this change. If the local routing information changes frequently, a large number of new LSPs are generated, which occupies a lot of system resources and decreases system performance.

To speed up network convergence and prevent the system from being affected, run the **timer lsp-generation** command to configure an intelligent timer for generating LSPs. This timer can adjust the delay in generating LSPs based on the routing information change frequency. This command can implement different functions when different parameters are specified:

- When only *max-interval* is specified, the intelligent timer functions as an ordinary one-time triggering timer.

- When both *init-interval* and *incr-interval* are specified, the delay in generating an LSP for the first time is determined by *init-interval*, and the delay in generating an LSP with the same LSP ID for the second time is determined by *incr-interval*. Subsequently, each time routes change, the delay in generating an LSP doubles the last delay until the delay reaches the value specified by *max-interval*. After the delay remains at the value specified by *max-interval* for three times or the IS-IS process is restarted, the delay decreases to the value specified by *init-interval*.
- When *init-interval* is specified but *incr-interval* is not, the delay in generating an LSP for the first time is determined by *init-interval*, and the delay in generating subsequent LSPs is determined by *max-interval*. After the delay remains at the value specified by *max-interval* for three times or the IS-IS process is restarted, the delay decreases to the value specified by *init-interval*.
- The initial delay for generating an LSP is *init-interval*; the delay for generating the LSP with the same LSP ID is *incr-interval*. From the third time on, the delay for generating the LSP doubles each time until the delay reaches *max-interval*. After *max-interval* expires without flapping or the IS-IS process is restarted, the delay decreases to *init-interval*.

Precautions

If the delay in generating an LSP is too long, a device cannot advertise routing information changes to neighbors in time. This slows down network convergence.

Example

Set the delay in generating LSPs to 5s.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer lsp-generation 5
```

Set the maximum delay in generating LSPs to 20s, initial delay to 50 ms, and incremental delay to 2000 ms.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer lsp-generation 20 50 2000
```

7.6.111 timer lsp-max-age

Function

The **timer lsp-max-age** command sets the maximum lifetime for the LSPs generated by an IS-IS process.

The **undo timer lsp-max-age** command restores the default setting.

By default, the maximum lifetime of LSPs is 1200 seconds.

Format

timer lsp-max-age *age-time*

undo timer lsp-max-age

Parameters

Parameter	Description	Value
age-time	Specifies the maximum lifetime for LSPs.	The value is an integer that ranges from 2 to 65535, in seconds.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch generates the system LSP, the system fills in the LSP with its maximum lifetime. After other switches receive this LSP, the lifetime of the LSP is reduced accordingly. If the switch does not receive an updated LSP, the lifetime of the LSP is reduced to 0, and the switch retains the LSP for another 60 seconds. If the switch still does not receive any updated LSP within 60 seconds, the switch deletes the LSP.

You can run the **timer lsp-max-age** command to adjust the maximum lifetime of LSPs to ensure the validity of existing LSPs before new LSPs are received.

Precautions

The maximum lifetime of LSPs must be longer than the interval for updating LSPs to ensure that LSPs can be updated before being deleted.

Example

Set the maximum lifetime of the LSPs generated by the current IS-IS process to 25 minutes (1500 seconds).

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer lsp-max-age 1500
```

7.6.112 timer lsp-refresh

Function

The **timer lsp-refresh** command sets the interval for updating LSPs.

The **undo timer lsp-refresh** command restores the default setting.

By default, the interval for updating LSPs is 900 seconds.

Format

timer lsp-refresh *refresh-time*

undo timer lsp-refresh

Parameters

Parameter	Description	Value
refresh-time	Specifies the interval for updating LSPs.	The value is an integer that ranges from 1 to 65534, in seconds.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IS-IS network, LSDB synchronization is implemented through LSP flooding. During LSP flooding, a device sends an LSP to its neighbors and then the neighbors send the received LSP to their respective neighbors except the device that first sends the LSP. In this manner, the LSP is flooded among the devices of the same level. LSP flooding allows each device of the same level to have the same LSP information and synchronize its LSDB with each other.

LSPs need to be periodically flooded. When the system generates the system LSP, the system fills in the LSP with its maximum lifetime. After other devices receive this LSP, the lifetime of the LSP is reduced accordingly. If the device does not receive an updated LSP, the lifetime of the LSP is reduced to 0, and the device retains the LSP for another 60 seconds. If the device still does not receive any updated LSP within 60 seconds, the device deletes the LSP.

You can run the **timer lsp-refresh** command to set the interval for updating LSPs to control network convergence speed.

Precautions

If the interval for updating LSPs is small, LSPs may be updated frequently, which occupies a lot of bandwidth resources. If the interval is long, routing information changes cannot be notified in a timely manner.

Example

Set the interval for updating LSPs to 1200 seconds.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer lsp-refresh 1200
```

7.6.113 timer spf

Function

The **timer spf** command sets the delay in SPF calculation.

The **undo timer spf** command restores the default setting.

By default, the maximum delay in SPF calculation is 5 seconds.

Format

timer spf *max-interval* [*init-interval* [*incr-interval*]]

undo timer spf

Parameters

Parameter	Description	Value
max-interval	Specifies the maximum delay in SPF calculation.	The value is an integer that ranges from 1 to 120, in seconds. The default value is 5s.
init-interval	Specifies the initial delay in SPF calculation. If the *init-interval* parameter is not specified, the intelligent timer functions as an ordinary one-time triggering timer.	The value is an integer that ranges from 1 to 60000, in milliseconds. By default, it is 50 milliseconds.
incr-interval	Specifies the incremental delay in two SPF calculations. If the *incr-interval* parameter is not specified, the delay in SPF calculation for the first time is determined by *init-interval*. From the second time on, the delay in SPF calculation is determined by *max-interval*.	The value is an integer that ranges from 1 to 60000, in milliseconds. The default value is 200 milliseconds.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In IS-IS, route calculation is required when an LSDB changes. Frequent route calculations, however, consume lots of system resources and decrease system performance. Delaying SPF calculation can improve route calculation efficiency. However, a long delay in SPF calculation slows down route convergence.

To speed up route convergence without affecting the efficiency of switches, configure an intelligent timer for SPF calculation. This timer automatically adjusts the delay in SPF calculation based on the LSDB change frequency.

When SPF calculation is performed for the first time, the interval is *init-interval*. Each time a route changes, the interval is added by *incr-interval* until the interval reaches *max-interval*. After *max-interval* expires without flapping or the IS-IS process is restarted, the delay decreases to *init-interval*.

When only *max-interval* is used, the intelligent timer becomes a one-short triggered timer.

Example

Set the delay in SPF calculation to 5s.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer spf 5
```

Set the maximum delay in SPF calculation to 15s, initial delay to 10 ms, and incremental delay to 5000 ms.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] timer spf 15 10 5000
```

7.6.114 virtual-system

Function

The **virtual-system** command sets the virtual system ID for an IS-IS process. If no virtual system ID is set, no extended LSP can be generated. A maximum of 50 virtual system IDs can be configured for an IS-IS process.

The **undo virtual-system** command deletes the virtual system ID of an IS-IS process.

By default, no virtual system ID is configured for an IS-IS process.

Format

virtual-system *virtual-system-id*

undo virtual-system *virtual-system-id*

Parameters

Parameter	Description	Value
virtual-system-id	Specifies a virtual system ID for an IS-IS process.	The value is 6 bytes in length and in XXXX.XXXX.XXXX format.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Like a common system ID, a virtual system ID must be unique in a routing domain.

The **virtual-system** command is used together with the **lsp-fragments-extend** command. The configured virtual system ID takes effect only when LSP fragment extension is enabled and the IS-IS process is restarted using the **reset isis all** command.

If LSP fragment extension is not enabled and the IS-IS process is not restarted, you can configure the virtual system ID but the configured virtual system ID does not take effect.

Before running this command, run the **network-entity** command in the IS-IS view to configure a network entity title for the IS-IS process.

Example

Set the virtual system ID of IS-IS process 1 to 2222.2222.2222.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 10.0000.0000.0001.00
[HUAWEI-isis-1] virtual-system 2222.2222.2222
```

7.7 IPv6 IS-IS Configuration Commands

7.7.1 Command Support

Only the following switch models support IPv6 IS-IS:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

7.7.2 display isis ipv6 bfd interface

Function

The **display isis ipv6 bfd interface** command displays information about the interface enabled with IPv6 BFD for IS-IS.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display isis [*process-id*] **ipv6 bfd interface**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an IS-IS process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

BFD can provide millisecond-level fault detection. It can work with IS-IS to fast detect faults on neighboring devices and instruct IS-IS to recalculate routes for correct packet forwarding. You can run the **display isis ipv6 bfd interface** command to check information about the interface enabled with IPv6 BFD for IS-IS.

Example

Display information about the interface enabled with IPv6 BFD.

```
<HUAWEI> display isis 1 ipv6 bfd interface
                 IPV6 BFD information of interface for ISIS(1)
                ----------------------------------------------
 Interface                   BFD6.State     Min-Tx        Min-Rx        Mul
 GE0/0/1                      enable         150           150           3
 GE0/0/2                      enable         150           150           3
 Total interfaces: 2                   Total IPv6 bfd enabled interfaces: 2
```

Table 7-119 Description of the **display isis ipv6 bfd interface** command output

Item	Description
Interface	Interface enabled with IPv6 BFD for IS-IS
BFD6.State	IPv6 BFD status on the interface: ● enable ● disable To enable IPv6 BFD for IS-IS, run the **ipv6 bfd all-interfaces enable (IS-IS)** or **isis ipv6 bfd enable** command.

Item	Description
Min-Tx	Configured minimum interval for sending IPv6 BFD packets. To the parameters of IPv6 BFD sessions, run the **ipv6 bfd all-interfaces (IS-IS)** or **isis ipv6 bfd** command.
Min-Rx	Configured minimum interval for receiving IPv6 BFD packets. To the parameters of IPv6 BFD sessions, run the **ipv6 bfd all-interfaces (IS-IS)** or **isis ipv6 bfd** command.
Mul	Local detection multipliers of IPv6 BFD packets. To the parameters of IPv6 BFD sessions, run the **ipv6 bfd all-interfaces (IS-IS)** or **isis ipv6 bfd** command.
Total interfaces	Number of interfaces enabled with the IS-IS process
Total IPv6 bfd enabled interfaces	Number of interfaces enabled with IPv6 BFD for IS-IS

7.7.3 display isis ipv6 bfd session

Function

The **display isis ipv6 bfd session** command displays information about the IPv6 BFD session for IS-IS.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display isis [*process-id* | **vpn-instance** *vpn-instance-name*] **ipv6 bfd session** { **all** | **peer** *ipv6-address* | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an IS-IS process.	The value is an integer ranging from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the name of an IPv6 VPN instance, which is case sensitive.	The value must be an existing VPN instance name.
all	Indicates all the interfaces that run the IS-IS process.	-

Parameter	Description	Value
peer *ipv6-address*	Specifies the IPv6 link-local address of a peer.	The prefix is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
interface *interface-type interface-number*	Specifies the interface whose IPv6 BFD session statistics need to be collected.	-

Type	Level of the peer: - L1: Level-1 - L2: Level-2 - L12: Level-1-2
IPv6 BFD State	IPv6 BFD status: - up: indicates that the IPv6 BFD session is established successfully. - down: indicates that the IPv6 BFD fails to be established.
TX	Negotiated minimum interval for sending IPv6 BFD packets
RX	Negotiated minimum interval for receiving IPv6 BFD packets
Multiplier	Remote detection multiplier
LocDis	Local identifier dynamically assigned by IPv6 BFD
Local IPv6 Address	IPv6 link-local address
RemDis	Remote identifier dynamically assigned by IPv6 BFD
Peer IPv6 Address	IPv6 link-local address of the peer

Item	Description
Diag	Diagnostic information: ● No diagnostic information: IPv6 BFD runs properly, and no diagnostic information is displayed. ● Administrator down: The session is set Down by the network administrator. ● Global IPv6 BFD is not enabled: Global IPv6 BFD is disabled. ● IPv6 BFD session number reaches the MAX BFD: The number of IPv6 BFD sessions reaches the upper limit. ● No IPv6 BFD packets were received: The device does not receive any IPv6 BFD packet. ● Neighbour is down: The neighbor goes Down. ● Administrator down event received: The device receives an event indicating that the IPv6 BFD session is set Down by the network administrator.
Total IPv6 BFD session(s)	Total number of IPv6 BFD sessions

7.7.4 ipv6 auto-cost enable

Function

The **ipv6 auto-cost enable** command enables IS-IS to automatically calculate the interface cost on an IPv6 network according to the interface bandwidth.

The **undo ipv6 auto-cost enable** command disables IS-IS from automatically calculating the interface cost on an IPv6 network according to the interface bandwidth.

By default, the automatic interface cost calculation function is disabled on an IPv6 network.

Format

ipv6 auto-cost enable [**compatible**]

undo ipv6 auto-cost enable

Parameters

Parameter	Description	Value
compatible	Specifies the IS-IS to calculate the cost of an interface on an IPv6 network based on the bandwidth of the interface automatically in compatible.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function is enabled, for a certain IS-IS interface, if the cost of the interface is not configured in the interface view, and the global cost is not configured in the IS-IS view, the system calculates the cost for the interface automatically.

If the cost style of the system is wide or wide-compatible:

When **auto-cost enable** command is configured, Interface cost = (Bandwidth-reference/Link-bandwidth) x 10.

The cost style is set by the **cost-style** command. The Bandwidth-reference is set by the **ipv6 bandwidth-reference** command. The Link-bandwidth is the interface bandwidth.

If the cost-style of the system is narrow, narrow-compatible, or compatible, the cost of each interface is determined according to the following table.

Table 7-121 Relationship of the IS-IS interface cost and the bandwidth

Cost	Range of Interface Bandwidth
60	Interface bandwidth ≤ 10 Mbit/s
50	10 Mbit/s < Interface bandwidth ≤ 100 Mbit/s
40	100 Mbit/s < Interface bandwidth ≤ 155 Mbit/s
30	155 Mbit/s < Interface bandwidth ≤ 622 Mbit/s
20	622 Mbit/s < Interface bandwidth ≤ 2.5 Gbit/s
10	2.5 Gbit/s < Interface bandwidth

Precautions

The priority of the cost value of the global IPv6 configured by the **ipv6 circuit-cost** command is higher than the auto cost value.

This command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

The **ipv6 auto-cost enable** command cannot change the cost of the loopback interface.

Example

Enable IS-IS to automatically calculate the interface cost on an IPv6 network according to the interface bandwidth.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 auto-cost enable
```

7.7.5 ipv6 bandwidth-reference

Function

The **ipv6 bandwidth-reference** command sets the bandwidth reference value used in automatic interface cost calculation on an IPv6 network.

The **undo ipv6 bandwidth-reference** command restores the default setting.

By default, the bandwidth reference value is 100 Mbit/s.

Format

ipv6 bandwidth-reference *bandwidth-reference-value*

undo ipv6 bandwidth-reference

Parameters

Parameter	Description	Value
bandwidth-reference-value	Specifies the bandwidth reference value used in automatic interface cost calculation.	The value is an integer that ranges from 1 to 2147483648, in Mbit/s.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To make the link cost of IS-IS routes reflect the actual link cost, configure a proper link cost for all interfaces or enable the automatic interface cost calculation function. To enable automatic interface cost calculation, set a proper bandwidth reference value.

You can run the **ipv6 bandwidth-reference** command to set a proper reference bandwidth value. After the automatic interface cost calculation function is enabled, the system automatically calculates the interface cost according to the bandwidth reference value set using the command.

The **bandwidth** *bandwidth* command can only set an interface bandwidth obtained by the NMS from the MIB. It cannot change an interface actual bandwidth and interface cost.

Precautions

The **ipv6 bandwidth-reference** command takes effect only after IPv6 is enabled for the IS-IS process using the **ipv6 enable** command.

Example

Set the IPv6 reference bandwidth value used in automatic interface cost calculation to 200 Mbit/s.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 bandwidth-reference 200
```

7.7.6 ipv6 bfd all-interfaces enable (IS-IS)

Function

The **ipv6 bfd all-interfaces enable** command enables IPv6 BFD for IS-IS globally in the IS-IS process.

The **undo ipv6 bfd all-interfaces enable** command disables IPv6 BFD for IS-IS globally in the IS-IS process.

By default, IPv6 BFD for IS-IS is disabled in the IS-IS process.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ipv6 bfd all-interfaces enable

undo ipv6 bfd all-interfaces enable

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPv6 BFD for IS-IS can provide millisecond level fault detection, help IS-IS to detect faults on neighboring devices or links rapidly, and instruct IS-IS to recalculate routes for correct packet forwarding.

Prerequisites

The **ipv6 bfd all-interfaces enable** command can take effect only after global BFD is enabled by the **bfd** and IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Configuration Impact

After the **ipv6 bfd all-interfaces enable** command is run, all the interfaces in the IS-IS process are automatically enabled with IPv6 BFD for IS-IS. IS-IS establishes IPv6 BFD sessions on the interfaces whose IS-IS IPv6 neighbor status is Up (the DIS is Up on the broadcast network) by using the default IPv6 BFD parameters.

After the **ipv6 bfd all-interfaces enable** command is run, if you start the IS-IS process on the IS-IS interface that is not enabled with the IS-IS process, the interface is also automatically enabled with IPv6 BFD for IS-IS.

After the **ipv6 bfd all-interfaces enable** command is run, check whether all the interfaces need to be enabled with IPv6 BFD for IS-IS according to network planning. If some interfaces do not need to be enabled with IPv6 BFD for IS-IS, run the **isis ipv6 bfd block** command on these interfaces to block IPv6 BFD for IS-IS.

Precautions

If IPv6 BFD for IS-IS is neither enabled globally nor enabled on interfaces, you can configure IPv6 BFD parameters of IS-IS; however, IPv6 BFD sessions cannot be established.

Example

Configure IPv6 BFD for an IS-IS process.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 bfd all-interfaces enable
```

7.7.7 ipv6 bfd all-interfaces(IS-IS)

Function

The **ipv6 bfd all-interfaces** command configures the parameters of IPv6 BFD sessions.

The **undo ipv6 bfd all-interfaces** command restores the default parameters of IPv6 BFD sessions.

By default, the minimum interval for sending or receiving IPv6 BFD packets is 1000 milliseconds, and the local IPv6 BFD detection multiplier is 3.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ipv6 bfd all-interfaces { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* } *

undo ipv6 bfd all-interfaces { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* } *

Parameters

Parameter	Description	Value
min-rx-interval *receive-interval*	Specifies the minimum interval for receiving BFD packets from the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *transmit-interval*	Specifies the minimum interval for sending BFD packets to the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Indicates the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPv6 BFD for IS-IS can provide millisecond level fault detection, help IS-IS to detect faults on neighboring devices or links rapidly, and instruct IS-IS to recalculate routes for correct packet forwarding. The **isis ipv6 bfd** command can be used to configure IPv6 BFD detection parameters on a specified interface.

Prerequisites

The **ipv6 bfd all-interfaces** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Precautions

If only IPv6 BFD session parameters are configured but the **ipv6 bfd all-interfaces enable** command is not run, no IPv6 BFD sessions can be established.

After the local *min-rx-interval* is compared with the remote *min-tx-interval*, the larger value is chosen as the actual local receiving interval.

NOTE

> To ensure that the actual local receiving interval is the same as the local configured value, you are recommended to configure the same value for the local *min-rx-interval* and the remote *min-tx-interval*.
>
> Similarly, to ensure that the actual local IPv6 BFD detection multiplier is the same as the local configured value, you are recommended to configure the same value for the local *multiplier-value* and the remote *multiplier-value*.

If no IPv6 BFD packets are received from the peer within the actual local detection time, the IPv6 BFD session status is set to Down. The actual local detection time is calculated with the following formula: Actual local detection time = Actual local receiving interval x Local detection multiplier.

If IPv6 BFD parameters are configured in both an IS-IS process and an IS-IS interface, IPv6 BFD parameters configured on the interface take effect.

Example

Configure IPv6 BFD for an IS-IS process, and specify the minimum interval for sending IPv6 BFD packets to 300 ms.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 bfd all-interfaces enable
[HUAWEI-isis-1] ipv6 bfd all-interface min-tx-interval 300
```

7.7.8 ipv6 circuit-cost

Function

The **ipv6 circuit-cost** command sets the cost value of all IPv6 interfaces in IS-IS SPF calculation, that is, the global IPv6 cost value.

The **undo ipv6 circuit-cost** command deletes the configured global IPv6 cost value.

By default, the global IPv6 cost value is not set.

Format

ipv6 circuit-cost { *cost* | **maximum** } [**level-1** | **level-2**]

undo ipv6 circuit-cost [*cost* | **maximum**] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
cost	Specifies the cost value of IPv6 interfaces in IS-IS SPF calculation.	IF the IS-IS cost style is **wide** or **wide-compatible**, the cost value of imported routes ranges from 1 to 16777214. Otherwise, the value ranges from 1 to 63.
maximum	Sets the link cost value of an interface to 16777215. **NOTE** This parameter can be configured only when the IS-IS cost style is **wide** or **wide-compatible**. When the link cost value of an interface is set to 16777215, the neighbor TLV generated on the link cannot be used for route calculation and can only be used to transmit TE information.	-
level-1	Indicates the cost value of a Level-1 interface. If the interface level is not specified, the cost value is set for Level-1 and Level-2 interfaces.	-
level-2	Indicates the cost value of a Level-2 interface. If the interface level is not specified, the cost value is set for Level-1 and Level-2 interfaces.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, multiple valid routes to the same destination are available on large IPv6 networks. IS-IS calculates the optimal routes using SPF calculation and chooses the optimal routes for traffic forwarding. This process often causes the following two problems:

- All the traffic is forwarded through the optimal route, which may cause unbalanced load.
- If the optimal route on a network is disconnected intermittently, traffic is still forwarded through the optimal route, which causes traffic loss.

To solve the preceding problems, run the **ipv6 circuit-cost** command to change the cost value of all interfaces at a time and traffic can be forwarded through different physical links.

Precautions

The priority of the IPv6 cost value on the interface is higher than the priority of the global IPv6 cost value.

The **ipv6 circuit-cost** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Example

Set the global IPv6 cost value in SPF calculation to 20.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 circuit-cost 20
```

7.7.9 ipv6 circuit default-tag

Function

The **ipv6 circuit default-tag** command sets the administrative tag value of all interfaces in IS-IS processes on an IPv6 network.

The **undo ipv6 circuit default-tag** command restores the default tag value.

By default, the administrative tag value of all interfaces in IS-IS processes on an IPv6 network is 0.

Format

ipv6 circuit default-tag *tag* [**level-1** | **level-2**]

undo ipv6 circuit default-tag [*tag*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
tag	Specifies the administrative tag value of an interface in an IS-IS process on an IPv6 network.	The value is an integer that ranges from 1 to 4294967295.
level-1	Indicates the administrative tag value of all Level-1 interfaces in IS-IS processes on an IPv6 network. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-
level-2	Indicates the administrative tag value of all Level-2 interfaces in IS-IS processes on an IPv6 network. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Using the **ipv6 circuit default-tag** command, you can set the administrative tag value for all routes of a specified IS-IS process and use the tag to filter routes.

The administrative tag value is advertised together with the routing information.

- When the cost style of IS-IS is narrow or narrow-compatible, the administrative tag value is not advertised in the LSP and does not takes effect.
- When the cost style of IS-IS is wide, wide-compatible, or compatible, the administrative tag value is advertised in the LSP.

Precautions

The **ipv6 circuit default-tag** command takes effect only after IPv6 is enabled for the IS-IS process using the **ipv6 enable** command.

Example

Set the administrative tag value for a Level-1 IPv6 interface to 30.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 circuit default-tag 30 level-1
```

7.7.10 ipv6 default-route-advertise

Function

The **ipv6 default-route-advertise** command configures the switch to advertise default IPv6 routes.

The **undo ipv6 default-route-advertise** disables the switch from advertising default IPv6 routes.

By default, the switch does not advertise default IPv6 routes.

Format

ipv6 default-route-advertise [**always** | **match default** | **route-policy** *route-policy-name*] [**cost** *cost* | **tag** *tag* | [**level-1** | **level-2** | **level-1-2**]] * [**avoid-learning**]

undo ipv6 default-route-advertise

Parameters

Parameter	Description	Value
always	Indicates that the switch always advertises default IPv6 routes.	-
match default	Indicates that if the routing table contains a default IPv6 route generated by other routing protocols but not IS-IS, the default route is advertised through an LSP.	-
route-policy *route-policy-name*	Specifies the name of a route-policy. A Level-1-2 device advertises default routes to the IS-IS routing domain only when there are external routes matching the route-policy in the routing table of the device. This prevents routing blackhole when link faults make some important external routes unavailable but default routes are still advertised. This route-policy does not affect external route import in IS-IS.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
cost *cost*	Specifies the cost value of an advertised default route.	The value is an integer that ranges from 0 to 4261412864.
tag *tag*	Specifies the tag value of an advertised default route.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
level-1	Sets the level of advertised default IPv6 routes to Level-1. If the level is not specified, Level-2 default routes are generated by default.	-
level-2	Sets the level of advertised default IPv6 routes to Level-2. If the level is not specified, Level-2 default routes are generated by default.	-
level-1-2	Sets the level of advertised default IPv6 routes to Level-1-2. If the level is not specified, Level-2 default routes are generated by default.	-
avoid-learning	Prevents an IS-IS process from learning default routes and adding them to the routing table. If there has been an active default IPv6 route in the routing table, the default IPv6 route becomes inactive after this parameter is specified.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, if other routing protocols are configured on an IS-IS network, to forward traffic in the IS-IS routing domain outside the domain, use the following two methods:

- Configure IS-IS on a Level-1-2 device to advertise default routes into the IS-IS routing domain.
- Configure IS-IS on a Level-1-2 device to import routes of other routing domains into the IS-IS routing domain.

Advertising default routes is easy to configure and does not require an IS-IS process to learn external routes. You can run the **ipv6 default-route-advertise** command to configure IS-IS devices to advertise default routes into the IS-IS routing domain.

Precautions

Using the route-policy, you can force IS-IS to generate default routes only when there are matched routes in the routing table.

- If the **apply isis level-1** command is used in the route-policy view, IS-ISv6 can generate default routes in Level-1 LSPs. If the **apply isis level-1** command is used in the route-policy view, IS-IS can generate default routes in Level-1 LSPs.

- If the **apply isis level-2** command is used in the route-policy view, IS-ISv6 can generate default routes in Level-2 LSPs.
- If the **apply isis level-1-2** command is used in the route-policy view, IS-ISv6 can generate default routes in Level-1 and Level-2 LSPs.

The **ipv6 default-route-advertise** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, an ABR advertises the default IPv6 route to the IS-IS domain as long as the local routing table contains external routes.

Example

Configure the current switch to generate default IPv6 routes in Level-1-2 LSPs.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 default-route-advertise level-1-2
```

7.7.11 ipv6 enable(IS-IS)

Function

The **ipv6 enable** command enables the IPv6 capability of an IS-IS process.

The **undo ipv6 enable** command disables the IPv6 capability of an IS-IS process.

By default, the IPv6 capability of an IS-IS process is disabled.

Format

ipv6 enable [**topology** { **compatible** [**enable-mt-spf**] | **ipv6** | **standard** }]

undo ipv6 enable

Parameters

Parameter	Description	Value
topology	Specifies the network topology type.	-

Parameter	Description	Value
compatible	Sets the topology type to compatible. That is, the standard topology and the IPv6 topology are compatible. After IS-IS IPv6 adjacency relationship is established, IS-IS advertises IPv6 topology links and standard topology links. SPF, however, runs only in a standard topology. The compatible mode is helpful in a transition from the standard topology to the IPv6 topology.	-
enable-mt-spf	Indicates that SPF runs in the IPv6 topology in compatible mode.	-
ipv6	Sets the topology type to IPv6. That is, the IPv6 capability of an IS-IS process can be enabled in an IPv6 topology. Links on the network can be configured as IPv4 or IPv6 links. SPF calculation is performed separately in IPv4 and IPv6 topologies.	-
standard	Sets the topology type to standard. That is, the IPv6 capability of an IS-IS process can be enabled in the integrated topology. Network administrators must ensure that all links on the network support the same topology mode. If the IPv6 capability of an IS-IS process is enabled, **standard** is used by default.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

To enable the IPv6 capability of an IS-IS process, perform the following operations:

1. Run the **ipv6** command in the system view to enable IPv6 globally.
2. Run the **isis** command to enable an IS-IS process.
3. Run the **network-entity** command to set a NET for IS-IS.
4. Run the **ipv6 enable** command in the IS-IS view to enable the IPv6 capability of an IS-IS process.
5. On each interface that needs to run an IS-IS process, run the **ipv6 enable** command to enable the IPv6 capability and configure an IPv6 address.
6. Run the **isis ipv6 enable** command to enable IS-IS for IPv6 on each interface.

Example

Enable the IPv6 capability in the IPv6 topology in IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
```

```
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
[HUAWEI-isis-1] ipv6 enable topology ipv6
```

7.7.12 ipv6 filter-policy export

Function

The **ipv6 filter-policy export** command configures a filtering policy to allow IS-IS to filter the imported IPv6 routes to be advertised.

The **undo ipv6 filter-policy export** command cancels the filtering function.

By default, IS-IS does not filter imported IPv6 routes to be advertised.

Format

ipv6 filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*] | **unr**]

undo ipv6 filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **export** [*protocol* [*process-id*] | **unr**]

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic ACL6.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL.	The value of *acl6-name* is a string of 1 to 64 case-sensitive characters without spaces.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy to filter routes based on tag and other protocol parameters.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
protocol	Specifies the imported routes that need to be filtered when the routes are advertised. Currently, the *protocol* can be **direct**, **static**, **ripng**, **bgp**, **unr**, **ospfv3**, or another **isis** process. If the *protocol* parameter is not specified, all imported routes are filtered.	-
process-id	Specifies the process ID if *protocol* is **ripng**, **ospfv3**, or another **isis** process.	The value is an integer that ranges from 1 to 65535.
unr	Indicates the imported UNR routes that need to be filtered when the routes are advertised.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ipv6 filter-policy export** command together with the **ipv6 import-route** command can be used to filter only the imported routes that are advertised to other switches. If *protocol* is not specified, the routes that are imported from all other protocols are filtered. If *protocol* is specified, the routes that are imported from the specific protocol are filtered.

The **ipv6 filter-policy export** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Precautions

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all external IPv6 routes of the specified routing domain that are imported by IS-IS are advertised to the specified neighbor.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all external IPv6 routes of the specified routing domain that are imported by IS-IS are advertised to the specified neighbor.

Example

Configure IS-IS to filter the imported IPv6 routes using ACL6 2002 before advertising the IPv6 routes to other switches.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 filter-policy 2002 export
```

7.7.13 ipv6 filter-policy import

Function

The **ipv6 filter-policy import** command configures a filtering policy to allow IS-IS to filter the received routes to be added to the IPv6 routing table.

The **undo ipv6 filter-policy import** command cancels the filtering function.

By default, IS-IS does not filter the received routes to be added to the IPv6 routing table.

Format

ipv6 filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **import**

undo ipv6 filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **import**

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic ACL6.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL.	The value of *acl6-name* is a string of 1 to 64 case-sensitive characters without spaces.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy to filter routes based on tag and other protocol parameters.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS routing entries need to be added to an IPv6 routing table to guide IPv6 packet forwarding. If an IS-IS routing table has routes destined for a specified network segment, but these routes do not need to be sent to the IPv6 routing table, run the **ipv6 filter-policy import** command and specify an IPv6 prefix list or a route-policy to allow only the required IS-IS routes to be added to the IPv6 routing table.

Precautions

The **ipv6 filter-policy import** command can take effect only after IPv6 is enabled for the IS-IS process by the ipv6 enable command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all IPv6 routes received by IS-IS are delivered to the IPv6 routing table.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all IPv6 routes received by IS-IS are delivered to the IPv6 routing table.

Example

Filter received IPv6 routes using a route-policy.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 filter-policy route-policy test import
```

7.7.14 ipv6 import-route

Function

The **ipv6 import-route** command configures IS-IS to import IPv6 routes from other routing protocols.

The **undo ipv6 import-route** command disables IS-IS form importing IPv6 routes from other routing protocols.

By default, IS-IS does not import IPv6 routes from other routing protocols.

Format

ipv6 import-route { **direct** | **unr** | { **ospfv3** | **ripng** | **isis** } [*process-id*] | **bgp** [**permit-ibgp**] } **inherit-cost** [**tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

ipv6 import-route { **static** | **direct** | **unr** | { **ospfv3** | **ripng** | **isis** } [*process-id*] | **bgp** [**permit-ibgp**] } [**cost** *cost* | **tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

ipv6 import-route limit *limit-number* [**threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*] { **level-1** | **level-2** | **level-1-2** }

undo ipv6 import-route { **direct** | **unr** | { **ospfv3** | **ripng** | **isis** } [*process-id*] | **bgp** [**permit-ibgp**] } **inherit-cost** [**tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

undo ipv6 import-route { **static** | **direct** | **unr** | { **ospfv3** | **ripng** | **isis** } [*process-id*] | **bgp** [**permit-ibgp**] } [**cost** *cost* | **tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

undo ipv6 import-route limit [*limit-number*] [**threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*] { **level-1** | **level-2** | **level-1-2** }

Parameters

Parameter	Description	Value
direct	Indicates that the imported routes are direct routes.	-
static	Indicates that the imported routes are activated static routes.	-

Parameter	Description	Value
unr	Indicates that the routing protocol from which routes are imported is UNR. The user network route (UNR) is used to allocate routes to user traffic when users cannot use dynamic routing protocols during logins.	-
ospfv3	Indicates that the routing protocol from which routes are imported is OSPFv3.	-
ripng	Indicates that the routing protocol from which routes are imported is RIPng.	-
isis	Indicates that the routing protocol from which routes are imported is IS-IS.	-
process-id	When the protocol is **ospfv3**, **ripng**, or **isis**, a process ID needs to be specified.	The value is an integer that ranges from 1 to 65535.
bgp	Indicates that the routing protocol from which routes are imported is BGP.	-
permit-ibgp	Indicates that the imported routes are IBGP routes. If this parameter is not set, only EBGP routes can be imported.	-
inherit-cost	Indicates that the original cost value of imported external routes is retained.	-
cost *cost*	Specifies the cost value of imported routes.	The value is an integer that ranges from 0 to 4261412864. The default value is 0.
tag *tag*	Specifies the administrative tag of imported routes.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
level-1	Indicates that routes are imported into Level-1 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
level-2	Indicates that routes are imported into Level-2 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
level-1-2	Indicates that routes are imported into Level-1 and Level-2 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
limit *limit-number*	Specifies the maximum number of external IPv6 routes allowed to be imported to the IS-IS area.	The value is an integer ranging from 1 to 10000000.
threshold-alarm	Specifies the alarm threshold for imported routes.	-
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for imported routes.	The value is an integer ranging from 1 to 100. The default value is 80.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for imported routes.	The value is an integer ranging from 1 to 100. The default value is 70.

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If other routing protocols are configured on an IS-IS network, to forward traffic in the IS-IS routing domain outside the domain, use either of the following methods:

- Configure IS-IS on a Level-1-2 device to advertise default routes into the IS-IS routing domain.
- Configure IS-IS on a Level-1-2 device to import routes of other routing domains into the IS-IS routing domain.

If there are multiple Level-1-2 devices in the IS-IS routing domain, optimal routes destined for another routing domain need to be selected. This requires all devices in the IS-IS routing domain learn all or some external routes.

Configure IS-IS on a Level-1-2 device to import routes of other routing domains into the IS-IS routing domain. Alternatively, run the **route-policy** *route-policy-name* command to import some external routes from other routing domains.

Prerequisites

IS-IS has been enabled using the **isis** command and the IS-IS view has been displayed. IPv6 has been enabled for the IS-IS process using the **ipv6 enable** command.

Precautions

When routes of other routing protocols are imported, you can set the cost value and cost style of the imported routes. You can also configure IS-IS to retain the original cost value of the imported external routes. During route advertisement and route calculation, the original cost values of these routes are used. In this case, the cost style and cost value of the imported routes cannot be set, and static routes cannot be imported.

After the **ipv6 import-route direct** command is executed, routes to the network segment where the IPv6 address of the management interface belongs are also imported in the IS-IS routing table. Therefore, use this command with caution.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all IPv6 routes of the specified routing domain are imported to the IS-IS routing table.

Example

Configure IS-IS to import static IPv6 routes and set the cost value of the routes to 15.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 import-route static cost 15
```

Configure IS-IS to import OSPFv3 routes and retain the original cost value of the routes.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 import-route ospfv3 1 inherit-cost
```

7.7.15 ipv6 import-route isis level-1 into level-2

Function

The **ipv6 import-route isis level-1 into level-2** command configures IPv6 route leaking from Level-1 areas to Level-2 areas.

The **undo ipv6 import-route isis level-1 into level-2** command prohibits IPv6 route leaking from Level-1 areas to Level-2 areas.

By default, all Level-1 routing information, excluding information about default routes, is leaked to Level-2 areas.

Format

ipv6 import-route isis level-1 into level-2 [**filter-policy** { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct allow-filter-policy**] *

undo ipv6 import-route isis level-1 into level-2 [**filter-policy** { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct allow-filter-policy**] *

Parameters

Parameter	Description	Value
filter-policy	Specifies a filtering policy for IPv6 routes.	-
acl6-number	Specifies the number of a basic ACL6.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL.	The value of *acl6-name* is a string of 1 to 64 case-sensitive characters without spaces.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list. Only the routes that match the IPv6 prefix can be imported to Level-2 areas.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
tag *tag*	Specifies the administrative tag of imported routes.	The value is an integer that ranges from 1 to 4294967295.
direct allow-filter-policy	Specifies the filtering policy to filter the direct routes. Only the IS-IS Level-1 area direct routing information that matches the filtering policy can be shared with the Level-2 area with this parameter, and all Level-1 area direct routing information will be shared with the Level-2 area without this parameter.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ipv6 import-route isis level-1 into level-2** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Precautions

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all IPv6 routes in the Level-1 area leak to the Level-2 area.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all IPv6 routes in the Level-1 area leak to the Level-2 area.

Example

Control IPv6 route leaking from Level-1 areas to Level-2 areas on Level-1-2 routers using IPv6 prefix list **list**.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 import-route isis level-1 into level-2 filter-policy ipv6-prefix list
```

7.7.16 ipv6 import-route isis level-2 into level-1

Function

The **ipv6 import-route isis level-2 into level-1** command configures IPv6 route leaking from Level-2 areas to Level-1 areas.

The **undo ipv6 import-route isis level-2 into level-1** command prohibits IPv6 route leaking from Level-2 areas to Level-1 areas.

By default, Level-2 routing information is not leaked to Level-1 areas.

Format

ipv6 import-route isis level-2 into level-1 [**filter-policy** { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct** { **allow-filter-policy** | **allow-up-down-bit** } *] *

undo ipv6 import-route isis level-2 into level-1 [**filter-policy** { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct** { **allow-filter-policy** | **allow-up-down-bit** } *] *

Parameters

Parameter	Description	Value
filter-policy	Specifies a filtering policy for IPv6 routes.	-
acl6-number	Specifies the number of a basic ACL6.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL. The value is a string of case-sensitive characters.	The value of *acl6-name* is a string of 1 to 64 case-sensitive characters without spaces.

Parameter	Description	Value
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
tag *tag*	Specifies the administrative tag of imported routes.	The value is an integer that ranges from 1 to 4294967295.
direct allow-filter-policy	Specifies the filtering policy to filter the direct routes. Only the IS-IS Level-1 area direct routing information that matches the filtering policy can be shared with the Level-2 area with this parameter, and all Level-1 area direct routing information will be shared with the Level-2 area without this parameter.	-
direct allow-up-down-bit	Indicates that the Up or Down bit is used during the leak of directs routes. If **direct allow-up-down-bit** is specified, the direct routes that have already leaked to the Level-1 area have the lowest priority and cannot leak back.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ipv6 import-route isis level-2 into level-1** command must be configured on Level-1-2 routers at the area border.

The **ipv6 import-route isis level-2 into level-1** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Precautions

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all IPv6 routes in the Level-2 area leak to the Level-1 area.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all IPv6 routes in the Level-2 area leak to the Level-1 area.

Example

Configure the switch to perform IPv6 route leaking from a Level-2 area to a Level-1 area using filtering policy 2002.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 import-route isis level-2 into level-1 filter-policy 2002
```

7.7.17 ipv6 maximum load-balancing

Function

The **ipv6 maximum load-balancing** command sets the maximum number of IS-IS IPv6 equal-cost routes for load balancing.

The **undo ipv6 maximum load-balancing** command restores the default number of equal-cost routes for load balancing.

By default, IS-IS supports IPv6 load balancing and the maximum number of IS-IS IPv6 equal-cost routes is 8.

Format

ipv6 maximum load-balancing *number*

undo ipv6 maximum load-balancing [*number*]

Parameters

Parameter	Description	Value
number	Specifies the number of IPv6 equal-cost routes for load balancing.	The value is an integer that ranges from 1 to 8.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

The **ipv6 maximum load-balancing** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Example

Set the maximum number of IS-IS IPv6 equal-cost routes for load balancing to 2.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 100
[HUAWEI-isis-100] ipv6 enable
[HUAWEI-isis-100] ipv6 maximum load-balancing 2
```

7.7.18 ipv6 preference

Function

The **ipv6 preference** command configures the preference of IPv6 routes generated by the IS-IS protocol.

The **undo ipv6 preference** command restores the default reference of IPv6 routes generated by the IS-IS protocol.

By default, the preference of IPv6 routes generated by the IS-IS protocol is 15.

Format

ipv6 preference { **route-policy** *route-policy-name* | *preference* } *

undo ipv6 preference

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
preference	Specifies the preference of IPv6 routes generated by the IS-IS. A smaller value indicates a higher priority.	The value is an integer that ranges from 1 to 255.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The routing policy can be used to set the preference for the filtered routes. If the preference is set, only the routes that pass the route-policy can apply the preference specified by this command; otherwise, routes apply the default value of the preference.

Multiple dynamic routing protocols can be run on a switch at the same time. To properly select routes, the system sets a default preference for each routing protocol. If different protocols find routes to the same destination, the route of the protocol with a higher priority is preferred.

The **ipv6 preference** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Precautions

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured priority applies to all IS-IS IPv6 routes.

Example

Set the IS-IS protocol preference to 20.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
```

```
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 preference 20
```

7.7.19 ipv6 prefix-priority (IS-IS)

Function

The **ipv6 prefix-priority** command configures the convergence priority of IS-IS IPv6 routes.

The **undo ipv6 prefix-priority** command restores the default convergence priority of IS-IS IPv6 routes.

By default, the convergence priority of IS-IS IPv6 host routes and default routes is medium, and the convergence priority of other IS-IS IPv6 routes is low.

Format

ipv6 prefix-priority [**level-1** | **level-2**] { **critical** | **high** | **medium** } { **ipv6-prefix** *prefix-name* | **tag** *tag-value* }

undo ipv6 prefix-priority [**level-1** | **level-2**] { **critical** | **high** | **medium** }

Parameters

Parameter	Description	Value
level-1	Specifies the convergence priority of Level-1 IS-IS IPv6 routes.	-
level-2	Specifies the convergence priority of Level-2 IS-IS IPv6 routes.	-
critical	Sets the convergence priority of IS-IS IPv6 routes to critical.	-
high	Sets the convergence priority of IS-IS IPv6 routes to high.	-
medium	Sets the convergence priority of IS-IS IPv6 routes to medium.	-
ipv6-prefix *prefix-name*	Specifies the prefix name of IPv6 addresses for filtering routes to set the convergence priority for IS-IS IPv6 routes that match the specified IPv6 address prefix.	The value of *prefix-name* is a string of 1 to 169 case-sensitive characters without spaces.

Parameter	Description	Value
tag *tag-value*	Specifies the tag value used for filtering routes to set the convergence priority for IS-IS IPv6 routes that carry the specified tag value. To specify the tag value to filter the IPv6 routes that need to be set with the convergence priority, ensure that IS-IS IPv6 routes carry the tag value.	The value is an integer that ranges from 1 to 4294967295.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

This command takes effect only in IPv6 base topologies but not in VPNs.

The convergence priorities of IS-IS IPv6 routes are classified as critical, high, medium, and low in descending order.

After the **ipv6 prefix-priority** command is run to set the convergence priority for IS-IS IPv6 routes, the following situations occur:

- The convergence priority of existing IS-IS IPv6 routes is re-set according to the configuration of the **ipv6 prefix-priority** command.
- The convergence priority of new IS-IS IPv6 routes is set according to the filtering result of the **ipv6 prefix-priority** command.
- If an IS-IS IPv6 route meets the matching rules specified in multiple commands that are used to configure convergence priorities, this IS-IS IPv6 route is of top convergence priority among the set convergence priorities.
- no level is specified, the convergence priority is set for both Level-1 routes and Level-2 routes according to the configuration of the **ipv6 prefix-priority** command.

NOTE

The **ipv6 prefix-priority** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

After the **ipv6 prefix-priority** command is run to set the convergence priority for IS-IS IPv6 routes (including IS-IS IPv6 host routes and default routes), the convergence priority of all the IS-IS IPv6 routes that meet the matching rules is changed according to the configuration of the **ipv6 prefix-priority** command, and the convergence priority of the IS-IS IPv6 routes that do not meet the matching rules is changed to low.

Example

In an IPv6 base topology, set the convergence priority of IS-IS Level-1 routes with tag value 3 to critical.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 prefix-priority level-1 critical tag 3
```

7.7.20 ipv6 spf-priority

Function

The **ipv6 spf-priority** command configures a priority for SPF calculation in an IPv6 base topology.

The **undo ipv6 spf-priority** command restores the default priority for SPF calculation in an IPv6 base topology.

By default, the priority of SPF calculation in an IPv6 base topology is 64.

Format

ipv6 spf-priority *priority-value*

undo ipv6 spf-priority

Parameters

Parameter	Description	Value
priority-value	Specifies the priority for SPF calculation in an IPv6 base topology. A larger value indicates a higher priority.	The value is an integer that ranges from 1 to 127.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

A higher priority of SPF calculation in an IPv6 base topology means that the routes in the IPv6 base topology are converged preferentially, which ensures the proper operation of important services.

The **ipv6 spf-priority** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Example

Set the priority of SPF calculation in an IPv6 base topology to 30.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
```

```
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 spf-priority 30
```

7.7.21 ipv6 summary

Function

The **ipv6 summary** command configures IS-IS to generate IPv6 summarized routes.

The **undo ipv6 summary** command disables IS-IS from generating IPv6 summarized routes.

By default, IS-IS does not generate IPv6 summarized routes.

Format

ipv6 summary *ipv6-address prefix-length* [**avoid-feedback** | **generate_null0_route** | **tag** *tag* | [**level-1** | **level-1-2** | **level-2**]] *

undo ipv6 summary *ipv6-address prefix-length* [**level-1** | **level-1-2** | **level-2**]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the address range of IPv6 routes to be summarized.	-
prefix-length	Specifies the prefix length of an IPv6 route.	The value is an integer that ranges from 0 to 128.
avoid-feedback	Avoids learning summarized routes through SPF calculation.	-
generate_null0_route	Generates NULL0 routes to avoid routing loop.	-
tag *tag*	Specifies the administrative tag value.	The value is an integer that ranges from 1 to 4294967295.
level-1	Indicates that only routes in Level-1 areas are summarized. If the level is not specified, **level-2** is used by default.	-
level-1-2	Indicates that routes in Level-1 and Level-2 areas are summarized. If the level is not specified, **level-2** is used by default.	-

Parameter	Description	Value
level-2	Indicates that only routes in Level-2 areas are summarized. If the level is not specified, **level-2** is used by default.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

The routes with the same prefix can be aggregated into one route. This can reduce the scale of the routing table, the size of the LSPs generated by the local switch, and the scale of the LSDB. The aggregated routes can be the routes discovered by IS-IS or the imported IPv6 routes. After the aggregation, the smallest cost among those of the routes that are aggregated is used as the cost of the aggregated IPv6 route.

The **ipv6 summary** command can take effect only after IPv6 is enabled for the IS-IS process by the **ipv6 enable** command.

Example

Set a summarized route fc00::/32.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] ipv6 summary fc00:: 32
```

7.7.22 isis ipv6 bfd

Function

The **isis ipv6 bfd** command configures IPv6 BFD detection parameters on a specified interface.

The **undo isis ipv6 bfd** command restores the default values of IPv6 BFD detection parameters on a specified interface.

By default, the minimum interval for sending or receiving IPv6 BFD packets is 1000 milliseconds, and the local IPv6 BFD detection multiplier is 3.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis ipv6 bfd { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* } *

undo isis ipv6 bfd { **min-rx-interval** [*receive-interval*] | **min-tx-interval** [*transmit-interval*] | **detect-multiplier** [*multiplier-value*] } *

Parameters

Parameter	Description	Value
min-rx-interval *receive-interval*	Specifies the minimum interval for receiving BFD packets from the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *transmit-interval*	Specifies the minimum interval for sending BFD packets to the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Indicates the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPv6 BFD for IS-IS can provide millisecond level fault detection, help IS-IS to detect faults on neighboring devices or links rapidly, and instruct IS-IS to recalculate routes for correct packet forwarding. The **isis ipv6 bfd** command can be used to configure IPv6 BFD detection parameters on a specified interface.

Prerequisites

Before running the **isis ipv6 bfd** command, you need to run the **ipv6 enable** command in the IS-IS process and configure IS-IS on the interface.

The configured IPv6 BFD detection parameters take effect on an interface only when the **isis ipv6 bfd enable** command is configured on the interface.

Precautions

After the local *receive-interval* is compared with the remote *transmit-interval*, the larger value is chosen as the actual local receiving interval. If no IPv6 BFD packets are received from the peer within the actual local detection time, the IPv6 BFD session status is set to Down. The actual local detection time is calculated with the following formula: Actual local detection time = Actual local receiving interval x Local detection multiplier.

NOTE

To ensure that the actual local receiving interval is the same as the local configured value, you are recommended to configure the same value for the local *min-rx-interval* and the remote *min-tx-interval*.

Similarly, to ensure that the actual local IPv6 BFD detection multiplier is the same as the local configured value, you are recommended to configure the same value for the local *multiplier-value* and the remote *multiplier-value*.

The **isis ipv6 bfd** command takes priority over the **ipv6 bfd all-interfaces** command.

Example

Enable IPv6 BFD for IS-IS on Vlanif10, and specify the minimum interval for receiving IPv6 BFD packets to 400 ms and the local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] isis ipv6 bfd enable
[HUAWEI-Vlanif10] isis ipv6 bfd min-rx-interval 400 detect-multiplier 4
```

7.7.23 isis ipv6 bfd block

Function

The **isis ipv6 bfd block** command disables an interface from dynamically establishing an IPv6 BFD session.

The **undo isis ipv6 bfd block** command cancels the configuration.

By default, no interface is disabled from dynamically establishing a BFD session.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis ipv6 bfd block

undo isis ipv6 bfd block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the **ipv6 bfd all-interfaces enable** command is run in an IS-IS process, IPv6 BFD for IS-IS is enabled on all IS-IS interfaces that are associated with this IS-IS process. You can run the **isis ipv6 bfd block** command to disable an interface from dynamically establishing an IPv6 BFD session.

Prerequisites

To make the **isis ipv6 bfd block** command take effect, do as follows first:

1. Enable IPv6 globally in the system view by using the **ipv6** command.
2. Enable an IS-IS process by using the **isis** command.
3. Enable IPv6 capability of the IS-IS process by using the **ipv6 enable** command in the IS-IS view.
4. On each interface that runs an IS-IS process, enable IPv6 capability by using the **ipv6 enable** command.
5. Enable IS-IS on each interface by using the **isis ipv6 enable** command.

Precautions

The **isis ipv6 bfd block** command and the **isis ipv6 bfd enable** command are mutually exclusive and cannot be run on the same interface.

The function of the **isis ipv6 bfd block** command is similar to the function of the **undo isis ipv6 bfd enable** command, except that:

- After the **undo isis ipv6 bfd enable** command is configured on an IS-IS interface, if the **ipv6 bfd all-interfaces enable** command is reconfigured in the IS-IS view, the interface still has IPv6 BFD for IS-IS capabilities.

- After the **isis ipv6 bfd block** command is configured on an IS-IS interface, the interface does not have IPv6 BFD for IS-IS capabilities, even if the **ipv6 bfd all-interfaces enable** command is reconfigured in the IS-IS view.

NOTE

- To enable IPv6 BFD for IS-IS on most IS-IS interfaces, you need to configure the **isis ipv6 bfd block** command on the IS-IS interfaces that do not need to be enabled with IPv6 BFD for IS-IS, and then configure the **ipv6 bfd all-interfaces enable** command in the IS-IS view.
- To enable IPv6 BFD for IS-IS only on a few IS-IS interfaces, configure the **isis ipv6 bfd enable** command on these interfaces. In this situation, you can configure the **undo isis ipv6 bfd enable** or **isis ipv6 bfd block** command to disable IPv6 BFD for IS-IS on these interfaces.

Example

Disable Vlanif10 from dynamically establishing an IPv6 BFD session.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 bfd block
```

7.7.24 isis ipv6 bfd enable

Function

The **isis ipv6 bfd enable** command enables IPv6 BFD for IS-IS on the IS-IS interface and uses the default parameters to establish an IPv6 BFD session.

The **undo isis ipv6 bfd enable** command disables IPv6 BFD for IS-IS on the IS-IS interface.

By default, if IPv6 BFD for IS-IS is enabled in the IS-IS view, the IS-IS interface is also enabled with IPv6 BFD for IS-IS. If IPv6 BFD for IS-IS is not enabled in the IS-IS view, the IS-IS interface is not enabled with IPv6 BFD for IS-IS either.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis ipv6 bfd enable

undo isis ipv6 bfd enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPv6 BFD for IS-IS can provide millisecond level fault detection, help IS-IS to detect faults on neighboring devices or links rapidly, and instruct IS-IS to recalculate routes for correct packet forwarding. The **isis ipv6 bfd enable** command can be used to enable IPv6 BFD for IS-IS on a specified IS-IS interface.

If IPv6 BFD for IS-IS is not enabled globally, you can run the **isis ipv6 bfd enable** command on an interface to enable IPv6 BFD for IS-IS on this interface.

Prerequisites

To make the **isis ipv6 bfd enable** command take effect, do as follows:

1. Enable IPv6 globally in the system view by using the **ipv6** command.
2. Enable an IS-IS process by using the **isis** command.
3. Enable IPv6 capability of the IS-IS process by using the **ipv6 enable** command in the IS-IS view.
4. On each interface that runs an IS-IS process, enable IPv6 capability by using the **ipv6 enable** command.
5. Enable IS-IS on each interface by using the **isis ipv6 enable** command.

Example

Enable IPv6 BFD on Vlanif10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 bfd enable
```

7.7.25 isis ipv6 cost

Function

The **isis ipv6 cost** command sets the link cost value of an IS-IS interface in an IPv6 topology.

The **undo isis ipv6 cost** command restores the default link cost value of an IS-IS interface in an IPv6 topology.

By default, the link cost value of an IS-IS interface in an IPv6 topology is 10.

Format

isis ipv6 cost { *cost* | **maximum** } [**level-1** | **level-2**]

undo isis ipv6 cost [*cost* | **maximum**] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
cost	Specifies the IPv6 link cost value of an interface.	The value is an integer that varies according to the cost style. ● When the cost style is **narrow**, **narrow-compatible** or **compatible**, the value ranges from 1 to 63. ● When the cost style is **wide** or **wide-compatible**, the value ranges from 1 to 16777214. The default value is 10. To set the cost style, use the **cost-style** command.
maximum	Sets the link cost value of an interface to 16777215. **NOTE** This parameter can be configured only when the IS-IS cost style is **wide** or **wide-compatible**. When the link cost value of an interface is set to 16777215, the neighbor TLV generated on the link cannot be used for route calculation and can only be used to transmit TE information.	-
level-1	Specifies the link cost value of a Level-1 interface. If the interface level is not specified, link cost values of Level-1 and Level-2 interfaces are set.	-
level-2	Specifies the link cost value of a Level-2 interface. If the interface level is not specified, link cost values of Level-1 and Level-2 interfaces are set.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale IPv6 network, there may be multiple valid routes to the same destination. IS-IS uses the SPF algorithm to calculate an optimal route and transmits traffic over it, which brings the following problems:

- All traffic is transmitted over the optimal route, causing load imbalance.
- If the optimal route is faulty, traffic will get lost.

To solve the preceding problems, run the **isis ipv6 cost** command to set IPv6 link costs for interfaces so that traffic can be transmitted over different physical links.

Prerequisites

IS-IS has been enabled on a specified interface using the **isis ipv6 enable** [*process-id*] command in the interface view.

Configuration Impact

If the link cost of an interface is changed, routes will be re-calculated on the whole network, causing the changes in traffic forwarding paths.

The priority of the **ipv6 circuit-cost** command is lower than that of the **isis ipv6 cost** command.

If the IPv6 topology type is **compatible** or **standard**, the IPv6 and IPv4 link costs are the same on an interface even though the IPv6 link cost set using the **isis ipv6 cost** command is different from the IPv4 link cost. The IPv6 link cost set using the **isis ipv6 cost** command takes effect only when the IPv6 topology type is **compatible enable-mt-spf** or **ipv6**.

NOTE

The IPv6 topology type can be set for an IS-IS process using the **ipv6 enable(IS-IS)** command.

Example

Set the IPv6 link cost of VLANIF 10 to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 cost 50
```

Set the IPv6 link cost of GE0/0/1 to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 cost 50
```

7.7.26 isis ipv6 enable

Function

The **isis ipv6 enable** command enables the IS-IS IPv6 capability for an interface and specifies the ID of the IS-IS process to be associated with the interface.

The **undo isis ipv6 enable** command disables the IS-IS IPv6 capability of an interface and disassociates an IS-IS process from the interface.

By default, the IS-IS IPv6 capability is disabled on an interface.

Format

isis ipv6 enable [*process-id*]

undo isis ipv6 enable

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535. The default value is 1.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After completing the configuration of an IS-IS process in the system view, enable IS-IS IPv6 on the interface that runs IS-IS and associate the interface with the IS-IS process using the **isis ipv6 enable** command.

Prerequisites

The following steps have been performed:

1. Enable IPv6 globally using the **ipv6** command in the system view.
2. Enable an IS-IS process using the **isis** command and configure a network entity title (NET) for the device running IS-IS using the **network-entity** command.
3. Enable IPv6 for the IS-IS process using the **ipv6 enable (IS-IS)** command in the IS-IS view.
4. Enable IPv6 and configure an IPv6 address using the **ipv6 enable** command on each interface that runs the IS-IS process.

Precautions

An interface can be associated with only one IS-IS process.

NOTE

To perform IPv6-related IS-IS configurations, you must enable IPv6 first.

Example

Create IS-IS process 1, enable the IPv6 capability, and activate the IPv6 capability on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ipv6 address fc00:0:0:2::1/64
[HUAWEI-Vlanif10] isis ipv6 enable 1
```

Create IS-IS process 1, enable the IPv6 capability, and activate the IPv6 capability on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00:0:0:2::1/64
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 enable 1
```

7.7.27 isis ipv6 suppress-reachability

Function

The **isis ipv6 suppress-reachability** command suppresses the advertisement of direct routes on an IPv6 interface in a specified topology.

The **undo isis ipv6 suppress-reachability** command restores the default configuration of an IPv6 interface.

By default, the advertisement of IPv6 addresses on an interface is not suppressed.

Format

isis ipv6 suppress-reachability [**level-1** | **level-1-2** | **level-2**]

undo isis ipv6 suppress-reachability

Parameters

Parameter	Description	Value
level-1	Suppresses the advertisement of IPv6 addresses is suppressed on Level-1 interfaces. If the level is not specified, Level-1-2 is used by default.	-
level-1-2	Indicates that the advertisement of IPv6 addresses is suppressed on Level-1 and Level-2 interfaces. If the level is not specified, Level-1-2 is used by default.	-
level-2	Indicates that the advertisement of IPv6 addresses is suppressed on Level-2 interfaces. If the level is not specified, Level-1-2 is used by default.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

You must enable the IPv6 capability for an IS-IS process before running this command. For details, see the **isis ipv6 enable** command.

Example

Suppress the advertisement of IPv6 addresses on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 enable
[HUAWEI-Vlanif10] isis ipv6 suppress-reachability
```

Suppress the advertisement of IPv6 addresses on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
```

```
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 suppress-reachability
```

7.7.28 isis ipv6 tag-value

Function

The **isis ipv6 tag-value** command configures the IPv6 administrative tag value on an IS-IS interface.

The **undo ipv6 isis tag-value** command deletes the IPv6 administrative tag value on an IS-IS interface.

By default, an IS-IS interface has no IPv6 administrative tag value.

Format

isis ipv6 tag-value *tag* [**level-1** | **level-2**]

undo isis ipv6 tag-value [*tag*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
tag	Specifies the administrative tag value.	The value is an integer that ranges from 1 to 4294967295.
level-1	Indicates the administrative tag value of a Level-1 interface. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-
level-2	Indicates the administrative tag value of a Level-2 interface. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Using the **isis ipv6 tag-value** command, you can set the administrative tag value for all routes of a specified IS-IS process. The tag can be used as a filtering condition of a route-policy to filter routes.

Precautions

You must enable the IPv6 capability for an IS-IS process before running this command.

If the IS-IS cost style is wide, wide-compatible, or compatible, the administrative tag for an interface is advertised using an LSP.

Example

Set the IPv6 administrative tag value of VLANIF100 to 77.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] isis ipv6 enable
[HUAWEI-Vlanif100] isis ipv6 tag-value 77
```

Set the IPv6 administrative tag value of GE0/0/1 tp 77.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] isis 1
[HUAWEI-isis-1] ipv6 enable
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] isis ipv6 tag-value 77
```

7.8 BGP Configuration Commands

7.8.1 Command Support

Only the following switch models support BGP:

S5720I-SI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

NOTE

The S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S support only the BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, and BGP-IPv6 unicast address family view.

The S5731-S, S5731S-S, S6730-S, and S6730S-S support only the BGP-IPv4 multicast address family view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, and BGP-VPN instance IPv6 address family view.

7.8.2 active-route-advertise

Function

The **active-route-advertise** command enables BGP to advertise only the preferred routes in the IP routing table.

The **undo active-route-advertise** command restores the default setting.

By default, BGP advertises all preferred routes in the BGP routing table to neighbors.

Format

active-route-advertise

undo active-route-advertise

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, BGP advertises all preferred routes in the BGP routing table to neighbors. After the **active-route-advertise** is configured, only the routes preferred by BGP and also active at the routing management layer are advertised to neighbors.

Precautions

The **active-route-advertise** command and the **routing-table rib-only** command are mutually exclusive.

Example

Enable BGP to advertise only the preferred routes in the IP routing table to neighbors.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] active-route-advertise
```

7.8.3 aggregate (BGP)

Function

The **aggregate** command creates a summary route in the BGP routing table.

The **undo aggregate** command deletes a summary route from the BGP routing table.

By default, no summary route is created in the BGP routing table.

Format

aggregate *ipv4-address* { *mask* | *mask-length* } [**as-set** | **attribute-policy** *route-policy-name1* | **detail-suppressed** | **origin-policy** *route-policy-name2* | **suppress-policy** *route-policy-name3*] *

aggregate *ipv6-address prefix-length* [**as-set** | **attribute-policy** *route-policy-name1* | **detail-suppressed** | **origin-policy** *route-policy-name2* | **suppress-policy** *route-policy-name3*] *

undo aggregate *ipv4-address* { *mask* | *mask-length* } [**as-set** | **attribute-policy** *route-policy-name1* | **detail-suppressed** | **origin-policy** *route-policy-name2* | **suppress-policy** *route-policy-name3*] *

undo aggregate *ipv6-address prefix-length* [**as-set** | **attribute-policy** *route-policy-name1* | **detail-suppressed** | **origin-policy** *route-policy-name2* | **suppress-policy** *route-policy-name3*] *

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a summary route.	The address is in dotted decimal notation.
mask	Specifies the network mask of a summary route.	The mask is in dotted decimal notation.
mask-length	Specifies the network mask length of a summary route.	The value is an integer that ranges from 0 to 32.
ipv6-address	Specifies the IPv6 address of a summary route.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the length of the prefix of an IPv6 summary route.	The value is an integer that ranges from 0 to 128.

Parameter	Description	Value
as-set	Generates a route with the AS-SET.	-
attribute-policy *route-policy-name1*	Specifies the name of an attribute policy for summary routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
detail-suppressed	Advertises only the summary route.	-
origin-policy *route-policy-name2*	Specifies the name of a policy that allows route summarization.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
suppress-policy *route-policy-name3*	Specifies the name of a policy for suppressing the advertisement of specific routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP route summarization is classified into manual summarization and automatic summarization. The **aggregate** command can be used to configure manual summarization. This command can summarize routes in the local BGP routing table. Manually-summarized routes take precedence over automatically-summarized routes. The outbound interface of the summary route on the local switch is NULL0. When receiving the summary route, other switches automatically add the outbound interface.

The generated summary route inherits the Origin attribute from the specific routes if they have the same Origin attribute. If the specific routes have different Origin attributes, the summary route selects one as its own from these Origin attributes in descending order of preference: incomplete > egp > igp. If specific routes are not suppressed, the summary route carries the community attribute of every specific route.

The **aggregate** command adds a summary route to the BGP routing table.

- The parameter **as-set** is used to create a summary route whose AS_Path attribute contains AS_Path information of specific routes. Exercise caution when using this parameter if many AS_Path attributes need to be summarized because frequent changes in routes may cause route flapping.
- The parameter **detail-suppressed** is used to suppress the advertisement of specific routes. After **detail-suppressed** is configured, only summary routes are advertised. Summary routes carry the atomic-aggregate attribute, not the community attributes of specific routes.
- The parameter **suppress-policy** is used to suppress the advertisement of specific routes. The **if-match** clause of **route-policy** can be used to filter the routes to be suppressed. This means that only the routes matching the policy will be suppressed, and the other routes will still be advertised. The **peer route-policy** command can also be used to filter out the routes not to be advertised to peers.
- After the parameter **origin-policy** is used, only the routes matching **route-policy** are summarized.
- The parameter **attribute-policy** is used to set attributes for a summary route. If the AS_Path attribute is set in the policy using the **apply as-path** command and **as-set** is set in the **aggregate** command, the AS_Path attribute in the policy does not take effect. The **peer route-policy** command can also be used to set attributes for a summary route.

Prerequisites

Before the **aggregate** command is run, BGP must be enabled.

Configuration Impact

Summary routes are generated after you run the **aggregate** command. If **detail-suppressed** is configured in the command, the advertisement of specific routes will be suppressed. If **suppress-policy** is configured in the command, the advertisement of specific routes that match the policy will be suppressed.

Precautions

When the **undo aggregate** command is run, the system matches routes based on the configured parameter **attribute-policy**, **origin-policy**, **suppress-policy**, **as-set**, or **detail-suppressed**. If none of these parameters is configured, the **undo aggregate** command will fail to be executed.

Example

Create a summary route. The path that is used to advertise this route is an AS-SET consisting of all summarized paths.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] aggregate 172.16.0.0 255.255.0.0 as-set
```

7.8.4 as-notation plain

Function

The **as-notation plain** command configures a BGP 4-byte AS number to be displayed as an integer.

The **undo as-notation plain** command configures a BGP 4-byte AS number to be displayed in dotted notation.

By default, a BGP 4-byte AS number is displayed in dotted notation (that is, in the format of x.y).

Format

as-notation plain

undo as-notation plain

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, display commands such as the **display bgp peer** command display 4-byte AS numbers in dotted notation.

To display a 4-byte AS number as an integer, run the **as-notation plain** command. After the **as-notation plain** command is run, display commands display all 4-byte AS numbers as integers. These 4-byte AS numbers include:

- Independent 4-byte AS number
- 4-byte AS number in an extended community attribute
- 4-byte AS number in a route distinguisher (RD)

- 4-byte AS number in a VPN target (also called a route target)
- 4-byte AS number in the Site-of-Origin attribute

Assume that a 4-byte AS number in dotted notation is *x.y*. Following is the conversion relationship between an integral 4-byte AS number and a 4-byte AS number in dotted notation:

Integral 4-byte AS number = *x* x 65536 + *y*

For example, if a 4-byte AS number in dotted notation is 2.3, the corresponding integral 4-byte AS number is 131075 (2 x 65536 + 3).

Precautions

After the **as-notation plain** command is run, the formats of 4-byte AS numbers in configuration information generated by the system do not change.

- If integral 4-byte AS numbers are configured, 4-byte AS numbers in configuration information generated by the system are also displayed as integers.
- If 4-byte AS numbers in dotted notation are configured, 4-byte AS numbers in configuration information generated by the system are also displayed in dotted notation.

Changing the format of 4-byte AS numbers will affect matching results of AS_Path regular expressions and extended community attribute filters. Therefore, if the system is using an AS_Path regular expression or an extended community attribute filter as an import or export policy, you must reconfigure an AS_Path regular expression using the **ip as-path-filter** command or an extended community attribute filter using the **ip extcommunity-filter** command after changing the format of 4-byte AS numbers. This reconfiguration ensures that routes match the import or export policy.

- If integral 4-byte AS numbers are configured, you must change 4-byte AS numbers in AS_Path regular expressions and extended community attribute filters to integral 4-byte AS numbers.
- If 4-byte AS numbers in dotted notation are configured, you must change 4-byte AS numbers in AS_Path regular expressions and extended community attribute filters to 4-byte AS numbers in dotted notation.

Example

Configure a BGP 4-byte AS number to be displayed as an integer.

```
<HUAWEI> system-view
[HUAWEI] as-notation plain
Warning: If the configuration takes effect, the regular expression of the filter for 4-byte AS path should be
changed to the asplain format, otherwise match will fail. Continue? [Y/N]y
```

Configure a BGP 4-byte AS number to be displayed in dotted notation.

```
<HUAWEI> system-view
[HUAWEI] undo as-notation plain
Warning: If the configuration takes effect, the regular expression of the filter for 4-byte AS path should be
changed to the asdot format, otherwise match will fail. Continue? [Y/N]y
```

7.8.5 as-path-limit

Function

The **as-path-limit** command sets the maximum number of AS numbers in the AS_Path attribute.

The **undo as-path-limit** command restores the default setting.

By default, no limit is configured on the maximum number of AS numbers in the AS_Path attribute, but the maximum number of AS numbers carried in the AS_Path attribute is limited by the BGP message length.

Format

as-path-limit [*as-path-limit-num*]

undo as-path-limit

Parameters

Parameter	Description	Value
as-path-limit-num	Specifies the maximum number of AS numbers in the AS-Path attribute.	The value is an integer that ranges from 1 to 2000. **NOTE** ● The maximum value of *as-path-limit-num* for the 2-byte and 4-byte AS numbers is the same. ● If *as-path-limit-num* is not specified, the maximum number of AS numbers in the AS_Path attribute is 255.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used to restrict the maximum number of AS numbers in the AS_Path attribute only when the AS_Path attribute is reconstructed or the aggregated routes are generated.

Precautions

After the **as-path-limit** command is configured, a switch checks whether the number of AS numbers in the AS-Path attribute of each received or advertised route exceeds the maximum value. If the number of AS numbers exceeds the maximum value, the local switch discards the route. Therefore, if the maximum number of AS numbers in the AS-Path attribute is set too small, routes are lost.

Example

Set the maximum number of AS numbers in the AS-Path attribute to 200.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] as-path-limit 200
```

7.8.6 auto-frr

Function

The **auto-frr** command enables BGP Auto FRR.

The **undo auto-frr** command disables BGP Auto FRR.

By default, BGP Auto FRR is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

auto-frr

undo auto-frr

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This function is applicable to networks that require a low packet loss rate and a short delay.

Using BGP Auto FRR together with BFD is recommended. They can rapidly detect a link fault and switch traffic to a standby link if a fault occurs.

Precautions

If both the **ip frr** command and the **auto-frr** command are configured, the **ip frr** command takes precedence over the **auto-frr** command. If a route fails to match the routing policy specified in the **ip frr** command, the **auto-frr** command takes effect.

NOTE

On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the **auto-frr** command can implement fast active/standby link switchovers of the forwarding plane and fast route convergence of the control plane. On other switch models, this command can only implement fast route convergence of the control plane.

Example

Enable BGP Auto FRR for unicast routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] auto-frr
```

7.8.7 bestroute as-path-ignore

Function

The **bestroute as-path-ignore** command configures BGP to ignore the AS_Path attribute when it selects the optimal route.

The **undo bestroute as-path-ignore** command restores the default configuration.

By default, BGP uses the AS_Path attribute as one of route selection rules.

Format

bestroute as-path-ignore

undo bestroute as-path-ignore

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **bestroute as-path-ignore** command is used, BGP does not compare the AS path lengths of routes. By default, the route with the shortest AS path is preferred.

Precautions

After the **bestroute as-path-ignore** command is run, the AS_Path attribute is not used as one of the BGP route selection rules.

Example

Configure BGP to ignore the AS_Path attribute when selecting the optimal route.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] bestroute as-path-ignore
```

7.8.8 bestroute igp-metric-ignore

Function

The **bestroute igp-metric-ignore** command configures BGP to ignore the metric value of the next-hop IGP route when selecting the optimal route.

The **undo bestroute igp-metric-ignore** command restores the default setting.

By default, BGP selects a route with the smallest metric value of the next-hop IGP route as the optimal route.

Format

bestroute igp-metric-ignore

undo bestroute igp-metric-ignore

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a BGP network, the BGP device always receives multiple routes with the same prefix but to different paths from neighbors. BGP must select the optimal route to the prefix to guide packet forwarding. By default, BGP compares the next-hop IGP route metric values of these routes and selects the route with the smallest metric value as the optimal route.

To customize route selection policies, you can run the **bestroute igp-metric-ignore** command to configure BGP to ignore the metric value of the next-hop IGP route when selecting the optimal route.

Example

Configure BGP to ignore the IGP metric when selecting the optimal route.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] bestroute igp-metric-ignore
```

7.8.9 bestroute l2vpn-preference vpls

Function

The **bestroute l2vpn-preference vpls** command configures BGP to compare the L2VPN preferences of routes when selecting the optimal route.

The **undo bestroute l2vpn-preference vpls** command restores the default setting.

By default, BGP does not compare the L2VPN preferences when selecting the optimal route.

Format

bestroute l2vpn-preference vpls

undo bestroute l2vpn-preference vpls

Parameters

None

Views

BGP-L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP often receives routes with the same prefix but different next hops from multiple peers. In this case, BGP needs to select the optimal route and deliver it to the routing table to guide packet forwarding.

To configure BGP to compare the L2VPN preferences of routes when selecting the optimal route, run the **bestroute l2vpn-preference vpls** command.

Precautions

This command is valid only for Kompella VPLS.

After this command is configured, routes with the same prefix are preferentially selected.

When you run the **multi-homing-preference** command to configure multi-homing preferences for VSIs, ensure that the preference configured on the local device and that configured on the remote device are different. Otherwise, the **bestroute l2vpn-preference vpls** configuration does not take effect.

Example

Configure BGP to compare the L2VPN preferences of routes when selecting the optimal route.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] l2vpn-ad-family
[HUAWEI-bgp-af-l2vpn-ad] bestroute l2vpn-preference vpls
```

7.8.10 bestroute med-confederation (BGP)

Function

The **bestroute med-confederation** command enables BGP to compare the Multi Exit Discriminator (MED) values of routes in a confederation when BGP selects the optimal route.

The **undo bestroute med-confederation** command restores the default settings.

By default, BGP compares the MED values of the routes that are from the same AS only.

Format

bestroute med-confederation

undo bestroute med-confederation

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-IPv6 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, BGP compares only MED values of routes from the same AS, not including sub-ASs in a confederation. To enable BGP to compare MED values of routes in a confederation when selecting the optimal route, run the **bestroute med-confederation** command.

After the **bestroute med-confederation** command is configured, BGP compares MED values only when AS_Path does not contain the external AS (AS that is not in the confederation) number. Otherwise, BGP does not compare MED values.

For example, ASs 65000, 65001, 65002, and 65004 belong the same confederation. Routes to the same destination are listed as follows:

- path1: AS_Path=65000 65004, med=2
- path2: AS_Path=65001 65004, med=3
- path3: AS_Path=65002 65004, med=4
- path4: AS_Path=65003 65004, med=1

After the **bestroute med-confederation** command is run, the AS_Path attributes of paths 1, 2, and 3 does not contain the numbers of ASs that belong to other confederations. Therefore, when selecting routes based on MED values, BGP compares the MED values of paths 1, 2, and 3 only. This is because the AS_Path attribute of path 4 contains the number of an AS that does not belong to this confederation.

Example

Configure BGP to compare the MED values of routes only in the confederation when selecting the optimal route.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] bestroute med-confederation
```

7.8.11 bestroute med-none-as-maximum

Function

The **bestroute med-none-as-maximum** command configures BGP to assign the maximum Multi Exit Discriminator (MED), 4294967295, to a route without an MED in route selection.

The **undo bestroute med-none-as-maximum** command restores the default configuration.

By default, BGP assigns 0 to a route without an MED in route selection.

Format

bestroute med-none-as-maximum

undo bestroute med-none-as-maximum

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **bestroute med-none-as-maximum** command takes effect in BGP route selection and is used only when the MED is null in the route attributes. If the MED is null and the **bestroute med-none-as-maximum** command is not run, the system probably cannot select an optimal route.

Configuration Impact

During BGP route selection, if the **bestroute med-none-as-maximum** command is run, a route without any MED is assigned the maximum MED of 4294967295.

Example

Configure BGP to assign the maximum MED of 4294967295 to a route without an MED in route selection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] bestroute med-none-as-maximum
```

7.8.12 bestroute nexthop-resolved

Function

The **bestroute nexthop-resolved** command configures the condition of the route selection of labeled BGP IPv4 routes, VPNv4 routes, or VPNv6 routes for next hop recursion.

The **undo bestroute nexthop-resolved** command restores the default configuration.

By default, labeled BGP IPv4 routes, VPNv4 routes, or VPNv6 routes participate in route selection only when their next hops recurse to IP addresses.

Product	Support
S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

bestroute nexthop-resolved { **ip** | **tunnel** }

undo bestroute nexthop-resolved

Parameters

Parameter	Description	Value
ip	Allows labeled routes that recurse to IP addresses to participate in route selection.	-
tunnel	Allows labeled routes that recurse to MPLS tunnels to participate in route selection.	-

Views

BGP view, BGP-IPv4 unicast address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In Route Reflector (RR) networking where the next hop of a labeled BGP IPv4 route is changed or non-RR networking, BGP needs to check whether there is an LSP destined for the next hop. If the LSP is not found, BGP needs to establish an LSP in advance. If the default setting is adopted, a labeled BGP IPv4 unicast route may be selected prior to LSP establishment. As a result, services are incorrectly switched before LSP establishment and service stability is affected. The **bestroute nexthop-resolved tunnel** command can be run to allow route selection only after the labeled BGP IPv4 route recurses to an LSP. This ensures service stability.

By default, a VPNv4 route or VPNv6 routes can participate in route selection if its next hop recurses to an IP address. The system adds the optimal VPNv4 route or VPNv6 route to the forwarding table for traffic forwarding. However, traffic cannot be forwarded over the route if the route does not recurse to an LSP. In this situation, run the **bestroute nexthop-resolved tunnel** command to enable VPNv4 routes or VPNv6 routes to be available in route selection only when their next hops recurse to LSPs to ensure uninterrupted traffic forwarding.

Precautions

The **bestroute nexthop-resolved ip** and **bestroute nexthop-resolved tunnel** commands are mutually exclusive.

Example

In the BGP VPNv4 view, configure BGP VPNv4 routes that recurse to LSP tunnels to participate in route selection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] bestroute nexthop-resolved tunnel
```

In the BGP VPNv6 view, configure BGP VPNv6 routes that recurse to LSP tunnels to participate in route selection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv6-family vpnv6
[HUAWEI-bgp-af-vpnv6] bestroute nexthop-resolved tunnel
```

7.8.13 bestroute routerid-prior-clusterlist

Function

The **bestroute routerid-prior-clusterlist** command enables Originator_ID to take precedence over Cluster_List during BGP route selection.

The **undo bestroute routerid-prior-clusterlist** command restores the default configurations.

By default, Cluster_List takes precedence over Originator_ID during BGP route selection.

Format

bestroute routerid-prior-clusterlist

undo bestroute routerid-prior-clusterlist

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view, BGP-IPv4 multicast address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-L2VPN address family view

Default Level

2: Configuration level

Usage Guidelines

On a BGP network, after a device receives multiple routes with the same prefix but different paths from different peers, the device needs to select an optimal route from these routes to forward packets. By default, Cluster_List takes precedence over Originator_ID during BGP route selection. To enable Originator_ID to take precedence over Cluster_List during BGP route selection, run the **bestroute routerid-prior-clusterlist** command.

Example

Enable Router ID to take precedence over Cluster_List during BGP route selection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] bestroute routerid-prior-clusterlist
```

7.8.14 bgp

Function

The **bgp** command enables BGP and displays the BGP view.

The **undo bgp** command disables BGP.

By default, BGP is disabled.

Format

bgp { *as-number-plain* | *as-number-dot* }

undo bgp [*as-number-plain* | *as-number-dot*]

Parameters

Parameter	Description	Value
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the x.y format. Here, "x" and "y" are integers that range from 1 to 65535 and 0 to 65535 respectively.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP is an inter-AS dynamic routing protocol. BGP running within an AS is called Internal BGP (IBGP), and BGP running between ASs is called External BGP (EBGP).

Whether to apply BGP to routing information transmission between ASs depends on the following conditions:

- If at least one of the following conditions is met, BGP can be used:
  - An AS allows data packets to pass through on their way to another AS.
  - Multiple connections to external ISPs and the Internet exist in ASs.
  - Data flows entering or leaving ASs must be controlled.
- If one of the following conditions is met, BGP does not need to be used:
  - Users are connected to only one ISP network.
  - The ISP does not need to provide Internet access services for users.
  - ASs adopt default routes between each other.

Precautions

- After the **bgp** command is run, BGP is enabled.
- Each device runs in only one AS; therefore, each device can be specified with only one local AS number.
- If the BGP AS number is changed, the route calculation result of the local or remote OSPF VPN process may be affected. Because the tag value of the LSAs of the OSPF VPN process is calculated based on the BGP AS number, the local tag value of the OSPF VPN process and the tag value carried in the LSA advertised by the OSPF VPN process change. After receiving an LSA, the local or remote OSPF process checks the tag of the LSA. If the local tag of the OSPF process is the same as the tag of the received LSA, the LSA is not used for OSPF route calculation.

NOTICE

After the **undo bgp** [*as-number-plain* | *as-number-dot*] command is run, BGP services may be interrupted, and all BGP configurations on the device are cleared. Therefore, exercise caution when you run this command.

Example

Enable BGP and enter the BGP view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp]
```

7.8.15 bgp dynamic-session-limit

Function

The **bgp dynamic-session-limit** command configures a maximum number for dynamic BGP peer sessions.

The **undo bgp dynamic-session-limit** command restores the default configuration.

By default, a maximum of 100 dynamic BGP peer sessions can be established after the dynamic BGP peer function is enabled.

Format

bgp dynamic-session-limit *limit-value*

undo bgp dynamic-session-limit [*limit-value*]

Parameters

Parameter	Description	Value
limit-value	Specifies the maximum number of dynamic BGP peer sessions allowed.	The value is an integer that ranges from 1 to 256.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the dynamic BGP peer function is enabled using the **peer listen-net** command, BGP listens to BGP connection requests from the network segment specified in the command and establish BGP peer relationships dynamically. If a large number of dynamic BGP peer sessions are established, excessive system resources will be consumed. To prevent this problem, run the **bgp dynamic-session-limit** command to configure a maximum number for dynamic BGP peer sessions as required.

Precautions

This command does not apply to static BGP peer sessions.

Example

Configure the maximum number of dynamic BGP peer sessions to 128.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] bgp dynamic-session-limit 128
```

7.8.16 bgp fast-refresh enable

Function

The **bgp fast-refresh enable** command enables the BGP Prefix Independent Convergence (PIC) function.

The **undo bgp fast-refresh enable** command disables the BGP PIC function.

By default, the BGP PIC function is enabled on the switch.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

bgp fast-refresh enable

undo bgp fast-refresh enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When there are primary and backup paths for a BGP route, and a fault occurs on the primary path, the route must be updated and traffic must be switched to the backup path as soon as possible. This process is called BGP route convergence. As the network expands in scale and route prefixes, the BGP route convergence speed is affected by the number of route prefixes. More route prefixes indicate slower route convergence speed. If a network fault occurs, many packets are lost due to the slow route convergence speed. This can have a large impact on some services that are sensitive to packet loss. BGP PIC is also called BGP fast refresh. It indicates that the BGP route convergence speed is independent of the number of route prefixes. After this function is enabled, the BGP route convergence speed becomes faster without being affected by the number of route prefixes. This function reduces data loss during route convergence. When this function becomes unavailable, you can run the **undo bgp fast-refresh enable** command to disable it. BGP routes are then converged as usual; however, the route convergence speed is slow.

Precautions

- Only IBGP routes support the BGP PIC function, and VPN routes do not support this function.
- If the BGP load balancing (ECMP) or BGP Auto FRR function has been configured on the device or the next hop of a BGP route recurses to a tunnel interface, the BGP PIC function does not take effect.
- Disabling the BGP PIC function requires the device to be restarted after the configuration is saved or requires all BGP ASs to be **reset**. Otherwise, disabling the BGP PIC function takes effect only for the subsequently generated routing tables.

  Enabling the BGP PIC function requires the device to be restarted.

Example

Disable the BGP PIC function on the switch.

```
<HUAWEI> system-view
[HUAWEI] undo bgp fast-refresh enable
Warning: The operation will take effect only on routing tables generated later.
Please save configuration and reboot this device or reset all BGP ASs after this
 operation.
```

7.8.17 check-first-as

Function

The **check-first-as** command enables the function to check the first AS number in the AS_Path list that is carried in the Update message sent by the EBGP peer.

The **undo check-first-as** command disables the function.

By default, the function is enabled.

Format

check-first-as

undo check-first-as

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, BGP checks the first AS number in the AS_Path list that is carried in the Update message sent by the EBGP peer. If only the first AS number indicates the AS where the EBGP peer locates, the Update message is accepted. Otherwise, the Update message is denied, and the EBGP connection goes Down.

Precautions

The **check-first-as** command is not listed in the configuration file.

After the **undo check-first-as** command is configured, loops have a greater chance to occur. Therefore, use the command with caution.

Follow-up Procedure

After the configuration is complete, run the **refresh bgp** command if you want to check the received routes again.

Example

Check the first AS number in the AS_Path list that is carried in the Update message sent by the EBGP peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] check-first-as
```

7.8.18 compare-different-as-med

Function

The **compare-different-as-med** command enables BGP to compare the MEDs in the routes of peers in different ASs.

The **undo compare-different-as-med** command restores the default configuration.

By default, BGP does not compare the MEDs in the routes of peers in different ASs.

Format

compare-different-as-med

undo compare-different-as-med

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The command is used to control the MEDs to change the policy of BGP route selection. If the **compare-different-as-med** command is run, BGP will compare the MEDs of the routes from different ASs. If there are multiple reachable paths to the same destination, BGP prefers the route with the smallest MED.

Precautions

Do not use this command unless different ASs use the same IGP and route selection mode.

Example

Enable BGP to compare the MEDs in the routes of peers in different ASs.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] compare-different-as-med
```

7.8.19 confederation id

Function

The **confederation id** command configures a BGP confederation and specifies a confederation ID for the BGP confederation.

The **undo confederation id** command removes the specified BGP confederation.

By default, no BGP confederation is configured.

Format

confederation id { *as-number-plain* | *as-number-dot* }

undo confederation id

Parameters

Parameter	Description	Value
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A large AS may contain a huge number of fully meshed IBGP peer relationships. In this situation, configure a confederation.

Divide the AS into multiple small sub-ASs and group them into a confederation. Then establish EBGP connections between sub-ASs and establish fully meshed IBGP connections within the same sub-AS. Some key attributes of routes, such as the next hop, MED, and local preference are not discarded when these routes pass through sub-ASs. This can reduce the number of fully meshed IBGP peer relationships in an AS and keep the integrity of the original AS.

Precautions

The confederation ID is equal to the AS number. An external AS must specify the confederation ID when specifying the AS number of the peer. All the sub-ASs in the same confederation must be configured with the same confederation ID that must be different from the number of any sub-AS.

Example

Configure a confederation ID. An AS is divided into sub-ASs 65001, 65002, 65003, and 65004, and their confederation ID is 9. Peer 10.2.3.4 is a member of the AS confederation. Peer 10.4.5.6 is a member outside the AS confederation. For the external members, confederation 9 is a complete AS.

```
<HUAWEI> system-view
[HUAWEI] bgp 65001
[HUAWEI-bgp] confederation id 9
[HUAWEI-bgp] confederation peer-as 65002 65003 65004
[HUAWEI-bgp] peer 10.2.3.4 as-number 65002
```

```
[HUAWEI-bgp] peer 10.4.5.6 as-number 65005
```

7.8.20 confederation nonstandard

Function

The **confederation nonstandard** command configures standard devices (in RFC 3065) in a confederation to communicate with nonstandard devices.

The **undo confederation nonstandard** command configures standard devices in a confederation to communicate only with standard devices.

By default, only standard devices in a confederation can communicate with each other.

Format

confederation nonstandard

undo confederation nonstandard

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To communicate with nonstandard devices, configure this command on all switches in a confederation.

Precautions

After the confederation ID is configured, running the **confederation nonstandard** command will disconnect the sessions between a router and its IBGP peers as well as its confederation EBGP peers. Then, new connections are reestablished.

Example

Enable the switch to communicate with nonstandard routers. AS 100 contains two sub-ASs, 64000 and 65000.

```
<HUAWEI> system-view
[HUAWEI] bgp 64000
[HUAWEI-bgp] confederation id 100
[HUAWEI-bgp] confederation peer-as 65000
[HUAWEI-bgp] confederation nonstandard
```

7.8.21 confederation peer-as

Function

The **confederation peer-as** command configures the number of each sub-AS of the same confederation.

The **undo confederation peer-as** command removes the specified sub-AS from the confederation.

By default, no sub-AS number of a confederation is configured.

Format

confederation peer-as { *as-number-plain* | *as-number-dot* } &<1-32>

undo confederation peer-as { *as-number-plain* | *as-number-dot* } &<1-32>

Parameters

Parameter	Description	Value
as-number-plain	Specifies the number of an AS, which is an integer.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of an AS, which is in dotted notation.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A large AS may contain a huge number of fully meshed IBGP peer relationships. In this situation, configure a confederation.

Prerequisites

The **confederation id** command specifies the confederation ID of each sub-AS. If the confederation ID is not configured, this configuration is invalid.

Precautions

The sub-ASs configured in this command belong to the same confederation, and each sub-AS uses fully meshed network.

Example

Configure sub-ASs for a confederation.

```
<HUAWEI> system-view
[HUAWEI] bgp 1090
[HUAWEI-bgp] confederation id 100
[HUAWEI-bgp] confederation peer-as 1091 1092 1093
```

7.8.22 confederation route unicast-to-label disable

Function

The **confederation route unicast-to-label disable** command prevents non-RRs from advertising the IPv6 non-labeled routes learned from peers in the local confederation as labeled routes carrying a label of all Fs to the BGP peers in another confederation.

The **undo confederation route unicast-to-label disable** command restores the default configuration.

By default, non-RRs can advertise the IPv6 non-labeled routes learned from peers in the local confederation as labeled routes carrying a label of all Fs to the BGP peers in another confederation.

Product	Support
S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5731-S, S5731S-S, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

confederation route unicast-to-label disable

undo confederation route unicast-to-label disable

Parameters

None

Views

BGP-IPv6 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

If two PEs that are not RRs reside in two confederations, the PEs can advertise labeled routes carrying a label of all Fs to each other by default. However, non-Huawei devices may consider the label of all Fs invalid, and if these non-Huawei devices receive such labeled routes, BGP peer relationships may be disconnected. To prevent this problem, run the **confederation route unicast-to-label disable** command to prevent the PEs from advertising labeled routes carrying a label of all Fs.

Example

Prevent non-RRs from advertising the IPv6 non-labeled routes learned from peers in the local confederation as labeled routes carrying a label of all Fs to the BGP peers in another confederation.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] confederation id 100
[HUAWEI-bgp] confederation peer-as 38 39
[HUAWEI-bgp] peer 192.168.1.1 as-number 38
[HUAWEI-bgp] peer fc00:0:0:191::1 as-number 39
[HUAWEI-bgp] ipv6-family unicast
[HUAWEI-bgp-af-ipv6] peer 192.168.1.1 enable
[HUAWEI-bgp-af-ipv6] peer 192.168.1.1 label-route-capability
[HUAWEI-bgp-af-ipv6] peer fc00:0:0:191::1 enable
[HUAWEI-bgp-af-ipv6] confederation route unicast-to-label disable
```

7.8.23 dampening

Function

The **dampening** command enables BGP route flap suppression and modifies BGP route flap suppression parameters.

The **undo dampening** command restores the default configuration.

By default, BGP route flap suppression is disabled.

Format

dampening [ibgp] [*half-life-reach reuse suppress ceiling* | **route-policy** *route-policy-name*] *

undo dampening [ibgp]

Parameters

Parameter	Description	Value
half-life-reach	Specifies the half life of a reachable route.	The value is an integer that ranges from 1 to 45, in minutes. The default value is 15.
reuse	Specifies the threshold for the route to be unsuppressed. If the penalty of the route falls below the threshold, the route is reused.	The value is an integer that ranges from 1 to 20000. The default value is 750.
suppress	Specifies the threshold for the route to be suppressed. If the penalty value of the route exceeds the threshold, the route is not used.	The value is an integer that ranges from 1 to 20000, which must be greater than the value of *reuse*. The default value is 2000.
ceiling	Specifies the penalty ceiling.	The value is an integer that ranges from 1001 to 20000. The configured value must be greater than that of *suppress*. The default value is 16000.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ibgp	Specifies the route type as IBGP route. If this parameter is not specified, the route type is EBGP route. **NOTE** This parameter takes effect only in the BGP-VPNv4 address family view.	-

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view, BGP-IPv4 multicast address family view, BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP route flap dampening measures the stability of a route by using a penalty value. The greater the penalty value, the less stable the route. Each time route flapping occurs, that is, when the switch receives a Withdraw packet or an Update packet for a route, BGP adds a certain penalty value (1000) for the route.

When the penalty value of the route exceeds the suppression threshold, the route is suppressed. The switch does not add the route to the IP routing table or advertise any Update packet to other BGP peers. If the route is marked with the d flag, the last packet received by the switch is an Update packet; if the route is marked with the h flag, the last packet received by the switch is a Withdraw packet. After the penalty value reaches a certain limit, it does not increase any more. The limit is called the penalty ceiling.

After the route is suppressed for a certain period, the penalty value is reduced by half. If the penalty value of a route marked with the d flag decreases to the reuse threshold, the d flag is removed, and the route becomes available and is selected preferentially. After that, the route can be added to the IP routing table and used to send Update packets to other BGP peers. If the penalty value of a route marked with the h flag decreases to 0, the route is deleted from the BGP routing table.

You can run the **display bgp routing-table label** command to check the d flag and h flag indicating the routes that have been dampened and were dampened respectively.

Precautions

If the **dampening** command is run multiple times, the latest configuration overrides the previous one.

After the **dampening** command is run, the system suppresses unstable routes. This means that the system does not add unstable routes to the BGP routing table or advertise them to other BGP peers.

Note the following items when configuring BGP route flap dampening:

- The value of *suppress* must be greater than that of *reuse* and smaller than that of *ceiling*.
- If MaxSuppressTime obtained by using the formula of MaxSuppressTime = *half-life-reach* x 60 x (ln(*ceiling*/*reuse*)/ln(2)) is smaller than 1, suppression cannot be performed. You need to ensure that the value of MaxSuppressTime is equal to or greater than 1. This means that the value of *ceiling*/*reuse* must be great enough.

NOTE

The **dampening** command is valid only for EBGP routes.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-**

policy nonexistent-config-check disable command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured dampening parameters apply to all routes; if no dampening parameters are configured, the default dampening parameters apply to the routes.

Example

Enable EBGP route dampening and modify EBGP route damping parameters.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] dampening 10 1000 2000 5000
```

7.8.24 default ipv4-unicast

Function

The **default ipv4-unicast** command enables the IPv4 unicast address family for BGP peers by default.

The **undo default ipv4-unicast** command disables the IPv4 unicast address family for BGP peers by default.

By default, the IPv4 unicast address family is enabled for BGP peers.

Format

default ipv4-unicast

undo default ipv4-unicast

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the IPv4 unicast address family needs to be enabled by default for created BGP peers, the **default ipv4-unicast** command can be used to configure the default address family of BGP to the IPv4 unicast address family.

If the IPv4 unicast address family does not need to be enabled by default for created BGP peers, the **undo default ipv4-unicast** command can be used to disable the IPv4 unicast address family for all peers.

Precautions

After the **undo default ipv4-unicast** command is run, the **peer enable** command needs to be run if the created BGP peer needs to be enabled with the IPv4 unicast address family.

Example

Enable the IPv4 unicast address family for all peers.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] default ipv4-unicast
```

7.8.25 default local-preference

Function

The **default local-preference** command sets the default local preference for BGP routes.

The **undo default local-preference** command restores the default configuration.

By default, the local preference for BGP routes is 100.

Format

default local-preference *local-preference*

undo default local-preference

Parameters

Parameter	Description	Value
local-preference	Specifies the local preference for BGP routes. The greater the value, the higher the preference.	The value is an integer that ranges from 0 to 4294967295.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Local_Pref attribute is used to determine an optimal route for traffic before traffic leaves an AS. When the switch that runs BGP has multiple routes to the same destination, the switch selects the route with the highest local preference as the optimal route.

Precautions

If the switch is already configured with a default local preference for BGP routes, the configuration of a new default local preference will override the previous configuration.

The local preference is exchanged only between IBGP peers and is not advertised to other ASs.

Example

Set the default local preference for BGP routes to 200.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] default local-preference 200
```

7.8.26 default med

Function

The **default med** command sets the default multi-exit-discriminator (MED) for BGP routes.

The **undo default med** command restores the default configuration.

By default, the MED is 0.

Format

default med *med*

undo default med

Parameters

Parameter	Description	Value
med	Specifies the MED for BGP routes.	The value is an integer that ranges from 0 to 4294967295.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **default med** command is valid only for the routes imported by using the **import-route (BGP)** command and the routes summarized by BGP on the local device.

The **default med** command sets the default MED and controls route selection for the traffic entering an AS. If the other attributes of routes to the same destination are the same, BGP will select the route with the smallest MED as the optimal route.

Precautions

If a default MED is configured on a device, configuring a new default MED will override the previous configuration and the new default MED will overwrite the previous one.

The MED is transmitted between two neighboring ASs only. Devices in an AS do not advertise the received MED to peers in other ASs.

Example

Set the default MED of a BGP route to 10.

```
<HUAWEI> system-view
[HUAWEI] bgp 1
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] default med 10
```

7.8.27 default-route imported

Function

The **default-route imported** command enables the import of default routes in the local IP routing table to the BGP routing table.

The **undo default-route imported** command disables the import of the default routes in the local IP routing table to the BGP routing table.

By default, BGP does not add the default route to the BGP routing table.

Format

default-route imported

undo default-route imported

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This configuration reduces the number of routes on the network and minimizes the routing table size. If a default route exists in the local IP routing table and the **default-route imported** command is run, the system imports the default route to the BGP routing table. After the default route is imported, the packets can be transmitted over the default route when no matched routing entry is found in the routing table, preventing packet loss.

Precautions

To import default routes, you need to run both the **default-route imported** command and the **import-route (BGP)** command. If only the **import-route (BGP)** command is used, default routes cannot be imported. In addition, the **default-route imported** command is used to import only the default routes that exist in the local routing table.

When a device needs to advertise default routes to a peer (group) and no default route exists in the local routing table, the **peer default-route-advertise** command needs to be used.

Example

Import default routes to the BGP routing table.

```
<HUAWEI> system-view
[HUAWEI] bgp 1
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] default-route imported
[HUAWEI-bgp-af-ipv4] import-route ospf 1
```

7.8.28 deterministic-med (BGP)

Function

The **deterministic-med** command enables the BGP deterministic-MED function so that routes with the same leftmost AS number are first compared during route selection.

The **undo deterministic-med** command disables the BGP deterministic-MED function so that routes are compared against each other according to the sequence in which they are received.

By default, the BGP deterministic-MED function is disabled.

Format

deterministic-med

undo deterministic-med

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

After the BGP deterministic-MED function is enabled, when an optimal route is to be selected from routes that are received from different ASs and carry the same prefix, routes are first grouped based on the leftmost AS number in the AS_Path attribute. Routes with the same leftmost AS number are grouped together, and after comparison, an optimal route is selected for the group. The group optimal route is then compared with optimal routes from other groups to determine the final optimal route. This mode of route selection ensures that the sequence in which routes are received is irrelevant to the route selection result.

If the BGP deterministic-MED function is disabled, routes are compared against each other according to the sequence in which they are received. In this manner, the sequence in which routes are received is relevant to the result of route selection.

For example: Assume that the following BGP routes are available on the switch.

- Route A1: AS(PATH) 12, med 100, igp metric 13, internal, rid 4.4.4.4
- Route A2: AS(PATH) 12, med 150, igp metric 11, internal, rid 5.5.5.5
- Route B: AS(PATH) 3, med 0, igp metric 12, internal, rid 6.6.6.6

If Route A1, Route A2, and Route B are received in turn, Route A1 and Route A2 are first compared. The leftmost AS number of Route A1 is the same as the leftmost AS number of Route A2, and therefore Route A1 is selected because its MED is smaller. After that, Route A1 and Route B are compared. Because the leftmost AS numbers of the two routes are different, the optimal route cannot be selected by comparing the MEDs of the two routes unless the **compare-different-as-med** command is configured. As a result, Route B is selected because its IGP metric is smaller.

If Route A2, Route B, and Route A1 are received in turn, Route A2 and Route B are first compared. Because leftmost AS number of Route A2 is different from the leftmost AS number of Route B, the optimal route cannot be selected by comparing the MEDs of the two routes unless the **compare-different-as-med** command is configured. As a result, Route A2 is selected because its IGP metric is smaller. After that, Route A2 and Route A1 are compared. The leftmost AS number of Route A1 is the same as the leftmost AS number of Route A2, and therefore Route A1 is selected because its MED is smaller.

Judging from the preceding route selection procedure, when the BGP deterministic-MED function is disabled, the sequence in which routes are received is relevant to the result of route selection. After the BGP deterministic-MED function is enabled, the sequence in which routes are received is no longer relevant to the result of route selection. Route A1 and Route A2 have the same leftmost AS number, Route A1 and Route A2 are compared first regardless of the sequence in which routes are received.

Example

Enable the deterministic-MED function in the BGP view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] deterministic-med
```

7.8.29 display bgp bfd session

Function

The **display bgp bfd session** command displays information about BFD sessions between BGP peers.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp bfd session { [**vpnv4 vpn-instance** *vpn-instance-name*] **peer** *ipv4-address* | **all** }

Parameters

Parameter	Description	Value
vpnv4 vpn-instance *vpn-instance-name*	Displays information about the BFD session between BGP peers with the specified IPv4 VPN instance name.	The value must be an existing VPN instance name.
peer *ipv4-address*	Displays information about the BFD session of the BGP peer with the specified IPv4 address.	The value is in dotted decimal notation.
all	Displays all BFD sessions between BGP peers.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The BFD session set up by BGP helps BGP quickly discover faults between BGP peers and informs BGP to recalculate routes for packet forwarding.

Run the **display bgp bfd session** command to display information about the BFD session set up by BGP in the following situations:

- Check whether the BFD session is successfully set up or view detailed information about the BFD session that is successfully configured.
- Check whether the BFD session set up by BGP is successfully deleted after running the **undo peer bfd enable** command.
- Verify the configuration after running the **undo peer bfd block** command to prevent a peer from inheriting the BFD function of the peer group.
- Verify the configuration after running the **peer bfd** command to set BFD parameters.

The information about the BFD session of a specified BGP peer can be displayed by specifying different parameters.

- Run the **display bgp bfd session vpnv4 vpn-instance** *vpn-instance-name* **peer** *ipv4-address* command to display information about the BFD session of a specified BGP peer in a specified VRF.
- Run the **display bgp bfd session peer** *ipv4-address* command to display information about the BFD session of a specified BGP peer on the public network.
- Run the **display bgp bfd session all** command to display information about the BFD sessions of all BGP peers.

Prerequisites

The BFD session has been set up using the **peer bfd enable** command. If the BFD session has not been set up by BGP, no information is displayed after running the **display bgp bfd session** command.

Example

Display all BFD sessions between BGP peers.

```
<HUAWEI> display bgp bfd session all
  Local_Address      Peer_Address       LD/RD       Interface
  10.1.1.2           10.1.1.1           8192/8193   Unknown
  Tx-interval(ms)    Rx-interval(ms)    Multiplier  Session-State
  1000               1000               3           Up
  Wtr-interval(m)
0
```

Table 7-122 Description of the display bgp bfd session command output

Item	Description
Local_Address	Local address
Peer_Address	Peer address

Item	Description
LD/RD	Local/remote discriminator
Interface	Interface on which the BFD session is set up **NOTE** Information about the interface on which the BFD session is set up only when the directly connected interface is used to set up the EBGP neighbor relationship. In other cases, information about the interface is displayed as Unknown.
Tx-interval (ms)	Interval for sending BFD packets, in milliseconds
Rx-interval (ms)	Interval for receiving BFD packets, in milliseconds
Multiplier	Local detection multiple
Session-State	BFD status ● Admin down: The BFD session is closed on the local end. ● BFD global disable: BFD is disabled globally. ● BFD session number exceed: The number of BFD sessions exceeds the maximum limit. ● Detect down: BFD detects a link status fault and interrupts the connection. ● Init: The BFD session is in the initialized state. ● Neighbor down: The peer end detects that the BFD session goes Down and informs the local end of the change, and the local end then sets the neighbor status to Down. ● Receive admin down: The BFD session is closed on the peer end (for example, the BFD session is disabled on the peer end). ● Up: The BFD session is set up.
Wtr-interval(m)	Interval for flap dampening, in minutes

7.8.30 display bgp error

Function

The **display bgp error** command displays BGP errors.

Format

display bgp error

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When a BGP fault occurs, run the **display bgp error** command to display BGP error information. BGP error information includes peer error information, route error information, and resource threshold-crossing error information.

Precautions

If no BGP fault occurs, no information is displayed after running the **display bgp error** command.

Example

Display BGP errors.

```
<HUAWEI> display bgp error
 Error Type    : Peer Error
 Date/Time     : 2010/03/22 11:40:39 UTC-08:00
 Peer Address  : 10.1.1.2
 VRF Name      : Public
 Error Info    : Router-ID conflict

 Error Type    : Peer Error
 Date/Time     : 2010/03/22 11:40:39 UTC-08:00
 Peer Address  : 10.1.1.2
 VRF Name      : Public
 Error Info    : Incorrect remote AS

 Error Type    : Route Error
 AddressFamily : IPv4-UNC
 InstanceID    : 0
 Discard count : 20

 Error Type    : Resource exceed limit
 Date/Time     : 2010/03/22 11:40:39 UTC-08:00
 Limit info    : Route number limit

 Error Type    : Resource exceed limit
 Date/Time     : 2010/03/22 11:40:39 UTC-08:00
 Limit info    : Label number limit
```

Table 7-123 Description of the display bgp error command output

Item	Description
Error Type	Error type: ● Peer Error: indicates neighbor errors. ● Route Error: indicates route errors. ● Resource exceed limit: indicates that resources exceed the limit.
Date/Time	Date and Time when an error occurs
Peer Address	Address of a peer
VRF Name	VPN Instance name
Error Info	Error information: ● Router-ID conflict: indicates that router IDs conflict. ● Incorrect remote AS: indicates an incorrect remote AS number.
AddressFamily	Address family
Discard count	Number of discarded routes
Limit info	Information indicating that resources exceed the limit: ● Memory shortage: indicates that memory exceeds the limit. ● Route number limit: indicates that the number of routes exceeds the limit. ● Label number limit: indicates that the number of labels exceeds the limit.

7.8.31 display bgp error discard

Function

The **display bgp error discard** command displays the information about the discarded error BGP packets.

Format

display bgp error discard [**peer** { *ipv4-address* | *ipv6-address* }]

Parameters

Parameter	Description	Value
peer	Displays errors on a specified peer.	-
ipv4-address	Displays errors on a peer with the specified IPv4 address.	It is in dotted decimal notation.
ipv6-address	Displays errors on a peer with the specified IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When a BGP fault occurs, the **display bgp error discard** command can be run to check the information about discarded error packets. The errors include cluster ID conflicts and the threshold overflow of AS-Path attributes.

By specifying the **peer** parameter, you can check the information about the error packets discarded by a specified BGP peer.

Precautions

The **display bgp error discard** command can be used to check only the error routing. To check the error routing among BGP peers, run the **display bgp error** command.

Example

Display information about discarded BGP error packets.

```
<HUAWEI> display bgp error discard
BGP Discard Info Counts:
Routes received with cluster ID loop           : 0
Routes received with as path count over limit  : 0
Routes advertised with as path count over limit: 0

 No discard record.
```

Table 7-124 Description of the display bgp error discard command output

Item	Description
BGP Discard Info Counts	Number of discarded BGP routes

Item	Description
Routes received with cluster ID loop	Number of discarded BGP routes with a duplicate cluster ID
Routes received with as path count over limit	Number of received BGP routes discarded due to the number of AS-Paths exceeding the upper threshold
Routes advertised with as path count over limit	Number of sent BGP routes discarded due to the number of AS-Paths exceeding the upper threshold
No discard record	No record about packet discarding

7.8.32 display bgp group

Function

The **display bgp group** command displays information about BGP peer groups.

Format

display bgp group [*group-name*]

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **group** [*group-name*]

display bgp vpls group [*group-name*]

display bgp ipv6 group [*group-name*]

display bgp vpnv6 all group [*group-name*]

display bgp vpnv6 vpn-instance *vpn-instance-name* **group** [*group-name*]

display bgp l2vpn-ad group [*group-name*]

display bgp { **mdt** | **mvpn** } **all group** [*group-name*]

NOTE

The **mdt,mvpn** parameter is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
vpnv4	Displays information about BGP VPNv4 peer groups.	-
all	Displays information about all BGP VPNv4 or VPNv6 peer groups.	-
vpn-instance *vpn-instance-name*	Displays information about BGP peer groups in a specified VPN instance.	The value must be an existing VPN instance name.
vpls	Displays information about BGP peer groups of VPLS.	- **NOTE** The **vpls** parameter is supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H.
ipv6	Displays information about IPv6 peer groups.	-
vpnv6	Displays information about BGP VPNv6 peer groups.	- **NOTE** The **vpnv6** parameter is supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H.
l2vpn-ad	Displays information about BGP peer groups of L2VPN-AD.	- **NOTE** The **l2vpn-ad** parameter is supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H.

1: Monitoring level

Usage Guidelines

Usage Scenario

Configuring BGP peer groups simplifies BGP network configuration and improves the route advertisement efficiency.

The **display bgp group** command displays information about the peer group, including peers in the peer group and configuration information about the peer group. This command is used in the following scenarios:

- Verify the configuration after running the **group** command to configure the peer group.
- Verify the configuration after running the **peer group** command to add a peer to the peer group.
- Verify the configuration after running the **undo peer group** command to delete a peer from the peer group.
- Verify the configuration after modifying the configuration of the peer group.

Precautions

BGP has multiple address families, each of which is configured independently. Information about peer groups in address families can be displayed by specifying different parameters.

If no parameter is specified, the **display bgp group** command displays default information about peer groups in the IPv4 unicast address family.

Example

Display information about a peer group named **my-peer**.

```
<HUAWEI> display bgp group my-peer

 BGP peer-group: my-peer
 Remote AS: 200
 listen-net: 10.1.1.0 24
 Authentication type configured: None
 Group's BFD has been enabled
 Type : internal
 Configured hold timer value: 180
 Keepalive timer value: 60
 Minimum route advertisement interval is 15 seconds
 listen-only has been configured
 PeerSession Members:
   10.2.2.2

 Maximum allowed route limit: 8000  Threshold: 75%, Parameter:  always connect-retry(default)
 Status codes: * - Dynamic
 Peer Preferred Value: 0
 No routing policy is configured
 Peer Members:
  Peer            V    AS  MsgRcvd  MsgSent  OutQ  Up/Down       State PrefRcv
  10.1.1.2        4   200        0        0     0 00:00:47      Active       0
```

Table 7-125 Description of the **display bgp group** command output

Item	Description
BGP peer-group	Name of a BGP peer group.
Remote AS	Number of the AS where a peer group resides.
listen-net	Network segment from which BGP listens to BGP connection requests.
Authentication type configured	Configured BGP authentication type. The value can be: ● MD5 ● None: indicates that no BGP authentication is configured.
Group's BFD has been enabled	BFD has been enabled for a peer group.
Type	Type of a peer group: ● internal: indicates that the peer group is an IBGP peer group. ● external: indicates that the peer group is an EBGP peer group.
Configured hold timer value	Value of the Hold timer.
Keepalive timer value	Value of the Keepalive timer.
Minimum route advertisement interval	Minimum interval between route advertisements.
listen-only has been configured	The peer or peer group only detects connection requests, and does not initiate any connection.
PeerSession Members	Peers that set up sessions.
Maximum allowed route limit	Maximum number of allowed BGP routes.
Threshold	Threshold for the quantity of received BGP routes (in percentage) out of the maximum number of routes that can be received.

Item	Description
Parameter	If **peer route-limit** command is configured, this parameter will be displayed: ● always connect-retry(default): By default, BGP always attempts to re-establish a connection after the BGP session is terminated due to the number of routes exceeding the threshold. ● alert-only: When the number of routes reaches the threshold, the switch generates only log information without terminating the BGP session. ● idle-forever: After the BGP session is terminated due to the number of routes exceeding the threshold, BGP does not re-establish a connection if the **reset bgp** command is not executed. ● idle-timeout: After the BGP session is terminated due to the number of routes exceeding the threshold, BGP automatically attempts to re-establish a connection if the timer expires.
Status codes: * - Dynamic	Status code. If the value starts with an asterisk (*), the peer is a dynamic peer. Currently, the value can only be *** - Dynamic**.
Peer Preferred Value	Preferred value of a peer.
Peer Members	Information about peers.
Peer	IP address of a peer.
V	BGP version.
AS	Number of the AS where a member of a peer group resides.
MsgRcvd	Number of received messages.
MsgSent	Number of sent messages.
OutQ	Number of messages to be sent to peers.
Up/Down	Period of time during which a BGP session keeps the current state.

Item	Description
State	BGP state mechanism: - Idle: indicates that BGP denies any request of entering. This is the initiatory status of BGP. Upon receiving a Start event, BGP initiates a TCP connection to the remote BGP peer, starts the ConnectRetry Timer with the initial value, detects a TCP connection initiated by the remote BGP peer, and changes its state to Connect. - Idle(Admin): indicates that the peer relationship is shut down initiatively and no attempt is made to establish the neighbor relationship. If the **peer ignore** command is configured or the peer is set to the Down state through the MIB, the neighbor is in the Idle (Admin) state. - Idle(Ovlmt): indicates that the peer relationship is interrupted because the number of routes exceeds the upper threshold. After a BGP peer relationship is interrupted due to the running of the **peer route-limit** command, the status of the BGP peer relationship is displayed as Idle(Ovlmt). If the **reset bgp** command is not run, the BGP peer relationship will not be reestablished. - Connect: indicates that BGP waits for the TCP connection to be set up before it determines whether to perform other operations. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the TCP connection fails, BGP restarts the ConnectRetry Timer with the initial value, continues to detect a TCP connection initiated by the remote peer, and changes its state to Active. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer

Item	Description
	with the initial value, initiates a TCP connection to the remote BGP peer, and stays in the Connect state. ● Active: indicates that BGP tries to set up a TCP connection. This is the intermediate status of BGP. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer with the initial value and changes its state to Connect. – If BGP initiates a TCP connection with an unknown IP address, the TCP connection fails. When this occurs, BGP restarts the ConnectRetry Timer with the initial value and stays in the Active state. ● OpenSent: indicates that BGP has sent one Open message to its peer and waits for an Open message from the peer. – If there are no errors in the Open message received, BGP changes its state to OpenConfirm. – If there are errors in the Open message received, BGP sends a Notification message to the remote peer and changes its state to Idle. – If the TCP connection fails, BGP restarts the ConnectRetry Timer with the initial value, continues to detect a TCP connection initiated by the remote peer, and changes its state to Active. ● OpenConfirm: indicates that BGP waits for a Notification message or a Keepalive message. – If BGP receives a Notification message, or the TCP connection fails, BGP changes its state to Idle. – If BGP receives a Keepalive message, BGP changes its state to Established.

Item	Description
	- Established: indicates that BGP peers can exchange Update, Notification and Keepalive packets. – If BGP receives an Update or a Keepalive message, its state stays in Established. – If BGP receives a Notification message, BGP changes its state to Idle.
PrefRcv	Indicates the number of route prefixes received by the local peer from the remote peer.

Display information about all BGP VPNv4 peer groups.

```
<HUAWEI> display bgp vpnv4 all group
Group in VPNV4:

7.8.33 display bgp ipv6 bfd session

Function

The **display bgp ipv6 bfd session** command displays information about the BFD session set up by BGP.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp ipv6 bfd session { [**vpnv6 vpn-instance** *vpn-instance-name*] **peer** *ipv6-address* | **all** }

Parameters

Parameter	Description	Value
vpnv6	Displays the BFD session of VPNv6.	-
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance.	The value must be an existing VPN instance name.
peer *ipv6-address*	Specifies the IPv6 address of the peer.	-
all	Displays all BFD sessions set up by BGP.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The BFD session set up by BGP4+ helps BGP4+ quickly discover faults between BGP4+ peers and inform BGP4+ to recalculate routes for packet forwarding.

Run the **display bgp ipv6 bfd session** command to display information about the BFD session set up by BGP4+ in the following situations:

- Check whether the BFD session is successfully set up or view detailed information about the BFD session that is successfully configured.
- Check whether the BFD session set up by BGP4+ is successfully deleted after running the **undo peer bfd enable** command.
- Verify the configuration after running the **undo peer bfd block** command to restore a peer inheriting the BFD function of the peer group.
- Verify the configuration after running the **peer bfd** command to set BFD parameters.

The information about the BFD session of a specified peer can be displayed by specifying different parameters.

- Run the **display bgp ipv6 bfd session vpnv6 vpn-instance** *vpn-instance-name* **peer** *ipv6-address* command to display information about the BFD session of a specified peer in a VPN instance.
- Run the **display bgp ipv6 bfd session peer** *ipv6-address* command to display information about the BFD session of a specified peer on the public network.

- Run the **display bgp ipv6 bfd session all** command to display information about the BFD sessions of all BGP4+ peers.

Prerequisites

The BFD session has been set up using the **peer bfd enable** command. If the BFD session has not been set up by BGP4+, no information is displayed after running the **display bgp ipv6 bfd session** command.

Example

Display all BFD sessions set up by BGP.

```
<HUAWEI> display bgp ipv6 bfd session all
  Local_Address  : FC00:3::1
  Peer_Address   : FC00:3::2
  Tx-interval(ms): 100         Rx-interval(ms): 100
  Multiplier     : 4           Interface      : GigabitEthernet0/0/1
  LD/RD          : 8193/8207   Session-State  : Up
  Wtr-interval(m): 0
```

Table 7-128 Description of the **display bgp ipv6 bfd session** command output

Item	Description
Local_Address	Local address
Peer_Address	Peer address
Tx-interval (ms)	Interval for sending BFD packets, in milliseconds
Rx-interval (ms)	Interval for receiving BFD packets, in milliseconds
Multiplier	Local detection multiple
Interface	Interface on which the BFD session is set up **NOTE** Information about the interface on which the BFD session is set up only when the directly connected interface is used to set up the EBGP neighbor relationship. In other cases, information about the interface is displayed as Unknown.
LD/RD	Local/remote discriminator

Item	Description
Session-State	BFD status ● Admin down: The BFD session is closed on the local end. ● BFD global disable: BFD is disabled globally. ● BFD session number exceed: The number of BFD sessions exceeds the maximum limit. ● Detect down: BFD detects a link status fault and interrupts the connection. ● Init: The BFD session is in the initialized state. ● Neighbor down: The peer end detects that the BFD session goes Down and informs the local end of the change, and the local end then sets the neighbor status to Down. ● Receive admin down: The BFD session is closed on the peer end (for example, the BFD session is disabled on the peer end). ● Up: The BFD session is set up.
Wtr-interval(m)	Interval for flap dampening, in minutes

7.8.34 display bgp ipv6 routing-table

Function

The **display bgp ipv6 routing-table** command displays BGP IPv6 routes.

Format

display bgp ipv6 routing-table [**verbose**]

display bgp ipv6 routing-table *ipv6-address* [*prefix-length*]

display bgp ipv6 routing-table as-path-filter { *as-path-filter-number* | *as-path-filter-name* }

display bgp ipv6 routing-table community [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp ipv6 routing-table community-filter { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp ipv6 routing-table different-origin-as

display bgp ipv6 routing-table regular-expression *as-regular-expression*

display bgp ipv6 routing-table peer *ipv6-address* { **accepted-routes** | **advertised-routes** [*dest-ipv6-address* [*prefix-length*]] | **received-routes** [**active**] }

display bgp ipv6 routing-table peer *ipv6-address* **received-routes** *dest-ipv6-address* [*prefix-length* [**original-attributes**]]

display bgp ipv6 routing-table peer *ipv4-address* **received-routes** *dest-ipv6-address* [*prefix-length* [**original-attributes**]]

display bgp ipv6 routing-table time-range *start-time end-time*

Parameters

Parameter	Description	Value
verbose	Displays detailed information about BGP4+ public network routes.	-
ipv6-address	Specifies the IPv6 address of the peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the length of the prefix.	The value is an integer that ranges from 0 to 128.
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS-Path filter.	It is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS-Path filter.	The name is a string of 1 to 51 characters without any space. It is case-sensitive.
community	Displays the routing information of the specified BGP community attribute in the routing table.	-
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.

Parameter	Description	Value
aa:nn	Specifies the community attribute number.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-
whole-match	Indicates the exact matching.	-
community-filter	Displays the routes that match the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The name is a string of 1 to 51 characters. The string cannot be all numbers.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
different-origin-as	Displays routes that have the same destination address but different source ASs.	-

Parameter	Description	Value
peer	Displays the routing information for the specified BGP peer.	-
ipv4-address	Specifies the IPv4 address of the peer. **NOTE** The parameter is not supported on S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, and S5736-S.	The value is in dotted decimal notation.
advertised-routes	Displays the routes advertised to the specified peer.	-
dest-ipv6-address	Specifies the destination IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
received-routes	Displays the routes received from the specified peer.	-
active	Displays the active routes received from the specified peer.	-
original-attributes	Displays the original attributes of a public route from a specified BGP peer before the route is filtered by the local import policy. To display such attributes, the **peer keep-all-routes** command must have been run.	-
regular-expression *as-regular-expression*	Specifies the matched AS regular expression.	The value is a string of 1 to 80 characters.

Parameter	Description	Value
accepted-routes	Displays the routes that are received from the peer and filtered through a routing policy.	-
time-range *start-time end-time*	Displays IPv6 BGP routes that flap within the specified time period. For example, the value 0d0h5m0s of *start-time* indicates 5 minutes before the current time. The value 0d0h10m0s of *end-time* indicates 10 minutes before the current time. All IPv6 BGP routes with the Keepalive time in the range of 5 to 10 minutes are displayed.	The value ranges of *start-time* and *end-time* both are 0d0h0m0s-10000d23h59m59s.

Usage Guidelines

You can specify different parameters to view the specific routing information.

You can run the **display bgp ipv6 routing-table time-range** *start-time end-time* command to view BGP4+ routes that flap within the specified time period. For example, if service traffic is abnormal or CPU usage of the device remains high within a certain time period, you can run this command to check whether route flapping occurs within the specified time period. The faulty route can be viewed in the command output, facilitating fault location.

Example

Display BGP IPv6 routes.

```
<HUAWEI> display bgp ipv6 routing-table

 BGP Local router ID is 10.1.1.1
 Status codes: * - valid, > - best, d - damped, x - best external,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete
```

```
 Total Number of Routes: 1
 *>  Network  : FC00:0:0:2000::                      PrefixLen : 64
     NextHop  : FC00:0:0:2000::1                     LocPrf    :
     MED      : 0                            PrefVal   : 0
     Label    :
     Path/Ogn : i
```

Displays BGP IPv6 routes that flap within the specified time period.

```
<HUAWEI> display bgp ipv6 routing-table time-range 0d5h0m0s 1d5h0m0s
BGP Local router ID is 10.1.1.2
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 *>i Network  : FC00:0:0:100::100                     PrefixLen : 128
     NextHop  : FC00:0:0:12::1                       Duration  : 05h46m16s
     Peer     : FC00:0:0:12::1
     Path/Ogn : ?
 * i
     NextHop  : FC00:0:0:112::1                       Duration  : 05h46m16s
     Peer     : FC00:0:0:112::1
     Path/Ogn : ?
 *>i Network  : FC00:0:0:111::111                     PrefixLen : 128
     NextHop  : FC00:0:0:12::1                       Duration  : 05h46m16s
     Peer     : FC00:0:0:12::1
     Path/Ogn : ?
 * i
     NextHop  : FC00:0:0:112::1                       Duration  : 05h46m16s
     Peer     : FC00:0:0:112::1
     Path/Ogn : ?
```

Table 7-129 Description of the display bgp ipv6 routing-table command output

Item	Description
BGP Local router ID	Indicates the router ID of the local BGP device.
Network	Indicates the network address in the BGP routing table.
PrefixLen	Indicates the prefix length.
NextHop	Indicates the next-hop address of the packet.
LocPrf	Indicates the local preference.
MED	Indicates the MED of the route.
PrefVal	Indicates the preferred value.
Label	Indicates the label value.
Duration	Route duration
Peer	Peer IP address
Path/Ogn	Indicates the AS_Path number and the Origin attribute.

Display detailed information about the specified invalid BGP4+ routes.

```
<HUAWEI> display bgp ipv6 routing-table FC00::1
 BGP local router ID : 10.1.1.1
 Local AS number : 100
 Paths:   1 available, 0 best, 0 select
 BGP routing table entry information of FC00::1/128
 From: 10::2 (10.1.1.2)
 Route Duration: 00h17m46s
 Relay IP Nexthop: ::
 Relay IP Out-Interface:
 Original nexthop: FC00::2
 AS-path 200, origin incomplete, MED 0, localpref 100, pref-val 0, internal, pre 255, invalid for IP
unreachable
 Not advertised to any peer yet
```

Table 7-130 Description of the display bgp ipv6 routing-table command output

Item	Description
BGP local router ID	ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Paths	Information about paths of BGP routes
BGP routing table entry information of FC00::1/128	The following information is about FC00::1/128 routing entries.
From	IP address of the router that sends the route. 10.1.1.2 is the source interface IP address of the peer with which the BGP connection is established, and 10::2 is the router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.
Original nexthop	Original next hop.
AS-path 200	AS_Path attribute.

Item	Description
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
MED	Multi-Exit discriminator of route.
localpref	Local priority.
pref-val	Value preferred by the protocol.
internal	The BGP route is an internal route.
pre 255	The priority of the BGP route is 255.
invalid for IP unreachable	Reason why a route is invalid: ● invalid for route-policy not pass: The route does not match the route-policy. ● invalid for supernet route: The route is a supernet route. ● invalid for IP unreachable: The route fails to recurse to another route. ● invalid for supernet route not advertise: No supernet routes are advertised. ● invalid for supernet label route not advertise: No supernet labeled routes are advertised. ● invalid for next-hop unreachable: The next-hop IP address is unreachable. ● invalid for tunnel unreachable: The route fails to recurse to a tunnel.

Item	Description
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

7.8.35 display bgp ipv6 routing-table statistics

Function

The **display bgp ipv6 routing-table statistics** command displays statistics about BGP IPv6 routes.

Format

display bgp ipv6 routing-table statistics

display bgp ipv6 routing-table statistics as-path-filter { *as-path-filter-number* | *as-path-filter-name* }

display bgp ipv6 routing-table statistics community [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp ipv6 routing-table statistics community-filter { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp ipv6 routing-table peer *ipv6-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

display bgp ipv6 routing-table statistics regular-expression *as-regular-expression*

display bgp ipv6 routing-table statistics different-origin-as

Parameters

Parameter	Description	Value
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 characters without any space. It is case-sensitive.
community	Displays the routing information of the specified BGP community attribute in the routing table.	-

Parameter	Description	Value
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
aa:nn	Specifies the community attribute number.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with the No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
community-filter	Displays the routing information that matches the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The name is a string of 1 to 51 characters. The string cannot be all numbers.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
peer	Displays the routing information for the specified BGP peer.	-
ipv6-address	Specifies the IPv6 address of the peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
advertised-routes	Displays the routes advertised to the specified peer.	-
received-routes	Displays the routes received from the specified peer.	-
active	Displays the active routes received from the specified peer.	-

Parameter	Description	Value
regular-expression *as-regular-expression*	Specifies the matched AS regular expression.	The value is a string of 1 to 80 characters.
different-origin-as	Displays routes that have the same destination address but different source ASs.	-

1: Monitoring level

Usage Guidelines

You can run the **display bgp ipv6 routing-table statistics** command to check statistics about BGP IPv6 routes.

Example

Display statistics of BGP IPv6 routes.

```
<HUAWEI> display bgp ipv6 routing-table statistics

 Total Number of Routes: 4
```

Table 7-131 Description of the **display bgp ipv6 routing-table statistics** command output

Item	Description
Total Number of Routes	Total number of routes in the routing table.

7.8.36 display bgp mdt brief

Function

The **display bgp mdt brief** command displays brief information about VPN instances in BGP MDT address family.

Format

display bgp mdt { **all** | **vpn-instance** *vpn-instance-name* } **brief**

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Displays information about MDT and all VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display bgp mdt brief** command is used to display brief information about VPN instances in BGP MDT address family.

Example

Display brief information about MDT and all VPN instances.

```
<HUAWEI> display bgp mdt all brief

MDT:
  Rd Num              Peer Num           Route Num
  0                 1                  0

VPN-Instance(IPv4-MDT-family):
  VPN-Instance Name   Peer Num            Route Num
  vrf0                  0                 0
  vrf1                  0                 0
  vrf11                 0                 0
  vrf12                 0                 0
  vrf13                 0                 0
  vrf14                 0                 0
  vrf2                  0                 20
  vrf3                  0                 20
  vrf4                  0                 24
  vrf5                  0                 24
  vrf6                  0                 0
  vrf7                  0                 0
  vrf8                  0                 20
```

Table 7-132 Description of the **display bgp mdt all brief** command output

Item	Description
Rd Num	Number of Route Distinguishers (RDs).
Peer Num	Number of peers.
Route Num	Number of routes.
VPN-Instance Name	Name of a VPN instance.

7.8.37 display bgp mdt routing-table

Function

The **display bgp mdt routing-table** command displays the information of BGP MDT routes.

Format

display bgp mdt { **all** | **vpn-instance** *vpn-instance-name* } **routing-table** [*network* [{ *mask* | *mask-length* } [**longer-prefixes**]]]

display bgp mdt route-distinguisher *route-distinguisher* **routing-table** [*network* [*mask* | *mask-length*]]

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table regular-expression** *as-regular-expression*

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table community** [*aa:nn* | *community-number*] & <1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp mdt all routing-table peer *ipv4-address* [**advertised-routes** [**statistics** | *ipv4-address*] | **received-routes** [**active**] [**statistics**]]

display bgp mdt all routing-table peer *ipv4-address* **received-routes** *network*

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Display all the BGP MDT routing information.	-
route-distinguisher *route-distinguisher*	Displays the BGP MDT routing information of the specified Route Distinguisher (RD).	-
vpn-instance *vpn-instance-name*	Displays the BGP MDT routing information of the specified VPN instance.	The value must be an existing VPN instance name.
network	Specifies the IPv4 network address.	It is in dotted decimal notation.
mask | *mask-length*	Specifies mask in dotted decimal notation or mask-length.	The value of mask-length is an integer that ranges from 0 to 32.
longer-prefixes	Matches according to the mask longer than the specified length.	-
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals.
cidr	Displays the BGP MDT routing information about the Classless Inter-Domain Routing (CIDR).	-
different-origin-as	Displays routes that have the same destination address but different source ASs.	-

Parameter	Description	Value
regular-expression *as-regular-expression*	Specifies the matched AS regular expression.	The value is a string of 1 to 80 characters.
community-filter	Displays the BGP MDT routing information that matches the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community	Displays the BGP MDT routing information of the specified BGP community attribute in the routing table.	-
aa:nn	Specifies the community attribute number.	Both aa and nn are integers ranging from 0 to 65535. You can set a maximum of 29 community numbers.
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-

Parameter	Description	Value
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-
whole-match	Indicates the exact matching.	-
peer *ipv4-address*	Displays the BGP MDT routing information for the specified BGP peer.	-
advertised-routes	Displays the BGP MDT routing information advertised to the specified peer.	-
statistics	Display the statistics of the BGP MDT routes.	-
ipv4-address	Specifies the IPv4 network address.	It is in dotted decimal notation.
received-routes	Displays the BGP MDT routing information received from the specified peer.	-
active	Displays the BGP MDT routing information received from the specified peer.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view the specific routing information of BGP MDT routes. If the length of the destination address mask of an IPv4 route is the same as that of its natural mask, the mask length is not displayed.

Example

Display all the BGP MDT routing information.

```
<HUAWEI> display bgp mdt all routing-table
```

```
 BGP Local router ID is 192.168.7.1
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total number of routes from all PE: 3
 Route Distinguisher: 100:1

      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn

 Not advertised to any peer yet
```

Table 7-134 Description of the **display bgp mdt all routing-table peer received-routes** command output

Item	Description
BGP local router ID	ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Route Distinguisher	Route distinguisher.
BGP routing table entry information of 2.2.2.2/32	The following information is about 2.2.2.2/32 routing entries.
From	IP address of the router that sends the route. 2.2.2.2 is the IP address of the source interface of the peer with which the BGP connection is established, and 2.2.2.9 is the Router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.

Item	Description
Original nexthop	Original next hop.
Qos information	QoS information.
Ext-Community	Extended community attribute.
AS-path Nil	AS_Path attribute, with Nil indicating that the attribute value is null.
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
localpref	Local priority.
pref-val	Value preferred by the protocol.
valid	The BGP route is a valid route.
internal	The BGP route is an internal route.
best	The BGP route is an optimal route.
select	The BGP route is a preferred route.
pre 255	The priority of the BGP route is 255.
IGP cost	Cost of the relied next hop route of BGP route.
MDT group address	Group address of MDT.
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

7.8.38 display bgp mdt routing-table statistics

Function

The **display bgp mdt routing-table statistics** command displays the statistics of the BGP MDT routes.

Format

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics**

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics regular-expression** *as-regular-expression*

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp mdt { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics community** [*aa:nn* | *community-number*] & <1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Displays all the statistics of the BGP MDT routes.	-
route-distinguisher *route-distinguisher*	Displays the BGP MDT routing statistics of the specified Route Distinguisher (RD).	-
vpn-instance *vpn-instance-name*	Displays the BGP MDT routing statistics of the specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matched AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals.
cidr	Displays the BGP MDT routing statistics about the Classless Inter-Domain Routing (CIDR).	-
different-origin-as	Displays the routes that have the same destination address but different source AS number.	-
regular-expression *as-regular-expression*	Indicates the matched AS regular expression.	The value is a string of 1 to 80 characters.
community-filter	Displays the BGP MDT routing statistics that matches the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
whole-match	Indicates exact matching.	-
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.

Parameter	Description	Value
community	Displays the BGP MDT routing statistics of the specified BGP community attribute in the routing table.	-
aa:nn	Specifies the community number.	Both aa and nn are integers ranging from 0 to 65535. You can set a maximum of 29 community numbers.
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with the No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-

Views

Usage Guidelines

None

Example

Displays all the statistics of the BGP MDT routes.

```
<HUAWEI> display bgp mdt all routing-table statistics

 Total number of routes from all PE: 20
```

```
Total number of routes of IPv4-MDT-family for vpn-instance vpn1: 12
```

Table 7-135 Description of the **display bgp mdt routing-table statistics** command output

Item	Description
Total number of routes from all PE	The number of the routes received from PEs in the BGP MDT routing table.
Total number of routes of IPv4-MDT-family for vpn-instance	The number of the routes of the specified VPN instance in the BGP MDT routing table.

7.8.39 display bgp multicast group

Function

The **display bgp multicast group** command displays the information about an MBGP peer group.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the peer group is specified, the detailed information on the specified peer group is displayed.

If the peer group is not specified, the information on all MBGP peer groups is displayed.

Example

Display the information about peer group **my-peer**.

```
<HUAWEI> display bgp multicast group my-peer
BGP peer-group: my-peer
 Remote AS: 1
 Authentication type configured: None
 Type : external
 Configured hold timer value: 180
 Keepalive timer value: 60
 Connect-retry timer value: 32
 Minimum route advertisement interval is 30 seconds
 PeerSession Members:
   172.16.14.1
 It's route-reflector-client
 Peer Preferred Value: 0
 No routing policy is configured
 Peer Members:
  Peer         V  AS  MsgRcvd  MsgSent  OutQ   Up/Down    State   PrefRcv
  172.16.14.1  4   1      43       29      0    00:03:03   Established   21
```

Table 7-136 Description of the display bgp multicast group command output

Item	Description
BGP peer-group: my-peer	Peer group: name of the group
Remote AS	The number of the AS where the peer resides
Authentication type configured	Indicates the configured BGP authentication type: ● MD5 ● Keychain (kk), in which kk indicates the name of the configured keychain authentication ● None, which indicates no BGP authentication is configured
Type	Indicates the types of peers: ● internal: The type of the peer group is IBGP ● external: The type of the peer group is EBGP
Configured hold timer value	Value of the holdtime timer
Keepalive timer value	Value of the Keepalive timer

Item	Description
Connect-retry timer value	Value of the Connect-retry timer
Minimum route advertisement interval	Shortest interval for advertising routes
PeerSession Members	Indicates peers that set up session connections
It's route-reflector-client	The local device is a route reflector client
Peer Preferred Value	Preferred value of peers
Peer	IP address of the peer
V	MBGP version
AS	The number of the AS where the peer resides
MsgRcvd	Number of messages received
MsgSent	Number of messages sent
OutQ	Number of messages to be sent to the peer
Up/Down	Time during which the MBGP session is in the current state
State	Indicates the MBGP state mechanism: ● Idle: indicates that MBGP denies the connection request. This is the initiate status of MBGP. ● Active: indicates that MBGP tries to set up TCP connection. This is the intermediate status of MBGP. ● Established: In the status, MBGP peers can exchange Update, Notification and Keepalive packets. ● Connect: indicates that MBGP performs other actions after the TCP connection is set up. ● OpenSent: indicates that MBGP waits for an Open message from the peer. ● OpenConfirm: indicates that MBGP waits for a Notification message or a Keepalive message.
PrefRcv	The number of prefixes received by the local peer from the remote peer

7.8.40 display bgp multicast network

Function

The **display bgp multicast network** command displays the routes to be advertised by MBGP through the **network** command.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast network

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to display all the configurations of the **network (BGP)** command in the IPv4 multicast address family view. Routes can be imported and then advertised by MBGP only when the route prefix satisfies the following conditions:

- It is specified in the **network** command.
- It already exists in the IP routing table.
- It is active.

Example

Display the routing information of a network segment advertised by MBGP.

```
<HUAWEI> display bgp multicast network
 BGP Local Router ID is 10.2.2.9
 Local AS Number is 100(Multicast)
 Network         Mask           Route-policy

 10.1.1.1       255.255.255.0
 10.2.2.2       255.255.255.0
```

Table 7-137 Description of the display bgp multicast network command output

Item	Description
BGP Local Router ID	ID of the local MBGP router
Local AS Number	Number of the local AS
Network	Network address locally advertised
Mask	Mask of the network address
Route-policy	Used routing policy

7.8.41 display bgp multicast paths

Function

The **display bgp multicast paths** command displays AS_Path information of MBGP.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast paths [*as-regular-expression*]

Parameters

Parameter	Description	Value
as-regular-expression	Displays the AS_Path regular expression.	The value is a string of 1 to 80 characters.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp multicast paths** command to check AS_Path information of MBGP.

Example

Display information about MBGP paths.

```
<HUAWEI> display bgp multicast paths 1

Total Number of Routes: 17
Total Number of Paths: 1

   Address         Refcount   MED        Path/Origin
   0x54169A4        17         0          1?
```

Table 7-138 Description of the display bgp multicast paths command output

Item	Description
Total Number of Routes	Total number of routes
Total Number of Paths	Total number of AS paths
Address	Address of the path attribute node in the local database in the hexadecimal format
Refcount	Number of times that the route is referenced
MED	Multi-Exit discriminator
Path	AS_Path list of the route
Origin	Origin of the route

7.8.42 display bgp multicast peer

Function

The **display bgp multicast peer** command displays information about a specified MBGP peer. If *peer-address* is not specified, information about all MBGP peers is displayed.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast peer [[*peer-address*] **verbose**]

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MBGP peer.	The value is in dotted decimal notation.
verbose	Specifies detailed information about an MBGP peer.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp multicast peer** command to check information about a specified MBGP peer. If *peer-address* is not specified, information about all MBGP peers is displayed.

Example

Display information about all MBGP peers.

```
<HUAWEI> display bgp multicast peer

 BGP local router ID : 10.13.13.9
 Local AS number : 1
 Total number of peers : 1                Peers in established state : 1

  Peer            V    AS  MsgRcvd  MsgSent  OutQ  Up/Down       State PrefRcv

  10.2.1.2        4     2       36       37     0 00:15:35 Established      24
```

Table 7-139 Description of the display bgp multicast peer command output

Item	Description
BGP local router ID	ID of the local MBGP router
Local AS number	Local AS number
Total number of peers	Total number of peers
Peers in established state	Number of peers in established state
Peer	IP address of peers
V	MBGP version of peers
AS	AS number
MsgRcvd	Number of messages received
MsgSent	Number of messages sent
OutQ	Messages to be sent to the specified peers
Up/Down	Period during which the MBGP session is in the current state
State	Status of the peers
PrefRcv	Number of prefixes received by the local peer from the remote peer

7.8.43 display bgp multicast routing-table

Function

The **display bgp multicast routing-table** command displays the MBGP routing information of a specified network in the MBGP routing table.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table [*ip-address* [*mask-length* [**longer-prefixes**] | *mask* [**longer-prefixes**]]]

Parameters

Parameter	Description	Value
ip-address	Specifies an IPv4 address.	The address is in dotted decimal notation.
mask-length	Specifies the mask length of the IPv4 address.	The value is an integer that ranges from 0 to 32.
mask	Specifies the mask of the IPv4 address.	The value is in dotted decimal notation.
longer-prefixes	Matches routes whose masks are shorter than the specified mask length.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If *ip-address* is not specified, this command will display all the information in the MBGP routing table.

Example

Display MBGP routing information.

```
<HUAWEI> display bgp multicast routing-table

 BGP local router ID is 10.13.13.9
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete
 Total Number of Routes: 14
      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn

 *>   10.1.2.0/24        10.2.1.2                             0      2?
 *>   10.1.13.0/24        0.0.0.0         0                    0      ?
 *>   10.1.13.2/32        0.0.0.0         0                    0      ?
 *>   10.2.1.0/24        0.0.0.0         0                    0      ?
 *>   10.2.1.0/24        10.2.1.2         0                    0      2?
 *>   10.2.1.1/32        0.0.0.0         0                    0      ?
 *>   10.2.13.0/24        0.0.0.0         0                    0      ?
 *>   10.2.13.1/32        0.0.0.0         0                    0      ?
 *>   10.2.13.2/32        0.0.0.0         0                    0      ?
```

Table 7-140 Description of the display bgp multicast routing-table command output

Item	Description
BGP local router ID	BGP local router ID.
Status codes	Status of a routing entry.
Total Number of Routes	Total number of routes in the routing table.
Network	Indicates the network address in the MBGP routing table.
NextHop	Indicates the next-hop address for the packet.
MED	Indicates the MED of the route.
LocPrf	Indicates the local preference.
PrefVal	Indicates the preferred value.
Path/Ogn	Indicates the AS_Path number and the Origin attribute.

Display detailed information about the specified invalid MBGP routes.

```
<HUAWEI> display bgp multicast routing-table 192.168.1.1

Not advertised to any peers yet
```

Table 7-141 Description of the display bgp multicast routing-table command output

Item	Description
BGP local router ID	ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Paths	Information about paths of BGP routes
BGP routing table entry information of 192.168.1.1/32	The following information is about 192.168.1.1/32 routing entries.
From	IP address of the router that sends the route. 10.1.1.2 is the IP address of the source interface of the peer with which the BGP connection is established, and 10.2.2.2 is the Router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.
Original nexthop	Original next hop.

Item	Description
Qos information	QoS information. - 0x20000000: indicates that the **apply behavior** command has been run. - 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. - 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. - 0x0: indicates that the preceding QoS configurations are not performed.
AS-path 200	AS_Path attribute.
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: - IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. - EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. - Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
MED	Multi-Exit discriminator of route.
localpref	Local priority.
pref-val	Value preferred by the protocol.
internal	The BGP route is an internal route.
pre 255	The BGP route preference is 255.

Item	Description
invalid for IP unreachable	Reason why a route is invalid: ● invalid for route-policy not pass: The route does not match the route-policy. ● invalid for supernet route: The route is a supernet route. ● invalid for IP unreachable: The route fails to recurse to another route. ● invalid for supernet route not advertise: No supernet routes are advertised. ● invalid for supernet label route not advertise: No supernet labeled routes are advertised. ● invalid for next-hop unreachable: The next-hop IP address is unreachable. ● invalid for tunnel unreachable: The route fails to recurse to a tunnel.
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

7.8.44 display bgp multicast routing-table as-path-filter

Function

The **display bgp multicast routing-table as-path-filter** command displays information about the routes that match the AS_Path filter.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table as-path-filter { *as-path-filter-number* | *as-path-filter-name* }

Parameters

Parameter	Description	Value
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer that ranges from 1 to 256.

Parameter	Description	Value
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The value is a string of 1 to 51 case-sensitive characters without spaces.

Usage Guidelines

You can run the **display bgp multicast routing-table as-path-filter** command to check information about the routes that match the AS_Path filter.

Example

Display information about the routes that match the AS_Path filter 1.

```
<HUAWEI> display bgp multicast routing-table as-path-filter 1
BGP local router ID is 10.14.14.9
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete
 Total Number of Routes: 15
      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn
 *>i  10.1.13.0/24       10.2.1.1        0          100        0      1?
 *>i  10.2.1.0/24        10.2.1.1        0          100        0      1?
 *>i  10.2.13.0/24       10.2.1.1        0          100        0      1?
 *>i  10.2.13.1/32       10.2.1.1        0          100        0      1?
```

Table 7-142 Description of the display bgp multicast routing-table as-path-filter command output

Item	Description
BGP local router ID	BGP local router ID

MED	Multi-Exit discriminator
LocPrf	Local preference
PrefVal	Preferred value of protocols
Path/Ogn	AS path and Origin attribute

7.8.45 display bgp multicast routing-table cidr

Function

The **display bgp multicast routing-table cidr** command displays routing information of classless inter-domain routing (CIDR).

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table cidr

Parameters

None.

Views

All views

LocPrf	Local preference
PrefVal	Preferred value of protocols
Path/Ogn	AS path and Origin attribute

7.8.46 display bgp multicast routing-table community

Function

The **display bgp multicast routing-table community** command displays routing information of a specified MBGP community.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table community [*aa:nn* | *community-number*] & <1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

Parameters

Parameter	Description	Value
aa:nn	Specifies the MBGP community number. You can specify a maximum of 29 MBGP communities.	Both aa and nn are integers ranging from 0 to 65535.
community-number	Specifies the MBGP community number. You can specify a maximum of 29 community numbers.	The value is an integer that ranges from 0 to 4294967295.

Parameter	Description	Value
internet	Displays the MBGP routes with the Internet community attribute. The Internet community attribute indicates the matching routes sent to all remote peers.	-
no-advertise	Displays MBGP routes with the no-advertise community attribute. The no-advertise community attribute indicates that the matching routes are not sent to any peer.	-
no-export	Indicates MBGP routes with the no-export community attribute. The no-expert community attribute indicates that the matching routes are not advertised to other ASs but to other sub-ASs in the confederation.	-
no-export-subconfed	Displays MBGP routes with the no-export-subconfed community attribute. The no-export-subconfed community attribute indicates that the matching routes are not advertised outside the local AS.	-
whole-match	Indicates precise matching.	-

NextHop	Next hop address for forwarding packets
MED	Multi-Exit discriminator
LocPrf	Local preference
PrefVal	Preferred value of protocols
Community	Community attribute

7.8.47 display bgp multicast routing-table community-filter

Function

The **display bgp multicast routing-table community-filter** command displays the multicast routing information that matches a specified MBGP community list.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table community-filter { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

Parameters

Parameter	Description	Value
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community-filter-name	Specifies the name of the community filter.	The value is a string of 1 to 51 case-sensitive characters without spaces.
whole-match	Indicates exact matching.	-

7.8.51 display bgp multicast routing-table flap-info

Function

The **display bgp multicast routing-table flap-info** command displays information about MBGP route flapping.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table flap-info [*ip-address* [*mask* [**longer-match**] | *mask-length* [**longer-match**]] | **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* }]

display bgp multicast routing-table flap-info regular-expression *as-regular-expression*

Parameters

Parameter	Description	Value
ip-address	Specifies an IPv4 network address.	The address is in dotted decimal notation.
mask	Specifies the mask of an IPv4 network address.	The address is in dotted decimal notation.
mask-length	Specifies the mask length of the IPv4 network address.	The value is an integer that ranges from 0 to 32.
longer-match	Indicates the longest prefix matching rules.	-
regular-expression *as-regular-expression*	Displays the statistics of route flapping that matches the AS_Path regular expression. *as-regular-expression* specifies the AS path regular expression.	The value is a string of 1 to 80 characters.
as-path-filter *as-path-filter-number*	Displays the statistics of the route flapping for the specified AS path list. *as-path-filter-number* indicates the matched AS path list number.	The value is an integer that ranges from 1 to 256.

Parameter	Description	Value
as-path-filter *as-path-filter-name*	Displays the statistics of the route flapping for the specified AS path list. *as-path-filter-name* indicates the matched AS path list name.	The value is a string of 1 to 51 case-sensitive characters without spaces.

 *>   10.1.1.0/24         10.2.1.1        1      00:00:29           1?
```

Table 7-149 Description of the display bgp multicast routing-table flap-info command output

Item	Description
BGP Local router ID	BGP local router ID
Network	Network address in the MBGP routing table
From	IP address of MBGP peer from which the route is received
Flaps	Count of route flapping
Duration	Duration of route flapping
Reuse	Reuse value
Path/Ogn	AS_Path number and Origin attribute

7.8.52 display bgp multicast routing-table peer

Function

The **display bgp multicast routing-table peer** command displays the routes received from or sent to a specified MBGP peer.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table peer *peer-address* { **advertised-routes** [*network* [{ *mask* | *mask-length* } [**longer-prefixes**]]] | **received-routes** [**active**] | **accepted-routes** }

display bgp multicast routing-table peer *peer-address* **received-routes** *network* [{ *mask* | *mask-length* } [**longer-prefixes** | **original-attributes**]]

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MBGP peer.	The value is in dotted decimal notation.
advertised-routes	Indicates the routes sent to a specified peer.	-
network	Specifies the IPv4 network address.	The value is in dotted decimal notation.
mask	Specifies the address mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
longer-prefixes	Uses the longest match rule to select routes.	-
received-routes	Indicates the routes received from a specified peer.	-
active	Displays the active routes received from the specified peer.	-
accepted-routes	Displays routing information that is received from neighbors and matches the filter policy.	-

Parameter	Description	Value
original-attributes	Displays the original attributes of a public route from a specified BGP peer before the route is filtered by the local import policy. To display such attributes, the **peer keep-all-routes** command must have been run.	-

```

Table 7-150 Description of the display bgp multicast routing-table peer command output

Item	Description
BGP local router ID	BGP local router ID
Total Number of Routes	Total number of routes
Network	Network address in the MBGP routing table
NextHop	Next hop address for forwarding packets
MED	Multi-Exit discriminator
LocPrf	Local preference

Item	Description
PrefVal	Preferred value of protocols
Path/Ogn	AS path and Origin attribute

7.8.53 display bgp multicast routing-table regular-expression

Function

The **display bgp multicast routing-table regular-expression** command displays the routes that match the specified AS_Path regular expression.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table regular-expression *as-regular-expression*

Parameters

Parameter	Description	Value
as-regular-expression	Specifies the AS_Path regular expression.	The value is a string of 1 to 80 case-sensitive characters without spaces.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp multicast routing-table regular-expression** command to check the routes that match the specified AS_Path regular expression.

Example

Display the routes that match the AS_Path regular expression 2.

```
<HUAWEI> display bgp multicast routing-table regular-expression 2
BGP local router ID is 10.13.13.9
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
```

```
            Origin : i - IGP, e - EGP, ? - incomplete
Total Number of Routes: 13
     Network            NextHop        MED      LocPrf     PrefVal Path/Ogn
*>   10.1.2.0/24        10.2.1.2                          0      2?
*>   10.2.1.0/24        10.2.1.2       0                   0      2?
*>   10.7.1.0/24        10.2.1.2                          0      2?
*>   10.7.1.1/32        10.2.1.2                          0      2?
*>   10.7.1.2/32        10.2.1.2       0                   0      2?
*>   10.11.12.0/24       10.2.1.2       0                   0      2?
*>   10.11.12.1/32       10.2.1.2       0                   0      2?
```

Table 7-151 Description of the display bgp multicast routing-table regular-expression command output

Item	Description
BGP local router ID	BGP local router ID.
Network	Network address in the MBGP routing table.
NextHop	Next-hop address for packets.
MED	MED of the route.
LocPrf	Local preference.
PrefVal	Preferred value.
Path/Ogn	AS_Path number and Origin attribute.

7.8.54 display bgp multicast routing-table statistics

Function

The **display bgp multicast routing-table statistics** command displays statistics about routes in the MBGP routing table.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast routing-table statistics

display bgp multicast routing-table peer *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

Parameters

Parameter	Description	Value
peer *ipv4-address*	Displays the number of routes with a specified peer address.	The value is in dotted decimal notation.
advertised-routes	Displays the number of routes advertised to a specified peer.	-
received-routes	Displays the number of routes received from a specified peer.	-
active	Displays the number of active routes.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp multicast routing-table statistics** command to check statistics about routes in the MBGP routing table.

Example

Display statistics about routes in the MBGP routing table.

```
<HUAWEI> display bgp multicast routing-table statistics
Total Number of Routes: 50
```

Table 7-152 Description of the display bgp multicast routing-table statistics command output

Item	Description
Total Number of Routes	Total number of routes in the MBGP routing table

7.8.55 display bgp multicast update-peer-group

Function

The **display bgp multicast update-peer-group** command displays information about MBGP update-groups.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display bgp multicast update-peer-group [**index** *update-group-index*]

Parameters

Parameter	Description	Value
index *update-group-index*	Specifies the index of an update-group.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the index of an update-group is specified, the command will display detailed information about the specified update-group.

Example

Display information about MBGP update-groups.

```
<HUAWEI> display bgp multicast update-peer-group
 The Multicast instance's update peer group number : 1
 Keep buffer update peer group number : 0
 BGP Version : 4

 Group ID : 0
 Group Type : external
 Addr Family : IPv4-MLC
 AdvMinTimeVal : 30
 Total Peers : 1
 Leader Peer : 192.168.1.2
 Peers List : 192.168.1.2
```

Table 7-153 Description of the display bgp multicast update-peer-group command output

Item	Description
The Multicast instance's update peer group number	Indicates the number of update-groups in the instance.
Keep buffer update peer group number	Number of packets in update-groups saved in the batch buffer.

Item	Description
BGP Version	Indicates the BGP version.
Group ID	Indicates the ID of the update-group.
Group Type	Indicates the type of the update-group, which can be one of the following: ● external: indicates an EBGP update-group. ● internal: indicates an IBGP update-group. ● external-confed: indicates an EBGP update-group in the confederation. ● internal-confed: indicates an IBGP update-group in the confederation. ● unknown: indicates an update-group of an unknown type.
Addr Family	Indicates the address family.
AdvMinTimeVal	Indicates the minimum interval for sending Update packets with the same route prefix.
Total Peers	Indicates the total number of peers in an update-group.
Leader Peer	Indicates the representative of an update-group.
Peers List	Indicates a list of peers.

7.8.56 display bgp mvpn brief

Function

The **display bgp mvpn brief** command displays brief information about VPN instances in BGP MVPN address family.

Format

display bgp mvpn { **all** | **vpn-instance** *vpn-instance-name* } **brief**

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Displays brief information about MVPN and all VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display bgp mvpn brief** command is used to display brief information about VPN instances in BGP MVPN address family.

Example

Display brief information about MVPN and all VPN instances.

```
<HUAWEI> display bgp mvpn all brief

MVPN:
  Rd Num            Peer Num          Route Num
  0                1                 0

VPN-Instance(IPv4-MVPN-family):
  VPN-Instance Name   Peer Num           Route Num
  vrf0              0                0
  vrf1              0                0
  vrf11              0                0
  vrf12              0                0
  vrf13              0                0
  vrf14              0                0
  vrf2              0                20
  vrf3              0                20
  vrf4              0                24
  vrf5              0                24
  vrf6              0                0
  vrf7              0                0
  vrf8              0                20
```

Table 7-154 Description of the **display bgp mvpn all brief** command output

Item	Description
Rd Num	Number of Route Distinguishers (RDs).
Peer Num	Number of peers.

Item	Description
Route Num	Number of routes.
VPN-Instance Name	Name of a VPN instance.

7.8.57 display bgp mvpn routing-table

Function

The **display bgp mvpn routing-table** command displays the information of BGP MVPN routes.

Format

display bgp mvpn { **all** | **vpn-instance** *vpn-instance-name* } **routing-table** [*network* [{ *mask* | *mask-length* } [**longer-prefixes**]]]

display bgp mvpn route-distinguisher *route-distinguisher* **routing-table** [*network* [*mask* | *mask-length*]]

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table regular-expression** *as-regular-expression*

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table community** [*aa:nn* | *community-number*] & <1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp mvpn all routing-table peer *ipv4-address* { **advertised-routes** [*network*] | **received-routes** [**active**] }

display bgp mvpn all routing-table peer *ipv4-address* **received-routes** *network*

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Display all the BGP MVPN routing information.	-
vpn-instance *vpn-instance-name*	Displays the BGP MVPN routing information of the specified VPN instance.	The value must be an existing VPN instance name.
network	Specifies the IPv4 network address.	It is in dotted decimal notation.
mask | *mask-length*	Specifies mask in dotted decimal notation or mask-length.	The value of mask-length is an integer that ranges from 0 to 32.
longer-prefixes	Matches according to the mask longer than the specified length.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays BGP routing information of the specified Route Distinguisher (RD).	The RD formats are divided into the following types: ● 2-byte AS number:32-bit user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. ● Integral 4-byte AS number: 2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of x.y, where x and y are integers that range from 1 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● 32-bit IP address:16-bit user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.

Parameter	Description	Value
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals.
cidr	Displays the BGP MVPN routing information about the Classless Inter-Domain Routing (CIDR).	-
different-origin-as	Displays routes that have the same destination address but different source ASs.	-
regular-expression *as-regular-expression*	Specifies the matched AS regular expression.	The value is a string of 1 to 80 characters.
community-filter	Displays the BGP MVPN routing information that matches the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
whole-match	Indicates the exact matching.	-
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.

Parameter	Description	Value
community	Displays the BGP MVPN routing information of the specified BGP community attribute in the routing table.	-
aa:nn	Specifies the community attribute number.	Both aa and nn are integers ranging from 0 to 65535. You can set a maximum of 29 community numbers.
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-
peer *ipv4-address*	Displays the BGP MVPN routing information for the specified BGP peer.	It is in dotted decimal notation.
advertised-routes	Displays the BGP MVPN routing information advertised to the specified peer.	-
received-routes	Displays the BGP MVPN routing information received from the specified peer.	-

Parameter	Description	Value
active	Displays the active BGP MVPN routing information received from the specified peer.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view the specific routing information of BGP MVPN routes. If the length of the destination address mask of an IPv4 route is the same as that of its natural mask, the mask length is not displayed.

Example

Display all the BGP MVPN routing information.

```
<HUAWEI> display bgp mvpn all routing-table

 BGP Local router ID is 192.168.7.1
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total number of routes from all PE: 3

Table 7-156 Description of the display bgp mvpn all routing-table peer received-routes command output

Item	Description
BGP local router ID	ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Route Distinguisher	Route distinguisher.
BGP routing table entry information of 2.2.2.2/32	The following information is about 2.2.2.2/32 routing entries.
From	IP address of the router that sends the route. 2.2.2.2 is the IP address of the source interface of the peer with which the BGP connection is established, and 2.2.2.9 is the Router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.
Original nexthop	Original next hop.
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *ip-precedence* command has been run and the *ip-precedence* varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.
Ext-Community	Extended community attribute.
AS-path Nil	AS_Path attribute, with Nil indicating that the attribute value is null.

Item	Description
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
localpref	Local priority.
pref-val	Value preferred by the protocol.
valid	The BGP route is a valid route.
internal	The BGP route is an internal route.
best	The BGP route is an optimal route.
select	The BGP route is a preferred route.
pre 255	The priority of the BGP route is 255.
IGP cost	Cost of the relied route.
PMSI: Flags 0, PIM-SM, label 0:0:0, Sender address: 2.2.2.2, Group address: 232.1.1.1	In NG MVPNs, P-Multicast Service Interfaces (PMSIs) are logical channels that transmit multicast VPN services over the public network. ● Flags: Point-to-Multipoint (P2MP) tunnel flags. ● PIM-SM: The PIM-SM protocol. ● label: Label information about the PMSI. ● Sender address: IP address of the sender PE. ● Group address: IP address of the multicast group.

Item	Description
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

7.8.58 display bgp mvpn routing-table statistics

Function

The **display bgp mvpn routing-table statistics** command displays the statistics of the BGP MVPN routes.

Format

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics**

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics regular-expression** *as-regular-expression*

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp mvpn { **all** | **route-distinguisher** *route-distinguisher* | **vpn-instance** *vpn-instance-name* } **routing-table statistics community** [*aa:nn* | *community-number*] & <1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp mvpn all routing-table peer *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Displays all the statistics of the BGP MVPN routes.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the BGP MVPN routing statistics of the specified Route Distinguisher (RD).	-
vpn-instance *vpn-instance-name*	Displays the BGP MVPN routing statistics of the specified VPN instance.	The value must be an existing VPN instance name.
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matched AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals.
cidr	Displays the BGP MVPN routing statistics about the Classless Inter-Domain Routing (CIDR).	-
different-origin-as	Displays the routes that have the same destination address but different source AS number.	-
regular-expression *as-regular-expression*	Indicates the matched AS regular expression.	The value is a string of 1 to 80 characters.
community-filter	Displays the BGP MVPN routing statistics that matches the specified BGP community filter.	-
community-filter-name	Specifies the name of the community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
whole-match	Indicates exact matching.	-

Parameter	Description	Value
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community	Displays the BGP MVPN routing statistics of the specified BGP community attribute in the routing table.	-
aa:nn	Specifies the community number.	Both aa and nn are integers ranging from 0 to 65535. You can set a maximum of 29 community numbers.
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
internet	Displays the BGP routes with Internet community attribute.	-
no-advertise	Displays the BGP routes with the No-Advertise community attribute.	-
no-export	Displays the BGP routes with the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes with the No-Export-Subconfed community attribute.	-
peer *ipv4-address*	Displays the BGP MVPN routing statistics for the specified BGP peer.	It is in dotted decimal notation.
advertised-routes	Displays the BGP MVPN routing statistics advertised to the specified peer.	-
received-routes	Displays the BGP MVPN routing statistics from the specified peer.	-

Parameter	Description	Value
active	Displays the active BGP MVPN routing statistics received from the specified peer.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

None.

Example

Display all the statistics of the BGP MVPN routing table.

```
<HUAWEI> display bgp mvpn all routing-table statistics

 Total number of routes from all PE: 20

 Total number of routes of IPv4-MVPN-family for vpn-instance vpn1: 12
```

Table 7-157 Description of the **display bgp mvpn routing-table statistics** command output

Item	Description
Total number of routes from all PE	The number of the routes received from PEs in the BGP MVPN routing table
Total number of routes of IPv4-MVPN-family for vpn-instance	The number of the routes of the specified VPN instance in the BGP MVPN routing table

7.8.59 display bgp network

Function

The **display bgp network** command displays the routes imported into the BGP routing table by using the **network** command.

Format

display bgp network

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **network**

display bgp ipv6 network

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **network** (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
vpnv4	Displays the VPNv4 routes that are advertised by using the **network** command.	-
vpnv6	Displays the VPNv6 routes that are advertised by using the **network** command.	-
all	Displays all the VPNv4 routes that are advertised by using the **network** command.	-
vpn-instance *vpn-instance-name*	Displays the routes of a specified VPN instance that are advertised by using the **network** command.	The value must be an existing VPN instance name.
ipv6	Displays the IPv6 routes advertised by BGP.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

BGP cannot discover routes by itself. Run the **network (BGP)** command and the **import-route (BGP)** command to import routes from other protocols, such as IGP routes or static routes, to the BGP routing table.

The **display bgp network** command displays the routing information advertised by BGP through the **network (BGP)** command.

Precautions

BGP has multiple address families and the routing information about each address family is isolated from each other. The routing information about address families advertised by BGP through the **network (BGP)** command can be displayed by specifying different parameters.

If no parameter is specified, the **display bgp network** command displays the routing information about the IPv4 unicast address family advertised by BGP through the **network (BGP)** command.

Example

Display information about routes that are imported using the **network** command.

```
<HUAWEI> display bgp network
  BGP Local Router ID is 10.1.1.9
  Local AS Number is 10(Public)
  Network          Mask            Route-policy

  10.2.0.0         255.255.0.0
  10.0.0.0         255.0.0.0       Policy1
  10.4.4.0         255.255.255.0
```

Table 7-158 Description of the display bgp network command output

Item	Description
Local AS Number	Indicates the local AS number.
Network	Indicates the locally-advertised network address.
Mask	Indicates the mask of the network address.
Route-policy	Indicates the used routing policy.

Display information about BGP VPNv4 routes that are imported using the **network** command.

```
<HUAWEI> display bgp vpnv4 all network
  BGP Local Router ID is 10.2.2.9
  Local AS Number is 100
 VPN-Instance vrf1, Router ID 10.2.2.9:
  Network          Mask            Route-policy
  10.4.4.4         255.255.255.255
 VPN-Instance vrf2, Router ID 2.2.2.9:
  Network          Mask            Route-policy
  10.5.5.5         255.255.255.255
```

Table 7-159 Description of the display bgp vpnv4 all network command output

Item	Description
VPN-Instance	Name of the VPN instance
Router ID	Router ID of the local BGP router.

Display IPv6 routes advertised by BGP.

```
<HUAWEI> display bgp ipv6 network
  BGP Local Router ID is 10.5.5.5
  Local AS Number is 100(PublicV6)
  Network          Prefix           Route-policy
  FC00:0:0:100::   64
  FC00:0:0:200::   64
```

Display VPNv6 routes locally advertised by BGP (by using the **network** command) for a specified VPN instance.

```
<HUAWEI> display bgp vpnv6 vpn-instance vpn1 network
  BGP Local Router ID is 10.1.1.1
  Local AS Number is 100
  Route Distinguisher: 100:1
  (vpn1)
  Network          Prefix           Route-policy
  FC00:0:0:2000::  100               policy1
```

Table 7-160 Description of the display bgp vpnv6 network command output

Item	Description
BGP Local Router ID	Indicates the ID of the local BGP device. The ID is in the same format as an IPv4 address.
Local AS Number	Indicates the local AS number.
Route Distinguisher	Indicates the route distinguisher for the VPN instance.
Prefix	Indicates the network address mask advertised by the local BGP device.

Display the VPNv6 routes locally advertised by BGP (by using the **network** command).

```
<HUAWEI> display bgp vpnv6 all network
  BGP Local Router ID is 10.2.2.9
  Local AS Number is 100
  Route Distinguisher: 100:4
  (vpn1)
  Network          Prefix           Route-policy
  FC00:0:0:1::1    128
  FC00:0:0:2::2    128
  Route Distinguisher: 100:5
  (vrf1)
  Network          Prefix           Route-policy
  FC00:0:0:3::3    128
  Route Distinguisher: 100:9
  (vrf2)
  Network          Prefix           Route-policy
  FC00:0:0:8::9    128
```

7.8.60 display bgp paths

Function

The **display bgp paths** command displays the AS_Path information of BGP routes.

Format

display bgp paths [*as-regular-expression*]

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **paths** [*as-regular-expression*]

display bgp ipv6 paths [*as-regular-expression*]

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **paths** [*as-regular-expression*] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp { **mdt** | **mvpn** } { **all** | **vpn-instance** *vpn-instance-name* } **paths** [*as-regular-expression*]

NOTE

The **mdt,mvpn** parameter is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
as-regular-expression	Specifies the regular expression used to match the AS_Path information.	The name is a string of 1 to 80 characters.
vpnv4	Displays the AS_Path information of the routes of a VPNv4 instance.	-
vpnv6	Displays the AS_Path information of the routes of a VPNv6 instance.	-
all	Displays the AS_Path information of all VPNv4 routes.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv6	Displays the path attributes of IPv6-BGP routes in the local BGP database.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display bgp paths** command displays the path attributes of BGP stored in the system.

BGP usually has a large number of path attributes. The **display bgp paths** command displays a lot of BGP path information for viewing. After configuring *as-regular-expression*, the **display bgp paths** command displays only the path attributes of BGP that match *as-regular-expression*. For details on a regular expression, see Filtering Output Information Based on the Regular Expression in "CLI Overview" in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Basic Configuration*.

Precautions

BGP has a number of address families and the path attributes of BGP in each address family is stored independently. By default, the **display bgp paths** command displays only the path attributes of BGP in the IPv4 unicast address family. The path attributes of BGP in other address families can be displayed by specifying address family parameters.

Example

Display the AS_Path information.

```
<HUAWEI> display bgp paths

 Total number of routes of IPv4-family for vpn-instance _public_: 6
 Total Number of Paths: 1

 Address          Refcount        MED  Path/Origin
 1282430404              6          0  N?
```

Table 7-161 Description of the display bgp paths command output

Item	Description
Address	Indicates the address of the route in the local database, in hexadecimal notation.
Refcount	Indicates the number of times that the route is referenced.
MED	Indicates the MED of the route.
Path	Indicates the list of ASs through which the packet has to pass through.
Origin	Indicates the origin of the route.

7.8.61 display bgp peer

Function

The **display bgp peer** command displays information about BGP peers.

Format

display bgp [**vpnv4 vpn-instance** *vpn-instance-name*] **peer** [{ *group-name* | *ipv4-address* } **log-info** | [*ipv4-address*] **verbose**]

display bgp vpnv4 all peer [[*ipv4-address*] **verbose**]

display bgp vpls peer [[*ipv4-address*] **verbose**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp ipv6 peer [**verbose**]

display bgp ipv6 peer *ipv6-address* { **log-info** | **verbose** }

display bgp ipv6 peer *ipv4-address* **verbose**

display bgp vpnv6 all peer [[*ipv4-address*] **verbose**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv6 vpn-instance *vpn-instance-name* **peer** [{ *group-name* | *ipv6-address* } **log-info** | [*ipv6-address*] **verbose**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp l2vpn-ad peer [[*ipv4-address*] **verbose**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp l2vpn peer [[*ipv4-address*] **verbose**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp { **mdt** | **mvpn** } **all peer** [[*ipv4-address*] **verbose**](supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv4-address	Specifies the IPv4 address of a peer to be displayed.	It is in dotted decimal notation.

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
log-info	Indicates to display log information of the specified peer.	-
verbose	Indicates to display detailed peer information.	-
vpnv4	Indicates to display information about peers in a VPNv4 instance.	-
all	Indicates to display information about peers in all VPNv4 or VPNv6 instances.	-
vpls	Displays information about peers in the BGP-VPLS view.	-
ipv6-address	Specifies the IPv6 address of a peer to be displayed.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
vpnv6	Indicates to display BGP VPNv6 peer information.	-
l2vpn-ad	Displays information about peers in the BGP L2VPN-AD view.	-
l2vpn	Displays information about peers in the BGP L2VPN view.	-

Usage Guidelines

Usage Scenario

The **display bgp peer** command displays information about a BGP peer. You can implement the following operations based on the command output:

- To check the status of BGP connections
- To check information about a BGP peer
- To check whether a BGP peer is successfully configured using the **peer as-number** command
- To check whether a BGP peer is successfully deleted using the **undo peer as-number** command

Precautions

BGP has multiple address families. By default, the **display bgp peer** command displays information about BGP peers in IPv4 unicast address family only. If you want to view information about BGP peers in another address family, you need to specify its address family parameter.

To view detailed information about a BGP peer, such as information about BGP timers, the number of sent and received routes, capacities supported, the number of sent and received BGP messages, and enabled functions, specify **verbose** in the command.

If **log-info** is specified in the command, log information about a BGP peer is displayed, including information about BGP peer flapping.

Example

Display peer information.

```
<HUAWEI> display bgp peer

 Status codes: * - Dynamic

 BGP Local router ID : 10.2.3.4
 local AS number : 10
 Total number of peers : 2                 Peers in established state : 1
 Total number of dynamic peers : 0

  Peer        V    AS  MsgRcvd  MsgSent  OutQ  Up/Down       State PrefRcv

  10.1.1.1    4   100        0        0     0 00:00:07        Idle       0
  10.2.5.6    4   200       32       35     0 00:17:49 Established       0
```

Table 7-162 Description of the display bgp peer command output

Item	Description
Status codes: * - Dynamic	Status code. If the value starts with an asterisk (*), the peer is a dynamic peer. Currently, the value can only be *** - Dynamic**.

Item	Description
BGP Local router ID	Indicates the ID of the BGP local router. **NOTE** If two ends have the same BGP local router ID, no BGP peer relationship can be established between them. In this situation, run the **router id** command in the BGP view on either end to change the BGP local router ID. Changing it to the IP address of a loopback interface is recommended.
local AS number	Indicates the local AS number.
Total number of peers	Indicates the number of peers.
Peers in established state	Indicates the number of peers in established state.
Total number of dynamic peers	Total number of dynamic BGP peers.
Peer	Indicates the IP address of the peer.
V	Indicates the BGP version used on the peer.
AS	Indicates the AS number.
MsgRcvd	Indicates the number of received messages.
MsgSent	Indicates the number of sent messages.
OutQ	Indicates the message to be sent to the specified peer.
Up/Down	Indicates the period of time during which a BGP session keeps the current state.

Item	Description
State	Status of the peer: - Idle: indicates that BGP denies any request of entering. This is the initiatory status of BGP. Upon receiving a Start event, BGP initiates a TCP connection to the remote BGP peer, starts the ConnectRetry Timer with the initial value, detects a TCP connection initiated by the remote BGP peer, and changes its state to Connect. - Idle(Admin): indicates that the peer relationship is shut down initiatively and no attempt is made to establish the peer relationship. If the **peer ignore** command is configured or the peer is set to the Down state through the MIB, the neighbor is in the Idle (Admin) state. - No neg: The capabilities of the BGP peer's address family have not been negotiated. - Idle(Ovlmt): indicates that the peer relationship is interrupted because the number of routes exceeds the upper threshold. After a BGP peer relationship is interrupted due to the running of the **peer route-limit** command, the status of the BGP peer relationship is displayed as Idle(Ovlmt). If the **reset bgp** command is not run, the BGP peer relationship will not be reestablished. - Connect: indicates that BGP waits for the TCP connection to be set up before it determines whether to perform other operations. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the TCP connection fails, BGP restarts the ConnectRetry Timer

Item	Description
	with the initial value, continues to detect a TCP connection initiated by the remote peer, and changes its state to Active. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer with the initial value, initiates a TCP connection to the remote BGP peer, and stays in the Connect state. ● Active: indicates that BGP tries to set up a TCP connection. This is the intermediate status of BGP. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer with the initial value and changes its state to Connect. – If BGP initiates a TCP connection with an unknown IP address, the TCP connection fails. When this occurs, BGP restarts the ConnectRetry Timer with the initial value and stays in the Active state. ● OpenSent: indicates that BGP has sent one Open message to its peer and waits for an Open message from the peer. – If there are no errors in the Open message received, BGP changes its state to OpenConfirm. – If there are errors in the Open message received, BGP sends a Notification message to the remote peer and changes its state to Idle. – If the TCP connection fails, BGP restarts the ConnectRetry Timer with the initial value, continues

Item	Description
	to detect a TCP connection initiated by the remote peer, and changes its state to Active. ● OpenConfirm: indicates that BGP waits for a Notification message or a Keepalive message. – If BGP receives a Notification message, or the TCP connection fails, BGP changes its state to Idle. – If BGP receives a Keepalive message, BGP changes its state to Established. ● Established: indicates that BGP peers can exchange Update, Notification and Keepalive packets. – If BGP receives an Update or a Keepalive message, its state stays in Established. – If BGP receives a Notification message, BGP changes its state to Idle.
PrefRcv	Indicates the number of route prefixes sent from the peer.

Display detailed information about the peer 10.2.2.9.

```
<HUAWEI> display bgp peer 10.2.2.9 verbose

         BGP Peer is 10.2.2.9,  remote AS 100
         Type: IBGP link
         BGP version 4, Remote router ID 10.1.1.1

 Route refresh capability has been enabled
 4-byte-as capability has been enabled
 Listen-only has been configured
 Peer's BFD has been enabled
 Peer Preferred Value: 0
 Routing policy configured:
 No routing policy is configured
```

Table 7-163 Description of the display bgp peer verbose command output

Item	Description
Type	Indicates the BGP link type, which can be IBGP or EBGP.
BGP version	Indicates the BGP version.
remote router ID	Indicates the router ID of the peer.
Update-group ID	Indicates the ID of the update-group to which the peer belongs.

Item	Description
BGP current state	Current state of BGP: ● Idle: indicates that BGP denies any request of entering. This is the initiatory status of BGP. Upon receiving a Start event, BGP initiates a TCP connection to the remote BGP peer, starts the ConnectRetry Timer with the initial value, detects a TCP connection initiated by the remote BGP peer, and changes its state to Connect. ● Idle(Admin): indicates that the peer relationship is shut down initiatively and no attempt is made to establish the peer relationship. If the **peer ignore** command is configured or the peer is set to the Down state through the MIB, the neighbor is in the Idle (Admin) state. ● No neg: The capabilities of the BGP peer's address family have not been negotiated. ● Idle(Ovlmt): indicates that the peer relationship is interrupted because the number of routes exceeds the upper threshold. After a BGP peer relationship is interrupted due to the running of the **peer route-limit** command, the status of the BGP peer relationship is displayed as Idle(Ovlmt). If the **reset bgp** command is not run, the BGP peer relationship will not be reestablished. ● Connect: indicates that BGP waits for the TCP connection to be set up before it determines whether to perform other operations. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the TCP connection fails, BGP restarts the ConnectRetry Timer

Item	Description
	with the initial value, continues to detect a TCP connection initiated by the remote peer, and changes its state to Active. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer with the initial value, initiates a TCP connection to the remote BGP peer, and stays in the Connect state. ● Active: indicates that BGP tries to set up a TCP connection. This is the intermediate status of BGP. – If the TCP connection succeeds, BGP stops the ConnectRetry Timer, sends an Open message to the remote peer, and changes its state to OpenSent. – If the ConnectRetry Timer has expired before a TCP connection is established, BGP restarts the timer with the initial value and changes its state to Connect. – If BGP initiates a TCP connection with an unknown IP address, the TCP connection fails. When this occurs, BGP restarts the ConnectRetry Timer with the initial value and stays in the Active state. ● OpenSent: indicates that BGP has sent one Open message to its peer and waits for an Open message from the peer. – If there are no errors in the Open message received, BGP changes its state to OpenConfirm. – If there are errors in the Open message received, BGP sends a Notification message to the remote peer and changes its state to Idle. – If the TCP connection fails, BGP restarts the ConnectRetry Timer with the initial value, continues

Item	Description
	to detect a TCP connection initiated by the remote peer, and changes its state to Active. ● OpenConfirm: indicates that BGP waits for a Notification message or a Keepalive message. – If BGP receives a Notification message, or the TCP connection fails, BGP changes its state to Idle. – If BGP receives a Keepalive message, BGP changes its state to Established. ● Established: indicates that BGP peers can exchange Update, Notification and Keepalive packets. – If BGP receives an Update or a Keepalive message, its state stays in Established. – If BGP receives a Notification message, BGP changes its state to Idle.
BGP current event	Indicates the current BGP event.
BGP last state	Indicates the last BGP status, which may be Idle, Connect, Active, OpenSent, OpenConfirm, or Established.
BGP Peer Up count	Indicates the flapping count of a BGP peer in a specified period of time.
Received total routes	Indicates the number of received route prefixes.
Received active routes total	Indicates the number of received active route prefixes.
Received mac routes	Number of MAC routes received.
Advertised total routes	Indicates the number of sent route prefixes.
Port	Indicates the port number. ● Local: indicates the local port number, which is always 179. BGP uses TCP at the transport layer. ● Remote: indicates the port number used on the peer.

Item	Description
Configured	Indicates locally configured timers. ● Connect-retry Time: indicates the ConnectRetry interval for a BGP peer or peer group, in seconds. When BGP initiates a TCP connection, the ConnectRetry timer is stopped if the TCP connection is established successfully. If the first attempt to establish a TCP connection fails, BGP tries again to establish the TCP connection after the ConnectRetry timer expires. ● Min Hold Time: indicates the minimum Holdtime configured on the local device, in seconds. ● Active Hold Time: indicates the hold time. If BGP does not receive any Keepalive message from the peer in the hold time, BGP considers that the peer is Down and then instructs other peers to remove the routes that are sent from the peer. ● Keep Alive Time: indicates the interval for sending Keepalive messages to the peer. BGP peers send Keepalive messages to each other periodically to maintain their relationships.
Received : Active Hold Time	Indicates the hold time on the peer.
Negotiated : Active Hold Time	Indicates the hold time agreed between the BGP peers after capability negotiation.
Address family IPv4 Unicast	Indicates the IPv4 unicast address family.
Address family IPv6 Unicast	Indicates the IPv6 unicast address family.

Item	Description
Received	Indicates the number of packets received from a peer. - Total: indicates the total number of messages received from a peer. - Update messages: indicates the number of Update messages received from a peer. - Open messages: indicates the number of Open messages received from a peer. - KeepAlive messages: indicates the number of Keepalive messages received from a peer. - Notification messages: indicates the number of Notification messages received from a peer. - Refresh messages: indicates the number of route-refresh messages received from a peer.
Sent	Indicates the number of messages sent to a peer. - Total: indicates the total number of messages sent to a peer. - Update messages: indicates the number of Update messages sent to a peer. - Open messages: indicates the number of Open messages sent to a peer. - KeepAlive messages: indicates the number of Keepalive messages sent to a peer. - Notification messages: indicates the number of Notification messages sent to a peer. - Refresh messages: indicates the number of route-refresh messages sent to a peer.
Authentication type configured	Indicates the authentication type configured.

Item	Description
Last keepalive received	Indicates the time when the Keepalive packet is received last time. It can be in the following formats: ● YYYY/MM/DD HH:MM:SS ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM DST ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM ● YYYY/MM/DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is set through the **clock timezone** command; DST indicates that the daylight saving time is set through the **clock daylight-saving-time** command.
Last keepalive sent	Indicates the time when the Keepalive packet is sent last time. It can be in the following formats: ● YYYY/MM/DD HH:MM:SS ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM DST ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM ● YYYY/MM/DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is set through the **clock timezone** command; DST indicates that the daylight saving time is set through the **clock daylight-saving-time** command.

Item	Description
Last update received	Indicates the time when the Update packet is received last time. It can be in the following formats: ● YYYY/MM/DD HH:MM:SS ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM DST ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM ● YYYY/MM/DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is set through the **clock timezone** command; DST indicates that the daylight saving time is set through the **clock daylight-saving-time** command.
Last update sent	Indicates the time when the Update packet is sent last time. It can be in the following formats: ● YYYY/MM/DD HH:MM:SS ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM DST ● YYYY/MM/DD HH:MM:SS UTC ±HH:MM ● YYYY/MM/DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is set through the **clock timezone** command; DST indicates that the daylight saving time is set through the **clock daylight-saving-time** command.
Minimum route advertisement interval is 15 seconds	Indicates the minimum interval between route advertisements. ● The minimum interval for advertising EBGP routes is 30 seconds. ● The minimum interval for advertising IBGP routes is 15 seconds.
Optional capabilities	(Optional) Indicates the peer-supported capabilities.
Route refresh capability has been enabled	Indicates that route refreshing has been enabled.

Item	Description
4-byte-as capability has been enabled	Indicates that the 4-byte AS number capability is enabled.
Listen-only has been configured	Indicates that only connection requests are snooped and no connections will be initiated proactively.
Peer Preferred Value	Indicates the preferred value of the peer.
Routing policy configured	Indicates the configured routing policy.
Peer's BFD has been enabled	Indicates that BFD has been enabled on the peer.

Display log information on BGP peer 10.1.1.2.

7.8.62 display bgp resource

Function

The **display bgp resource** command displays statistics about BGP specification information.

Format

display bgp resource

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check statistics about BGP specification information, run the **display bgp resource** command. This command displays only the total number of supported BGP peer sessions, including the numbers of various configured sessions.

Example

Display statistics about BGP specification information.

```
<HUAWEI> display bgp resource

 BGP Peer session support total number : 64

  Capacity Statistics     Used Number

  BGP Peer Session          3
  IBGP Peer Session         3
  EBGP Peer Session          0
```

Table 7-165 Description of the **display bgp resource** command output

Item	Description
BGP Peer session support total number	Maximum number of BGP peer sessions that are supported.
Capacity Statistics	BGP peer session type.
Used Number	Number of currently configured peer sessions.
BGP Peer Session	Total number of currently configured BGP peer sessions.
IBGP Peer Session	Number of IBGP peer sessions, including confederation IBGP and common IBGP peer sessions.
EBGP Peer Session	Number of EBGP peer sessions, including confederation EBGP and common EBGP peer sessions.

7.8.63 display bgp routing-table

Function

The **display bgp routing-table** command displays information about BGP routes. Information about specified routes can be displayed by specifying different parameters.

Format

display bgp routing-table [**verbose** | *ipv4-address* [{ *mask* | *mask-length* } [**longer-prefixes**]]]

display bgp routing-table [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp routing-table regular-expression *as-regular-expression*

display bgp routing-table community-filter { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp routing-table community [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp routing-table peer *ipv4-address* **received-routes** *ipv4-address* [{ *mask* | *mask-length* } [**longer-prefixes** | **original-attributes**]]

display bgp routing-table peer *ipv4-address* { **advertised-routes** [*ipv4-address* [{ *mask* | *mask-length* } [**longer-prefixes**]]] | **received-routes** [**active**] }

display bgp routing-table peer *ipv4-address* **accepted-routes**

display bgp routing-table time-range *start-time end-time*

Parameters

Parameter	Description	Value
verbose	Displays detailed information about BGP public network routes.	-
ipv4-address	Specifies an IPv4 network address.	The value is in dotted decimal notation.
mask | *mask-length*	Specifies a mask in dotted decimal notation or the mask length.	-
longer-prefixes	Matches any route whose prefix mask is longer than the specified length.	-
as-path-filter	Displays the routes that match a specified filter.	-
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer in the range from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The value is a string of 1 to 51 case-sensitive characters. It cannot contain spaces.

Parameter	Description	Value
cidr	Displays Classless InterDomain Routing (CIDR) information.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 characters.
different-origin-as	Displays routes that have the same destination address but different source AS numbers.	-
community-filter	Displays the routes that match a specified BGP community filter.	-
community-filter-name	Specifies the name of a community filter.	The name is a string of 1 to 51 characters. The string cannot contain only digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer in the range from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer in the range from 100 to 199.
community	Displays the routes carrying the specified BGP community attribute in the routing table.	-
community-number	Specifies a community number.	The value is an integer in the range from 0 to 4294967295.
aa:*nn*	Specifies a community number. A maximum of 29 community numbers can be set.	The values of *aa* and *nn* are both an integer in the range from 0 to 65535.
internet	Displays the BGP routes carrying the Internet community attribute.	-
no-advertise	Displays the BGP routes carrying the No-Advertise community attribute.	-

Parameter	Description	Value
no-export	Displays the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes carrying the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
peer *ipv4-address*	Displays routes of a specified peer.	-
advertised-routes	Displays the routes advertised to a specified peer.	-
received-routes	Displays the routes received from a specified peer.	-
active	Displays the active routes received from a specified peer.	-
original-attributes	Displays the original attributes of a public route from a specified BGP peer before the route is filtered by the local import policy. To display such attributes, the **peer keep-all-routes** command must have been run.	-
accepted-routes	Displays the routes that are received from the peer and filtered through a routing policy.	-

Parameter	Description	Value
time-range *start-time end-time*	Displays BGP routes that flap within the specified time period. For example, the value **0d0h5m0s** of *start-time* indicates 5 minutes before the current time. The value **0d0h10m0s** of *end-time* indicates 10 minutes before the current time. All BGP routes with the keepalive time in the range of 5 minutes to 10 minutes are displayed.	The value ranges of *start-time* and *end-time* are both **0d0h0m0s** to **10000d23h59m59s**.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can check information about specified routes by specifying different parameters.

The **display bgp routing-table** command is used to display active and inactive BGP routes on the public network.

Example

Display information about all BGP routes.

```
<HUAWEI> display bgp routing-table
 BGP Local router ID is 10.1.1.2
 Status codes: * - valid, > - best, d - damped, h - history,
               i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete
 Total Number of Routes: 4
      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn
 *     10.1.1.0/24        10.1.1.1        0                    0      100?
 *     10.1.1.2/32        10.1.1.1        0                    0      100?
 *>    10.1.1.0/24        10.1.1.1        0                    0      100?
 *>    10.1.1.0/24        10.1.1.1        0                    0      100?
```

Display routes with the community attribute.

```
<HUAWEI> display bgp routing-table community
 BGP Local router ID is 10.1.1.2
 Status codes: * - valid, > - best, d - damped, h - history,
               i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete
 Total Number of Routes: 4
      Network            NextHop        MED        LocPrf    PrefVal Community
```

```
*    10.1.1.0/24        10.1.1.1        0                  0      no-export
*    10.1.1.2/32        10.1.1.1        0                  0      no-export
*>   10.1.1.0/24        10.1.1.1        0                  0      no-export
*>   10.1.1.0/24        10.1.1.1        0                  0      no-export
```

Table 7-166 Description of the **display bgp routing-table** command output

Item	Description
BGP Local router ID	Router ID of the local BGP device.
Network	Network address in the BGP routing table.
NextHop	Next-hop address for packets.
MED	MED of a route.
LocPrf	Local preference.
PrefVal	Preferred value (PrefVal).
Path/Ogn	AS_Path number and Origin attribute.
Community	Community attribute information.

Display detailed information about a specified route.

```
<HUAWEI> display bgp routing-table 10.1.1.1
 BGP local router ID : 10.2.3.107
 Local AS number : 100
 Paths:   1 available, 1 best, 1 select
 BGP routing table entry information of 10.1.1.1/32:
 Imported route.
 From: 10.1.1.2 (10.1.1.2)
 Route Duration: 0d00h01m33s
 Direct Out-interface: Vlanif10
 Original nexthop: 10.1.1.2
 Qos information : 0x0
 AS-path 200, origin incomplete, MED 0, pref-val 0, valid, external, best, select, pre 255
 Advertised to such 1 peers:
    10.1.1.2
```

Table 7-167 Description of the **display bgp routing-table** command output

Item	Description
Local AS number	Local AS number.
Paths	Route selection result.
BGP routing table entry information of	Routing entry information.
Imported route	Route imported into the BGP routing table using the **import-route** command.
From	IP address of the device that advertises the route.

Item	Description
Route Duration	Route duration.
Direct Out-interface	Directly connected outbound interface.
Original nexthop	Original next hop. **NOTE** If no routes to the BGP original next hop are available in the IP routing table, BGP routes cannot be advertised. In this case, find out why there is no route to the original next hop (this fault is generally associated with IGP or static routes).
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* value varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* value varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.
AS-path	AS_Path attribute, with **Nil** indicating that the attribute value is null.
origin	Origin attribute of a BGP route. The value can be: ● IGP: If a route is added to the BGP routing table using the **network** command, its origin is IGP. ● EGP: indicates that the route is obtained through EGP. ● Incomplete: indicates that the origin of the route is unknown. For example, the origin attribute of the routes imported using the **import-route** command is Incomplete.
valid	Valid route.
external	External route.
best	Optimal route.
select	Preferred route.
pre	BGP route preference.

Display detailed information about a specified invalid BGP route.

```
<HUAWEI> display bgp routing-table 192.168.1.1
 BGP local router ID : 10.1.1.1
 Local AS number : 100
 Paths:   2 available, 0 best, 0 select
 BGP routing table entry information of 192.168.1.1/32:
 From: 10.1.1.2 (10.1.1.2)
 Route Duration: 00h01m31s
 Relay IP Nexthop: 0.0.0.0
 Relay IP Out-Interface:
 Original nexthop: 172.16.1.2
 Qos information : 0x0
 AS-path 200, origin incomplete, MED 0, localpref 100, pref-val 0, internal, pre 255, invalid for IP
unreachable
 Not advertised to any peer yet
```

Table 7-168 Description of the **display bgp routing-table** command output

Item	Description
BGP local router ID	ID of the local BGP router. The format is the same as an IPv4 address.
Local AS number	Local AS number.
Paths	Information about paths of BGP routes.
BGP routing table entry information of 192.168.1.1/32	The following information is about the route to 192.168.1.1/32.
From	IP address of the device that advertises the route.
Route Duration	Route duration.
Relay IP Nexthop	IP address of the recursive next hop.
Relay IP Out-Interface	Outbound interface obtained when the route recurses to another route.
Original nexthop	Original next hop.
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* value varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* value varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.

Item	Description
AS-path 200	AS_Path attribute.
origin incomplete	Origin attribute of a route. The value can be: - IGP: If a route is added to the BGP routing table using the **network (BGP)** command, its origin is IGP. - EGP: indicates that the route is obtained through EGP. - Incomplete: indicates that the origin of the route is unknown. For example, the origin of the routes that are added to the BGP routing table using the **import-route (BGP)** command is Incomplete.
MED	MED of a route.
localpref	Local preference.
pref-val	Preferred value (PrefVal).
internal	Internal route.
pre 255	The BGP route preference is 255.
invalid for IP unreachable	Reason why a route is invalid: - invalid for route-policy not pass: The route does not match the route-policy. - invalid for supernet route: The route is a supernet route. - invalid for IP unreachable: The route fails to recurse to another route. - invalid for supernet route not advertise: No supernet routes are advertised. - invalid for supernet label route not advertise: No supernet labeled routes are advertised. - invalid for next-hop unreachable: The next-hop IP address is unreachable. - invalid for tunnel unreachable: The route fails to recurse to a tunnel.
Not advertised to any peer yet	Flag indicating that the BGP route has not been advertised to any peer yet.

7.8.64 display bgp routing-table dampened

Function

The **display bgp routing-table dampened** command displays BGP dampened routes.

Format

display bgp [**vpnv4 vpn-instance** *vpn-instance-name*] **routing-table** [**statistics**] **dampened**

display bgp ipv6 routing-table [**statistics**] **dampened**

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table** [**statistics**] **dampened** (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table** [**statistics**] **dampened** (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
vpnv4	Displays the BGP routes of a VPNv4 instance.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
statistics	Displays the statistics of dampened routes.	-
ipv6	Displays all dampened IPv6 routes.	-
vpnv6	Displays the BGP routes of a VPNv6 instance.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the Route Distinguisher dampened BGP routes.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.

Usage Guidelines

If the length of the destination address mask of an IPv4 route is the same as that of its natural mask, the mask length is not displayed after the command is run.

Example

Display BGP dampened routes.

```
<HUAWEI> display bgp routing-table dampened

 BGP Local router ID is 10.1.41.102
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total Number of Routes: 8
     Network            From              Reuse     Path/Origin
  d  10.6.244.0/23      10.10.41.247      01:06:25  65534 4837 174 11096 6356i
  d  10.17.79.0/24      10.10.41.247      01:06:25  65534 837 3356 23504 29777i
  d  10.17.110.0/24     10.10.41.247      01:06:25  65534 837 3356 23504 29777i
  d  10.57.144.0/20     10.10.41.247      01:06:25  65534 4837 10026 9924 18429,18429i
  d  10.76.216.0/24     10.10.41.247      01:06:25  65534 4837 701 26959i
  d  10.78.142.0/24     10.10.41.247      01:06:25  65534 4837 701 26959i
  d  10.115.136.0/23    10.10.41.247      01:06:25  65534 4837 701 26956i
  d  10.243.170.0/24    10.10.41.247      01:06:25  65534 4837 701 26959i
```

Table 7-169 Description of the display bgp routing-table dampened command output

Item	Description
Network	Indicates the network address in the BGP routing table.
From	Indicates the IP address of the peer that receives the routes.
Reuse	Indicates the reuse value (in seconds).
Path/Origin	Indicates the AS_Path number and the Origin attribute.

Display IPv6 dampened routes in the BGP routing table.

```
<HUAWEI> display bgp ipv6 routing-table dampened

 BGP Local router ID is 10.0.0.2
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale,
               Origin : i - IGP, e - EGP, ? - incomplete

```

Table 7-170 Description of the **display bgp ipv6 routing-table dampened** command output

Item	Description
PrefixLen	Prefix length

7.8.65 display bgp routing-table dampening parameter

Function

The **display bgp routing-table dampening parameter** command displays configured BGP route dampening parameters.

Format

display bgp [**vpnv4 vpn-instance** *vpn-instance-name*] **routing-table dampening parameter**

display bgp ipv6 routing-table dampening parameter

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table dampening parameter** (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 all routing-table dampening parameter (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
vpnv4	Displays the BGP route dampening parameters of a VPNv4 instance.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv6	Displays configured BGP4+ route dampening parameters.	-
vpnv6	Displays the BGP route dampening parameters of a VPNv6 instance.	-

Usage Guidelines

You can run the **display bgp routing-table dampening parameter** command to check configured BGP route dampening parameters.

Example

Display BGP route dampening parameters.

```
<HUAWEI> display bgp routing-table dampening parameter
 Maximum Suppress Time(in second) : 3973
 Ceiling Value                    : 16000
 Reuse Value                      : 750
 HalfLife Time(in  second)        : 900
 Suppress-Limit                   : 2000
```

Table 7-171 Description of the display bgp routing-table dampening parameter command output

Item	Description
Maximum Suppress Time (in second)	Maximum time taken for route suppression, in seconds.
Ceiling Value	Penalty ceiling.
Reuse Value	Threshold for a route to be unsuppressed.
HalfLife Time(in second)	Half life of a reachable route, in seconds.
Suppress-Limit	Threshold for a route to be suppressed.

Display BGP4+ route dampening parameters.

```
<HUAWEI> display bgp ipv6 routing-table dampening parameter
 Maximum Suppress Time(in second) : 3069
 Ceiling Value                    : 16000
 Reuse Value                      : 750
 HalfLife Time(in  second)        : 900
 Suppress-Limit                   : 2000
```

7.8.66 display bgp routing-table flap-info

Function

The **display bgp routing-table flap-info** command displays statistics about BGP route flapping.

Format

display bgp [**vpnv4 vpn-instance** *vpn-instance-name*] **routing-table flap-info** [**regular-expression** *as-regular-expression*]

display bgp [**vpnv4 vpn-instance** *vpn-instance-name*] **routing-table flap-info** { **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *network-address* [{ *mask* | *mask-length* } [**longer-match**]] }

display bgp ipv6 routing-table flap-info [**regular-expression** *as-regular-expression*]

display bgp ipv6 routing-table flap-info { **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *network-address* [*prefix-length* [**longer-match**]] }

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table flap-info** [**regular-expression** *as-regular-expression*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table flap-info** { **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *network-address* [*prefix-length* [**longer-match**]] } (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table flap-info** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *ipv4-address* [{ *mask* | *mask-length* } [**longer-match**]]] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table flap-info** [**regular-expression** *as-regular-expression*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
vpnv4	Displays statistics about route flapping of a VPNv4 instance.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
regular-expression *as-regular-expression*	Displays statistics about the flapping routes that match the AS_Path regular expression.	The value is a string of 1 to 80 characters.
as-path-filter *as-path-filter-number*	Specifies the number of an AS_Path filter.	It is an integer that ranges from 1 to 256.

Parameter	Description	Value
as-path-filter *as-path-filter-name*	Specifies the name of an AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
network-address	Specifies the network address related to dampened routes.	-
mask	Specifies the network mask.	It is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
longer-match	Matches a route with a longer prefix.	-
prefix-length	Specifies the prefix length.	The value is an integer that ranges from 0 to 128.
vpnv6	Displays statistics about route flapping of a VPNv6 instance.	-
ipv4-address	Displays statistics about the flapping routes that match the IPv4 prefix.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the Route Distinguisher dampened BGP routes.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.

7.8.67 display bgp routing-table label

Function

The **display bgp routing-table label** command displays labeled routes in the BGP routing table.

Product	Support
S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5731-S, S5731S-S, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table label include-mask**

display bgp routing-table label [**statistics** | **include-mask**]

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table** [**statistics**] **label**

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table** [**statistics**] **label**

display bgp ipv6 routing-table [**statistics**] **label**

Parameters

Parameter	Description	Value
include-mask	Displays labeled routes carrying masks.	-

Parameter	Description	Value
statistics	Indicates statistics about labeled routes.	-
vpnv4	Displays VPNv4 labeled routes.	-
all	Displays the labeled routes of all VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv6	Displays BGP4+ labeled routes.	-
vpnv6	Displays VPNv6 labeled routes.	-

display bgp vpnv4 all routing-table peer *ipv4-address* **no-advertise** *network* [*mask* | *mask-length*] (supported only by the S5731-H, S5731S-H, S5731-S,

S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp ipv6 routing-table peer *ipv4-address* **no-advertise** *ipv6–network* [*prefix-length*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp multicast routing-table peer *ipv4-address* **no-advertise** *network* [*mask* | *mask-length*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv6 all routing-table peer *ipv4-address* **no-advertise** *ipv6–network* [*prefix-length*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table peer** *ipv6-address* **no-advertise** *ipv6–network* [*prefix-length*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp l2vpn-ad routing-table peer *ipv4-address* **no-advertise** *network* (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
peer *ipv4-address*	Displays the routes that a device is prevented from advertising to the specified IPv4 peer.	The value is in dotted decimal notation.
network	Displays the routes with the specified destination IPv4 address that are prevented from being advertised.	The value is in dotted decimal notation.
mask	Specifies the subnet mask of the specified IPv4 address.	The value is in dotted decimal notation.
mask-length	Specifies the subnet mask length of the specified IPv4 address.	The value is an integer that ranges from 0 to 32.
vpnv4	Displays the routes that a device is prevented from advertising to a specified peer in the VPNv4 address family.	-

Parameter	Description	Value
all	Displays the routes that a device is prevented from advertising to a specified peer in all VPN instances of the current address family.	-
vpn-instance *vpn-instance-name*	Displays the routes that a device is prevented from advertising to a specified peer in the specified VPN instance of the current address family.	The value must be an existing VPN instance name.
multicast	Displays the routes that a device is prevented from advertising to a specified peer in the IPv4 multicast address family.	-
ipv6	Displays the routes that a device is prevented from advertising to a specified peer in the IPv6 unicast address family.	-
peer *ipv6-address*	Displays the routes that a device is prevented from advertising to the specified IPv6 peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
ipv6–network	Displays the routes with the specified destination IPv6 address that are prevented from being advertised.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 0 to 128.
vpnv6	Displays the routes that a device is prevented from advertising to a specified peer in the VPNv6 address family.	-
l2vpn-ad	Displays the routes that a device is prevented from advertising to a specified peer in the L2VPN-AD address family.	-

1: Monitoring level

Usage Guidelines

To check the routes that a device is prevented from advertising to a specified peer in different address families, run the **display bgp routing-table peer no-advertise** command. The command output also includes the reasons why the routes are not advertised.

You can specify an address family to check the routes that a device is prevented from advertising to a specified peer in the address family. If you do not specify any address family, the command output shows the routes that a device is prevented from advertising to a specified peer in the IPv4 unicast address family.

Example

Display the route 10.3.3.4/32 that a device is prevented from advertising to peer with IP address 192.168.1.1 in the IPv4 unicast address family.

```
<HUAWEI> display bgp routing-table peer 192.168.1.1 no-advertise 10.3.3.4 32
 BGP routing table entry information of 10.3.3.4/32:
 From: 192.168.1.1 (10.1.1.1)
 Route Duration: 22h36m17s
 Relay IP Nexthop: 10.1.1.1
 Relay IP Out-Interface: Vlanif100
 Original nexthop: 192.168.1.1
 Qos information : 0x0
 AS-path Nil, origin incomplete, MED 0, localpref 100, pref-val 0, valid, internal, best, select, active, pre 255,
IGP cost 1
 No advertise without config reflect-client
```

Table 7-175 Description of the **display bgp routing-table peer no-advertise** command output

Item	Description
From	Peer from which the route was received.
Route Duration	Duration of the route.
Relay IP Nexthop	Next-hop IP address to which the route recurses.
Relay IP Out-Interface	Outbound interface to which the route recurses.
Original nexthop	Original next-hop IP address of the route.

Item	Description
Qos information	QoS information. - 0x20000000: indicates that the **apply behavior** command has been run. - 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. - 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. - 0x0: indicates that the preceding QoS configurations are not performed.
AS-path	AS_Path attribute. **Nil** indicates that the attribute value is null.
origin	Origin attribute: - IGP: indicates that the route is added to the BGP routing table using the **network (BGP)** command. - EGP: indicates that the route is learned through the EGP protocol. - Incomplete: indicates that the origin of the route cannot be identified. For example, if a route is imported using the **import-route (BGP)** command, its origin is **Incomplete**.
MED	MED of the route.
localpref	Local_Pref of the BGP route.
pref-val	PrefVal of the route.
valid	Valid route.
internal	Internal route.
best	Optimal route.
select	Selected route.
active	Active route.
pre 255	Priority of the route (255 in this example).
IGP cost 1	IGP cost of the route (1 in this example).

Item	Description
No advertise without config reflect-client	Reason why the route is not advertised: - No advertise with no-adv flag: The route carries the No-Advertise flag. - No advertise with peer default-route-advertise in vt family: The local device is configured to advertise only default routes to the peer in the VT address family. - No advertise with no-adv flag in community attr: The route carries the No-Advertise community attribute. - No advertise with no-export flag in community attr: The route carries the No-Export community attribute. - No advertise with no-export-subconfed flag in community attr: The route carries the No_Export_Subconfed community attribute. - No advertise by detail route with config aggregate: Specific routes for summarization are not advertised. - No advertise with config active-route-advertise: Only the active routes in the IP routing table are advertised. - No advertise with config peer upe and no export policy: The specified peer is a UPE, and the route fails to match the export policy. - No advertise without config reflect-client: No RR is configured. - No advertise with config reflect-client but without config reflect between-clients: Route reflection among RR clients is disabled. - No advertise for other reason: Other reasons prevent the route from being advertised.

7.8.69 display bgp routing-table peer statistics

Function

The **display bgp routing-table peer statistics** command displays statistics about received and advertised BGP routes.

Format

display bgp [**multicast** | **ipv6**] **routing-table peer statistics**

display bgp [**l2vpn** | **vpls** | **l2vpn-ad**] **routing-table peer statistics**

display bgp { **vpnv4** | **vpnv6** } { **all** | **vpn-instance** *vpn-instance-name* } **routing-table peer statistics**

display bgp l2vpn-ad routing-table [**all** | **vpls-ad** | **vpws** | **vpls**] **peer statistics**

NOTE

The **l2vpn**, **l2vpn-ad**, **vpls**, **vpls-ad**, **vpnv4**, and **vpnv6** parameters are supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H.

Parameters

Parameter	Description	Value
multicast	Displays statistics about routes in the IP multicast routing table.	-
l2vpn	Displays statistics about routes in the BGP-L2VPN address family.	-
vpls	Displays statistics about routes in the BGP VPLS address family.	-
ipv6	Displays statistics about routes in the BGP IPv6 unicast address family.	-
l2vpn-ad	Displays statistics about routes in the BGP L2VPN-AD address family.	-
vpnv4	Displays statistics about routes in the BGP-VPNv4 address family.	-
vpnv6	Displays statistics about routes in the BGP-VPNv6 address family.	-
all	Displays statistics about all types of routes.	-
vpn-instance *vpn-instance-name*	Specifies a VPN instance name.	The value must be an existing VPN instance name.
vpls-ad	Displays statistics about VPLS-AD routes.	-

Parameter	Description	Value
vpws	Displays statistics about virtual private wire service (VPWS) routes.	-
vpls	Displays statistics about virtual private LAN service (VPLS) routes.	-

1: Monitoring level

Usage Guidelines

To check statistics of received and advertised BGP routes, run the **display bgp routing-table peer statistics** command. You can specify parameters as needed. If no parameter is specified in the command, statistics about BGP IPv4 unicast routes are displayed.

Example

Display statistics about received and advertised BGP IPv4 unicast routes.

```
<HUAWEI> display bgp routing-table peer statistics
 BGP local router ID : 10.1.1.1
 Local AS number : 100
 Total number of peers : 3              Number of Peers in established state : 3

  Peer                  Received routes           Advertised routes

  10.2.2.2                1                      1
  10.2.2.3                1                      1
  10.3.3.3                2                      0
```

Table 7-176 Description of the **display bgp routing-table peer statistics** command output

Item	Description
BGP local router ID	Local router ID
Local AS number	AS number
Total number of peers	Total number of peers
Number of Peers in established state	Number of peers in the established state
Peer	IP address of a peer

Item	Description
Received routes	Total number of routes received from the peer
Advertised routes	Total number of routes advertised to the peer

7.8.70 display bgp routing-table statistics

Function

The **display bgp routing-table statistics** command displays statistics about BGP routes.

Format

display bgp routing-table statistics

display bgp routing-table statistics as-path-filter { *as-path-filter-number* | *as-path-filter-name* }

display bgp routing-table statistics cidr

display bgp routing-table statistics community [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp routing-table statistics community-filter { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp routing-table statistics dampened

display bgp routing-table statistics different-origin-as

display bgp routing-table statistics regular-expression *as-regular-expression*

display bgp routing-table peer *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

Parameters

Parameter	Description	Value
as-path-filter *as-path-filter-number*	Displays the routes that match an AS-Path filter with the specified number.	It is an integer that ranges from 1 to 256.

Parameter	Description	Value
as-path-filter *as-path-filter-name*	Displays the routes that match an AS-Path filter with the specified name.	The name is a string of 1 to 51 characters without any space. It is case-sensitive.
cidr	Displays CIDR information.	-
community	Displays the routes carrying the specified BGP community attribute in the routing table.	-
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
aa:*nn*	Specifies the community attribute number.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays the matching routes that can be sent to any peer.	-
no-advertise	Displays the BGP routes carrying the No-Advertise community attribute.	-
no-export	Displays the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes carrying the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
community-filter	Displays the routes that match a specified BGP community filter.	-
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.

Parameter	Description	Value
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community-filter-name	Specifies the name of a community filter.	The name is a string of 1 to 51 characters. The string cannot be all numbers.
dampened	Displays the statistics of BGP dampened roues.	-
different-origin-as	Displays routes that have the same destination address but different source AS numbers.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 characters.
peer *ipv4-address*	Displays the routing information for the specified BGP peer.	It is in dotted decimal notation.
advertised-routes	Displays the routes advertised to the specified peer.	-
received-routes	Displays the routes received from the specified peer.	-
active	Specifies the number of active routes.	-

Usage Guidelines

The **display bgp routing-table statistics** command is used to display statistics about BGP routes on the public network.

The **display bgp routing-table statistics as-path-filter** command is used to display statistics about the BGP routes that match the specified AS_Path filter on the public network.

The **display bgp routing-table statistics cidr** command is used to display statistics about the BGP CIDR information of the public network.

The **display bgp routing-table statistics community** command is used to display statistics about the BGP routes carrying the specified community attribute on the public network.

The **display bgp routing-table statistics community-filter** command is used to display statistics about the BGP routes that match the specified community filter on the public network.

The **display bgp routing-table statistics dampened** command is used to display statistics about BGP dampened routes on the public network.

The **display bgp routing-table statistics different-origin-as** command is used to display statistics about the BGP routes with the same destination address but different source AS numbers on the public network.

The **display bgp routing-table statistics regular-expression** command is used to display statistics about the BGP routes whose AS_Path information matches the AS_Path regular expression on the public network.

Example

Display route statistics.

```
<HUAWEI> display bgp routing-table statistics
 Total Number of Routes: 4
```

Table 7-177 Description of the display bgp routing-table statistics command output

Item	Description
Total Number of Routes	Total number of routes in the routing table

7.8.71 display bgp update-peer-group

Function

The **display bgp update-group** command displays information about update-groups. By setting **index** in the command displays detailed information about a specified update-group. If no address family is specified, information about the update-group of the IPv4 unicast address family is displayed by default.

Format

display bgp update-peer-group [**index** *update-group-index*]

display bgp ipv6 update-peer-group [**index** *update-group-index*]

display bgp vpnv4 all update-peer-group [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 vpn-instance *vpn-instance-name* **update-peer-group** [**index** *update-group-index*]

display bgp vpnv6 all update-peer-group [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv6 vpn-instance *vpn-instance-name* **update-peer-group** [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp l2vpn all update-peer-group [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpls all update-peer-group [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp l2vpn-ad update-peer-group [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp { **mdt** | **mvpn** } **all update-peer-group** [**index** *update-group-index*] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
index *update-group-index*	Specifies the index of an update-group.	The value is an integer that ranges from 0 to 65535.
ipv6	Displays information about the BGP update-groups of IPv6 routes.	-
vpnv4	Displays information about the BGP update-groups of a VPNv4 instance.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
vpnv6	Displays information about the BGP update-groups of a VPNv6 instance.	-

Parameter	Description	Value
all	Displays information about all the update-groups in a VPNv6 address family.	-
l2vpn	Displays information about L2VPN BGP update-groups.	-
vpls	Displays information about VPLS BGP update-groups.	-
l2vpn-ad	Displays information about L2VPN-AD BGP update-groups.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify the index of an update-group to view detailed information about the specified update-group. If no address family is specified, information about the update peer-groups in the IPv4 unicast address family is displayed by default.

Example

Display information about the update peer-groups in the IPv4 unicast address family.

```
<HUAWEI> display bgp update-peer-group
 The Public instance's update peer group number : 1
 Keep buffer update peer group number : 0
 BGP Version : 4
 Group ID : 0
 Group Type : external
 Addr Family : IPv4-UNC
 AdvMinTimeVal : 30
 Total Peers : 1
 Leader Peer : 192.168.1.2
 Peers List : 192.168.1.2
```

Table 7-178 Description of the display bgp update-peer-group command output

Item	Description
The Public instance's update peer group number	Number of update-groups in the instance

Item	Description
Keep buffer update peer group number	Number of packets in update-groups saved in the batch buffer
BGP Version	Indicates the BGP version.
Group ID	Indicates the ID of the update-group.
Group Type	Indicates the type of the update-group, which can be one of the following: ● external: indicates that this is an EBGP peer group. ● internal: indicates that this is an IBGP peer group. ● unknown: indicates that the type is unknown.
Addr Family	Indicates the address family.
AdvMinTimeVal	Indicates the minimum interval for sending Update packets with the same route prefix.
Total Peers	Indicates the total number of peers in an update-group.
Leader Peer	Indicates the representative of an update-group.
Peers List	Indicates a list of peers.

Display information about the update-group with a specified index.

```
<HUAWEI> display bgp update-peer-group index 0
 Group ID : 0
 BGP Version : 4
 Group Type : external
 Addr Family : IPv4-UNC
 AdvMinTimeVal : 30
 Total Peers : 1
  Leader Peer : 192.168.1.2

 Total format packet number : 3
 Total send packet number : 3
 Total replicate packet number : 0
 The replication percentages(%) : 0

 Peers List : 192.168.1.2
```

Table 7-179 Description of the display bgp update-peer-group index command output

Item	Description
Total format packet number	Indicates the total number of formatted packets.
Total send packet number	Indicates the total number of sent packets.

Item	Description
Total replicate packet number	Indicates the total number of replicate packets, which equals the total number of sent packets minus the total number of formatted packets.
The replication percentages(%)	Indicates the replication percentage, which is obtained with the formula: (Total number of sent packets - Total number of formatted packets) x 100/Total number of formatted packets.

7.8.72 display bgp vpnv4 brief

Function

The **display bgp vpnv4 brief** command displays brief information about VPNv4 and VPN instances (IPv4 address family).

Format

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **brief**

Parameters

Parameter	Description	Value
all	Displays information about all VPNv4 and VPN instances (IPv4 address family).	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the **display bgp vpnv4 brief** command is used to display information about VPNv4 and VPN instances (IPv4 address family), the VPN instances are displayed and arranged alphabetically by name.

Example

Display brief information about VPNv4 instances and all VPN instances (IPv4 address family).

```
<HUAWEI> display bgp vpnv4 all brief

VPNV4 :
 Rd Num            Peer Num           Route Num
 0              1              0

VPN-Instance(IPv4-family):
 VPN-Instance Name   Peer Num            Route Num
 vrf0              0              0
 vrf1              0              0
 vrf11              0              0
 vrf12              0              0
 vrf13              0              0
 vrf14              0              0
 vrf2              0              20
 vrf3              0              20
 vrf4              0              24
 vrf5              0              24
 vrf6              0              0
 vrf7              0              0
 vrf8              0              20
```

Table 7-180 Description of the display bgp vpnv4 brief command output

Item	Description
Rd Num	Indicates the number of RDs.
Peer Num	Indicates the number of peers.
Route Num	Indicates the number of routes.
VPN-Instance Name	Indicates the name of a VPN instance.

7.8.73 display bgp vpnv4 routing-table

Function

The **display bgp vpnv4 routing-table** command displays BGP routes of VPNv4 address family and the private networks.

Format

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
all	Displays all BGP VPNv4 routes.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the BGP routes with the specified RD.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number: 2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.
vpn-instance *vpn-instance-name*	Displays the BGP routes of a specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS-Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS-Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
cidr	Displays CIDR information.	-
different-origin-as	Displays the routes that have the same destination address but different source AS numbers.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 characters.
verbose	Displays detailed information about BGP VPNv4 routes.	-
ipv4-address	Specifies the destination address.	-
mask	Specifies a mask in dotted decimal notation.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
peer *ipv4-address*	Displays routes of a specified peer.	-
advertised-routes	Displays the routes advertised to a specified peer.	-

Parameter	Description	Value
network	Specifies the IPv4 network address.	The value is in dotted decimal notation.
longer-prefixes	Matches any route whose prefix mask is longer than the specified length.	-
received-routes	Displays the routes received from a specified peer.	-
active	Displays the active routes received from a specified peer.	-
original-attributes	Displays the original attributes of a BGP route from a specified BGP peer before the route is filtered by the local import policy. To display such attributes, the **peer keep-all-routes** command must have been run.	-
community-filter	Displays the routes that match a specified BGP community filter.	-
community-filter-name	Specifies the name of a community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
whole-match	Indicates exact matching.	-
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community	Displays the routes carrying the specified BGP community attribute in the routing table.	-

Parameter	Description	Value
community-number	Specifies the number of a community.	-
aa:*nn*	Specifies the community number. A maximum of 29 community numbers can be set.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays the matching routes that can be sent to any peer.	-
no-advertise	Displays the BGP routes carrying the No-Advertise community attribute.	-
no-export	Displays the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes carrying the No-Export-Subconfed community attribute.	-
accepted-routes	Displays the routes that are received from a neighbor and accepted by a routing policy.	-
time-range *start-time end-time*	Displays information about BGP VPNv4 routes that have undergone status flapping during the specified period. For example, when *start-time* is set to 0d0h5m0s and *end-time* is set to 0d0h10m0s, information about all BGP VPNv4 routes whose lifetime ranges from 5 to 10 minutes is displayed.	In the values of *start-time* and *end-time*, d ranges from 0 to 10000, h ranges from 0 to 23, m ranges from 0 to 59, and s ranges from 0 to 59.

Usage Guidelines

You can specify different parameters to view the specific routing information.

When BGP routing table is displayed, if the length of the destination address mask of an IPv4 route is the same as that of its natural mask, the mask length is not displayed.

You can run the **display bgp vpnv4** { **all** | **vpn-instance** *vpn-instance-name* } **routing-table time-range** *start-time end-time* command to view BGP VPNv4 routes that flap within the specified time period. For example, if service traffic is abnormal or CPU usage of the device remains high within a certain time period, you can run this command to check whether route flapping occurs within the specified time period. The faulty route can be viewed in the command output, facilitating fault location.

Example

Display all the BGP routing information of the VPN instance named vpn1.

```
<HUAWEI> display bgp vpnv4 vpn-instance vpn1 routing-table

 BGP Local router ID is 10.1.1.9
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 VPN-Instance vpn1, Router ID 10.1.1.9:

 Total Number of Routes: 4
      Network            NextHop        MED        LocPrf    PrefVal Path/Ogn

Table 7-181 Description of the display bgp vpnv4 routing-table command output

Item	Description
BGP Local router ID	ID of the local BGP device.
Network	Network address in the BGP routing table.
NextHop	Next Hop address through which the packet has to be sent
MED	MED of the route.
LocPrf	Local preference.
PrefVal	Preferred value.
Peer	Peer IP address
Duration	Route duration
Path/Ogn	AS_Path number and the origin attribute.
Community	Community attribute information.

Display information about a specified VPNv4 route.

Imported route	Routes imported to BGP using the **import-route** command.
Label information (Received/ Applied)	Information about labels, including received and sent labels.
From	IP address of the route originator.
Route Duration	Route duration.
Direct Out-interface	Direct outbound interface.
Original nexthop	Original next hop.
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.
Ext-Community	Extended community attribute of BGP.
AS-path	AS_Path attribute.
origin	Origin attribute of the BGP route. ● IGP: indicates that the origin attribute of a route added to the BGP routing table by using the **network** command is IGP. ● EGP: indicates that the origin attribute of a route obtained by using EGP is EGP. ● Incomplete: indicates that the origin attribute of a route whose source is unknown is Incomplete. For example, the origin attribute of the routes imported by using the **import-route** command is Incomplete.
pref-val	Preferred value.
valid	Valid BGP route.

Item	Description
external	The BGP route is learned from the EBGP peer.
best	The BGP route is the optimal route.
select	The BGP route is a preferred route.
pre 255	The preference of the BGP route is 255.
Advertised to such 1 peers	The BGP route has been advertised to one peer.
Not advertised to any peer yet	The BGP route has not been advertised to any peer.
VPN-Instance vpna, Router ID 10.2.2.9	The VPN instance is vpna, the Route ID is 10.2.2.9
Total Number of Routes	Number of routes in VPN instance vpna.

Display detailed information about the specified invalid BGP VPNv4 routes.

```
<HUAWEI> display bgp vpnv4 all routing-table 192.168.4.4
 BGP local router ID : 10.1.1.1
 Local AS number : 100

 Total routes of Route Distinguisher(10:10): 1
 BGP routing table entry information of 192.168.4.4/32:
 Label information (Received/Applied): 1025/NULL
 From: 10.1.1.2 (10.1.1.2)
 Route Duration: 00h12m26s

```

Table 7-183 Description of the display bgp vpnv4 routing-table command output

Item	Description
BGP local router ID	ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
Total routes of Route Distinguisher(10:10)	Total number of BGP VPNv4 routes of the specified RD.
BGP routing table entry information of 192.168.4.4/32	The following information is about 192.168.4.4/32 routing entries.
Label information (Received/ Applied)	Label information (received or sent).
From	IP address of the device that sends the route. 10.1.1.2 is the IP address of the source interface of the peer with which the BGP connection is established, and 10.1.1.2 is the Router ID of the peer.
Route Duration	Duration of routes.
Relay IP Nexthop	Recursive next hop.
Relay IP Out-Interface	Recursive outbound interface.
Relay Tunnel Out-Interface	Tunnel recursed outbound interface.
Relay token	Recursive token value used for MPLS forwarding, which is a part of tunnel ID and is assigned by the system.
Original nexthop	Original next hop.
Qos information	QoS information. ● 0x20000000: indicates that the **apply behavior** command has been run. ● 0x40000001–0x40000FFF: indicates that the **apply qos-local-id** *qos-local-id* command has been run and the *qos-local-id* varies from 1 to 4095. ● 0x80000001–0x80000007: indicates that the **apply ip-precedence** *precedence* command has been run and the *precedence* varies from 1 to 7. ● 0x0: indicates that the preceding QoS configurations are not performed.
Ext-Community	Extended community attribute.
AS-path Nil	AS_Path attribute, with Nil indicating that the attribute value is null.

Item	Description
origin incomplete	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
MED	Multi-Exit discriminator of route.
localpref	Local priority.
pref-val	Value preferred by the protocol.
valid	The BGP route is a valid route.
internal	The BGP route is an internal route.
best	The BGP route is an optimal route.
select	The BGP route is a preferred route.
pre 255	The priority of the BGP route is 255.

Item	Description
invalid for tunnel unreachable	Reason why a route is invalid: ● invalid for route-policy not pass: The route does not match the route-policy. ● invalid for supernet route: The route is a supernet route. ● invalid for IP unreachable: The route fails to recurse to another route. ● invalid for supernet route not advertise: No supernet routes are advertised. ● invalid for supernet label route not advertise: No supernet labeled routes are advertised. ● invalid for next-hop unreachable: The next-hop IP address is unreachable. ● invalid for tunnel unreachable: The route fails to recurse to a tunnel.
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.
VPN-Instance vrf1, Router ID 10.1.1.1	The local VPN instance is vrf1, and its router ID is 10.1.1.1.
Total Number of Routes	Total number of BGP VPNv4 routes that match 192.168.4.4/32 in VPN instance vrf1.

7.8.74 display bgp vpnv4 routing-table statistics

Function

The **display bgp vpnv4 routing-table statistics** command displays statistics about BGP VPNv4 routes.

Format

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table statistics**

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **cidr** | **different-origin-as**]

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table statistics regular-expression** *as-regular-expression* (supported only by the S5731-

H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table statistics regular-expression** *as-regular-expression*

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table statistics community** [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table statistics community** [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp vpnv4 { **all** | **route-distinguisher** *route-distinguisher* } **routing-table statistics community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* } (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table statistics community-filter** { { *community-filter-name* | *basic-community-filter-number* } [**whole-match**] | *advanced-community-filter-number* }

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table statistics dampened**

display bgp vpnv4 all routing-table peer *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics** (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display bgp vpnv4 vpn-instance *vpn-instance-name* **routing-table peer** *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

Parameters

Parameter	Description	Value
all	Displays all the statistics of BGP VPNv4 routes.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays statistics about the BGP routes with a specified RD.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number: 2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.
vpn-instance *vpn-instance-name*	Displays statistics about the BGP routes of a specified VPN instance.	The value must be an existing VPN instance name.
as-path-filter	Displays the routes that match the specified filter.	-

Parameter	Description	Value
as-path-filter-number	Specifies the number of the matching AS-Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS-Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
cidr	Displays CIDR statistics.	-
different-origin-as	Displays statistics about the routes that have the same destination address but different source AS numbers.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 characters.
community	Displays statistics about the routes carrying the specified BGP community attribute in the routing table.	-
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
aa:*nn*	Specifies a community attribute value.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays statistics about the matching routes that can be sent to any peer.	-
no-advertise	Displays statistics about the BGP routes carrying the No-Advertise community attribute.	-

Parameter	Description	Value
no-export	Displays statistics about the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays statistics about the BGP routes carrying the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
community-filter	Displays statistics about the routes that match a specified BGP community filter.	-
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
community-filter-name	Specifies the name of a community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits.
dampened	Displays the statistics of BGP dampened routes.	-
active	Displays statistics about the routes that have the same destination address but different source AS numbers.	-
peer *ipv4-address*	Displays statistics about routes of a specified peer.	It is in dotted decimal notation.
advertised-routes	Displays statistics about the routes advertised to a specified peer.	-

Parameter	Description	Value
received-routes	Displays statistics about the routes received from a specified peer.	-

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp vpnv4 routing-table statistics** command to check statistics about BGP VPNv4 routes.

Example

Display statistics about BGP VPNv4 routes.

```
<HUAWEI> display bgp vpnv4 all routing-table statistics

 Total number of routes from all PE: 2

 VPN-Instance vpn1, Router ID 10.1.1.9:

 Total Number of Routes: 2
```

Table 7-184 Description of the display bgp vpnv4 routing-table statistics command output

Item	Description
Total number of routes from all PE	Total number of VPNv4 routes
VPN-Instance vpn1	Indicating the name of VPN instance is vpn1.
Router ID 10.1.1.9	Indicating the router ID is 10.1.1.9.
Total Number of Routes	Total number of routes of the VPN instance.
Route Distinguisher	RD of the VPN instance IPv4 address family.

7.8.75 display bgp vpnv6 brief

Function

The **display bgp vpnv6 brief** command displays brief information about VPNv6 and VPN instances (IPv6 address family).

Product	Support
S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5731-S, S5731S-S, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **brief**

Parameters

Parameter	Description	Value
all	Displays information about all VPNv6 and VPN instances (IPv6 address family).	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPNv6 instance.	The value must be an existing VPN instance name.

1: Monitoring level

Usage Guidelines

After the **display bgp vpnv6 brief** command is used to display information about VPNv6 and VPN instances (IPv6 address family), the VPN instances are displayed and arranged alphabetically by name.

Example

Display brief information about VPNv6 and VPN instances (IPv6 address family).

```
<HUAWEI> display bgp vpnv6 all brief
VPNV6:
  Rd Num              Peer Num            Route Num
    2                   1                   2

VPN-Instance(IPv6-family):
  VPN-Instance Name   Peer Num            Route Num
    vrf0                1                   2
    vrf1                0                   0
    vrf11               0                   0
    vrf12               0                   0
    vrf13               0                   0
    vrf14               0                   0
    vrf2                0                   20
    vrf3                0                   20
    vrf4                0                   24
    vrf5                0                   24
    vrf6                0                   0
```

Table 7-185 Description of the display bgp vpnv6 all brief command output

Item	Description
Rd Num	Number of RDs.
Peer Num	Number of peers.
Route Num	Number of routes.
VPN-Instance Name	Name of a VPN instance.

7.8.76 display bgp vpnv6 routing-table

Function

The **display bgp vpnv6 routing-table** command displays BGP VPNv6 routes.

Product	Support
S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported

display bgp vpnv6 all routing-table peer *ipv4-address* { **advertised-routes** [*dest-ipv6-address* [*prefix-length*]] | **received-routes** [**active**] }

Parameters

Parameter	Description	Value
all	Displays statistics about all BGP VPNv6 routes.	-
vpn-instance *vpn-instance-name*	Displays the BGP routes of a specified an IPv6 address family-enabled VPN instance on the local end.	The value must be an existing VPN instance name.

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays the BGP routes with the specified RD.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a peer to be displayed.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
verbose	Displays detailed information about BGP VPNv6 routes.	-
prefix-length	Specifies the prefix length of an IPv6 address.	-
as-path-filter	Displays the routes that match the specified filter.	-
as-path-filter-number	Specifies the number of the matching AS-Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS-Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
community	Displays the routes carrying the specified BGP community attribute in the routing table.	-
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
aa:nn	Specifies the community number. A maximum of 29 community numbers can be set.	-
internet	Displays the BGP routes carrying the Internet community attribute.	-
no-advertise	Displays the BGP routes carrying the No-Advertise community attribute.	-

Parameter	Description	Value
no-export	Displays the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays the BGP routes carrying the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
community-filter	Displays the routes that match a specified BGP community filter.	-
community-filter-name	Specifies the name of a community filter.	-
basic-community-filter-number	Specifies the number of a basic community filter.	-
advanced-community-filter-number	Specifies the number of an advanced community filter.	-
different-origin-as	Displays the routes that have the same destination address but different source AS numbers.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 characters.
peer *ipv6-address*	Displays the BGP routes of a specified peer.	-
ipv4-address	Specifies the IPv4 address of the peer.	The value is in dotted decimal notation.
advertised-routes	Displays the routes advertised to a specified peer.	-

Parameter	Description	Value
dest-ipv6–address	Specifies the destination IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
received-routes	Displays the routes received from a specified peer.	-
active	Displays the active routes received from a specified peer.	-
original-attributes	Displays the original attributes of a BGP route from a specified BGP peer before the route is filtered by the local import policy. To display such attributes, the **peer keep-all-routes** command must have been run.	-
accepted-routes	Displays the routes that are received from a neighbor and accepted by a routing policy.	-
time-range *start-time end-time*	Displays information about BGP VPNv6 routes that have undergone status flapping during the specified period. For example, when *start-time* is set to 0d0h5m0s and *end-time* is set to 0d0h10m0s, information about all BGP VPNv6 routes whose lifetime ranges from 5 to 10 minutes is displayed.	In the values of *start-time* and *end-time*, d ranges from 0 to 10000, h ranges from 0 to 23, m ranges from 0 to 59, and s ranges from 0 to 59.

Usage Guidelines

Information about specified routes can be displayed by specifying different parameters.

To view information about BGP VPNv6 route flapping during a specified period, you can run the **display bgp vpnv6** { **all** | **vpn-instance** *vpn-instance-name* } **routing-table time-range** *start-time end-time* command. When service traffic is abnormal during a period of time, you can run this command to check whether route flapping occurs. When the CPU usage is high during a period of time, you can run this command to check whether a large number of routes have undergone status flapping. This command allows you to find the flapping routes, which facilitates fault location.

Example

Display all BGP VPNv6 routes.

```
<HUAWEI> display bgp vpnv6 all routing-table

 BGP Local router ID is 10.1.1.1
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total number of routes from all PE: 3

Table 7-186 Description of the display bgp vpnv6 all routing-table command output

Item	Description
BGP Local router ID	ID of the local BGP router. The ID is in the same format as an IPv4 address.

Item	Description
Total number of routes from all PE	Total number of BGP VPNv6 routes received by the switch from its peer PEs.
Network	Destination network or host address of the route.
PrefixLen	Prefix length of the destination network or host address of the route.
NextHop	IPv6 address of the next hop.
LocPrf	Local preference of the BGP route. The default value is 100.
MED	MED of the route. The default value is 0.
PrefVal	Preferred value of the route.
Label	Label carried by the data packet destined for the destination network or host address of the route.
Duration	Route duration.
Peer	IP addresses of the peer.
Path/Ogn	AS_Path number and Origin attribute of the route.

Display the routes of an IPv6 address family-enabled VPN instance named vpn1 on the local device.

```
<HUAWEI> display bgp vpnv6 vpn-instance vpn1 routing-table

 BGP Local router ID is 10.1.1.9
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale

unreachable
 Not advertised to any peer yet
```

Table 7-187 Description of the display bgp vpnv6 routing-table command output

Item	Description
BGP local router ID	Router ID of the local BGP device. The format is the same as the IPv4 address.
Local AS number	Local AS number.
VPN-Instance vrf1, Router ID 10.1.1.1	The local VPN instance is vrf1, and its router ID is 10.1.1.1.
Paths	Information about paths of BGP routes
BGP routing table entry information of fc00:0:0:2001::5/128	The following information is about fc00:0:0:2001::5/128 routing entries.
Label information (Received/ Applied)	Label information (received or sent).
From	IP address of the router that sends the route. 10.1.1.2 is the source interface IP address of the peer with which the BGP connection is established, and 10.1.1.2 is the router ID of the peer.
Route Duration	Duration of routes.
Relay Tunnel Out-Interface	Tunnel recursed outbound interface.
Relay token	Recursive token value used for MPLS forwarding, which is a part of tunnel ID and is assigned by the system.
Original nexthop	Original next hop.
Ext-Community	Extended community attribute.
AS-path Nil	AS_Path attribute, with Nil indicating that the attribute value is null.

Item	Description
origin	Well-known mandatory property. This property defines the origin of a path and records how a route turns to a BGP route. The property has the following three values: ● IGP: The priority of this value is the highest. The origin property of the routes that are added to the BGP routing table by using the **network (BGP)** command is IGP. ● EGP: The priority of this value is second to that of IGP. The origin property of the routes imported from EGP is EGP. ● Incomplete: The priority of this value is the lowest. The value indicates the origin of a route is unknown. The origin property of the routes that are added to the BGP routing table by using the **import-route (BGP)** command is Incomplete.
MED	Multi-Exit discriminator of route.
localpref	Local priority.
pref-val	Preferred value of the protocol.
internal	The BGP route is an internal route.
pre 255	The priority of the BGP route is 255.
invalid for tunnel unreachable	Reason why a route is invalid: ● invalid for route-policy not pass: The route does not match the route-policy. ● invalid for supernet route: The route is a supernet route. ● invalid for IP unreachable: The route fails to recurse to another route. ● invalid for supernet route not advertise: No supernet routes are advertised. ● invalid for supernet label route not advertise: No supernet labeled routes are advertised. ● invalid for next-hop unreachable: The next-hop IP address is unreachable. ● invalid for tunnel unreachable: The route fails to recurse to a tunnel.

Item	Description
Not advertised to any peer yet	The BGP route has not been advertised to any peer yet.

7.8.77 display bgp vpnv6 routing-table statistics

Function

The **display bgp vpnv6 routing-table statistics** command displays statistics about BGP VPNv6 routes.

Product	Support
S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5731-S, S5731S-S, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

display bgp vpnv6 route-distinguisher *route-distinguisher* **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **different-origin-as**]

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table statistics** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | **different-origin-as**]

display bgp vpnv6 route-distinguisher *route-distinguisher* **routing-table statistics regular-expression** *as-regular-expression*

display bgp vpnv6 { **all** | **vpn-instance** *vpn-instance-name* } **routing-table statistics regular-expression** *as-regular-expression*

display bgp vpnv6 route-distinguisher *route-distinguisher* **routing-table statistics community** [*community-number* | *aa:nn*] &<1-29> [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] * [**whole-match**]

display bgp vpnv6 all routing-table peer *ipv4-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

display bgp vpnv6 vpn-instance *vpn-instance-name* **routing-table peer** *ipv6-address* { **advertised-routes** | **received-routes** [**active**] } **statistics**

Parameters

Parameter	Description	Value
all	Displays statistics about all BGP VPNv6 routes.	-

Parameter	Description	Value
route-distinguisher *route-distinguisher*	Displays BGP routes with the specified RD.	The RD formats are divided into the following types: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.
vpn-instance *vpn-instance-name*	Displays statistics about the BGP routes of a specified VPN instance.	The value must be an existing VPN instance name.
as-path-filter	Displays the routes that match the specified filter.	-

Parameter	Description	Value
as-path-filter-number	Specifies the number of the matching AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter-name	Specifies the name of the matching AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
different-origin-as	Displays statistics about the routes that have the same destination address but different source AS numbers.	-
regular-expression *as-regular-expression*	Specifies the regular expression used to match the AS_Path information.	The value is a string of 1 to 80 case-sensitive characters. It cannot contain spaces.
community	Displays statistics about the routes carrying the specified BGP community attribute in the routing table.	-
community-number	Specifies the community number.	The value is an integer that ranges from 0 to 4294967295.
aa:nn	Specifies the community number.	Both *aa* and *nn* are integers ranging from 0 to 65535.
internet	Displays statistics about the BGP routes carrying the Internet community attribute.	-
no-advertise	Displays statistics about the BGP routes carrying the No-Advertise community attribute.	-

Parameter	Description	Value
no-export	Displays statistics about the BGP routes carrying the No-Export community attribute.	-
no-export-subconfed	Displays statistics about the BGP routes carrying the No-Export-Subconfed community attribute.	-
whole-match	Indicates exact matching.	-
community-filter	Displays statistics about the routes that match a specified BGP community filter.	-
community-filter-name	Specifies the name of a community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces.
basic-community-filter-number	Specifies the number of a basic community filter.	The value is an integer that ranges from 1 to 99.
advanced-community-filter-number	Specifies the number of an advanced community filter.	The value is an integer that ranges from 100 to 199.
peer *ipv6-address*	Displays statistics about the BGP routes of a specified peer.	-
advertised-routes	Displays statistics about the routes advertised to a specified peer.	-
received-routes	Displays statistics about the routes received from a specified peer.	-
active	Specifies the number of active routes.	-
peer *ipv4-address*	Displays the routing information for the specified BGP peer.	-

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display bgp vpnv6 routing-table statistics** command to check statistics about BGP VPNv6 routes.

Example

Display statistics about BGP VPNv6 routes on the local device.

```
<HUAWEI> display bgp vpnv6 all routing-table statistics

 Total number of routes from all PE: 2

 VPN-Instance vpn1, Router ID 10.4.4.4 :

 Total Number of Routes: 2
```

Display statistics about the BGP4+ routes of an IPv6 address family-enabled VPN instance named **vpn1** on the local device.

```
<HUAWEI> display bgp vpnv6 vpn-instance vpn1 routing-table statistics

 Total Number of Routes: 5
```

Display statistics about the BGP VPNv6 routes received from peer 10.1.1.1.

```
<HUAWEI> display bgp vpnv6 all routing-table peer 10.1.1.1 received-routes statistics
  Received routes total: 1
```

Display statistics about the VPNv6 routes that have the Internet community attribute and specified RD on the local device.

```
<HUAWEI> display bgp vpnv6 route-distinguisher 100:1 routing-table statistics community internet

 Total number of routes from all PE: 1

 VPN-Instance vpn1, Router ID 10.4.4.4 :

 Total Number of Routes: 2
```

Display statistics about the BGP VPNv6 routes that match a specified community filter on the local device.

```
<HUAWEI> display bgp vpnv6 all routing-table statistics community-filter 1

 Total number of routes from all PE: 1

 VPN-Instance vpn1, Router ID 10.4.4.4 :

 Total Number of Routes: 2
```

Display statistics about the BGP VPNv6 routes that match a specified AS_Path regular expression.

```
<HUAWEI> display bgp vpnv6 all routing-table statistics regular-expression 65420*

 Total number of routes from all PE: 1
```

```
 VPN-Instance vpn1, Router ID 10.4.4.4 :

 Total Number of Routes: 1
```

Display statistics of BGP routes sent by the local device to peer 2001:db8:1::1 of the IPv6 VPN instance named **vpn1**.

```
<HUAWEI> display bgp vpnv6 vpn-instance vpn1 routing-table peer 2001:db8:1::1 received-routes
statistics
  Received routes total: 2
```

Display statistics about the IPv6 routes sent by the local device to peer 2001:db8:1::1 in a VPN instance named **vpn1**.

```
<HUAWEI> display bgp vpnv6 vpn-instance vpn1 routing-table peer 2001:db8:1::1 advertised-routes
statistics
  Advertised routes total: 2

  Default originated : 0
```

7.8.78 display default-parameter bgp

Function

The **display default-parameter bgp** command displays default configurations in BGP initialization.

Format

display default-parameter bgp

Parameters

None

1: Monitoring level

Usage Guidelines

You can run the **display default-parameter bgp** command to check default configurations in BGP initialization.

Example

Display default configurations in BGP initialization.

```
<HUAWEI> display default-parameter bgp
BGP version                  : 4
EBGP preference              : 255
IBGP preference              : 255
Local preference             : 255
BGP connect-retry            : 32s
```

```
BGP holdtime                 : 180s
BGP keepAlive                : 60s
EBGP route-update-interval  : 30s
IBGP route-update-interval  : 15s
Default local-preference    : 100
Default MED                  : 0
Default TRACKING TIMER      : 9
IPv4-family unicast         : enable
EBGP-interface-sensitive    : enable
Reflect between-clients     : enable
Check-first-as              : enable
Synchronization             : disable
Nexthop-resolved rules      :
    IPv4-family             : unicast(ip)
                              label-route(ip)
                              multicast(ip)
                              vpn-instance(tunnel)
                              vpnv4(ip)
    IPv6-family             : unicast(ip)
                              vpn-instance(tunnel)
                              vpnv6(ip)
                              6PE(tunnel)
    L2VPN-AD-family         : ip
 Routing-table limit max-alarm upper limit : 100
 Routing-table limit max-alarm lower limit : 95
 Routing-table limit threshold-alarm upper limit : 80
 Routing-table limit threshold-alarm lower limit : 70
```

Table 7-188 Description of the **display default-parameter bgp** command output

Item	Description
BGP version	BGP version number.
EBGP preference	EBGP route preference.
IBGP preference	IBGP route preference.
Local preference	Local route preference.
BGP connect-retry	BGP ConnectRetry interval.
BGP holdtime	BGP holdtime interval.
BGP keepAlive	BGP keepalive interval.
EBGP route-update-interval	Minimum interval for sending EBGP Update messages.
IBGP route-update-interval	Minimum interval for sending IBGP Update messages.
Default local-preference	Local preference of a BGP route.
Default MED	MED of a BGP route.
Default TRACKING TIMER	The interval between peer unreachability discovery and connection interruption.
IPv4-family unicast	BGP-IPv4 unicast address family view.

Item	Description
EBGP-interface-sensitive	The BGP session between the directly connected peer and an interface is deleted immediately when the interface becomes Down.
Reflect between-clients	Route reflection between clients.
Check-first-as	The first AS number in the AS_Path list that is carried in the Update message sent by the EBGP peer is checked.
Synchronization	Synchronization between IBGP and IGP.
Nexthop-resolved rules	Default recursion mode of preferred routes.
Routing-table limit max-alarm upper limit	Upper alarm threshold for the number of BGP routes.
Routing-table limit max-alarm lower limit	Lower alarm threshold for the number of BGP routes.
Routing-table limit threshold-alarm upper limit	Default upper alarm threshold for the number of BGP routes.
Routing-table limit threshold-alarm lower limit	Default lower alarm threshold for the number of BGP routes.

7.8.79 display mbgp routing-table

Function

The **display mbgp routing-table** command displays MBGP routes.

Format

display mbgp routing-table [*ipv4-address* [*mask* | *mask-length*]] [**verbose**]

Parameters

Parameter	Description	Value
ipv4-address	Specifies the destination IP address in dotted decimal notation.	-
mask | *mask-length*	Specifies mask in dotted decimal notation or mask-length.	-

Parameter	Description	Value
verbose	Displays detailed information about active and inactive routes. If the parameter **verbose** is not specified, detailed information about active routes is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view the specific routing information.

Example

Display information about all MBGP routes.

```
<HUAWEI> display mbgp routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: MBGP
         Destinations : 1        Routes : 1

Destination/Mask  Proto  Pre  Cost  Flags  NextHop  Interface

  10.5.5.1/32     MBGP   255     0     R   10.1.1.1  Vlanif10
```

Table 7-189 Description of the display mbgp routing-table command output

Item	Description
Route Flags	Flag of a route: - R: indicates that the route is a recursive route. - D: indicates that the route is delivered to the FIB table. - T: indicates a route whose next hop belongs to a VPN instance.
Routing Tables: MBGP	Indicates an MBGP routing table.
Destinations	Indicates the total number of destination networks or hosts.
Routes	Indicates the total number of routes.
Destination/Mask	Indicates the address and mask length of the destination network or host.

Item	Description
Proto	Indicates the protocol through which routes are learned.
Pre	Indicates the preference.
Cost	Indicates the route cost.
Flags	Indicates the route flag, that is, Route Flags in the header of the routing table.
NextHop	Indicates the next hop.
Interface	Indicates the outbound interface through which the next hop is reachable.

Display the detailed information of the specified routes.

```
<HUAWEI> display mbgp routing-table 5.5.5.1 verbose
Routing Table : MBGP
Summary Count : 1

 Destination: 10.5.5.1/32
    Protocol: MBGP           Process ID: 0
  Preference: 255                  Cost: 0
     NextHop: 10.1.1.1        Neighbour: 0.0.0.0
       State: Active Adv GotQ       Age: 00h43m25s
         Tag: 0              Priority: 0
       Label: NULL            QoSInfo: 0x0
RelayNextHop: 0.0.0.0       Interface: Vlanif 10
    TunnelID: 0x0               Flags: R
```

Table 7-190 Description of the display mbgp routing-table verbose command output

Item	Description
Destination	Indicates the address and mask length of the destination network or host.
Protocol	Indicates the routing protocol.
Process ID	Indicates the process ID of the routing protocol.
Preference	Indicates the preference of the route.
Cost	Indicates the route cost.
NextHop	Indicates the next hop.
Neighbour	Indicates the neighbor.

Item	Description
State	Indicates the status of routes: - Active: indicates active routes. - Invalid: indicates invalid routes. - Inactive: indicates inactive routes. - NoAdv: indicates the routes that cannot be advertised. - Adv: indicates the routes that can be advertised. - Del: indicates the routes to be deleted. - GotQ: indicates the route that finds the next hop and outbound interface or the route that finds the tunnel. - WaitQ: indicates the route that does not find the next hop or outbound interface or the route that does not find the tunnel. - Stale: indicates the routes with the stale flag. The routes are used in GR.
Age	Indicates the lifetime of the route.
Tag	Indicates the administrative tag for routes.
Priority	Indicates the priority.
Label	Indicates the allocated MPLS label.
QoSInfo	Indicates QoS information.
RelayNextHop	Indicates the relay next hop.
Interface	Indicates the outbound interface through which the next hop is reachable.
Tunnel ID	Indicates the tunnel ID.
Flags	Indicates the route flag, that is, Route Flags in the header of the routing table.

7.8.80 display mbgp routing-table statistics

Function

The **display mbgp routing-table statistics** command displays the statistics of the MBGP routes.

Format

display mbgp routing-table statistics

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Route statistics include:

- Total number of routes that are added or deleted by the protocol
- Number of active routes or inactive routes that are labeled for deletion but are not actually deleted

Example

Display statistics of the MBGP routing table.

```
<HUAWEI> display mbgp routing-table statistics
Proto     total      active      added        deleted      freed
          routes     routes      routes       routes       routes
MBGP      6          4           10           0            0
```

Table 7-191 Description of the display mbgp routing-table statistics command output

Item	Description
Proto	Routing protocol
total routes	Total number of routes in the routing table
active routes	Number of active routes in the routing table
added routes	Number of active and inactive routes added in the routing table
deleted routes	Number of routes to be deleted from the routing table
freed routes	Number of routes that are permanently deleted from the routing table

7.8.81 ebgp-interface-sensitive

Function

The **ebgp-interface-sensitive** command immediately resets a BGP session on an interface that is directly connected to an external peer when the interface goes Down.

The **undo ebgp-interface-sensitive** command disables the function.

By default, this function is enabled.

Format

ebgp-interface-sensitive

undo ebgp-interface-sensitive

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the **ebgp-interface-sensitive** command is not configured, the system does not immediately select the sub-optimal route for packet transmission when an interface goes Down. Instead, the system waits for a period of time (defaulting to 180 seconds) before checking whether another interface can be used to send packets to the same destination address. This will interrupt services for a period of time. If the **ebgp-interface-sensitive** command is run, BGP can quickly detect EBGP link faults and use another interface to establish a BGP peer relationship with the remote peer.

When the interface used for a BGP connection alternates between Up and Down states, running the **undo ebgp-interface-sensitive** command can prevent the repeated reestablishment and deletion of the BGP session in the event of route flapping. This reduces the use of network bandwidth.

Precautions

If the interface used for a BGP connection alternates between Up and Down states, it would be better not to run the **ebgp-interface-sensitive** command to prevent route flapping.

Example

Enable the function that automatically resets a BGP session.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ebgp-interface-sensitive
```

7.8.82 ext-community-change enable

Function

The **ext-community-change enable** command enables a device to change extended community attributes based on a Route-Policy.

The **undo ext-community-change enable** command disables a device from changing extended community attributes based on a Route-Policy.

By default, extended community attributes cannot be changed based on a Route-Policy.

Format

ext-community-change enable

undo ext-community-change enable

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, BGP prevents a device from changing extended community attributes from a peer or peer group based on an import policy or changing extended community attributes to be advertised to a peer or peer group based on an export policy. To enable a device to change extended community attributes from a peer or peer group based on an import policy and change extended community attributes to be advertised to a peer or peer group based on an export policy before advertising them, run the **ext-community-change enable** command.

Precautions

- The **ext-community-change enable** and **peer route-policy import** commands must both be run so that the device can change extended community attributes from a peer or peer group based on an import policy.
- The **ext-community-change enable** command must be run with either of the following commands so that the extended community attributes changed based on an export policy can be advertised to a peer or peer group.
  - **peer advertise-ext-community**
  - **peer route-policy export**

Example

Enable the device to change extended community attributes of the BGP routes received from peer 10.1.1.1 based on a Route-Policy named **policy1**.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy1 permit node 10
[HUAWEI-route-policy] if-match as-path-filter 2
[HUAWEI-route-policy] apply extcommunity rt 10.1.1.1:1 additive
[HUAWEI-route-policy] quit
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] ext-community-change enable
[HUAWEI-bgp-af-ipv4] peer 10.1.1.1 route-policy policy1 import
```

7.8.83 filter-policy export (BGP)

Function

The **filter-policy export** command configures a device to filter the routes to be advertised. BGP advertises only the routes that pass filtering.

The **undo filter-policy export** command restores the default configuration.

By default, the routes to be advertised are not filtered.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } **export** [*protocol* [*process-id*]]

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **export** [*protocol* [*process-id*]]

undo filter-policy export [*protocol* [*process-id*]]

undo filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } **export** [*protocol* [*process-id*]]

undo filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **export** [*protocol* [*process-id*]]

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IPv4 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol	Specifies the name of a routing protocol.	The BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, and BGP-VPN instance IPv4 address family view support **direct**, **isis**, **ospf**, **rip**, **static**, and **unr**. The BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view support **direct**, **isis**, **ospfv3**, **ripng**, **static**, and **unr**.
process-id	Specifies the number of a process that needs to perform matching. If *protocol* is **direct**, **static**, or **unr**, no process ID is required.	The value is an integer that ranges from 1 to 65535.
acl6-number	Specifies the number of a basic ACL6.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
acl6-name *acl6-name*	Specifies the name of a named ACL6.	The value is a string of 1 to 64 case-sensitive characters without spaces. The name should start with a letter and can contain numbers, hyphens (-), or underscores (_).
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- *protocol* [*process-id*] is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, and BGP-VPN instance IPv6 address family view.
- **acl-name** *acl-name*, *acl-number*, and **ip-prefix** *ip-prefix-name* are valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, and BGP-VPNv4 address family view.
- **acl6-name** *acl6-name*, *acl6-number*, and **ipv6-prefix** *ipv6-prefix-name* are valid only in the BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, and BGP-VPNv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-MDT address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

The **filter-policy export** command affects the routes advertised by BGP. After the command is run, BGP filters the routes that are imported by using the **import-route** command. Only the routes that pass the filtering can be added to the local BGP routing table and advertised by BGP.

If *protocol* is specified, only the routes imported from the specified protocol will be filtered. If *protocol* is not specified, the routes imported from all protocols will be filtered.

Precautions

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes are advertised to the specified peer.

Example

Use ACL 2000 to filter all the routes to be advertised by BGP.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] filter-policy 2000 export
```

7.8.84 filter-policy import (BGP)

Function

The **filter-policy import** command configures a device to filter received routes.

The **undo filter-policy import** command restores the default configuration.

By default, received routes are not filtered.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } **import**

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **import**

undo filter-policy import

undo filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } **import**

undo filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **import**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.

Parameter	Description	Value
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IPv4 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
acl6-number	Specifies the number of a basic ACL6.	-
acl6-name *acl6-name*	Specifies the name of a named ACL6.	The value is a string of 1 to 64 case-sensitive characters without spaces. The name should start with a letter and can contain numbers, hyphens (-), or underscores (_).
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- **acl-name** *acl-name*, *acl-number*, and **ip-prefix** *ip-prefix-name* are valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, and BGP-VPNv4 address family view.
- **acl6-name** *acl6-name*, *acl6-number*, and **ipv6-prefix** *ipv6-prefix-name* are valid only in the BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, and BGP-VPNv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **filter-policy import** command is used to filter the routes received by BGP to determine whether to add them to the BGP routing table.

When the **rule** command is run to configure rules for an ACL, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.

When the **rule (basic ACL6 view)** or **rule (advanced ACL6 view)** command is run to configure rules for an ACL6, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.

Precautions

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes advertised by the specified peer are accepted.

Example

Use ACL 2000 to filter the routes received by BGP.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] filter-policy 2000 import
```

7.8.85 graceful-restart (BGP)

Function

The **graceful-restart** command enables GR for the BGP speaker.

The **undo graceful-restart** command restores the default configuration.

By default, GR is disabled.

Format

graceful-restart

undo graceful-restart

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **graceful-restart** command is configured to enable GR for the switch, to prevent traffic interruption, another GR-capable device can assist the switch to perform GR when BGP on the switch restarts due to an active/standby switchover, and the switch can assist other GR-capable devices to perform GR when BGP on other devices restarts.

Follow-up Procedure

After running the **graceful-restart** command, run the **graceful-restart timer wait-for-rib** command to set the time for waiting for the End-Of-RIB flag.

Precautions

Enabling or disabling GR may delete and reestablish all BGP sessions and instances.

If the **graceful-restart timer wait-for-rib** command has been configured, using the **undo graceful-restart** command will delete the **graceful-restart timer wait-for-rib** command configuration.

Example

Enable GR for the speaker in BGP process 100.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] graceful-restart
```

7.8.86 graceful-restart peer-reset

Function

The **graceful-restart peer-reset** command enables a device to reset a BGP connection in GR mode.

The **undo graceful-restart peer-reset** command restores the default configuration.

By default, a device is not enabled to reset a BGP connection in GR mode.

Format

graceful-restart peer-reset

undo graceful-restart peer-reset

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Currently, BGP does not support dynamic capability negotiation. Therefore, each time a new BGP capability is enabled on a BGP speaker, the BGP speaker tears down existing sessions with its peer and renegotiates BGP capabilities.

With the GR reset function configured, when you enable a new BGP capability on the BGP speaker, the BGP speaker enters the GR state, resets the BGP session, and renegotiates BGP capabilities with the peer. In the whole process, the BGP speaker re-establishes the existing sessions but does not delete the routing entries for the existing sessions, so that the existing services are not interrupted.

Prerequisites

GR has been enabled by running the **graceful-restart** command. If this prerequisite is not met, the system does not allow you to configure the **graceful-restart peer-reset** command.

Precautions

After you run the **undo graceful-restart** command to disable GR, the **graceful-restart peer-reset** command configuration will be deleted automatically.

Example

Enable the switch to reset a BGP connection in GR mode.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] graceful-restart
[HUAWEI-bgp] graceful-restart peer-reset
```

7.8.87 graceful-restart timer restart

Function

The **graceful-restart timer restart** command sets the maximum period from the time when the peer finds that the local peer restarts to the time when the BGP session is reestablished.

The **undo graceful-restart timer restart** command deletes the setting.

By default, the maximum period from the time when the peer finds that the local peer restarts to the time when the BGP session is reestablished is 150 seconds.

Format

graceful-restart timer restart *time*

undo graceful-restart timer restart

Parameters

Parameter	Description	Value
time	Specifies the maximum period from the time when the peer finds that the local peer restarts to the time when the BGP session is reestablished.	The value ranges from 3 to 4095, in seconds.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Modifying the maximum period for reestablishing the BGP session leads to the reestablishment of the BGP peer relationship.

NOTE

The **graceful-restart timer restart** command can be run only after the **graceful-restart** command is run.

Example

Set the maximum period for reestablishing the BGP session to 250 seconds.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] graceful-restart
[HUAWEI-bgp] graceful-restart timer restart 250
```

7.8.88 graceful-restart timer wait-for-rib

Function

The **graceful-restart timer wait-for-rib** command sets the length of time that the BGP restarter waits for the End-Of-RIB flag.

The **undo graceful-restart timer wait-for-rib** command deletes the configured length of time that the BGP restarter waits for the End-Of-RIB flag.

By default, the time that the BGP restarter waits for the End-Of-RIB flag is 600 seconds.

Format

graceful-restart timer wait-for-rib *time*

undo graceful-restart timer wait-for-rib

Parameters

Parameter	Description	Value
time	Specifies the length of time that the BGP restarter waits for the End-Of-RIB flag.	The value is an integer that ranges from 3 to 3000, in seconds.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the BGP session is set up or reestablished, the BGP restarter must receive the End-Of-RIB flag in the period set by using this command. If the BGP restarter does not receive the End-Of-RIB flag, ensure that the switch can exit from the GR process.

Prerequisites

The **graceful-restart timer wait-for-rib** command can be run only after the **graceful-restart** command is run.

Configuration Impact

The latest configuration overrides the previous one.

Precautions

If there are a large number of routes, set a larger value for the *time* parameter to ensure that all routes will be updated.

Example

Set the time that the BGP restarter waits for the End-Of-RIB flag to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] graceful-restart timer wait-for-rib 100
```

7.8.89 group

Function

The **group** command creates a peer group.

The **undo group** command deletes a peer group.

By default, no peer group is created.

Format

group *group-name* [**external** | **internal**]

undo group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
external	Creates an EBGP peer group.	-
internal	Creates an IBGP peer group.	-

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A peer group is a group of peers with the same configurations. After a peer is added to a peer group, it inherits the configurations of this peer group. Peers in a peer group inherit the configurations of the peer group. When the configurations of the peer group are changed, the configurations of these peers are changed accordingly.

On a large-scale BGP network, there are a large number of peers and many of them have the same configurations. To configure these peers, you have to repeatedly use some commands. In such a case, configuring peer groups can simplify configurations. If the configurations for several peers are the same, these peers can be added to a created and configured peer group. The peers in the peer group then inherit the configurations of the peer group.

Precautions

If the **group** command is run multiple times, the latest configuration does not override the previous one.

If the type (IBGP or EBGP) of a peer group is not specified, an IBGP peer group is created by default.

The configuration of a peer takes precedence over that of the peer group to which the peer belongs.

If an attribute configuration of a BGP peer in a peer group differs from that of the peer group, you can disable the attribute configuration of the peer by using an **undo** command; then the peer inherits the attribute configuration of the peer group.

NOTICE

Deleting a peer group closes the connections on the peers that have no AS numbers in the peer group. Before deleting a peer group, you are recommended to delete these peers or configure AS numbers for these peers.

Example

Create an IBGP peer group named in.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group in internal
```

Create an EBGP peer group named ex, and set its AS number to 500.1.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group ex external
[HUAWEI-bgp] peer ex as-number 500.1
```

7.8.90 import-route (BGP)

Function

The **import-route** command configures BGP to import routes of other routing protocols and types.

The **undo import-route** command restores the default setting.

By default, BGP does not import routes.

Format

import-route *protocol* [*process-id*] [**med** *med* | **route-policy** *route-policy-name*] *

undo import-route *protocol* [*process-id*]

Parameters

Parameter	Description	Value
protocol	Specifies the routing protocol type and route type.	The BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, and BGP-VPN instance IPv4 address family view support **direct**, **isis**, **ospf**, **rip**, **static**, and **unr**. The BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view support **direct**, **isis**, **ospfv3**, **ripng**, **static**, and **unr**.
process-id	Specifies a process ID if BGP is configured to import routes. If *protocol* is **direct**, **static**, or **unr**, no process ID is required.	The value is an integer that ranges from 1 to 65535.
med *med*	Specifies the MED.	The value is an integer that ranges from 0 to 4294967295.
route-policy *route-policy-name*	Indicates that routes are filtered and route attributes are modified by using the Route-Policy specified by the parameter when these routes are imported from other protocols.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP can import routes by using the **import-route** command or **network** command:

- In import mode, BGP imports IGP routes, including RIP, OSPF, and IS-IS routes, into the BGP routing table based on protocol type. To ensure the validity of imported IGP routes, BGP can also import static routes and direct routes in import mode.

- In network mode, BGP imports the routes in the IP routing table one by one into the BGP routing table. The network mode is more accurate than the import mode.

Precautions

If the **default-route imported** command has not been used, BGP cannot import default routes when you run the **import-route** command to import routes from other protocols.

After the **import-route direct** command is executed, routes to the network segment where the IP address of the management interface belongs are also imported in the BGP routing table. Therefore, use this command with caution.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all routes of the specified protocol are imported to the BGP routing table.

Example

Import routes from RIP process 1.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] import-route rip 1
```

7.8.91 ipv4-family

Function

The **ipv4-family** command enables the IPv4 address family of BGP, and then displays the address family view.

The **undo ipv4-family** command deletes the configurations in the IPv4 address family.

By default, the BGP-IPv4 unicast address family view is displayed.

Format

ipv4-family unicast

ipv4-family multicast

ipv4-family vpnv4 [**unicast**] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

ipv4-family vpn-instance *vpn-instance-name*

ipv4-family { **mdt** | **mvpn** }

undo ipv4-family vpnv4 [**unicast**](supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

undo ipv4-family { **multicast** | **vpn-instance** *vpn-instance-name* }

undo ipv4-family { **mdt** | **mvpn** }

NOTE

The **mdt, mvpn, multicast** parameter is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
unicast	Displays the unicast address family view.	-
multicast	Displays the multicast address family view.	-
vpnv4	Displays the BGP-VPNv4 address family view.	-
vpn-instance *vpn-instance-name*	Associates a specified VPN instance with the IPv4 address family. You can enter the BGP-VPN instance IPv4 address family view by using the parameter.	The value must be an existing VPN instance name.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before performing BGP configurations in an IPv4 address family, you need to run the **ipv4-family** command in the BGP view to enable the IPv4 address family, and then enter the address family view. By default, BGP uses the IPv4 unicast address family.

Precautions

To disable the IPv4 unicast address family from being the default BGP route, run the **undo default ipv4-unicast** command.

Example

Enter the BGP-IPv4 unicast address family view.

```
<HUAWEI> system-view
```

```
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4]
```

7.8.92 ipv6-family

Function

The **ipv6-family** command enters the IPv6 address family view of BGP.

The **undo ipv6-family** command quits the IPv6 address family view and deletes the configurations in the view.

Format

ipv6-family [**vpnv6**](supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

ipv6-family [**unicast** | **vpn-instance** *vpn-instance-name*]

undo ipv6-family [**vpnv6**] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

undo ipv6-family [**unicast** | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
unicast	Displays the unicast address family view.	-
vpnv6	Displays the BGP-VPNv6 address family view.	-
vpn-instance *vpn-instance-name*	Associates a specified VPN instance with the IPv6 address family. You can enter the BGP-VPN instance IPv6 address family view by using the parameter. **NOTE** The parameter is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.	The value must be an existing VPN instance name.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If no parameter is specified, the IPv6 address family view is displayed by default. The **undo ipv6-family** command without any parameter is used to delete configurations in the BGP-IPv6 unicast address family view.

Precautions

The **undo ipv6-family** command without any parameters deletes all IPv6 unicast address family configurations.

Example

Enter the BGP-IPv6 unicast address family view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv6-family
[HUAWEI-bgp-af-ipv6]
```

7.8.93 load-balancing as-path-ignore

Function

The **load-balancing as-path-ignore** command configures a router not to compare the AS_Path attributes of routes that are to be used for load balancing.

The **undo load-balancing as-path-ignore** command configures a router to compare the AS_Path attributes of routes that are to be used for load balancing.

By default, a router compares the AS-Path attributes of routes that are to be used for load balancing.

Format

load-balancing as-path-ignore

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **load-balancing as-path-ignore** command is run, a router does not compare the AS_Path attributes of the routes (including the AS_Path length and content) that are to be used for load balancing. This command applies to the scenarios where EBGP and IBGP routes carry out load balancing. Exercise caution when using the command because the execution of this command will change the conditions of load balancing.

Precautions

The **load-balancing as-path-ignore** command and the **bestroute as-path-ignore** command are mutually exclusive. This means that if the **bestroute as-path-ignore** command is configured, the **load-balancing as-path-ignore** command cannot be configured.

Example

Configure a router not to compare the AS-Path attributes of the routes that are to be used for load balancing.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] load-balancing as-path-ignore
```

7.8.94 maximum load-balancing (BGP)

Function

The **maximum load-balancing** command configures the maximum number of equal-cost routes for load balancing.

The **undo maximum load-balancing** command restores the default value.

By default, the maximum number of equal-cost routes is 1, indicating that load balancing is not implemented.

Format

maximum load-balancing [**ebgp** | **ibgp**] *number* [**ecmp-nexthop-changed**]

undo maximum load-balancing [**ebgp** | **ibgp**]

Parameters

Parameter	Description	Value
ebgp	Indicates that only EBGP routes implement load balancing.	-

Parameter	Description	Value
ibgp	Indicates that only IBGP routes implement load balancing.	-
number	Specifies the maximum number of equal-cost routes in the BGP routing table.	BGP: The value is an integer that ranges from 1 to 8 on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S and S6720S-S. The value ranges from 1 to 16 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S BGP4+: The value is an integer that ranges from 1 to 8.
ecmp-nexthop-changed	Configures a BGP device to change the next-hop addresses of only the routes that participate in load balancing to its address.	-

NOTE

ecmp-nexthop-changed is valid only in the BGP view, BGP IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After BGP load balancing is configured, BGP routes that meet the following conditions and have the same AS_Path attribute will become equal-cost routes and implement load balancing:

- PrefVal values are the same.
- Local_Pref attributes are the same.

- All BGP routes are aggregated or non-aggregated routes.
- Accumulated Interior Gateway Protocol metric (AIGP) values are the same.
- Lengths of the AS_path attributes are the same.
- Origin types (IGP, EGP, or Incomplete) are the same.
- Multi_Exit Discriminator (MED) values are the same.
- All BGP routes are EBGP or IBGP routes.
- The IGP metric values within an AS are the same.

Configuring BGP load balancing better utilizes network resources.

After the **maximum load-balancing ebgp** *number* command is run, only EBGP routes take part in load balancing. After the **maximum load-balancing ibgp** *number* command is run, only IBGP routes take part in load balancing. If [**ebgp** | **ibgp**] is not set, both EBGP routes and IBGP routes take part in load balancing, and the number of EBGP routes involved in load balancing is the same as that of IBGP routes involved in load balancing.

If you run the **maximum load-balancing** *number* command, the device changes the next-hop addresses of the routes to be advertised to a local address no matter whether the routes are used for load balancing. However, in RR or BGP confederation scenarios, the device does not change the next-hop addresses of non-local routes to be advertised to a local address.

If you run the **maximum load-balancing** { **ebgp** | **ibgp** } *number* command, the device does not change the next-hop addresses of the routes to be advertised to a local address no matter whether the routes are used for load balancing.

If you run the **maximum load-balancing** [**ebgp** | **ibgp**] *number* **ecmp-nexthop-changed** command, the device changes the next-hop addresses of the routes to be advertised to a local address only when the routes are used for load balancing.

Configuration Impact

If the **maximum load-balancing** command is run for multiple times, the latest configuration overrides the previous one.

Precautions

The **maximum load-balancing** *number* command cannot be configured together with the **maximum load-balancing ebgp** *number* or **maximum load-balancing ibgp** *number* command.

Example

Set two equal-cost routes to a specified destination.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] maximum load-balancing 2
```

7.8.95 maximum load-balancing eibgp

Function

The **maximum load-balancing eibgp** command configures the maximum number of EBGP and IBGP routes for load balancing.

The **undo maximum load-balancing eibgp** command deletes the configured maximum number of EBGP and IBGP routes for load balancing.

By default, the maximum number of EBGP and IBGP routes for load balancing is not configured.

Format

maximum load-balancing eibgp *number* [**ecmp-nexthop-changed**]

undo maximum load-balancing eibgp

Parameters

Parameter	Description	Value
number	Specifies the maximum number of equal-cost EBGP and IBGP routes.	The value is an integer that ranges from 1 to 8 on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S and S6720S-S. The value ranges from 1 to 16 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S
ecmp-nexthop-changed	Configures a BGP device to change the next-hop addresses of only the routes that participate in load balancing to its address.	-

Views

BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **maximum load-balancing eibgp** command is used in a VPN where a CE is dual-homed to two PEs. When the CE and one PE belong to an AS and the CE and the other PE belong to a different AS, you can set the number of EBGP and IBGP routes to be used for load balancing. This allows VPN traffic to be balanced among EBGP and IBGP routes.

After BGP load balancing is configured, BGP routes that meet the following conditions and have the same AS_Path attribute will become equal-cost routes and implement load balancing:

- PrefVal values are the same.
- Local_Pref attributes are the same.
- All BGP routes are summarized or non-summarized routes.
- Accumulated Interior Gateway Protocol metric (AIGP) values are the same.
- Lengths of the AS_path attributes are the same.
- Origin types (IGP, EGP, or Incomplete) are the same.
- Multi_Exit Discriminator (MED) values are the same.
- Protocol priorities are the same. By default, EBGP and IBGP routes have the same protocol priority (255). If the EBGP or IBGP route protocol priority is changed using a route-policy, load balancing cannot be implemented.
- Load balancing cannot be implemented between black-hole routes and non-black-hole routes.
- Load balancing cannot be implemented between labeled routes and non-labeled routes.
- Load balancing cannot be implemented between local routes and non-local routes.

Configuring BGP load balancing better utilizes network resources.

If you run the **maximum load-balancing eibgp** *number* command, the device changes the next-hop addresses of the routes to be advertised to a local address no matter whether the routes are used for load balancing. However, in RR or BGP confederation scenarios, the device does not change the next-hop addresses of non-local routes to be advertised to a local address.

If you run the **maximum load-balancing eibgp** *number* **ecmp-nexthop-changed** command, the device changes the next-hop addresses of the routes to be advertised to a local address only when the routes are used for load balancing.

Configuration Impact

If the **maximum load-balancing eibgp** command is run for multiple times, the latest configuration overrides the previous one.

Load balancing cannot be implemented between crossed and non-crossed routes.

Example

Set the maximum number of EBGP and IBGP routes for load balancing to 3.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpna
[HUAWEI-vpn-instance-vpna] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpna-af-ipv4] quit
[HUAWEI-vpn-instance-vpna] quit
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vpna
[HUAWEI-bgp-vpna] maximum load-balancing eibgp 3
```

7.8.96 network (BGP)

Function

The **network** command configures BGP to statically add routes in the IP routing table to the BGP routing table and advertise these routes to peers.

The **undo network** command deletes the routes statically added to the BGP routing table.

By default, BGP does not statically add routes in the IP routing table to the BGP routing table.

Format

network { *ipv4-address* [*mask* | *mask-length*] | *ipv6-address prefix-length* } [**route-policy** *route-policy-name*]

undo network { *ipv4-address* [*mask* | *mask-length*] | *ipv6-address prefix-length* }

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of the route to be imported by BGP.	It is in dotted decimal notation.
mask	Specifies the IP address mask. If no mask is specified, the IP address is considered as a classful address.	It is in dotted decimal notation.
mask-length	Specifies the mask length of the IP address. If no mask length is specified, the IP address is considered as a classful address.	The value is an integer that ranges from 0 to 32.
ipv6-address	Specifies the IPv6 address of the route to be imported by BGP.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of the IPv6 network address advertised by BGP.	The value is an integer that ranges from 0 to 128.
route-policy *route-policy-name*	Specifies the name of the route-policy that is used for route import.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP itself cannot discover routes. Instead, it imports routes discovered by other protocols such as IGP or static routes into the BGP routing table. These imported routes then are transmitted within an AS or between ASs. Before adding routes to the BGP routing table, BGP filters these routes by the routing protocol. If routes in the local IP routing table need to be statically added to the BGP routing table and then advertised, you can use the **network** command.

The Origin attribute of the routes imported into the BGP routing table by using the **network** command is IGP.

If a route with a specific prefix or mask is added to the BGP routing table by using the **network** command, this route is the optimal route selected from all types of protocol routes. Unlike the **network** command, the **import-route (BGP)** command is used to add all routes of a particular protocol such as RIP, OSPF, IS-IS, static route, or direct route to the BGP routing table.

Precautions

The **network** command is used to import exactly-matching routes. This means that only the routes in the local IP routing table that exactly match the specified destination address and prefix length can be added to the BGP routing table. If *mask* is not specified, routes are exactly matched against the natural network mask.

When using the **undo network** command to delete the existing configuration, specify a correct mask.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, routes in the local routing table are added to the BGP routing table.

Example

Configure BGP to import the local route 10.0.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] network 10.0.0.0 255.255.0.0
```

7.8.97 nexthop recursive-lookup (BGP)

Function

The **nexthop recursive-lookup** command configures BGP to recurse the next hop based on a routing policy.

The **undo nexthop recursive-lookup** command restores the default setting.

By default, BGP does not recurse the next hop based on a routing policy.

Format

nexthop recursive-lookup route-policy *route-policy-name*

undo nexthop recursive-lookup route-policy

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Indicates the name of a routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP needs route recursion in case of indirect next hops. If an indirect next hop is not recursed based on a routing policy, a BGP route may recurse to an incorrect forwarding path, causing traffic loss. Therefore, next hop recursion should be performed according to certain conditions.

The **nexthop recursive-lookup route-policy** *route-policy-name* command can be run to control next hop recursion based on a routing policy. If a recursive route is filtered out by the routing policy, the route is considered unreachable. This prevents BGP routes from recursing to incorrect forwarding paths.

Prerequisites

The next hop to which a BGP route recurses has been determined and a routing policy has been configured.

NOTICE

Before configuring a routing policy, ensure that all desired recursive routes will not be filtered out by the routing policy.

Precautions

The command does not apply to the routes received from directly connected EBGP peers or LinkLocal peers and default routes.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, route recursion is not restricted.

Example

Configure next hop recursion based on the routing policy **rp_nexthop**.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] nexthop recursive-lookup route-policy rp_nexthop
```

7.8.98 nexthop recursive-lookup delay

Function

The **nexthop recursive-lookup delay** command configures the delay in responding to changes of the next hop.

The **undo nexthop recursive-lookup delay** command restores the default setting.

By default, the delay in responding to changes of the next hop is not configured.

Format

nexthop recursive-lookup delay [*delay-time*]

undo nexthop recursive-lookup delay

Parameters

Parameter	Description	Value
delay-time	Specifies the delay in responding to changes of the next hop.	The value is an integer that ranges from 1 to 100, in seconds. The default value is 5 seconds.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-IPv4 multicast address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the route path on the upstream of a PE connected to an RR changes, if the PE detects that the recursive next hop becomes unreachable before the RR instructs the PE to switch the route, the PE withdraws the original optimal route advertised to its connected CE. After the RR re-advertises the switched route to the PE, the PE re-advertises an optimal route to the CE after route selection. During the route switchover, a huge volume of traffic will be dropped. If the **nexthop recursive-lookup delay** command is run on the PE to delay responding to the next hop unreachable event and to respond to this event only after the RR advertises the switched route, the volume of lost traffic will be reduced during route switchover.

Example

Set the delay in responding to changes of the next hop to 10s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] nexthop recursive-lookup delay 10
```

7.8.99 nexthop recursive-lookup non-critical-event delay

Function

The **nexthop recursive-lookup non-critical-event delay** command enables a device to respond to non-urgent BGP next-hop recursion changes after a specified delay time.

The **undo nexthop recursive-lookup non-critical-event delay** command enables a device to immediately respond to non-urgent BGP next-hop recursion changes.

By default, a device immediately responds to non-urgent BGP next-hop recursion changes.

Format

nexthop recursive-lookup non-critical-event delay [*delay-time*]

undo nexthop recursive-lookup non-critical-event delay

Parameters

Parameter	Description	Value
delay-time	Specifies the delay time.	The value is an integer that ranges from 1 to 100, in seconds. The default value is 5.

Views

BGP view, BGP-IPv4 unicast address family view, or BGP-VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If repeated recursion causes the BGP next hop to frequently change on a device, the device frequently selects and advertises routes. To prevent unwanted re-routing and route advertisement, run the **nexthop recursive-lookup delay** command to enable the device to respond to BGP next-hop recursion changes after a specified delay time. The recursion results are as follows:

- Urgent recursion result change: The recursive next hop is changed, and BGP route reachability is also changed. For example, if a fault occurs on a network, a device finds no next-hop route or tunnel to which a BGP route recurses. As a result, traffic is interrupted.
- Non-urgent recursion result change: The recursive next hop is changed, and BGP route reachability is not affected. For example, after the interface or type of a tunnel to which the next hop of a BGP route recurses is changed, traffic keeps traveling over the BGP route.

To delay a response to the non-urgent recursion change, run the **nexthop recursive-lookup non-critical-event delay** command, not the **nexthop recursive-lookup delay** command.

Configuration Impact

After the **nexthop recursive-lookup delay** command is run, the device delays responses to all next-hop recursion changes. After the **nexthop recursive-lookup non-critical-event delay** command is run, the device delays responses only to non-urgent BGP next-hop recursion changes. If both commands are run, the

nexthop recursive-lookup non-critical-event delay command takes precedence over the **nexthop recursive-lookup non-critical-event delay** command. **Table 7-192** provides examples of the two commands.

Table 7-192 Functions and their descriptions

Example	Description
[HUAWEI-bgp] **nexthop recursive-lookup delay**	The device responds to all BGP next-hop recursion changes after a 5-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay**	The device immediately responds to urgent BGP next-hop recursion changes and responds to non-urgent BGP next-hop recursion changes after a 5-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup delay 3**	The device responds to all BGP next-hop recursion changes after a 3-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay 6**	The device immediately responds to urgent BGP next-hop recursion changes and responds to non-urgent BGP next-hop recursion changes after a 6-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup delay** [HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay**	The device responds to all BGP next-hop recursion changes after a 5-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup delay 3** [HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay**	The device responds to urgent BGP next-hop recursion changes after a 3-second delay and responds to non-urgent BGP next-hop recursion changes after a 5-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup delay 3** [HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay 6**	The device responds to urgent BGP next-hop recursion changes after a 3-second delay and responds to non-urgent BGP next-hop recursion changes after a 6-second delay.
[HUAWEI-bgp] **nexthop recursive-lookup delay** [HUAWEI-bgp] **nexthop recursive-lookup non-critical-event delay 6**	The device responds to urgent BGP next-hop recursion changes after a 5-second delay and responds to non-urgent BGP next-hop recursion changes after a 6-second delay.

Precautions

The delay time specified in the **nexthop recursive-lookup non-critical-event delay** command must be greater than or equal to that specified in the **nexthop recursive-lookup delay** command if both commands are run.

Example

Enable the device to respond to non-urgent BGP next-hop recursion changes after a **10**-second delay.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] nexthop recursive-lookup non-critical-event delay 10
```

7.8.100 out-delay

Function

The **out-delay** command configures a delay for sending Update packets to all BGP peers.

The **undo out-delay** command deletes the configured delay value.

The default delay value is 0, indicating that the intermediate device on the primary path sends Update packets without a delay.

Format

out-delay *delay-value*

undo out-delay

Parameters

Parameter	Description	Value
delay-value	Specifies the delay for sending Update packets.	The value is an integer that ranges from 0 to 3600, in seconds.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a scenario with both primary and backup routes, traffic may be lost after it switches back to the primary path. Use a VPN FRR scenario as an example. PE3 and CE2 connect both to PE1 and PE2. The primary path is PE3 -> PE1 -> CE2, and the backup path is PE3 -> PE2 -> CE2. CE2 uses BGP to communicate with PE1 and PE2. FRR is configured on PE3. If PE1 restarts or the link between PE3 and PE1 fails, traffic switches from the primary path to the backup path. After the primary path recovers, traffic switches back to the primary path. If PE3 completes refreshing forwarding entries before PE1 does, PE1 may temporarily fail to forward traffic from PE3, and packet loss may occur. The severity of packet loss is proportional to the number of routes stored on PE1.

To solve this problem, run the **out-delay** command on PE1 to configure a delay for sending Update packets. An appropriate delay ensures that traffic switches back to the primary path after PE1 completes refreshing forwarding entries.

To configure a delay for sending Update packets to all BGP peers, run the **out-delay** command. To configure a delay for sending Update packets to a specified BGP peer or peer group, run the **peer out-delay** command.

Precautions

If you run the **peer out-delay** command more than once, the latest configuration overrides the previous one.

If the **out-delay** and **peer route-update-interval** commands are both configured, only the **out-delay** command takes effect.

If a network has high route convergence requirements, do no use the **out-delay** command.

Example

Set the delay for sending Update packets to all BGP peers to 300s in the BGP view.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] out-delay 300
```

7.8.101 peer advertise-community

Function

The **peer advertise-community** command configures a device to advertise a community attribute to its peer or peer group.

The **undo peer advertise-community** command restores the default setting.

By default, a device advertises no community attribute to its peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **advertise-community**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **advertise-community**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BPG-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP L2VPN-AD address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer advertise-community** command is used to configure a device to advertise a community attribute to its peer or peer group. If a device advertises a community attribute to its peer group, all the members of the peer group will inherit the configuration. This simplifies the application of routing policies and facilitates route maintenance and management.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A specific community attribute has been defined in a routing policy.

Example

Configure a device to advertise a community attribute to its peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 advertise-community
```

7.8.102 peer advertise-ext-community

Function

The **peer advertise-ext-community** command enables a device to advertise an extended community attribute to its peer or peer group.

The **undo peer advertise-ext-community** command restores the default setting.

By default, a device advertises no extended community attribute to its peer or peer group.

Product	Support

Format

peer { *group-name* | *ipv6-address* } **advertise-ext-community**

undo peer { *group-name* | *ipv6-address* } **advertise-ext-community**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Views

BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer advertise-ext-community** command is used to enable a device to advertise an extended community attribute to a specified peer or peer group. If a device advertises an extended community attribute to a specified peer group, all the members of the peer group will inherit the configuration. This simplifies the application of routing policies and facilitates route maintenance and management.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A specific extended community attribute has been defined in a routing policy.

Example

Configure a device to advertise an extended community attribute to its peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 2:3::4:5 as-number 200
[HUAWEI-bgp] ipv6-family vpn-instance abc
[HUAWEI-bgp6-abc] peer 2:3::4:5 as-number 200
[HUAWEI-bgp6-abc] peer 2:3::4:5 advertise-ext-community
```

7.8.103 peer allow-as-loop

Function

The **peer allow-as-loop** command sets the number of local AS number repetitions.

The **undo peer allow-as-loop** command restores the default setting.

By default, the local AS number cannot be repeated.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **allow-as-loop** [*number*] [**global-as** [**vpn-as**]]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **allow-as-loop** [*number*] [**global-as** [**vpn-as**]]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	The value is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
number	Specifies the number of local AS number repetitions.	The value is an integer in the range from 1 to 10. The default value is 1.
global-as	Specifies a global AS number of BGP.	-
vpn-as	Specifies the AS number of a VPN instance.	-

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, and BGP L2VPN-AD address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.
- The **global-as** and **vpn-as** parameters apply only to BGP VPN instance IPv4 and BGP VPN instance IPv6 address family views.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP uses AS numbers to detect routing loops. The AS numbers in the AS_Path of each received route are matched against the local AS number configured using the **bgp** command, the fake AS number configured using the **peer fake-as** command, and the VPN instance AS number configured using the **as-number** command. The largest number of times any of the configured AS numbers is repeated is considered as the maximum number. In the Hub and Spoke networking, if EBGP runs between a Hub-PE and a Hub-CE on a Hub site, the route sent from the Hub-PE to the Hub-CE carries the AS number of the Hub-PE. If the Hub-CE sends a routing update to the Hub-PE, the Hub-PE will deny it because the routing update contains the AS number of the Hub-PE.

To ensure proper route transmission in the Hub and Spoke networking, configure all the BGP peers on the path, along which the Hub-CE advertises private network routes to the Spoke-CE, to accept the routes in which the AS number repeats once.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

If the **peer allow-as-loop** command is run for a peer or peer group multiple times, the latest configuration overrides the previous one.

Example

Set the number of local AS number repetitions to 2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 allow-as-loop 2
```

7.8.104 peer as-number

Function

The **peer as-number** command creates a peer or configures an AS number for a specified peer group.

The **undo peer as-number** command deletes a specified peer or the AS number of a specified peer group.

By default, no BGP peer is configured, and no AS number is specified for a peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **as-number** { *as-number-plain* | *as-number-dot* }

peer *group-name* **as-number** { *as-number-plain* | *as-number-dot* } [**optional-as** { *optional-as-number-plain* | *optional-as-number-dot* } &<1-5>]

undo peer { *group-name* **as-number** | *ipv4-address* | *ipv6-address* }

undo peer *group-name* **as-number** { *as-number-plain* | *as-number-dot* } [**optional-as** { *optional-as-number-plain* | *optional-as-number-dot* } &<1-5>]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer. The IPv4 address can be the IP address of an interface that is directly connected to the peer or the IP address of a loopback interface of the reachable peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.
optional-as	Specifies an optional AS number.	-
optional-as-number-plain	Specifies an integral optional AS number.	The value is an integer that ranges from 1 to 4294967295.
optional-as-number-dot	Specifies an optional AS number in dotted notation.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer** { *ipv4-address* | *ipv6-address* } **as-number** { *as-number-plain* | *as-number-dot* } command is used to create a BGP peer.

The **peer** *group-name* **as-number** { *as-number-plain* | *as-number-dot* } command is used to configure an AS number for a specified peer group.

Dynamic peers on the same network segment must be added to the same peer group. If the dynamic peers reside in different ASs, run the **peer** *group-name* **as-number** { *as-number-plain* | *as-number-dot* } **optional-as** { *optional-as-number-plain* | *optional-as-number-dot* } &<1-5> command to configure an optional AS number for the peer group.

Precautions

If a peer does not join any peer group or the peer group to which a peer belongs is not configured with an AS number, deleting the AS number of the peer will reset the peer relationship.

If a peer in a peer group is not configured with an AS number, deleting the AS number of the peer group will interrupt the connection on the peer.

The AS number of an external peer group must be different from the local AS number.

Example

Set the AS number to 100 for IPv4 peer 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.1 as-number 100
```

Set the AS number to 100 for a peer group named test.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group test
[HUAWEI-bgp] peer test as-number 100
```

Set the peer AS number and optional AS number for the peer group named **dynamic-group** to 65546 and 65547, respectively.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group dynamic-group external
[HUAWEI-bgp] peer dynamic-group as-number 65546 optional-as 65547
```

7.8.105 peer as-path-filter

Function

The **peer as-path-filter** command configures a BGP route filtering policy based on an AS_Path list for a peer or peer group.

The **undo peer as-path-filter** command cancels the existing configuration.

By default, no route filtering policy based on an AS_Path list is configured for a peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } { **import** | **export** }

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } { **import** | **export** }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
as-path-filter-number	Specifies the number of an AS_Path filter.	The value is an integer that ranges from 1 to 256.

Parameter	Description	Value
as-path-filter-name	Specifies the name of an AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters. It cannot be all numbers. When double quotation marks are used around the string, spaces are allowed in the string.
import	Applies a route filtering policy to received routes.	-
export	Applies a route filtering policy to routes to be advertised.	-

NOTE

- *ipv4-address* is valid only in the BGP view, BPG-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **peer as-path-filter** command is used to apply a route filtering policy based on an AS_Path list to BGP routes, the routes that do not match the policy are filtered out.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

The **ip as-path-filter** command has been run to define an AS-Path filter.

Precautions

Only one AS_Path filter can be used to filter the routes received from the same peer. Similarly, only one AS_Path filter can be used to filter routes to be advertised to the same peer.

Creating an AS_Path filter before it is referenced is recommended. By default, the command in an IPv4 address family cannot reference a non-existent AS_Path filter, but the command in an IPv6 address family can reference a non-existent AS_Path filter. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent AS_Path filter is referenced using the current command, all routes are advertised to the specified peer, or all routes advertised by the specified peer are accepted.

Example

Configure an AS_Path filter for a peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 as-path-filter 3 export
```

7.8.106 peer bfd

Function

The **peer bfd** command sets BFD detection parameters for a peer or peer group.

The **undo peer bfd** command restores default BFD detection parameter values.

By default, the interval for sending BFD packets is 1000 ms, the interval for receiving BFD packets is 1000 ms, and the local detection multiplier is 3.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

peer { *group-name* | *ipv4-address* } **bfd** { **min-tx-interval** *min-tx-interval* | **min-rx-interval** *min-rx-interval* | **detect-multiplier** *multiplier* } *

peer { *group-name* | *ipv6-address* } **bfd** { **min-tx-interval** *min-tx-interval* | **min-rx-interval** *min-rx-interval* | **detect-multiplier** *multiplier* } *

undo peer { *group-name* | *ipv4-address* } **bfd** { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo peer { *group-name* | *ipv6-address* } **bfd** { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo peer { *group-name* | *ipv4-address* } **bfd** { **min-tx-interval** *min-tx-interval* | **min-rx-interval** *min-rx-interval* | **detect-multiplier** *multiplier* } *

undo peer { *group-name* | *ipv6-address* } **bfd** { **min-tx-interval** *min-tx-interval* | **min-rx-interval** *min-rx-interval* | **detect-multiplier** *multiplier* } *

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
min-tx-interval *min-tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-rx-interval *min-rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection time multiplier.	The value is an integer that ranges from 3 to 50. By default, the value is 3.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD provides millisecond-level fault detection. It helps BGP to detect faults in neighboring devices or links more quickly, and instructs BGP to recalculate routes for correct packet forwarding. The **peer bfd** command can be used to set the values of BFD session parameters on a specified interface.

The BFD configuration of a peer takes precedence over that of the peer group to which the peer belongs. If BFD is not configured on a peer and the peer group to which the peer belongs is enabled with BFD, the peer will inherit the BFD configurations of the peer group.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A BFD session can be established only when the corresponding BGP session is in the Established state.

Precautions

If the **peer bfd** command is run multiple times, the latest configuration overwrites the previous one. The BFD session uses the latest parameters as the detection parameters.

Assume that BFD is configured on a peer group. If the **peer bfd block** command is not run on members of the peer group, the members will establish BFD sessions.

If BFD parameters are set on a peer, a BFD session will be established by using the BFD parameters on the peer.

Example

Configure BFD and set detection parameters on peer 10.2.2.9.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.2.2.9 as-number 200
[HUAWEI-bgp] peer 10.2.2.9 bfd min-tx-interval 100 min-rx-interval 100 detect-multiplier 5
```

7.8.107 peer bfd block

Function

The **peer bfd block** command prevents a peer from inheriting the BFD function of its peer group.

The **undo peer bfd block** command restores the default configuration.

By default, a peer inherits the BFD function from its peer group.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

peer { *ipv4-address* | *ipv6-address* } **bfd block**

undo peer { *ipv4-address* | *ipv6-address* } **bfd block**

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD provides millisecond-level fault detection. It helps BGP to detect faults in neighboring devices or links more quickly, and instructs BGP to recalculate routes for correct packet forwarding. If a peer group is configured with BFD, all members of the peer group will establish BFD sessions. The **peer bfd block** command can be used to prevent a peer from inheriting the BFD function from its peer group.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A BFD session has been established.

Precautions

After the **peer bfd block** command is run on a peer, the corresponding BFD session on the peer is deleted. As a result, fast link fault detection cannot be implemented.

The **peer bfd block** command and the **peer bfd enable** command are mutually exclusive. After the **peer bfd block** command is run, related BFD sessions are automatically deleted.

Example

Prevent peer 10.2.2.9 from inheriting the BFD function of its peer group.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.2.2.9 as-number 200
[HUAWEI-bgp] peer 10.2.2.9 bfd block
```

7.8.108 peer bfd enable

Function

The **peer bfd enable** command enables BFD for peers or a peer group.

The **undo peer bfd enable** command disables BFD for peers or a peer group.

By default, BFD is disabled for peers or a peer group.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **bfd enable** [**single-hop-prefer**]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **bfd enable**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
single-hop-prefer	Indicates that single-hop BFD sessions are preferentially established. **single-hop-prefer** takes effect only on IBGP peers. By default, **single-hop-prefer** is not specified, and multi-hop sessions are established between direct IBGP peers (Huawei devices). To interconnect a Huawei device and a non-Huawei device that defaults the sessions between IBGP peers to single-hop, configure **single-hop-prefer** in the command.	-

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP uses BFD to quickly detect faults in links between BGP4 peers. This accelerates network convergence. The **peer bfd enable** command is used to configure a device to establish a BFD session with its peer or peer group by using default detection parameter values.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A BFD session can be established only when the corresponding BGP peer relationship is in the Established state.

Precautions

The BFD configuration of a peer takes precedence over that of the peer group to which the peer belongs. If BFD is not configured on a peer and the peer group to which the peer belongs is enabled with BFD, the peer inherits the BFD configurations from the peer group.

Before enabling BFD on a BGP peer, enable BFD in the system view. If no BFD detection parameter is specified, a BFD session is established by using default parameter values.

NOTE

The **peer bfd block** command and the **peer bfd enable** command are mutually exclusive.

Example

Configure BFD for peer 10.2.2.9.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.2.2.9 as-number 200
[HUAWEI-bgp] peer 10.2.2.9 bfd enable
```

7.8.109 peer capability-advertise

Function

The **peer capability-advertise** command enables a BGP device to advertise optional BGP capabilities to its peer.

The **undo peer capability-advertise** command restores the default setting.

By default, a BGP device advertises route-refresh and 4-byte AS number capabilities to its peer.

Format

peer { *group-name* | *ipv4-address* } **capability-advertise** { **4-byte-as** | **route-refresh** | **conventional** }

peer *ipv6-address* **capability-advertise** { **4-byte-as** | **route-refresh** }

undo peer { *group-name* | *ipv4-address* } **capability-advertise** { **4-byte-as** | **route-refresh** | **conventional** }

undo peer *ipv6-address* **capability-advertise** { **4-byte-as** | **route-refresh** }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
4-byte-as	Indicates the 4-byte AS number capability.	-
route-refresh	Indicates the route-refresh capability.	-

Parameter	Description	Value
conventional	Indicates the regular router capability.	-

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer capability-advertise route-refresh** command is used to configure a device to advertise the route-refresh capability to its peer.

The **peer capability-advertise conventional** command is used to configure a device to advertise the regular router capability to its peer. If **conventional** is specified in the command, the router does not have all extension functions such as route-refresh capability, GR capability, and multi-address family negotiation. This allows the router to be compatible with routers of earlier versions.

The **peer capability-advertise 4-byte-as** command is used to configure a device to advertise the 4-byte AS number capability to its peer. If AS number resources are used up, this command can be used to configure devices to use 4-byte AS numbers.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

The corresponding BGP session must be in the Established state.

Precautions

If you enable or disable the route-refresh, general router, or 4-byte AS number function, the BGP peer relationship will be re-established, which can lead to a temporary network interruption. Therefore, exercise caution when running the related commands.

Example

Configure a BGP device to advertise the route-refresh capability to its peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.89.2.33 as-number 100
[HUAWEI-bgp] peer 10.89.2.33 capability-advertise route-refresh
```

7.8.110 peer connect-interface

Function

The **peer connect-interface** command specifies a source interface from which BGP packets are sent, and a source address used for initiating a connection.

The **undo peer connect-interface** command restores the default setting.

By default, the outbound interface of a BGP packet serves as the source interface of the BGP packet.

Format

peer { *group-name* | *ipv4-address* } **connect-interface** *interface-type interface-number* [*ipv4-source-address*]

peer { *group-name* | *ipv6-address* } **connect-interface** *interface-type interface-number* [*ipv6-source-address*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **connect-interface**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
interface-type interface-number	Specifies the type and number of an interface.	-
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
ipv4-source-address	Specifies an IPv4 source address used for establishing a connection.	It is in dotted decimal notation.
ipv6-source-address	Specifies an IPv6 source address used for establishing a connection.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The command is used in the following scenarios:

- To establish a BGP peer connection between two indirectly connected physical interfaces, the **peer connect-interface** command must be run on both sides.

  To establish a BGP peer connection between a local loopback interface and a remote interface, the loopback interface must be specified as the source interface in the command. To establish a BGP peer connection between a local physical interface and a remote interface, the physical interface must be specified as the source interface in the command.
- If multiple IP addresses are configured for the physical interface that needs a BGP peer connection established with a remote interface, the **peer connect-interface** command must be run, with *ipv4-source-address* or *ipv6-source-address* set to the source IP address.
- If two devices need multiple BGP peer connections established through different interfaces, the **peer connect-interface** command must be run for each BGP peer connection, with the source interface specified.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

Running the **peer connect-interface** command causes the teardown and re-establishment of peer relationships.

NOTE

Because the BGP peer relationships in various address families on the same device share one TCP connection, **connect-interface** configured in the BGP view can be inherited in the IPv4 unicast address family.

To enable a device to send BGP packets even if its physical interface fails, you can configure the device to use a loopback interface as the source interface of the BGP packets. When configuring a device to use a loopback interface as the source interface of BGP packets, note the following points:

- The loopback interface of the device's BGP peer must be reachable.
- In the case of an EBGP connection, the **peer ebgp-max-hop** command needs to be run to enable the two devices to establish an indirect peer relationship.

NOTE

If the specified interface borrows the IP address of another interface and then the IP address of the specified interface is changed, BGP still uses the borrowed IP address to keep the connection if no connection reestablishment is triggered, and data receiving and sending is not affected; if connection reestablishment is triggered, BGP uses the new IP address to reestablish the connection.

Example

Specify a source interface for sending BGP packets and a source address for initiating a connection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.16.2.3 as-number 100
[HUAWEI-bgp] peer 10.16.2.3 connect-interface vlanif 100
```

7.8.111 peer connected-check-ignore

Function

The **peer connected-check-ignore** command configures a device not to check the hop count when establishing a one-hop EBGP peer relationship using loopback interface addresses.

The **undo peer connected-check-ignore** command cancels the configuration.

By default, a device checks the hop count when establishing a one-hop EBGP peer relationship using loopback interface addresses.

Format

peer{ *group-name* | *ipv4-address* | *ipv6-address* } **connected-check-ignore**

undo peer{ *group-name* | *ipv4-address* | *ipv6-address* } **connected-check-ignore**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The value is a string of 1 to 47 case-sensitive characters, spaces not supported.
ipv4-address	Specifies the IPv4 address of a peer.	-
ipv6-address	Specifies the IPv6 address of a peer.	-

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To allow one-hop EBGP peer relationships to be established using loopback interface addresses, run the **peer connected-check-ignore** command or the **peer ebgp-max-hop** command (in which *hop-count* is greater than or equal to 2).

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

If the **peer connected-check-ignore** command is used on one end of an EBGP connection, it must also be used on the other end.

Example

Configure the device not to check the hop count when establishing a one-hop EBGP peer relationship using loopback interface addresses.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 connected-check-ignore
```

7.8.112 peer default-route-advertise

Function

The **peer default-route-advertise** command configures a BGP device to advertise a default route to its peer or peer group.

The **undo peer default-route-advertise** command restores the default setting.

By default, a BGP device does not advertise default routes to its peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **default-route-advertise** [**route-policy** *route-policy-name*] [**conditional-route-match-all** { *ipv4-address1* { *mask1* | *mask-length1* } } &<1-4> | **conditional-route-match-any** { *ipv4-address2* { *mask2* | *mask-length2* } } &<1-4>]

peer { *group-name* | *ipv4-address* | *ipv6-address* } **default-route-advertise** [**route-policy** *route-policy-name*] [**conditional-route-match-all** { *ipv6-address1* *prefix-length1* } &<1-4> | **conditional-route-match-any** { *ipv6-address2* *prefix-length2* } &<1-4>]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **default-route-advertise**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	The value is in dotted decimal notation.
prefix-length1	Specifies the IPv6 prefix range using the mask length.	The value is an integer that ranges from 0 to 128. If ::0 less-equal 128 is used, all IPv6 addresses will be matched.
prefix-length2	Specifies the IPv6 prefix range using the mask length.	The value is an integer that ranges from 0 to 128. If ::0 less-equal 128 is used, all IPv6 addresses will be matched.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
conditional-route-match-all	Configures the BGP device to send default routes to a peer or peer group when the routing table contains all conditional routes.	-

Parameter	Description	Value
ipv4-address1	Specifies the IPv4 address of conditional routes.	The value is in dotted decimal notation.
ipv6-address1	Specifies the IPv6 address of conditional routes.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
mask1	Specifies the mask of conditional routes.	The value is in dotted decimal notation.
mask-length1	Specifies the mask length of conditional routes.	The value is an integer that ranges from 0 to 32.
conditional-route-match-any	Configures the BGP device to send default routes to a peer or peer group when the routing table contains any conditional route.	-
ipv4-address2	Specifies the IPv4 address of conditional routes.	The value is in dotted decimal notation.
ipv6-address2	Specifies the IPv6 address of conditional routes.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
mask2	Specifies the mask of conditional routes.	The value is in dotted decimal notation.
mask-length2	Specifies the mask length of conditional routes.	The value is an integer that ranges from 0 to 32.

NOTE

- *ipv4-address* is only valid in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-IPv4 multicast address family view, and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is only valid in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.
- **conditional-route-match-all** and **conditional-route-match-any** are valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-IPv6 unicast address family view, and BGP-VPN instance IPv4 address family view.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Default routes are commonly used on a network that meets the following conditions:

- Each device has multiple EBGP peers and receives all routes on the network from each EBGP peer.
- There are multiple route reflectors (RRs), and each RR receives all routes on the network.

If load balancing is not implemented on the network, a BGP peer receives at most one copy of active routes on the network. If load balancing is implemented on the network, the number of active routes received by a BGP peer will be increased by multiple times, causing the number of routes on the network to sharply increase. To greatly reduce the number of routes on such a network, configure a BGP device to advertise only default routes to its BGP peer and use default routes for traffic load balancing.

Prerequisites

BGP peer relationships have been established using the **peer as-number** command.

Precautions

After this command is run, a BGP device sends a default route with the next hop as itself to its peer or peer group regardless of whether default routes exist in the routing table.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the attributes of the default route to be advertised to the specified peer or peer group are not changed.

Example

Configure a BGP device to advertise a default route to its peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 default-route-advertise
```

7.8.113 peer description (BGP)

Function

The **peer description** command configures a description for a peer or peer group.

The **undo peer description** command deletes the description of a peer or peer group.

By default, no description is configured for a peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **description** *description-text*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **description**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
description-text	Specifies a description, which can be letters and digits.	The value is a string of 1 to 80 characters, with spaces supported.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer description** can be used to configure a description for a peer or peer group, which facilitates management of peers or peer groups. The description records information about the peer or peer group, such as the VPN instance to which the peer or peer group belongs, and devices that establish peer relationships with the peer or peer group.

Precautions

The description configured by using the **peer description** command for a peer is displayed from the first non-space character, and a maximum of 80 characters can be displayed.

Follow-up Procedure

You can run **display bgp peer** *ipv4-address* **verbose** command can be used to view the description of a peer.

Example

Configure a description for a peer group named group1.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group group1
[HUAWEI-bgp] peer group1 description ISP1
```

7.8.114 peer ebgp-max-hop

Function

The **peer ebgp-max-hop** command configures a BGP device to establish an EBGP peer relationship with a peer on an indirectly-connected network and set the maximum number of hops between the two devices.

The **undo peer ebgp-max-hop** command restores the default setting.

By default, an EBGP connection can be set up only on a directly-connected physical link.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **ebgp-max-hop** [*hop-count*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **ebgp-max-hop**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
hop-count	Specifies the maximum number of hops.	The value is an integer that ranges from 1 to 255. The default value is 255. If the maximum number of hops is 1, a device cannot establish an EBGP connection with a peer on an indirectly-connected network.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A directly-connected physical link must be available between EBGP peers. Otherwise, the **peer ebgp-max-hop** command must be used to allow EBGP peers to establish a TCP connection over multiple hops.

If loopback interfaces are used to establish an EBGP peer relationship, the **peer ebgp-max-hop** command (*hop-count* ≥ 2) must be run; otherwise, the peer relationship cannot be established. If a one-hop EBGP peer relationship is established using loopback interface addresses, you can also run the **peer connected-check-ignore** command to establish an EBGP peer relationship.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

If the **peer ebgp-max-hop** command is used on one end of an EBGP connection, it must also be used on the other end.

The configurations of GTSM and EBGP-MAX-HOP affect the TTL values of sent BGP packets, and the configurations of the two functions are mutually exclusive.

Example

Allow an indirectly connected EBGP peer with the IP address of 10.1.1.2 to establish a connection with the local device.

```
<HUAWEI> system-view
```

```
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 ebgp-max-hop
```

7.8.115 peer enable (BGP)

Function

The **peer enable** command enables a BGP device to exchange routes with a specified peer or peer group in the address family view.

The **undo peer enable** command disables a BGP device from exchanging routes with a specified peer or peer group.

By default, only the peer in the BGP IPv4 unicast address family view is automatically enabled.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **enable**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **enable**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view,BGP-MDT address family view, BGP-MVPN address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, and BGP L2VPN-AD address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, only the peer in the BGP IPv4 unicast address family view is automatically enabled. After the **peer as-number** command is used in the BGP view, the system automatically runs the **peer enable** command to enable a peer. In other address family views, however, a peer must be enabled manually.

After the **undo default ipv4-unicast** command is run, the **peer enable** command needs to be run in the BGP view or the BGP-IPv4 unicast address family view to enable the IPv4 unicast address family for the created BGP peer.

Precautions

Enabling or disabling a BGP peer in an address family, for example, running the **peer enable** command or the **undo peer enable** command in a VPNv4 address family, causes teardown and re-establishment of the BGP connection of the peer in other address families.

Example

Disable a BGP device from exchanging IPv4 routes with a specified peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] undo peer 10.1.1.2 enable
```

7.8.116 peer fake-as

Function

The **peer fake-as** command specifies a fake AS number for a local peer.

The **undo peer fake-as** command restores the default setting.

By default, a peer uses the actual local AS number.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **fake-as** { *as-number-plain* | *as-number-dot* } [**prepend-global-as**]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **fake-as**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the x.y format. Here, "x" and "y" are integers that range from 1 to 65535 and 0 to 65535 respectively.
prepend-global-as	Indicates that the actual AS number is added to packets to be sent.	-

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer fake-as** command is often used for network deployment changing of carriers' networks. For example, if carrier A purchases the network of carrier B and the networks of the two carriers belong to different ASs, the ASs of the two carriers need to be combined and the AS number of carrier B needs to be changed to the AS number of carrier A. BGP peers (in another AS) of devices on carrier B's network may not be willing to have their BGP configurations changed or changed immediately during network combination. As a result, the connections with these BGP peers will be interrupted.

To ensure that the ASs are combined properly, you can run the **peer fake-as** command on the ASBR on carrier's B network to set the AS number of carrier B to the fake AS number of carrier A. This setting enables the BGP peers of devices in carrier B's network to use the fake AS number to set up connections.

NOTE

If **prepend-global-as** is specified in the command and the local end establishes an EBGP peer relationship with the remote end using the fake AS number, the local end adds the actual AS number to the packets to be sent to the remote end.

Prerequisites

Peers have been created by using the **peer as-number** command.

Precautions

If the **peer fake-as** command is run several times for a peer or a peer group, the latest configuration will overwrite the previous one.

The **peer fake-as** command takes effect only for EBGP peers, and the configured fake AS number cannot be the same as the peer AS number.

After the 4-byte AS number capability is disabled on a peer, configuring a 4-byte fake AS number for the peer may cause a failure to establish a BGP session.

Example

Set a 2-byte fake AS number for a peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 fake-as 99
```

Set a 4-byte fake AS number for a peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 fake-as 100.200
```

7.8.117 peer filter-policy

Function

The **peer filter-policy** command configures a filtering policy to advertise routes to or receive routes from peers or peer group.

The **undo peer filter-policy** command deletes the filtering policy used to advertise routes to or receive routes from peers or peer group.

By default, no filtering policy is configured to advertise routes to or receive routes from peers or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **filter-policy** { *acl-number* | **acl-name** *acl-name* | *acl6-number* | **acl6-name** *acl6-name* } { **import** | **export** }

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **filter-policy** { *acl-number* | **acl-name** *acl-name* | *acl6-number* | **acl6-name** *acl6-name* } { **import** | **export** }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of an ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
acl6-number	Specifies the number of a basic IPv6 ACL.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The name should start with a letter and can contain numbers, hyphens (-), or underscores (_).
import	Filters received routes.	-
export	Filters routes to be advertised.	-

NOTE

- *ipv4-address*, **acl-name** *acl-name*, and *acl-number* are valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address*, **acl6-name** *acl6-name*, and *acl6-number* are valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer filter-policy** command is used to configure an ACL-based policy for filtering routes received from peers or routes to be advertised to peers.

A proper basic ACL needs to be selected based on the address family of a peer or peer group.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

A basic ACL needs to be configured.

Precautions

If the **peer filter-policy** command is run multiple times, the latest configuration overwrites the previous one. For example, if the **peer 10.1.1.2 filter-policy 2600 import** command is run and then the **peer 10.1.1.2 filter-policy 2400 import** command is run, the configuration of the **peer 10.1.1.2 filter-policy 2400 import** command overwrites that of the **peer 10.1.1.2 filter-policy 2600 import** command.

When the **rule** command is run to configure rules for an ACL, only the source address range specified by **source** and the time period specified by **time-range** take effect.

Example

Set the IPv4 filtering policy for peers.

```
<HUAWEI> system-view
[HUAWEI] acl 2000
[HUAWEI-acl-basic-2000] rule permit
[HUAWEI-acl-basic-2000] quit
[HUAWEI] bgp 100
```

```
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 filter-policy 2000 import
```

Set the IPv6 filtering policy for peers.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2001
[HUAWEI-acl6-basic-2001] rule permit
[HUAWEI-acl6-basic-2001] quit

```

7.8.118 peer group

Function

The **peer group** command adds a peer to a peer group.

The **undo peer group** command deletes a peer from a peer group and all configurations of the peer.

By default, no peer is in peer group.

Format

peer { *ipv4-address* | *ipv6-address* } **group** *group-name*

undo peer { *ipv4-address* | *ipv6-address* } **group** *group-name*

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view, and BGP-EVPN address family view.
- *ipv6-address* is valid only in the BGP view, BGP-IPv6 unicast address family view, and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view, BGP-EVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale BGP network, there are a large number of peers and many of them have the same routing policies. To configure these peers, you have to repeatedly use some commands. In such a case, configuring peer groups can simplify configurations. If you intend to perform the same configuration on several peers, create and configure a peer group. Then, add the peers to the peer group. The peers will inherit the configurations of the peer group.

Precautions

- Peers with different AS numbers can be added to the same peer group. If a peer has an AS number, the peer keeps its own AS number after being added to a peer group. If a peer has no AS number but the peer group to which the peer will be added has an AS number, the peer inherits the AS number of the peer group after being added to the peer group.
- The members of a peer group can be configured with different route receiving and advertising policies.
- The **undo peer group** command has the same function with the **undo peer** command and the **undo peer enable** command.
- By default, only the IPv4 peers configured in the BGP-IPv4 unicast address family view are automatically added to a peer group. That is, after the **peer** *ipv4-address* **group** *group-name* command is configured in the BGP view, the system configures the **peer** *ipv4-address* **group** *group-name* command in the BGP-IPv4 unicast address family view. In other address family views, peers must be manually added to a peer group.

Example

Create an IBGP peer group named test, and then add a peer to it.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group test internal
[HUAWEI-bgp] peer 10.1.1.1 group test
```

Create an EBGP peer group named **test** and add an IPv6 peer to this peer group.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group test external
```

```
[HUAWEI-bgp] peer 2001:db8:1::1 as-number 200
[HUAWEI-bgp] peer 2001:db8:1::1 group test
[HUAWEI-bgp] ipv6-family unicast
[HUAWEI-bgp-af-ipv6] peer test enable
[HUAWEI-bgp-af-ipv6] peer 2001:db8:1::1 group test
```

7.8.119 peer ignore

Function

The **peer ignore** command prevents a BGP device from establishing a session with a peer or peer group.

The **undo peer ignore** command permits a BGP device from establishing a session with a peer or peer group.

By default, the device is permitted to set up the session with the BGP peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **ignore**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **ignore**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-VPN instance IPv4 address family view, and BGP-VPN instance IPv6 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a BGP device needs to transitorily close the session with a peer and reconfiguring the peer requires too much workload, the **peer ignore** command can be used to avoid the reconfiguration of the peer. For example, if the peer relationship frequently alternates between Up and Down because of the upgrade of a peer or the adjustment of the link, the BGP peer relationship needs to be interrupted temporarily. In this case, the **peer ignore** command can be used on the stabler end to prevent frequent flapping of the route or peer relationship.

The **peer ignore** command is used to tear down sessions between a BGP device and its peer or peer group and delete all related routing information. In the case of a peer group, a large number of sessions are suddenly torn down.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

After the **peer ignore** command is run on a device, the session between the device and its peer is closed and all the related routing information is cleared.

After a BGP session is successfully established, running the **peer ignore** command interrupts the BGP session. The interrupted BGP session cannot be established again, and the status of the corresponding BGP peer relationship is displayed as Idle.

Running the **peer ignore** command together with the **peer enable** command equals running of the **reset bgp** command. Both methods can be used to configure a device to re-establish a session.

Example

Prohibit a device from establishing any session with peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 ignore
```

7.8.120 peer ip-prefix

Function

The **peer ip-prefix** command configures a route filtering policy based on an IP address prefix list for a peer or peer group.

The **undo peer ip-prefix** command cancels the route filtering policy based on an IP address prefix list of a peer or peer group.

By default, no route filtering policy based on an IP address prefix list is configured for a peer or peer group.

Format

peer { *group-name* | *ipv4-address* } **ip-prefix** *ip-prefix-name* { **import** | **export** }

peer { *group-name* | *ipv4-address* | *ipv6-address* } **ipv6-prefix** *ipv6-prefix-name* { **import** | **export** }

undo peer { *group-name* | *ipv4-address* } **ip-prefix** [*ip-prefix-name*] { **import** | **export** }

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **ipv6-prefix** [*ipv6-prefix-name*] { **import** | **export** }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ip-prefix *ip-prefix-name*	Indicates the filtering policy that is based on the IPv4 prefix list of the peer or peer group.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
import	Applies a filtering policy to the routes received from a peer or peer group.	-
export	Applies a filtering policy to the routes to be advertised to a peer or peer group.	-
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
ipv6-prefix *ipv6-prefix-name*	Indicates the filtering policy that is based on the IPv6 prefix list of the peer or peer group.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view, and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer ip-prefix** command can be used to configure a route filtering policy that is based on an IP prefix list to filter routes received or routes to be advertised, implementing route control.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

If the **peer ip-prefix** command specifies an IP prefix list that does not exist for a peer or peer group, use the **ip ip-prefix** or **ip ipv6-prefix** command to create an IP prefix list.

Precautions

If an IP prefix list is specified for a peer group, all the members of the peer group inherit the configuration.

After an IP prefix list is specified for a peer or peer group, the peer or peers in the peer group filter the routes to be advertised to or received from other peers based on the IP prefix list. Only the routes that pass the filtering of the IP prefix list can be advertised or received.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes are advertised to the specified peer, or all routes advertised by the specified peer are accepted.

Example

Configure a route filtering policy based on an IP prefix list.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 ip-prefix list1 import
```

7.8.121 peer keychain (BGP)

Function

The **peer keychain** command configures the keychain authentication for establishing the TCP connection between BGP peers.

The **undo peer keychain** command restores the default setting.

By default, the keychain authentication is not configured for BGP peers.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

peer { *group-name* | *ipv4-address* } **keychain** *keychain-name*

undo peer { *group-name* | *ipv4-address* } **keychain**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a BGP peer.	It is in dotted decimal notation.
keychain-name	Specifies the name of the keychain authentication.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Views

BGP view, BGP-VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Configuring keychain authentication improves the security of the TCP connection. You must configure keychain authentication specified for TCP-based applications on both BGP peers. Note that encryption algorithms and passwords configured for the keychain authentication on both peers must be the same; otherwise, the TCP connection cannot be set up between BGP peers and BGP messages cannot be transmitted.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Before configuring the BGP keychain authentication, a keychain in accordance with the configured *keychain-name* must be configured first. For keychain configuration details, see Keychain Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Security*.

Precautions

The **peer keychain** command and the **peer password** command are mutually exclusive. SHA256 and HMAC-SHA256 encryption algorithm are recommended in keychain authentication.

Example

Configure the keychain authentication named test for BGP peers.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 keychain test
```

7.8.122 peer keep-all-routes

Function

The **peer keep-all-routes** command saves all the BGP routing updates from the specified peer or the peer group after the BGP connection is set up, even though those routes do not pass the configured ingress policy.

The **undo peer keep-all-routes** command restores the default setting.

By default, only the BGP routing updates received from the peers and passing the configured ingress policy are saved.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **keep-all-routes**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **keep-all-routes**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, and BGP-IPv6 unicast address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After changing a BGP import policy, you can reset BGP connections for the new import policy to take effect immediately, interrupting these BGP connections temporarily. If a device's peer does not support route-refresh, the **peer keep-all-routes** command can be used on the device to remain all routing updates received from the peer so that the device can refresh its routing table without closing the connection with the peer.

Precautions

If the switch does not support the route-refresh capability, the **peer keep-all-routes** command needs to be run on the switch and its peer. If the **peer keep-all-routes** command is run on a device for the first time, the sessions between the device and its peers will be reestablished.

If the switch supports the route-refresh capability, running this command does not result in re-establishment of the sessions between the switch and its peers. After the **refresh bgp** command is run on the switch, however, the switch does not refresh its routing table.

NOTE

If the switch supports the route-refresh capability, the **peer keep-all-routes** command does not need to be run on it.

Example

Configure a device to store all BGP routing updates received from its IPv4 peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 keep-all-routes
```

7.8.123 peer label-route-capability (BGP)

Function

The **peer label-route-capability** command enables a BGP device to send labeled routes to a specified peer or peer group.

The **undo peer label-route-capability** command disables this function.

By default, this function is disabled.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

BGP view and BGP-IPv4 unicast address family view:

peer { *group-name* | *ipv4-address* } **label-route-capability** [**check-tunnel-reachable**]

undo peer { *group-name* | *ipv4-address* } **label-route-capability**

BGP-IPv6 unicast address family view:

peer *ipv4-address* **label-route-capability**

undo peer *ipv4-address* **label-route-capability**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
check-tunnel-reachable	Checks tunnel reachability when imported routes are sent as labeled routes.	-

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

When the capability of sending labeled routes is enabled or disabled, BGP connection is automatically closed and the capability of the neighbor is re-negotiated.

To configure IPv6 provider edge (6PE), specify the peer as an IPv4 unicast address in the IPv6 unicast address family view.

Tunnel reachability checking can only be used to check tunnels on IPv4 public networks.

- If tunnel reachability checking is enabled, BGP advertises IPv4 unicast routes to peers when routed tunnels are unreachable or advertises labeled routes to peers when routed tunnels are reachable. This eliminates the risk of establishing an MP-EBGP peer relationship between PEs over a faulty label switched path (LSP) because this will cause data forwarding failures.
- If tunnel reachability checking is disabled, BGP advertises labeled routes to peers whether the tunnels for imported routes are reachable or not.

NOTE

To disable tunnel reachability checking, run the **peer** { *group-name* | *ipv4-address* } **label-route-capability** command, not the **undo peer label-route-capability** command.

Before you run the **peer label-route-capability** command, the **peer as-number** command should be used to create a peer or peer group.

Example

Enable BGP to send the labeled routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 200
[HUAWEI-bgp] peer 10.2.3.4 as-number 200
[HUAWEI-bgp] ipv6-family
[HUAWEI-bgp-af-ipv6] peer 10.2.3.4 enable
[HUAWEI-bgp-af-ipv6] peer 10.2.3.4 label-route-capability
```

7.8.124 peer listen-net

Function

The **peer listen-net** command configures BGP to listen to BGP connection requests from a specified network segment and establish BGP peer relationships dynamically.

The **undo peer listen-net** command restores the default configuration.

By default, BGP does not listen to BGP connection requests from any network segment.

Format

peer *group-name* **listen-net** *network* { *mask* | *mask-length* }

undo peer *group-name* **listen-net** *network* { *mask* | *mask-length* }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
network	Specifies the address of the network segment from which BGP listens to BGP connection requests.	The value is in dotted decimal notation.
mask	Specifies the mask of the network segment from which BGP listens to BGP connection requests.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the network segment from which BGP listens to BGP connection requests.	The value is an integer ranging from 0 to 32.

Views

BGP or BGP-VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple BGP peers reside on the same network segment, and the number of the peers may change, you can run the **peer listen-net** command to configure BGP to listen to BGP connection requests from the network segment, establish BGP peer relationships dynamically, and add the peers to a peer group. This spares the local device from adding or deleting BGP peer configurations in response to each change in the peer number, which reduces the maintenance workload.

Prerequisites

A peer group has been configured using the **group** *group-name* [**external** | **internal**] command.

Precautions

If you run the command multiple times, BGP listens to BGP connection requests from multiple network segments.

Example

Configure BGP to listen to BGP connection requests from network segment 10.1.1.0/24 and establish BGP peer relationships dynamically.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group test internal
[HUAWEI-bgp] peer test listen-net 10.1.1.0 24
```

7.8.125 peer listen-only

Function

The **peer listen-only** command configures a peer or peer group to only detect connection requests and not to initiatively send connection requests.

The **undo peer listen-only** command restores the default setting.

By default, a peer or peer group detects and sends connection requests.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **listen-only**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **listen-only**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer listen-only** command is used to configure a peer or peer group to only detect connection requests and not to initiatively send connection requests.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

If the **peer listen-only** command is run multiple times, the latest configuration overwrites the previous one.

After the **peer listen-only** command is executed, the local end does not initiate any connection request to a specified peer.

NOTICE

The **peer listen-only** command can be run at only one end of a peer relationship. If this command is run at both ends of a peer relationship, the ends fail to establish a connection.

Example

Configure peer 10.1.1.1 to only detect connection requests from the remote peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.1 as-number 200
[HUAWEI-bgp] peer 10.1.1.1 listen-only
```

7.8.126 peer log-change

Function

The **peer log-change** command enables a BGP device to log the session status and events of a specified peer or a peer group.

The **undo peer log-change** command disables a BGP device to log the session status and events of a specified peer or a peer group.

By default, a BGP device is enabled to log the session status and events of a specified peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **log-change**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **log-change**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

The **peer log-change** command can be used to enable a device to log the session status and events of a specified peer or peer group, facilitating service management.

Peer relationships have been established using the **peer as-number** command.

Example

Configure a BGP device to log the session status and events of peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 log-change
```

7.8.127 peer next-hop-invariable

Function

The **peer next-hop-invariable** command configures PEs in different ASs not to change next hops of routes when the PEs advertise them to their EBGP peers, and configures the PEs to use the next hops of imported IGP routes when the PEs advertise them to their IBGP peers.

The **undo peer next-hop-invariable** command restores the default setting.

By default, when advertising routes to its EBGP peers and imported IGP routes to IBGP peers, a BGP speaker changes the next hop to its interface address.

Format

peer { *ipv4-address* | *group-name* } **next-hop-invariable**

undo peer { *ipv4-address* | *group-name* } **next-hop-invariable**

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **peer next-hop-invariable** command is used on a device, the device does not change the next hop of an imported IGP route when advertising the route to its IBGP peers, and does not change the next hop of a route when advertising it to its EBGP peers.

In the inter-AS VPN option C networking where an RR is used, the **peer next-hop-invariable** command needs to be run to configure the RR not to change the next-hop address of a route when advertising the route to an EBGP peer. This ensures that the remote PE recurses a route to the BGP LSP destined for the local PE during traffic transmission.

Prerequisites

The **peer as-number** command has been used to create a peer or peer group.

Configuration Impact

After the **peer next-hop-invariable** command is used on a device, the device does not change the next hop of an imported IGP route when advertising the route to its IBGP peers, and does not change the next hop of a route when advertising it to its EBGP peers.

Precautions

The **peer next-hop-invariable** command configured on EBGP peers takes effect only for VPNv4 and VPNv6 routes.

If a device needs to advertise routes to its IBGP peer or peer group, the **peer next-hop-invariable** and **peer next-hop-local** commands are mutually exclusive on the device.

Example

Configure a BGP device not to change the next hop of a route when the BGP device advertises it to its EBGP peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] peer 10.1.1.2 enable
[HUAWEI-bgp-af-vpnv4] peer 10.1.1.2 next-hop-invariable
```

Use the next hop of an IGP route when advertising the IGP route to IBGP peers.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 next-hop-invariable
```

7.8.128 peer next-hop-local

Function

The **peer next-hop-local** command configures a BGP device to set its IP address as the next hop of routes when the BGP device advertises routes to an IBGP peer or peer group.

The **undo peer next-hop-local** command restores the default setting.

By default:

- A BGP router sets its interface IP address as the next-hop address of routes when advertising these routes to an EBGP peer.

- A BGP router does not change the next-hop address of non-labeled routes if the routes are from an EBGP peer and are to be sent to an IBGP peer. The router sets its interface IP address as the next-hop address of labeled routes if the routes are from an EBGP peer and are to be sent to an IBGP peer.
- A BGP router does not change the next-hop address of routes if the routes are from an IBGP peer and are to be sent to an IBGP peer.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **next-hop-local**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **next-hop-local**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BPG-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-L2VPN address family view, and BGP L2VPN-AD address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view, and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer next-hop-local** command is usually run on an autonomous system boundary router (ASBR). By default, when an ASBR forwards a route learned from an EBGP peer to its IBGP peers, the ASBR does not change the next hop of the route. The next-hop address of a route advertised by an EBGP peer is the address of the EBGP peer. After being forwarded to the IBGP peers, the route cannot become an active route because of the unreachable next hop. The **peer next-hop-local** command needs to be run to configure the ASBR to change the next hop of the route to its IP address when the ASBR advertises the route to an IBGP peer. As an IGP runs within the AS, the next hop of the route is reachable. As such, the route received by the IBGP peer is active.

Prerequisites

The **peer as-number** command has been used to create a peer or peer group.

Precautions

The **peer next-hop-local** command is applicable to IBGP peers.

Regarding non-labeled BGP routes on a public network, running the **peer next-hop-local** command on a route reflector to change the next hop of BGP routes does not take effect.

Regarding labeled BGP routes, running this command on a route reflector to change the next hop of BGP routes takes effect.

Running this command on a local device to change the next hop of routes imported or aggregated by the local device does not take effect.

If a device needs to advertise routes to its IBGP peer or peer group, the **peer next-hop-local** and **peer next-hop-invariable** commands are mutually exclusive on the device.

The **peer next-hop-local** command can be configured in the L2VPN-AD address family view, but the configuration does not take effect.

This command is not supported on RRs in BGP VPNv6 scenarios. If it is incorrectly configured on an RR in a BGP VPNv6 scenario, traffic will be interrupted.

Example

Configure a BGP device to set its IP address as the next hop of routes when advertising the routes to peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 next-hop-local
```

7.8.129 peer out-delay

Function

The **peer out-delay** command configures a delay for sending Update packets.

The **undo peer out-delay** command deletes the delay for sending Update packets.

The default delay is 0, indicating that Update packets are sent without a delay.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **out-delay** *delay-value*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **out-delay**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	The value is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
delay-value	Specifies the delay for sending Update packets.	The value is an integer that ranges from 0 to 3600, in seconds.

NOTE

- The *ipv4-address* parameter applies to the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-IPv6 unicast address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-VPN instance IPv4 address family view, BGP L2VPN-AD address family view and BGP-EVPN address family view.
- The *ipv6-address* parameter applies to the BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-IPv4 multicast address family view, BGP L2VPN-AD address family view, BGP-EVPN address family view.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a scenario in which primary and backup routes exist, packets may get lost after traffic switches back to the primary path from the backup path. Use a VPN FRR scenario as an example. PE3 and CE2 connect both to PE1 and PE2. The primary path is PE3 -> PE1 -> CE2, and the backup path is PE3 -> PE2 -> CE2. CE2 uses BGP to communicate with PE1 and PE2. FRR is configured on PE3. If PE1 restarts or the link between PE3 and PE1 is disconnected, traffic switches from the primary path to the backup path. After the primary path recovers, traffic switches back to the primary path. If PE3 completes refreshing forwarding entries before PE1 does so, PE1 may temporarily fail to forward traffic received from PE3, and packet loss may occur. The severity of packet loss is proportional to the number of routes stored on PE1.

To solve this problem, run the **peer out-delay** command on the PE1 to configure a delay for sending Update packets. An appropriate delay ensures that traffic switches back to the primary path after PE1 completes refreshing forwarding entries.

Precautions

If you run the **peer out-delay** command repeatedly, the latest configuration overrides the previous configurations.

If the **peer out-delay** and **peer route-update-interval** commands are both configured, only the **peer out-delay** command takes effect.

If a network has high route convergence requirements, do no use the **peer out-delay** command.

Example

In the BGP view, configure the delay for sending Update packets to 10.1.1.1 as 300s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.1 out-delay 300
```

7.8.130 peer password

Function

The **peer password** command enables a BGP device to implement MD5 authentication for BGP messages exchanged during the establishment of a TCP connection with a peer.

The **undo peer password** command restores the default setting.

By default, a BGP device does not perform MD5 authentication for BGP messages exchanged during the establishment of a TCP connection with a peer.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **password** { **cipher** *cipher-password* | **simple** *simple-password* }

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **password**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
cipher *cipher-password*	Specifies a cipher text password.	The value is a string of case-sensitive characters without spaces. When the value is displayed in plaintext, its length ranges from 1 to 255. When the value is displayed in ciphertext, its length ranges from 20 to 392.
simple *simple-password*	Specifies a plain text password. **NOTICE** If **simple** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is a string of 1 to 255 case-sensitive characters, without spaces.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-VPN instance IPv4 address family view, and BGP-VPN instance IPv6 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP uses TCP as the transport layer protocol. To enhance BGP security, MD5 authentication can be implemented for BGP packets exchanged during the establishment of a TCP connection. MD5 authentication sets the MD5 authentication password for the TCP connection, and the authentication is performed by TCP.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

After the **peer password** command is run, if the MD5 authentication fails, no TCP connection is established.

MD5 authentication and keychain authentication are mutually exclusive on a peer.

After the **peer password** command is run on a device to enable MD5 authentication, the device will re-establish the peer relationship with its peer.

Example

Configure authentication for the TCP connection between a device and peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 password cipher test
```

7.8.131 peer preferred-value

Function

The **peer preferred-value** command sets a preferred value for the routes that a BGP device learns from its peer.

The **undo peer preferred-value** command restores the default preferred value for the routes that a BGP device learns from its peer.

By default, the preferred value of a route learned from a BGP peer is 0.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **preferred-value** *value*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **preferred-value**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
value	Specifies the preferred value of the routes that a BGP device learns from its peer.	The value is an integer that ranges from 0 to 65535.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP L2VPN-AD address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **peer preferred-value** command is run, all the routes learned from the specified peer have the preferred value. If there are multiple routes to the same address prefix, the route with the highest preferred value is preferred.

Prerequisites

A BGP peer has been configured. If the **peer preferred-value** command is used but no BGP peer exists, a message is displayed, indicating that the peer does not exist.

Precautions

If a preferred value is set for the routes that a BGP device learns from a peer group, all members of the peer group inherit the configuration.

Example

Set the preferred value to 50 for the routes that a BGP device learns from a specified peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 preferred-value 50
```

7.8.132 peer public-as-only

Function

The **peer public-as-only** command configures the AS-Path attribute in a BGP Update packet not to carry the private AS number. Only the public AS number is contained in the update packets.

The **undo peer public-as-only** command restores the default setting.

By default, the AS-Path attribute in a BGP Update packet is allowed to carry private AS numbers.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **public-as-only** [**force**]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **public-as-only**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
force	In the following two cases, BGP does not delete the private AS number after the command is used: ● The AS_Path of a route contains the AS number of the peer. In this case, deleting the private AS numbers may lead to a routing loop. ● The AS_Path list contains both public network AS numbers and private AS numbers, indicating that the route has passed through the public network. Deleting the private AS numbers may lead to a forwarding error. To enable the device to delete the private AS numbers from the AS_Path attribute before sending update packets even in the preceding scenarios, specify **force** in the command.	-

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP L2VPN-AD address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In general, an AS number ranges from 1 to 4294967295. The public AS number ranges from 1 to 64511, and 65536 (1.0 in the format of x.y) to 4294967295 (65535.65535 in the format of x.y), and the private AS number ranges from 64512 to 65534. 65535 is used as the reserved AS number in certain circumstances.

Public AS numbers can be used on the Internet. Private AS numbers cannot be advertised to the Internet, and they are used only within ASs. If private AS numbers are advertised to the Internet, a routing loop may occur. After this command is configured, if the AS path attribute contains only private AS numbers, BGP deletes the private AS numbers and then advertises these update routes.

BGP does not delete private AS numbers in either of the following scenarios if the **peer public-as-only** command is run, without any parameter following **public-as-only** specified:

- The AS_Path attribute of a route carries the AS number of the remote peer. In this case, deleting private AS numbers may lead to a routing loop.
- The AS_Path attribute carries both public and private AS numbers, which indicates that the route has passed through the public network. In this case, deleting private AS numbers may lead to a traffic forwarding error.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Example

Configure a device to remove all private AS numbers from the AS_Path attribute when sending a BGP Update packet to its peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 public-as-only
```

7.8.133 peer reflect-client

Function

The **peer reflect-client** command configures the local device as the route reflector and the peer or peer group as the client of the route reflector.

The **undo peer reflect-client** command restores the default setting.

By default, the route reflector and its client are not configured.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **reflect-client**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **reflect-client**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view and BGP-EVPN address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view, BGP-EVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Full-meshed connections need to be established between IBGP peers to ensure the connectivity between the IBGP peers. If there are n switches in an AS, n*(n-1)/2 IBGP connections need to be established. A large number of IBGP peer use a lot of network and CPU resources. An RR can be used to solve the problem.

In an AS, one switch functions as an RR and other switches function as clients. The clients establish IBGP connections with the RR. The RR and its clients form a cluster. The RR reflects routes among the clients, and therefore the clients do not need to establish any IBGP connection. Assume that an AS has n devices. If one of the devices functions as a RR, and other devices function as clients, the number of IBGP connections to be established is n-1. This means that network and CPU resources are greatly reduced.

An RR is easy to configure, because it needs to be configured only on the device that functions as a reflector and clients do not need to know that they are clients.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

The device where the **peer reflect-client** command is run serves as the RR and a specified peer or peer group serves as the client of the RR.

The **peer reflect-client** command can be only used between IBGP peers or IBGP peer groups.

reflect-client configured in an address family is valid in this family address and cannot be inherited by other address families. Configuring **reflect-client** in a specified address family is recommended.

Example

Configure a peer as a client of an RR.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 reflect-client
```

7.8.134 peer route-limit

Function

The **peer route-limit** command sets the maximum number of routes that can be received from a peer.

The **undo peer route-limit** command restores the default setting.

By default, there is no limit on the number of routes that can be received from a peer.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-limit** *limit* [*percentage*] [**alert-only** | **idle-forever** | **idle-timeout** *minutes*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-limit**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
limit	Specifies the maximum number of routes that can be received from a peer.	-
percentage	Specifies the percentage of received routes when the switch starts to generate alarms.	The value is an integer that ranges from 1 to 100. The default value is 75.
alert-only	Indicates that if the number of received routes exceeds the limit, an alarm will be generated and no additional routes will be accepted.	-
idle-forever	Indicates that after the number of routes exceeds the limit, no connection is established automatically until the **reset bgp** command is run.	-
idle-timeout *minutes*	Specifies the value of the timeout timer. The connection, which is closed because the number of routes exceeds the threshold, is automatically reestablished after the timeout timer expires. Before the timer expires, the **reset bgp** command can be used to re-establish a connection.	The value is an integer that ranges from 1 to 1200, in minutes.

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view,BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP L2VPN-AD address family, BGP-L2VPN address family view, BGP-VPLS address family view, BGP-IPv6 unicast address family view, and BGP-VPNv6 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **peer route-limit** command is used to set the maximum number of routes that a BGP switch is allowed to receive from its peer. This provides a mechanism for controlling the routes received from peers in addition to distribution lists, filtering lists, and route mappings.

If a peer relationship between two devices is in the Established state, the following situations occur:

- If the number of routes received by the switch exceeds the upper limit and the **peer route-limit** command is used for the first time, the switch and its peer re-establish the peer relationship, regardless of whether **alert-only** is set.
- If the upper limit set on the switch is increased to be greater than the number of received routes, the switch sends Refresh packets to receive routes again. If the switch does not support the route-refresh capability, the switch needs to re-establish the connection with its peer.
- If the upper limit set on the switch is reduced but is still greater than the number of received routes, only configuration parameters need to be modified.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

If the **peer route-limit** command is run for a peer group, the peers of the peer group inherit the configuration.

If the peer relationship is in the Idle state because the number of received routes exceeds the upper limit and **idle-forever** or **idle-timeout** is set, the **reset bgp** command can be used to re-establish the peer relationship.

Assume that none of **alert-only**, **idle-forever**, and **idle-timeout** is configured. If the number of routes exceeds the upper limit, an alarm is generated and recorded in the log. Then, the peer relationship is disconnected. The devices try to re-establish the peer relationship after 30 seconds.

Example

Set the maximum number of routes that can be received from a peer to 5000.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 route-limit 5000
```

7.8.135 peer route-policy

Function

The **peer route-policy** command specifies a route-policy for filtering routes received from a peer or peer group or routes to be advertised to a peer or peer group.

The **undo peer route-policy** command restores the default setting.

By default, no route-policy is configured for filtering routes received from a peer or peer group or routes to be advertised to a peer or peer group.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-policy** *route-policy-name* { **import** | **export** }

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-policy** *route-policy-name* { **import** | **export** }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
route-policy-name	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
import	Applies a route-policy to routes to be imported from a peer or peer group.	-
export	Applies a route-policy to routes to be advertised to a peer or peer group.	-

NOTE

- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPNv6 address family view, and BGP L2VPN-AD address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a route-policy is created, the **peer route-policy** command is used to apply a Route-Policy to a peer or a peer group so that the routes advertised to or received from the peer or peer group can be controlled. To be specific, only the necessary routes are received from or advertised to the peer or peer group. In this manner, route management is implemented, the scale of the routing table is reduced, and fewer network resources are consumed.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

If the **peer route-policy** command specifies a route-policy that does not exist, use the **route-policy** command to create the route-policy.

Precautions

Currently, the **peer route-policy** command cannot be used to apply a route-policy to set preferences for BGP routes.

The **preference** command cannot configure the preference for routes imported using the **network** command or the **import-route** command. The preference for these routes is 0.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured priority is set for all routes; if no priority is configured, the default priority is set for the routes.

Example

Apply a route-policy named test-policy to the routes received from a peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer 10.1.1.2 route-policy test-policy import
```

7.8.136 peer route-update-interval

Function

The **peer route-update-interval** command sets the interval at which a device sends routing updates carrying the same prefix to a peer or peer group.

The **undo peer route-update-interval** command restores the default setting.

By default, the interval at which routing updates are sent to IBGP peers is 15s, and the interval at which routing updates are sent to EBGP peers is 30s.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-update-interval** *interval*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **route-update-interval**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
interval	Specifies the minimum interval at which routing updates are sent.	The value is an integer that ranges from 0 to 600, in seconds.

NOTE

- *group-name* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, and BGP-VPN instance IPv6 address family view.
- *ipv4-address* is valid only in the BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP-IPv6 unicast address family view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When routes change, the switch sends routing updates to notify its peers. If a route changes frequently, the **peer route-update-interval** command can be used to adjust the interval at which Update packets are sent for changes of this route. This frees the switch from sending Update packets for every route change.

Prerequisites

If the **peer route-update-interval** command is used but no peer exists, a message is displayed, indicating that the peer does not exist.

Precautions

If a route is withdrawn, the switch immediately sends an Update message to its peers, regardless of the **peer route-update-interval** configuration. If a route is added and the interval between the last route addition time and the current route addition time is greater than the interval configured using the **peer route-update-interval** command, the switch immediately sends an Update message to its peers. If a route is added and the interval between the last route addition time and the current route addition time is less than the interval configured using the **peer route-update-interval** command, the switch sends an Update message to its peers only after the configured interval expires.

Example

Set the interval at which routing updates are sent to a peer to 10s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 route-update-interval 10
```

7.8.137 peer timer

Function

The **peer timer** command sets the Keepalive timer and Hold timer for a peer or peer group.

The **undo peer timer** command restores the default values of the Keepalive timer and Hold timer.

By default, the value of a Keepalive timer is 60s and the value of a Hold timer is 180s.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **timer keepalive** *keepalive-time* **hold** *hold-time* [**min-holdtime** *min-holdtime*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **timer keepalive** *keepalive-time* **hold** *hold-time* [**min-holdtime** *min-holdtime*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **timer keepalive hold** [**min-holdtime**]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
keepalive-time	Specifies the Keepalive period.	The value is an integer that ranges from 0 to 21845, in seconds.
hold-time	Specifies the holdtime.	The value is an integer that can be 0, or ranges from 3 to 65535, in seconds. **NOTE** Setting the hold interval of a BGP peer or peer group to be longer than 20s is recommended. If the hold interval of a BGP peer or peer group is shorter than 20s, the session may be closed.
min-holdtime *min-holdtime*	Specifies the minimum Holdtime configured on the local device. **NOTE** The value of *min-holdtime* configured cannot exceed the value of *hold-time*.	The value is an integer that ranges from 20 to 65535, in seconds.

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After establishing a BGP connection, two peers send Keepalive messages periodically to each other to detect the status of the BGP connection. If a device receives no Keepalive message or any other types of packets from its peer within the holdtime, the device considers the BGP connection closed, and it closes the BGP connection.

When the peers set up a connection, the values of *keepalive-time* and *hold-time* are determined by negotiations between the peers. Each of the two peers sends the other an Open packet containing *hold-time*. The smaller of the *hold-time* values contained in the Open packets from both peers is used. The smaller of the locally configured *keepalive-time* value and one third of the negotiated *hold-time* value is used as the actual *keepalive-time* value.

The **peer timer** command is used to set the Keepalive period and holdtime.

- If short Keepalive period and holdtime are set, BGP can detect a link fault quickly and implement link switching. The number of Keepalive messages on the network, however, is increased. This increases device loads and consumption of network bandwidth resources.
- If long Keepalive period and holdtime are set, the number of Keepalive messages on the network is reduced. This reduces device loads. If, however, the Keepalive period is too long, BGP is unable to detect link status changes in a timely manner, causing many packets to be lost.

If the local device establishes BGP peer relationships with many devices, it needs to process huge BGP messages. If *hold-time* negotiated among BGP peers is small, the timer may expire before the local device processes the Keepalive messages sent from other BGP peers. The peer relationships are then interrupted, and routes flap. To solve the preceding problem, you can configure an appropriate value for **min-holdtime** *min-holdtime* based on the CPU processing capability of the local device.

If the value of *min-holdtime* is changed, but the values of *keepalive-time* and *hold-time* negotiated between two BGP peers remain unchanged, the established peer relationship is not affected. Only when the local device attempts to re-establish a relationship with a remote device, the value of *min-holdtime* configured on the local device takes effect. The local device compares *min-holdtime* with *hold-time* sent from the remote device. If the value of *min-holdtime* exceeds that of *hold-time*, *hold-time* negotiation fails, and the peer relationship fails to be established.

NOTE

If *min-holdtime* is configured on the local device, and the value of *hold-time* sent from the remote device is 0, *hold-time* negotiation between the two devices succeeds. The negotiated value of *hold-time* is 0, and the peer relationship is established. The value 0 of *hold-time* indicates that the peer relationship never expires.

Prerequisites

Peer relationships have been established using the **peer as-number** command.

Precautions

NOTICE

If the value of a timer changes, the BGP peer relationship between devices will be disconnected. This is because the devices need to re-negotiate the values of *keepalive-time* and *hold-time*. Therefore, exercise caution before changing the value of a timer.

The Keepalive period must be at least three times of the holdtime.

When setting the values of *keepalive-time* and *hold-time*, note the following points:

- The values of *keepalive-time* and *hold-time* cannot both be set to 0. This renders the BGP timers invalid. BGP is unable to detect link faults using the timers.
- The *hold-time* value cannot be significantly greater than the *keepalive-time* value. A setting of **timer keepalive 1 hold 65535**, for example, would be improper. If the holdtime is too long, link faults cannot be detected in a timely manner.

The Keepalive period and Holdtime can be configured globally, or on a particular peer or peer group. The Keepalive period and Holdtime configured on a specific peer or peer group take precedence over the global Keepalive period and Holdtime. Using this command can still change the Keepalive period and Holdtime configured on a peer or peer group, although they were globally configured through the **timer** command.

Example

Set the Keepalive timer and Hold timer for peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 timer keepalive 10 hold 30
```

7.8.138 peer tnl-policy

Function

The **peer tnl-policy** command applies the tunnel policy to the specified IPv4 peer.

The **undo peer tnl-policy** command removes the tunnel policy applied to the peer.

By default, no tunnel policy is applied to the peer.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

peer *ipv4-address* **tnl-policy** *tnl-policy-name*

undo peer *ipv4-address* **tnl-policy**

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of the peer.	-
tnl-policy-name	Specifies the name of the tunnel policy.	The name is a string of 1 to 39 characters. It is case-sensitive.

Views

BGP-IPv6 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

When you configure the 6PE to support the tunnel, you need to configure the tunnel policy and apply the tunnel policy by using the command.

Before you configure the **peer tnl-policy** command, the **peer as-number** command should be used to create a peer or peer group.

Example

Apply the tunnel policy to the specified peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 100
[HUAWEI-bgp] ipv6-family unicast
[HUAWEI-bgp-af-ipv6] peer 10.1.1.2 enable
[HUAWEI-bgp-af-ipv6] peer 10.1.1.2 tnl-policy policy-a
```

7.8.139 peer timer connect-retry

Function

The **peer timer connect-retry** command sets a ConnectRetry interval for a peer or peer group.

The **undo peer timer connect-retry** command restores the default setting.

By default, the ConnectRetry interval is 32s.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies an IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies an IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
connect-retry-time	Specifies a ConnectRetry interval.	The value ranges from 1 to 65535, in seconds.

NOTE

- *ipv4-address* can be set only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view.

Views

BGP view, BGP-VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When BGP initiates a TCP connection, the ConnectRetry timer is stopped if the TCP connection is established successfully. If the first attempt to establish a TCP connection fails, BGP tries again to establish the TCP connection after the ConnectRetry timer expires. The ConnectRetry interval can be adjusted as needed.

- The ConnectRetry interval can be reduced in order to lessen the time BGP waits to retry establishing a TCP connection after the first attempt fails.
- To suppress route flapping caused by constant peer flapping, the ConnectRetry interval can be increased to accelerate route convergence.

Prerequisites

The **peer as-number** command has been used to create a peer or peer group.

Precautions

A ConnectRetry interval can be configured globally, or on a particular peer or peer group. A ConnectRetry interval configured on a specific peer or peer group takes precedence over a global ConnectRetry interval.

- If both the **peer** { *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time* command and the **peer** *group-name* **timer connect-retry** *connect-retry-time* command are run on a device, the configuration of the **peer** { *ipv4-address* | *ipv6-address* }**timer connect-retry** *connect-retry-time* command takes effect, but the configuration of the **peer** *group-name* **timer connect-retry** *connect-retry-time* command does not.
- If both the **peer** { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time* command and the **timer connect-retry** *connect-retry-time* command are run on a device, the configuration of the **peer** { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time* command takes effect, but the configuration of the **timer connect-retry** *connect-retry-time* command does not.

Example

Set the ConnectRetry interval to 60s for peer 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 timer connect-retry 60
```

7.8.140 peer tracking

Function

The **peer tracking** command enables BGP peer tracking.

The **undo peer tracking** The command restores the interval between peer unreachability discovery and connection interruption to the default value (9s).

The **peer tracking disable** command disables BGP peer tracking.

The **undo peer tracking disable** command enables BGP peer tracking. The default interval between peer unreachability discovery and connection interruption is 9s.

By default, BGP peer tracking is enabled, and the interval between peer unreachability discovery and connection interruption is 9s.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **tracking** [**delay** *delay-time*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **tracking**

peer { *group-name* | *ipv4-address* | *ipv6-address* } **tracking disable**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **tracking disable**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a BGP peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a BGP peer.	The address is a 32-digit hexadecimal number in the X:X:X:X:X:X:X:X format.
delay *delay-time*	Indicates the interval between when BGP detects the peer unreachable and when BGP tears down the corresponding connection.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 9 seconds.

NOTE

- *ipv4-address* can be set only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* can be set only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a network where BFD is unsuitable to be deployed, you can configure BGP peer tracking on the local device to implement fast network convergence by rapidly detecting the unreachable state of the peer.

A proper value of *delay-time* can ensure network stability when a peer is detected unreachable.

- If *delay-time* is set to 0, BGP immediately tears down the connection between the local device and its peer after the peer is detected unreachable.

- If IGP route flapping occurs and *delay-time* for an IBGP peer is set to 0, the peer relationship between the local device and the peer alternates between Up and Down. Therefore, *delay-time* for an IBGP peer should be set to a value greater than the actual IGP route convergence time.
- When BGP neighbors successfully perform the GR negotiation, the active/standby switchover occurs on the BGP neighbors, to prevent the failure of GR, *delay-time* should be set to a value greater than GR convergence time. If *delay-time* is set to be smaller than the GR convergence time, the connection between the local device and the BGP peer will be torn down, which leads to the failure of GR.

Prerequisites

The **peer as-number** command has been used to create a peer or peer group.

Precautions

IGP is configured with GR, and the BGP neighbor relationship is established based on IGP routes. In such a situation, when a node fails on the network and the master/slave switchover occurs on the node, IGP does not delete the routes from the node, and BGP neighbors cannot sense the fault on the node. Therefore, the BGP peer tracking function does not take effect.

Example

Configure BGP peer tracking.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 tracking delay 20
```

7.8.141 peer valid-ttl-hops

Function

The **peer valid-ttl-hops** command applies the GTSM function on the peer or peer group.

The **undo peer valid-ttl-hops** command cancels the application of the GTSM function on the peer or peer group.

By default, the GTSM function on the peer or peer group is not configured.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **valid-ttl-hops** [*hops*]

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **valid-ttl-hops**

Parameters

Parameter	Description	Value
group-name	Specifies the name of the peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
hops	Specifies the number of TTL hops to be checked.	The value is an integer that ranges from 1 to 255. The default value is 255. If the value is configured as *hops*, the valid TTL range of the detected packet is [255 - *hops* + 1, 255].

NOTE

- *ipv4-address* is valid only in the BGP view and BGP-VPN instance IPv4 address family view.
- *ipv6-address* is valid only in the BGP view and BGP-VPN instance IPv6 address family view.

Views

BGP view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To protect a device against the attacks of forged BGP packets, you can configure GTSM to check whether the TTL value in the IP packet header is within the specified range.

Prerequisites

Before configuring GTSM for a peer group, run the **peer group** command to add peers to the peer group.

Precautions

When the **undo peer valid-ttl-hops** command is run and no parameter is specified, all the GTSM configurations on a peer or a peer group are deleted.

The configuration in the BGP view is also valid for the extension of MP-BGP. This is because they use the same TCP connection.

The GTSM configurations are symmetrical, that is, GTSM must be enabled on both ends of the BGP connection at the same time.

NOTE

- GTSM and EBGP-MAX-HOP are mutually exclusive because both of them affect the TTL of the sent BGP packet. Therefore, the two functions cannot be enabled on a peer or peer group simultaneously.
- If GTSM is enabled on two directly connected EBGP peers, the fast sensing function is invalid on the interfaces directly connecting the two EBGP peers. This is because BGP considers the EBGP peers indirectly connected when GTSM is enabled on the EBGP peers.

Example

Configure the GTSM function for the peer.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.2 as-number 200
[HUAWEI-bgp] peer 10.1.1.2 valid-ttl-hops 1
```

Configure the GTSM function for the peer group.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group gtsm-group external
[HUAWEI-bgp] peer gtsm-group valid-ttl-hops 1
```

7.8.142 preference (BGP)

Function

The **preference** command configures the protocol preferences for external routes, internal routes, aggregated routes, and crossed routes.

The **undo preference** command restores the default protocol preferences.

By default, the protocol preferences of external routes, internal routes, aggregated routes, and crossed routes are all 255.

Format

preference { *external internal local* | **route-policy** *route-policy-name* }

preference *external internal local* **route-policy** *route-policy-name*

undo preference

Parameters

Parameter	Description	Value
external	Specifies the protocol preference for external routes. An external route is the optimal route learned from an EBGP peer outside the local AS.	The value is an integer that ranges from 1 to 255. The smaller the value is, the higher the preference is.

Parameter	Description	Value
internal	Specifies the protocol preference for internal routes. An internal route is a route learned from an IBGP peer inside the local AS.	The value is an integer that ranges from 1 to 255. The smaller the value is, the higher the preference is.
local	Specifies the protocol preference for aggregated and crossed routes. This parameter takes effect for the following routes: ● Manually summarized routes generated using the **aggregate (BGP)** command ● Automatically summarized routes generated using the **summary automatic** command ● Routes generated through remote route cross ● Routes generated through local route cross For details about these routes, see **Precautions**.	The value is an integer that ranges from 1 to 255. The smaller the value is, the higher the preference is.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Running the **preference** command to set protocol preferences for BGP routes affects route selection among BGP routes and routes of other routing protocols.

After a route-policy is configured on a device, the device sets preferences only for the routes received from peers, which meet the matching rules. The routes that do not meet the rules use the default preference.

The smaller the preference value, the higher the preference.

Different protocol preferences can be configured for BGP routes in different address family views.

If both *external internal local* and **route-policy** *route-policy-name* are specified in the command, the priority of the routes that match the route-policy is set based on the route-policy, and the priorities of other routes are set based on the *external internal local* configuration.

Prerequisites

Create the route-policy first if the **preference** command uses the **route-policy** to set preferences.

Perform the following steps when the route-policy is used to set preferences:

- Use the **route-policy** command to create the route-policy, and enter the route-policy view.
- Configure the **if-match** clause to set the matching rules for routes. The relationship between the **if-match** clauses in a node of a route-policy is "AND". A route must match all the rules before the action defined by the **apply** clause is taken. If no **if-match** clause is specified, all routes will match the node in the route-policy.
- Use the **apply preference** command to set preferences for routes that pass the filtering.

Precautions

- Currently, the **peer route-policy** command cannot be used to apply a route-policy to set preferences for BGP routes.
- The **preference** command cannot configure the preference for routes imported using the **network** command or the **import-route** command. The preference for these routes is 0.
- Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured priority is set for all routes; if no priority is configured, the default priority is set for the routes.
- In this command, the *local* parameter specifies the protocol preference for aggregated routes and crossed routes. This parameter takes effect for the following routes:
  - Manually aggregated routes generated using the **aggregate (BGP)** command. The **Route type** field for this type of route displays **Aggregated route**. For example:

```
<HUAWEI> display bgp routing-table 10.0.0.0
 BGP local router ID : 192.168.2.4
 Local AS number : 200
 Paths:   1 available, 1 best, 1 select
 BGP routing table entry information of 10.0.0.0/8:
 Aggregated route
 Route Duration: 04h50m46s
 Direct Out-interface: NULL0
 Original nexthop: 127.0.0.1
 Qos information : 0x0
 AS-path {65001 10 100}, origin incomplete, pref-val 0, valid, local, best, select, active, pre 255
```

```
 Aggregator: AS 200, Aggregator ID 192.168.2.4, Atomic-aggregate
 Advertised to such 3 peers:
    10.1.7.2
    172.16.1.2
    192.168.1.2
...
```

- Automatically aggregated routes generated using the **summary automatic** command. The route type for these routes displays **Summary automatic route**. For example:

```
<HUAWEI> display bgp routing-table 10.0.0.0
 BGP local router ID : 192.168.2.4
 Local AS number : 200
 Paths:   1 available, 1 best, 1 select
 BGP routing table entry information of 10.0.0.0/8:
 Summary automatic route
 Route Duration: 04h50m46s
 Direct Out-interface: NULL0
 Original nexthop: 127.0.0.1
 Qos information : 0x0
 AS-path {65001 10 100}, origin incomplete, pref-val 0, valid, local, best, select, active, pre 255
 Aggregator: AS 200, Aggregator ID 192.168.2.4, Atomic-aggregate
 Advertised to such 3 peers:
    10.1.7.2
    172.16.1.2
    192.168.1.2
...
```

- Routes generated through remote route cross. The route type for these routes displays **Remote-Cross route**. For example:

```
[HUAWEI-diagnose] display bgp vpnv4 vpn-instance vrf routing-table 172.16.17.161

BGP local router ID : 10.17.0.17
Local AS number : 100

VPN-Instance vrf, Router ID 10.17.0.17:
Paths:   1 available, 1 best, 1 select
BGP routing table entry information of 172.16.17.161/32:
Remote-Cross route
Label information (Received/Applied): 155665/NULL
From: 10.216.0.1 (10.17.0.9)
Route Duration: 3d04h26m28s
 Relay Tunnel Out-Interface: Vlanif100
Relay token: 0x24e7
Relay Tunnel Key: 7
Original nexthop: 10.216.0.1
Qos information : 0x0
Ext-Community:RT <10 : 10>
AS-path 100, origin incomplete, localpref 150, pref-val 1, valid, internal, best, select, active, pre
255, IGP cost 1
...
```

- Routes generated through local route cross. The route type for these routes displays **Local-Cross route**. For example:

```
[HUAWEI-diagnose] display bgp vpnv4 vpn-instance vrf1 routing-table 10.2.2.0

 BGP local router ID :
10.1.1.1
 Local AS number :
100

 VPN-Instance vrf1, Router ID
10.1.1.1:
 Paths:   1 available, 1 best, 1
select
 BGP routing table entry information of
10.2.2.0/24:
 Local-Cross route(via VPN-Instance
vrf2)
```

```
 Route Duration:
00h26m00s
 Direct Out-interface:
Vlanif40
 Original nexthop:
10.2.2.2
 Qos information :
0x0
 Ext-Community:RT <100 :
1>
 AS-path Nil, origin incomplete, MED 0, pref-val 0, valid, local, best, select, active, pre 255
...
```

Example

Set the protocol preference to 2 for external routes, 2 for internal routes, and 20 for aggregated routes and crossed routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] preference 2 2 20
```

7.8.143 reflect between-clients

Function

The **reflect between-clients** command enables route reflection among clients.

The **undo reflect between-clients** command disables route reflection among clients.

By default, route reflection among clients is enabled.

Format

reflect between-clients

undo reflect between-clients

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view, BGP-EVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On some networks, if the clients of an RR establish full-mesh connections with each other, they can directly exchange routing information. Route reflection among clients is unnecessary. The **undo reflect between-clients** command can be used to prohibit the clients from reflecting routes to each other to reduce costs.

Prerequisites

An RR has been configured.

Precautions

The **reflect between-clients** command is run only on RRs.

Example

Disable route reflection among fully-meshed clients.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] group rr-client internal
[HUAWEI-bgp] peer 10.1.2.1 group rr-client
[HUAWEI-bgp] peer 10.1.3.1 group rr-client
[HUAWEI-bgp] peer 10.1.4.1 group rr-client
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] peer rr-client reflect-client
[HUAWEI-bgp-af-ipv4] undo reflect between-clients
```

7.8.144 reflect change-path-attribute

Function

The **reflect change-path-attribute** command enables a route-reflector (RR) to modify the route attributes of BGP routes using the export policy.

The **undo reflect change-path-attribute** command disables an RR from modifying the route attributes of BGP routes using the export policy.

By default, an RR is disabled from modifying route attributes of BGP routes using the export policy.

Format

reflect change-path-attribute

undo reflect change-path-attribute

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Using an RR to modify route attributes may cause route loops. According to RFC 4456, you cannot enable an RR to modify the route attributes using the export policy. So an RR is disabled from modifying route attributes using the export policy by default.

To re-plan the network traffic, run the **reflect change-path-attribute** command to enable the RR to modify the route attributes using the export policy. After the command is run, the following configurations take effect.

- Run the **apply as-path** command to modify the AS-Path attributes of BGP routes.
- Run the **apply comm-filter delete** command to delete all community attributes from BGP routes.
- Run the **apply community** command to modify the community attributes of BGP routes.
- Run the **apply cost** command to modify the cost of BGP routes, that is to modify its MED.
- Run the **apply ip-address next-hop** command to modify the next hop of BGP routes.
- Run the **apply ipv6 next-hop** command to modify the next hop of BGP4+ routes.
- Run the **apply local-preference** command to modify the local preference of BGP routes.
- Run the **apply origin** command to modify the Origin attributes of BGP routes.
- Run the **apply extcommunity** command to modify the extended community attributes of BGP routes.

After the **undo reflect change-path-attribute** command is used, the previous configurations on the RR do not take effect.

Precautions

Export policies on the RR do not take effect before the **reflect change-path-attribute** command is run. After the **reflect change-path-attribute** command is run, these configurations may take effect and affect BGP route selection. Exercise caution when using this command.

For example, peer relationships are established between Switch A(10.1.1.1) and Switch B(10.1.1.2), and Switch A functions as an RR. If two configurations are on SwitchA:

1.
```
[HUAWEI] bgp 65001
```

```
[HUAWEI-bgp] peer 10.1.1.2 next-hop-local
```

2.
```
[HUAWEI] route-policy aa permit node 10
[HUAWEI-route-policy] apply ip-address next-hop 10.3.3.3
[HUAWEI-route-policy] quit
[HUAWEI] bgp 65001
[HUAWEI-bgp] peer 10.1.1.2 route-policy aa export
```

Then:

- Before the **reflect change-path-attribute** command is run, the former configuration takes effect but the latter does not. After A receives routes information from its IBGP peers, it reflects the information to Switch B, and changes the next hop to 10.1.1.1.
- After the **reflect change-path-attribute** command is run, the latter configuration takes effect but the former does not. After A receives routes information from its IBGP peers, it reflects the information to Switch B, and changes the next hop to 10.3.3.3.

NOTE

After you enable the **reflect change-path-attribute** command on the RR, the **peer route-policy export** command takes precedence over the **peer next-hop-invariable** and **peer next-hop-local**.

Example

Enable the RR to modify the route attributes of the BGP routes by using the export policy.

```
<HUAWEI> system-view
[HUAWEI] bgp 65001
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] reflect change-path-attribute
```

7.8.145 reflector cluster-id

Function

The **reflector cluster-id** command sets a cluster ID for an RR.

The **undo reflector cluster-id** command restores the default setting.

By default, each RR uses its router ID as the cluster ID.

Format

reflector cluster-id *cluster-id*

undo reflector cluster-id

Parameters

Parameter	Description	Value
cluster-id	Specifies the cluster ID of an RR.	The value can be an integer that ranges from 1 to 4294967295 or in the format of an IPv4 address.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-VPNv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv6 address family view, BGP-VPLS address family view, BGP-L2VPN address family view, BGP L2VPN-AD address family view, BGP-EVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Sometimes, more than one RR needs to be configured in a cluster to improve network reliability and prevent single-point failures. If a cluster has more than one RR, the **reflector cluster-id** command needs to be used to set the same cluster ID for the RRs. This helps to identify the cluster and avoid routing loops.

Configuring an RR allows IBGP peers to advertise routes learned in the local AS to each other. The Cluster_List attribute is introduced to avoid loops within an AS. The Cluster_List is composed of a series of Cluster_IDs. It records all the RRs through which a route passes.

Precautions

If the **reflector cluster-id** command is run several times, the latest configuration overrides the previous one.

The **reflector cluster-id** command is run only on RRs.

To enable clients to receive routes reflected by RRs, ensure that the cluster ID of the RRs is different from the router ID of any client. If the cluster ID of the RRs is the same as the router ID of a client, the client will discard received routes.

Example

Configure the cluster ID to 50 for the switch, which is an RR in a cluster.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] reflector cluster-id 50
```

7.8.146 refresh bgp

Function

The **refresh bgp** command softly resets a BGP connection.

Format

refresh bgp [**vpn-instance** *vpn-instance-name* **ipv4-family** | **vpnv4**] { **all** | *ipv4-address* | **group** *group-name* | **external** | **internal** } { **export** | **import** }

refresh bgp ipv6 { **all** | **group** *group-name* | *ipv4-address* | *ipv6-address* | **external** | **internal** } { **export** | **import** } (The *ipv4-address* is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

refresh bgp vpnv6 { **all** | *ipv4-address* | **group** *group-name* | **external** | **internal** } { **export** | **import** }

refresh bgp vpn-instance *vpn-instance-name* **ipv6-family** { **all** | *ipv6-address* | **group** *group-name* | **external** | **internal** } { **export** | **import** } (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

refresh bgp l2vpn-ad { *ipv4-address* | **all** | **group** *group-name* | **internal** | **external** } { **import** | **export** }

refresh bgp { **mdt** | **mvpn** } { *ipv4-address* | **all** | **group** *group-name* | **internal** | **external** } { **import** | **export** }

NOTE

The **mdt, mvpn, l2vpn-ad**, **vpnv4**, and **vpnv6** parameter are only supported by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name* **ipv4-family**	Softly resets the connection of a specified VPN instance enabled with an IPv4 address family.	The value must be an existing VPN instance name.
vpnv4	Softly resets the BGP connections in a VPNv4 address family.	-
all	Softly resets all the BGP IPv4 connections.	-
ipv4-address	Specifies the IPv4 address of a BGP peer.	It is in dotted decimal notation.

Parameter	Description	Value
group *group-name*	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
external	Softly resets EBGP connections.	-
internal	Softly resets IBGP connections.	-
export	Triggers outbound soft resetting.	-
import	Triggers inbound soft resetting.	-
ipv6	Softly resets BGP4+ connections.	-
ipv6-address	Specifies the IPv6 address of a BGP4+ peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
vpnv6	Softly resets the BGP connections in a VPNv6 address family.	-
vpn-instance *vpn-instance-name* **ipv6-family**	Resets the connection of a specified VPN instance enabled with an IPv6 address family.	The value must be an existing VPN instance name.
l2vpn-ad	Softly resets the BGP connections related to L2VPN-AD.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a device's peer supports route-refresh, the **refresh bgp** command can be used on the device to softly reset the BGP connection with the peer. BGP soft resetting can be used to refresh the BGP routing table and apply new routing policies, without closing any BGP connection.

Prerequisites

Configuring BGP soft resetting requires that the peers support the route-refresh capability.

Precautions

After the **refresh bgp** command is run on a device configured with the **peer keep-all-routes** command, the device does not refresh its routing table.

Example

Perform inbound soft resetting for all BGP connections to make new configurations take effect.

```
<HUAWEI> refresh bgp all import
```

7.8.147 refresh bgp multicast

Function

The **refresh bgp multicast** command softly resets an MBGP connection. MBGP soft resetting can be used to refresh the MBGP routing table and apply new routing policies, without closing any MBGP connection.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

refresh bgp multicast { *peer-address* | **all** | **group** *group-name* } { **import** | **export** }

Parameters

Parameter	Description	Value
peer-address	Softly resets the MBGP connections with a specified peer.	The peer address is in dotted decimal notation.
all	Softly resets all MBGP connections.	-

Parameter	Description	Value
group-name	Specifies the name of an MBGP peer group. If the parameter is set, the MBGP connections between a device and the members of the specified MBGP peer group are softly reset.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
import	Triggers inbound soft resetting.	-
export	Triggers outbound soft resetting.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

MBGP soft resetting requires that all MBGP devices on a network support the route-refresh capability. The **reset bgp** command can be used on a device that does not support the route-refresh capability to reset the connections between the device and its peer and enable the device to refresh its routing table.

Example

Perform inbound soft resetting for all the MBGP connections to make new configurations take effect.

```
<HUAWEI> refresh bgp multicast all import
```

7.8.148 refresh bgp multicast external

Function

The **refresh bgp multicast external** command softly resets the connections between multicast EBGP peers.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

refresh bgp multicast external { **import** | **export** }

Parameters

Parameter	Description	Value
import	Triggers inbound soft resetting.	-
export	Triggers outbound soft resetting.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run the **refresh bgp multicast external** command to softly reset the connections between multicast EBGP peers.

Example

Trigger inbound soft resetting for all multicast EBGP connections.

```
<HUAWEI> refresh bgp multicast external import
```

7.8.149 refresh bgp multicast internal

Function

The **refresh bgp multicast internal** command softly resets the connections between multicast IBGP peers.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

refresh bgp multicast internal { **import** | **export** }

Parameters

Parameter	Description	Value
import	Triggers inbound soft resetting.	-
export	Triggers outbound soft resetting.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run the **refresh bgp multicast internal** command to softly reset the connections between multicast IBGP peers.

Example

Trigger inbound soft resetting for all multicast IBGP connections.

```
<HUAWEI> refresh bgp multicast internal import
```

7.8.150 reset bgp

Function

The **reset bgp** command resets specified BGP connections.

Format

reset bgp [**vpn-instance** *vpn-instance-name* **ipv4-family** | **vpnv4**] { **all** | *as-number-plain* | *as-number-dot* | *ipv4-address* | **group** *group-name* | **external** | **internal** } [**graceful**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

reset bgp ipv4 all [**graceful**]

reset bgp ipv6 { **all** | *as-number-plain* | *as-number-dot* | **group** *group-name* | *ipv6-address* | *ipv4-address* | **external** | **internal** } [**graceful**] (The *ipv4-address* is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.)

reset bgp vpls { **all** | *as-number-plain* | *as-number-dot* | *ipv4-address* | **external** | **internal** } (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

reset bgp vpnv6 { **all** | *as-number-plain* | *as-number-dot* | *ipv4-address* | **group** *group-name* | **external** | **internal** } [**graceful**] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

reset bgp vpn-instance *vpn-instance-name* **ipv6-family** { **all** | *as-number-plain* | *as-number-dot* | *ipv6-address* | **group** *group-name* | **external** } [**graceful**] (supported only by the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name* **ipv4-family**	Resets the connection of a specified VPN instance enabled with an IPv4 address family.	The value must be an existing VPN instance name.
vpnv4	Resets BGP connections associated with VPNv4.	-
all	Resets all BGP connections.	-
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.
ipv4-address	Resets the BGP connection with a specified peer.	It is in dotted decimal notation.
group *group-name*	Resets the BGP connection with a specified peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
external	Resets all EBGP connections.	-
internal	Resets all IBGP connections.	-
ipv4	Resets BGP IPv4 connections.	-
ipv6	Resets BGP IPv6 connections.	-
ipv6-address	Resets the TCP connection with a specified BGP4+ peer (all the routes learned by using the connection are deleted).	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
vpls	Resets BGP connections associated with VPLS.	-
vpnv6	Resets BGP connections associated with VPNv6.	-
vpn-instance *vpn-instance-name* **ipv6-family**	Resets the connection of a specified VPN instance enabled with an IPv6 address family.	The value must be an existing VPN instance name.
graceful	Resets BGP connections in GR mode.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **reset bgp** command is used to make new BGP configurations take effect.

If a BGP routing policy is configured on the device that does not support Route-Refresh, the **reset bgp** command can be used to make the new routing policy to take effect.

To reset a BGP connection in GR mode, run the **reset bgp** command with the **graceful** parameter specified and run the **graceful-restart peer-reset** command. If the **graceful** parameter is not specified in the **reset bgp** command or if the **graceful-restart peer-reset** command is not run, the GR reset mode does not take effect, so that routing entries will be deleted for existing sessions, interrupting services. The services will be restored after the BGP peer relationship is reestablished.

The **reset bgp ipv4 all** command resets all public-network BGP IPv4 connections.

Precautions

After the **reset bgp** command is run on a device, the TCP connection established by the BGP device and the corresponding peer is reestablished. Exercise caution when running this command.

Example

Reset all BGP connections.

```
<HUAWEI> reset bgp all
```

Reset BGP connections with the peer 2001:DB8:1::1.

```
<HUAWEI> reset bgp ipv6 2001:DB8:1::1
```

Reset all BGP connections with VPNv6.

```
<HUAWEI> reset bgp vpnv6 all
```

Reset BGP sessions with BGP peers within a specified 2-byte AS number.

```
<HUAWEI> reset bgp vpnv6 100
```

Reset BGP sessions with BGP peers within a specified 4-byte AS number.

```
<HUAWEI> reset bgp vpnv4 200.300
```

7.8.151 reset bgp dampening

Function

The **reset bgp dampening** command clears BGP route dampening information and releases the suppressed routes.

Format

reset bgp [**vpn-instance** *vpn-instance-name* **ipv4-family**] **dampening** [*ipv4-address* [*mask* | *mask-length*]]

reset bgp { **ipv6** | **vpn-instance** *vpn-instance-name* **ipv6-family** } **dampening** [*ipv6-address prefix-length*]

reset bgp vpnv4 dampening [*ipv4-address* [*mask* | *mask-length*]] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

NOTE

The **vpn-instance** *vpn-instance-name* **ipv6-family** is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears the route dampening information of the specified VPN instance.	The value must be an existing VPN instance name.
ipv4-family	Indicates an IPv4 unicast address family.	-
ipv4-address	Specifies an IPv4 network address.	It is in dotted decimal notation.

Parameter	Description	Value
mask	Specifies the network mask in dotted decimal notation. If neither of the mask and mask length is specified, the address is considered as a classful address.	It is in dotted decimal notation.
mask-length	Specifies the network mask length. If neither of the mask and mask length is specified, the address is considered as a classful address.	The value is an integer that ranges from 0 to 32.
ipv6	Clears IPv6 route dampening information and releases the suppressed routes.	-
ipv6-family	Indicates an IPv6 unicast address family.	-
ipv6-address	Specifies the IPv6 network address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the length of an IPv6 prefix in decimal notation. It specifies the number of bits in the network address.	The value is an integer that ranges from 0 to 128.
vpnv4	Clears the route dampening information of the BGP VPNv4 routes and releases the suppressed routes.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Route dampening is enabled to solve the problem of route instability. In most situations, BGP is applied to complex networks where routes change frequently. Route dampening is then used to suppress instable routes.

The **reset bgp dampening** command is used to clear the dampening information about specified routes on the public network and release specified suppressed routes. If no IP address is specified in the command, the dampening information about all the routes on the public network is cleared and all suppressed routes are released.

Prerequisites

You can use **display bgp routing-table dampened** command to view the information about suppressed routes.

Precautions

After the **reset bgp dampening** command is run, the suppressed routes are released. If the status of some routes still changes frequently, route flapping may occur. Routing flapping consumes a large number of bandwidth and CPU resources.

When *ipv6-address prefix-length* is not specified, after you run the **reset bgp ipv6 dampening** command, IPv6 route dampening information in the whole BGP routing table is cleared.

Example

Clear the dampening information about routes to network segment 10.1.0.0 and release suppressed routes.

```
<HUAWEI> reset bgp dampening 10.1.0.0 255.255.0.0
```

Clear the dampening information about the IPv6 routes to network segment FC00:0:0:1:: and release suppressed routes.

```
<HUAWEI> reset bgp ipv6 dampening fc00:0:0:1:: 64
```

Clear the dampening information about the routes of IPv6 VPN instance named vpn1.

```
<HUAWEI> reset bgp vpn-instance vpn1 ipv6-family dampening
```

7.8.152 reset bgp flap-info

Function

The **reset bgp flap-info** command clears route flapping statistics.

Format

reset bgp [**vpn-instance** *vpn-instance-name* **ipv4-family**] **flap-info** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *network-address* [*mask* | *mask-length*] | **regexp** *as-path-regexp*]

reset bgp { **ipv6** | **vpn-instance** *vpn-instance-name* **ipv6-family** } **flap-info** [**as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *network-ipv6-address prefix-length* | **regexp** *as-path-regexp*]

reset bgp [**vpn-instance** *vpn-instance-name* **ipv4-family**] *ipv4-address* **flap-info**

reset bgp { **ipv6** | **vpn-instance** *vpn-instance-name* **ipv6-family** } *ipv6-address* **flap-info**

reset bgp vpnv4 flap-info [**regexp** *as-path-regexp* | **as-path-filter** { *as-path-filter-number* | *as-path-filter-name* } | *ipv4-address* [*mask* | *mask-length*]] (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

reset bgp vpnv4 *ipv4-address* **flap-info** (supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

NOTE

The **vpn-instance** *vpn-instance-name* **ipv6-family** is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name* **ipv4-family**	Clears the route flapping information of a specified VPN instance enabled with an IPv4 address family.	The value must be an existing VPN instance name.
as-path-filter *as-path-filter-number*	Clears route flapping statistics based on the number of a specified AS_Path filter.	It is an integer that ranges from 1 to 256.
as-path-filter *as-path-filter-name*	Clears route flapping statistics based on the name of a specified AS_Path filter.	The value of *as-path-filter-name* is a string of 1 to 51 case-sensitive characters. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
network-address	Specifies the IPv4 prefix address that is used to filter the BGP IPv4 routes.	It is in dotted decimal notation.
mask	Specifies the network mask that is used to filter the BGP IPv4 routes. If neither the mask nor the mask length is specified, the address is processed as a classful address.	It is in dotted decimal notation.

Parameter	Description	Value
mask-length	Specifies the network mask length that is used to filter the BGP IPv4 routes. If neither the mask nor the mask length is specified, the address is processed as a classful address.	The value is an integer that ranges from 0 to 32.
regexp *as-path-regexp*	Clears statistics about the flapping routes that match the AS_Path regular expression.	-
ipv6	Clears the route flapping statistics on all IPv6 peers.	-
vpn-instance *vpn-instance-name* **ipv6-family**	Clears the route flapping information of a specified VPN instance enabled with an IPv6 address family.	The value must be an existing VPN instance name.
network-ipv6-address	Specifies the IPv6 prefix address that is used to filter the BGP IPv6 routes.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the network mask length that is used to filter the BGP IPv6 routes.	The value is an integer that ranges from 0 to 128.
ipv4-address	Specifies the network address of an IPv4 peer.	It is in dotted decimal notation.
ipv6-address	Specifies the network address of an IPv6 peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
vpnv4	Resets route flapping statistics of BGP VPNv4 routes.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The process of adding a route to and then deleting the route from a routing table is called route flapping.

When route flapping occurs, the routing protocol sends Update packets to neighbors. The neighbors that receive the Update packets need to recalculate routes and modify the routing table. Therefore, frequent route flapping consumes great bandwidth and CPU resources and even seriously affects network operations.

The **reset bgp flap-info** command is used to clear the flapping information about routes. This allows the switch to re-collect statistics about flapping routes and helps to monitor route changes and locate network problems.

Prerequisites

You can use **display bgp routing-table flap-info** command to view the information about BGP route flapping.

If there are a large number of flapping routes, define an AS_Path filter or an AS_Path regular expression to be referenced in the **reset bgp flap-info** command. The flapping statistics of the routes matching the AS_Path filter or the AS_Path regular expression are then cleared.

Precautions

After the **reset bgp flap-info** command is run, the flapping statistics of routes are reset and cannot be displayed.

Follow-up Procedure

After the flapping statistics of routes are cleared, run the **display bgp routing-table flap-info** command again to display the flapping statistics about BGP routes in order to locate problems.

Example

Clear the flapping statistics about the routes that match AS_Path filter 10.

```
<HUAWEI> reset bgp flap-info as-path-filter 10
```

Clear the flapping statistics about the BGP4+ routes of the VPN instance named vpn1.

```
<HUAWEI> reset bgp vpn-instance vpn1 ipv6-family flap-info
```

7.8.153 reset bgp flapping-count

Function

The **reset bgp flapping-count** command resets the flapping count of a specified BGP peer.

Format

reset bgp [**vpn-instance** *vpn-instance-name* **ipv4-family**] *ipv4-address* **flapping-count**

reset bgp { **ipv6** | **vpn-instance** *vpn-instance-name* **ipv6-family** } *ipv6-address* **flapping-count**

NOTE

The **vpn-instance** *vpn-instance-name* **ipv6-family** is only supported on S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name* **ipv4-family**	Specifies the name of VPN instance enabled with an IPv4 address family.	The value must be an existing VPN instance name.
ipv4-address	Specifies the IPv4 address of a BGP peer.	It is in dotted decimal notation.
ipv6	Clears the flapping count of a specified BGP IPv6 peer.	-
vpn-instance *vpn-instance-name* **ipv6-family**	Specifies the name of VPN instance enabled with an IPv6 address family.	The value must be an existing VPN instance name.
ipv6-address	Specifies the IPv6 address of a BGP peer.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP peer flapping affects the stability of a BGP network and BGP route convergence.

The **reset bgp flapping-count** command can be used to clear the flapping account of a BGP peer. This allows the switch to re-collect the flapping statistics of a peer to locate BGP network problems.

Precautions

After the **reset bgp flapping-count** command is run, the flapping statistics of BGP peers are reset and cannot be displayed.

Follow-up Procedure

After the reset bgp flapping-count command is used to clear the statistics count of a specified BGP peer, run the **display bgp peer** command to display the flapping count of BGP peers and locate BGP network problems.

Example

Clear the flapping count of a specified BGP peer.

```
<HUAWEI> reset bgp 10.116.10.2 flapping-count
```

7.8.154 reset bgp mdt

Function

The **reset bgp mdt** command resets the BGP connections of a BGP MDT address family.

Format

reset bgp mdt { **all** | *ipv4-address* | **group** *group-name* | *as-number-plain* | *as-number-dot* } [**graceful**]

reset bgp mdt { **internal** | **external** } [**graceful**]

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Resets all BGP connections of a BGP MDT address family.	-
as-number-plain	Specifies an integral AS number.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies an AS number in dotted notation.	The value is in the format of x.y, where x and y are integers that range from 1 to 65535 and from 0 to 65535, respectively.
ipv4-address	Resets the connection with a specified BGP peer.	The value is in dotted decimal notation.

Parameter	Description	Value
group *group-name*	Resets the connection with a specified BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
internal	Resets all IBGP connections.	-
external	Resets all EBGP connections.	-
graceful	Resets BGP connections in GR mode.	-

Usage Guidelines

Applicable Environment

When the BGP MDT configuration is changed, you can run the **reset bgp mdt** command to make the new configuration take effect immediately.

NOTICE

After the command is run, the TCP connection established by the BGP device is reset and the corresponding peer relationship is re-established. Therefore, exercise caution before you run this command.

Example

Reset all BGP connections of a BGP MDT address family.

```
<HUAWEI> reset bgp mdt all
```

7.8.155 reset bgp multicast

Function

The **reset bgp multicast** command resets the connections between a device and specified MBGP peers.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset bgp multicast { **all** | *peer-address* | **group** *group-name* | *as-number-plain* | *as-number-dot* | **external** | **internal** } [**graceful**]

Parameters

Parameter	Description	Value
all	Resets all MBGP connections.	-
peer-address	Resets the MBGP connection with a specified peer.	The peer address is in dotted decimal notation.
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the x.y format. Here, "x" and "y" are integers that range from 1 to 65535 and 0 to 65535 respectively.
external	Reset all EBGP connections.	-
internal	Reset all IBGP connections.	-
graceful	Specifies to reset MBGP connections in GR mode.	-

User view

Default Level

2: Configuration level

Usage Guidelines

NOTE

After the **reset bgp multicast** command is run on a device, the TCP connection established by the device and the corresponding peer is reset and then reestablished. Exercise caution when running this command.

Example

Reset the MBGP connections of all address families.

```
<HUAWEI> reset bgp multicast all
```

7.8.156 reset bgp multicast dampening

Function

The **reset bgp multicast dampening** command clears dampening information about routes in the MBGP routing table.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset bgp multicast dampening [*ip-address* [*mask* | *mask-length*]]

Parameters

Parameter	Description	Value
ip-address	Specifies a network address.	The value is in dotted decimal notation.
mask	Specifies the mask of a network address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of a network address.	The value is an integer that ranges from 0 to 32.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

If a network address is specified in the **reset bgp multicast dampening** command, running this command clears the dampening information about a specific route and releases the suppressed route.

Example

Clear the dampening information about routes to network segment 10.1.0.0 and release suppressed routes.

```
<HUAWEI> reset bgp multicast dampening 10.1.0.0 255.255.0.0
```

7.8.157 reset bgp multicast external

Function

The **reset bgp multicast external** command resets all multicast EBGP connections.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset bgp multicast external [**graceful**]

Parameters

Parameter	Description	Value
graceful	Resets MBGP connections in GR mode.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run the **reset bgp multicast external** command to reset all multicast EBGP connections.

Example

Reset all multicast EBGP connections.

```
<HUAWEI> reset bgp multicast external
```

7.8.158 reset bgp multicast flap-info

Function

The **reset bgp multicast flap-info** command clears route flapping statistics.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset bgp multicast flap-info [*ip-address* [*mask* | *mask-length*] | **as-path-filter** { *as-path-list-number* | *as-path-list-name* } | **regexp** *regexp*]

reset bgp multicast *ip-address* **flap-info**

Parameters

Parameter	Description	Value
ip-address	Specifies a network address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of a network address.	The value is an integer that ranges from 0 to 32.
mask	Specifies the mask of a network address.	The value is in dotted decimal notation.
as-path-filter *as-path-list-number*	Clears route flapping statistics based on the number of a specified AS_Path filter.	The value is an integer that ranges from 1 to 256.
as-path-filter *as-path-list-name*	Clears route flapping statistics based on the name of a specified AS_Path filter.	The value is a string of 1 to 51 case-sensitive characters without spaces.
regexp *regexp*	Clears flapping statistics about the routes that match the AS_Path regular expression.	The value is a string of 1 to 80 characters.

Views

2: Configuration level

Usage Guidelines

You can run the **reset bgp multicast flap-info** command to clear route flapping statistics.

Example

Clear the flapping statistics about the routes that match AS_Path filter 10.

```
<HUAWEI> reset bgp multicast flap-info as-path-filter 10
```

7.8.159 reset bgp multicast internal

Function

The **reset bgp multicast internal** command resets the multicast IBGP connections in an AS.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset bgp multicast internal [**graceful**]

Parameters

Parameter	Description	Value
graceful	Specifies to reset MBGP connections in GR mode.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run the **reset bgp multicast internal** command to reset the multicast IBGP connections in an AS.

Example

Reset all multicast IBGP connections.

```
<HUAWEI> reset bgp multicast internal
```

7.8.160 reset bgp mvpn

Function

The **reset bgp mvpn** command resets the BGP connections of a BGP MVPN address family.

Format

reset bgp mvpn { **all** | *ipv4-address* | **group** *group-name* | *as-number-plain* | *as-number-dot* } [**graceful**]

reset bgp mvpn { **internal** | **external** } [**graceful**]

NOTE

Only the following switch models support this command:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

Parameters

Parameter	Description	Value
all	Resets all BGP connections of a BGP MVPN address family.	-
as-number-plain	Specifies an integral AS number.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies an AS number in dotted notation.	The value is in the format of x.y, where x and y are integers that range from 1 to 65535 and from 0 to 65535, respectively.
ipv4-address	Resets the connection with a specified BGP peer.	The value is in dotted decimal notation.
group *group-name*	Resets the connection with a specified BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
internal	Resets all IBGP connections.	-
external	Resets all EBGP connections.	-
graceful	Resets BGP connections in GR mode.	-

2: Configuration level

Usage Guidelines

Applicable Environment

When the BGP MVPN configuration is changed, you can run the **reset bgp mvpn** command to make the new configuration take effect immediately.

NOTICE

After the command is run, the TCP connection established by the BGP device is reset and the corresponding peer relationship is re-established. Therefore, exercise caution before you run this command.

Example

Reset all BGP connections of a BGP MVPN address family.

```
<HUAWEI> reset bgp mvpn all
```

7.8.161 router-id (BGP)

Function

The **router-id** command configures a Router ID for the switch.

The **undo router-id** command deletes the Router ID configured for the switch.

By default, no BGP Router ID is configured, and the global Router ID configured through the **router id** command is used.

Format

router-id { *ipv4-address* | **vpn-instance auto-select** }

undo router-id [**vpn-instance auto-select**]

Parameters

Parameter	Description	Value
ipv4-address	Specifies a Router ID.	It is in dotted decimal notation.
vpn-instance auto-select	Configures automatic Router ID selection for all BGP-VPN instance IPv4 or IPv6 address families. If a Router ID is manually specified for a BGP-VPN instance IPv4 or IPv6 address family, the manually specified Router ID takes precedence over the automatically selected Router ID.	-

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **router-id** command is used to configure a Router ID for the switch. Each Router ID uniquely identifies one BGP switch in an AS.

By configuring automatic Router ID selection for a BGP-VPN instanceIPv4 or IPv6 address family, you can differentiate the configured Router ID of the BGP-VPN instance IPv4 or IPv6 address family from the BGP Router ID. For more information about the Router ID of a BGP-VPN instance IPv4 or IPv6 address family, see the **router-id (BGP-VPN Instance View)** command.

Prerequisites

The **bgp** command is run to enable BGP.

Precautions

Changing or deleting a configured Router ID in the BGP view resets a BGP session. If a BGP session has been established in a BGP-VPN instance IPv4 address family, deleting the configured Router ID resets the BGP session. Exercise caution when changing or deleting a Router ID.

By default, the switch that is not configured with any interface uses the Router ID of 0.0.0.0 assigned by routing management.

Example

Configure a Router ID for the switch.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] router-id 10.1.1.1
```

Configure automatic Router ID selection for all BGP-VPN instance IPv4 address families.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] router-id vpn-instance auto-select
```

7.8.162 router-id (BGP-VPN Instance View)

Function

The **router-id** command configures router ID for BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view.

The **undo router-id** command deletes the router ID configured for BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view.

By default, no router ID is configured for BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view, and the BGP router ID is used as the router ID.

Format

router-id { *ipv4-address* | **auto-select** }

undo router-id

Parameters

Parameter	Description	Value
ipv4-address	Specifies the router ID of a BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view. The router ID is expressed in the IPv4 address format.	It is in dotted decimal notation.
auto-select	Configures automatic route ID selection for the current BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view.	-

Views

BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By configuring router ID for BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view, you can differentiate the configured router ID of BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view from the BGP router ID.

For example, if two VPN instances named **vrf1** and **vrf2** are configured on a PE, and a BGP session needs to be established between the interfaces bound to the two VPN instances, you need to configure different router IDs for the two VPN instance IPv4 address families. If no router ID is configured for the two VPN instance IPv4 address families, no BGP session can be established because the two VPN instance IPv4 address families have the same router ID, which is consistent with the BGP router ID.

Rules for automatically selecting a router ID for a BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view are as follows:

- If loopback interfaces configured with IP addresses are bound to the VPN instance, the largest IP address among the IP addresses of the loopback interfaces is selected as the router ID.
- If no loopback interfaces configured with IP addresses are bound to the VPN instance, the largest IP address among the IP addresses of other interfaces bound to the VPN instance is selected as the router ID, regardless of whether the interface is Up or Down.

Precautions

If a BGP session has been established in a BGP VPN instance IPv4 address family or BGP-VPN instance IPv6 address family view, changing or deleting the configured router ID resets the BGP session. So, confirm the action before you use the **router-id** command.

Example

Configure a router ID for a BGP VPN instance IPv4 address family.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] quit
[HUAWEI-vpn-instance-vrf1] quit
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vrf1
[HUAWEI-bgp-vrf1] router-id 192.168.100.1
```

7.8.163 route-select delay

Function

The **route-select delay** command configures a delay for selecting routes.

The **undo route-select delay** command deletes the delay for selecting routes.

The default delay is 0, indicating that routes are selected without a delay.

Format

route-select delay *delay-value*

undo route-select delay

Parameters

Parameter	Description	Value
delay-value	Specifies the delay for selecting routes.	The value is an integer that ranges from 0 to 3600, in seconds.

Views

BGP view, BGP-IPv4 unicast address family view, ,BGP-MDT address family view, BGP-MVPN address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv6 address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-IPv4 multicast address family view, BGP L2VPN-AD address family view

Default Level

2: Configuration level

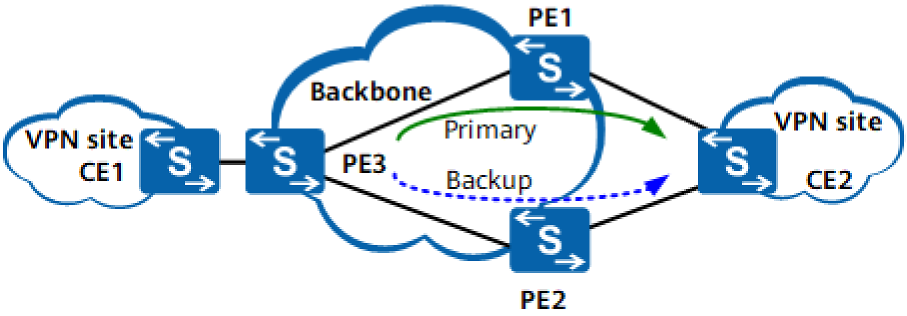
Usage Guidelines

Usage Scenario

In a scenario in which primary and backup routes exist, packets may get lost after traffic switches back to the primary path from the backup path. **Figure 7-3** illustrates a VPN FRR scenario. PE3 and CE2 connect both to PE1 and PE2. The primary path is PE3 -> PE1 -> CE2, and the backup path is PE3 -> PE2 -> CE2. CE2 uses BGP to communicate with PE1 and PE2. FRR is configured on PE3. If PE1 restarts or the link between CE2 and PE1 is disconnected, traffic switches from the primary path to the backup path. After the primary path recovers, traffic switches back to the primary path. If PE3 completes refreshing forwarding entries before PE1 does so, PE1 may temporarily fail to forward traffic after a switchback. As a result, packet loss may occur. The severity of packet loss is proportional to the number of routes stored on PE1.

To solve this problem, run the **route-select delay** command on PE3 to configure a delay for selecting a route to PE1. An appropriate delay ensures that traffic switches back to the primary path after PE1 completes refreshing forwarding entries.

Figure 7-3 VPN FRR networking



Precautions

If you run the **route-select delay** command repeatedly, the latest configuration overrides the previous configurations. If a route selection delay timer has started when you configure a new route select delay, the new route selection delay takes effect since the next route selection.

Example

Configure the delay for selecting routes as 300s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] route-select delay 300
```

7.8.164 routing-table limit threshold-alarm

Function

The **routing-table limit threshold-alarm** command configures alarm and alarm clear thresholds for the number of BGP routes.

The **undo routing-table limit threshold-alarm** command restores the default settings.

By default, the alarm threshold is 80%, and the alarm clear threshold is 70%.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

routing-table limit threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo routing-table limit threshold-alarm [**upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*]

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies an alarm threshold for the number of BGP routes.	The value is an integer that ranges from 1 to 100, in percentage. The default value is 80.
lower-limit *lower-limit-value*	Specifies an alarm clear threshold for the number of BGP routes.	The value is an integer that ranges from 1 to 100, in percentage. The default value is 70. *lower-limit-value* must be smaller than *upper-limit-value*; otherwise, alarms are generated and cleared repeatedly if route flapping occurs.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The number of BGP routes that can be added to a routing table is limited. If the value exceeds the limit, new routes cannot be added to the routing table, causing service interruptions. To address this problem, run the **routing-table limit threshold-alarm** command to configure alarm and alarm clear thresholds for the number of BGP routes. Alarms are then generated and cleared as expected. The alarms act as a prompt for checking whether an exception occurs and to take preventive measures.

- When the ratio of BGP routes to the maximum value exceeds *upper-limit-value*, an alarm is generated. New routes can still be accepted until the number of BGP routes reaches the maximum value.
- When the ratio falls below *lower-limit-value*, the alarm is cleared.

Configuration Impact

If the **routing-table limit threshold-alarm** command is run multiple times, the latest configuration takes effect.

Precautions

In addition to the **routing-table limit threshold-alarm** command, the **snmp-agent trap enable feature-name bgp trap-name** { **hwBgpRouteThresholdExceed** | **hwBgpRouteThresholdClear** } command must be run to enable the alarm and alarm clear functions; otherwise, alarms cannot be generated and cleared as expected.

Example

Configure alarm and alarm clear thresholds for the number of BGP routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] routing-table limit threshold-alarm upper-limit 70 lower-limit 60
```

7.8.165 routing-table rib-only

Function

The **routing-table rib-only** command prevents BGP routes from being added into the IP routing table.

The **undo routing-table rib-only** command restores the default setting.

By default, the preferred BGP routes are added to the IP routing table.

Format

routing-table rib-only [**route-policy** *route-policy-name*]

undo routing-table rib-only

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a Route-Policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In BGP/MPLS IP VPN networking, if the BGP routing table has large numbers of VPN routes, these routes will consume large numbers of memory resources after being delivered to the IP VPN routing table. If these routes are not used in traffic forwarding, you can run the **routing-table rib-only** command to prevent these routes from being added to the IP VPN routing table. If some of these routes are not used in traffic forwarding, you can run the **routing-table rib-only route-policy** command to prevent this part of routes from being added to the IP VPN routing table.

If a route reflector (RR) is used and preferred BGP routes do not need to be used during the forwarding, the **routing-table rib-only** command can be used to make BGP routes unable to be added to the IP routing table or the forwarding layer. This improves forwarding efficiency and the system capacity.

When **route-policy** *route-policy-name* is specified in the command, the routes matching the policy are not added to the IP routing table, and the routes not matching the policy are added to the IP routing table with the route attributes unchanged.

Configuration Impact

After the **routing-table rib-only** command is run, the routes preferred by BGP are not added to the IP routing table.

The **routing-table rib-only** command does not take effect on the labeled routes.

Precautions

The **routing-table rib-only** command and the **active-route-advertise** command are mutually exclusive.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all routes are not delivered to the IP routing table.

Example

Configure the routing policy named **ribonly** to prevent certain BGP routes from being added into the IP routing table.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] routing-table rib-only route-policy ribonly
```

7.8.166 shutdown (BGP)

Function

The **shutdown** command terminates all sessions between a device and its BGP peers.

The **undo shutdown** command restores the default setting.

By default, the function of closing all sessions between a device and its BGP peers is disabled.

Format

shutdown

undo shutdown

Parameters

None

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

NOTICE

Running the **shutdown** command closes all sessions between a device and its peers. Exercise caution when using this command.

During system upgrade or maintenance, the sessions between a device and its BGP peers need to be closed to minimize the impact of BGP route flapping on the network. If a large number of BGP peers exist, the **shutdown** command can be run in the BGP view to close all sessions with BGP peers. This frees you from running the **peer ignore** command repeatedly to close the sessions one by one.

Example

Close all sessions between a device and its BGP peers.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] shutdown
Warning: All BGP peer sessions will be interrupted. Continue? [Y/N]:y
```

7.8.167 slow-peer detection disable

Function

The **slow-peer detection disable** command disables slow peer detection.

The **undo slow-peer detection disable** command restores the default configuration.

By default, slow peer detection is enabled.

Format

slow-peer detection disable

undo slow-peer detection disable

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An update peer-group may consist of multiple BGP peers. If a network problem (congestion for example) occurs and slows down the speed at which the local device advertises routes to a BGP peer in the update peer-group, the speed at which the local device advertises routes to other BGP peers in the update peer-group is affected. To address this problem, slow peer detection is enabled by default.

When slow peer detection is enabled, the local device identifies the BGP peer to which routes are sent the slowest based on the time taken to send 100 packets to each BGP peer. If this time is greater than the period threshold for slow peer detection plus the average time taken to send 100 packets to BGP peers (excluding the longest and shortest times), the local device considers the peer a slow peer and removes it from the update peer-group. Slow peer detection prevents this slow peer from affecting route advertisement to other peers in the update peer-group.

To disable slow peer detection, run this command.

Example

Disable slow peer detection.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] slow-peer detection disable
```

7.8.168 slow-peer detection threshold

Function

The **slow-peer detection threshold** command sets a period threshold for slow peer detection.

The **undo slow-peer detection** command restores the default configuration.

By default, the period threshold for slow peer detection is 300s.

Format

slow-peer detection threshold *threshold-value*

undo slow-peer detection [**threshold** *threshold-value*]

Parameters

Parameter	Description	Value
threshold *threshold-value*	Specifies a period threshold for slow peer detection.	The value is an integer that ranges from 120 to 3600, in seconds.

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv6 unicast address family view, BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view, or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When slow peer detection is enabled, the local device identifies the BGP peer to which routes are sent the slowest based on the time taken to send 100 packets to each BGP peer. If this time is greater than the period threshold for slow peer detection plus the average time taken to send 100 packets to BGP peers (excluding the longest and shortest times), the local device considers the peer a slow peer and removes it from the update peer-group. Slow peer detection prevents this slow peer from affecting route advertisement to other peers in the update peer-group.

By default, slow peer detection is enabled and the period threshold for slow peer detection is 300s. To adjust the period threshold for slow peer detection, run this command.

Configuration Impact

If the command is run more than once, the latest configuration overrides the previous one.

Precautions

After a slow peer is removed from the update peer-group, the peer relationship between the local device and the slow peer is reestablished.

Example

Set the period threshold for slow peer detection to 200s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] slow-peer detection threshold 200
```

7.8.169 summary automatic

Function

The **summary automatic** command enables automatic aggregation for the locally imported routes.

The **undo summary automatic** command disables automatic aggregation for the locally imported routes.

By default, automatic aggregation is disabled for the locally imported routes.

Format

summary automatic

undo summary automatic

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the BGP-IPv4 unicast address family view, the **summary automatic** command is used to configure a BGP device to automatically aggregate locally imported routes on the public network.

In the BGP-VPN instance IPv4 address family view, the **summary automatic** command is used to configure a BGP device to automatically aggregate locally imported routes on a private network.

The **summary automatic** command is used to aggregate the routes imported by BGP. These routes can be direct routes, static routes, RIP routes, OSPF routes, or IS-IS routes. After this command is run on a BGP device, the BGP device aggregates routes based on the natural network segment (for example, 10.1.1.0/24 and 10.2.1.0/24 are aggregated to 10.0.0.0/8, a Class A address), and sends only the aggregated route to its peers. This reduces the number of routes.

Precautions

BGP route aggregation is classified into manual aggregation and automatic aggregation. The command is used to implement automatic aggregation. Manual aggregation takes precedence over automatic aggregation.

The **summary automatic** command is invalid for the routes imported by using the **network** command.

Example

Enable automatic aggregation for imported routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] summary automatic
```

7.8.170 supernet unicast advertise

Function

The **supernet unicast advertise enable** command configures a BGP device to advertise BGP supernet unicast routes to its peers.

The **undo supernet unicast advertise enable** or **supernet unicast advertise disable** command restores the default configuration.

By default, BGP supernet unicast routes are considered invalid and cannot be advertised to BGP peers or delivered to the IP routing table.

Format

supernet unicast advertise enable

supernet unicast advertise disable

undo supernet unicast advertise enable

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-VPN instance IPv4 address family view, BGP-IPv6 unicast address family view, or BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A BGP supernet route has the same destination address and next-hop address or has a more detailed destination address than the next-hop address. Any route that meets one of the following conditions is a BGP supernet route.

- If you perform bitwise AND operations on the destination address mask with the destination address and next-hop address, respectively, the calculated network addresses are the same, and the destination address mask is greater than or equal to the next-hop address mask.
- If you perform bitwise AND operations on the destination address mask with the destination address and next-hop address, respectively, the calculated network addresses are different. However, if you perform bitwise AND operations on the next-hop address mask with the destination address and next-hop address, respectively, the calculated network addresses are the same.

For example, the route destined for 10.6.6.6 in the following command output is a BGP supernet route.

```
<HUAWEI> display bgp routing-table
 BGP Local router ID is 10.1.1.2
 Status codes: * - valid, > - best, d - damped,
               h - history,  i - internal, s - suppressed, S - Stale
               Origin : i - IGP, e - EGP, ? - incomplete

 Total Number of Routes: 1
       Network            NextHop        MED        LocPrf    PrefVal Path/Ogn
   *>i  10.6.6.6/32        10.6.6.6       0          100       0      ?
```

BGP supernet routes include BGP supernet labeled routes and BGP supernet unicast routes. To allow a Huawei device to advertise BGP supernet unicast routes that it receives from a connected non-Huawei device to its BGP peers, run the **supernet unicast advertise enable** command on the Huawei device.

Example

Configure a BGP device to advertise BGP supernet unicast routes to its peers.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] supernet unicast advertise enable
```

7.8.171 timer (BGP)

Function

The **timer** command sets the values for the Keepalive timer and Hold timer.

The **undo timer** command restores the default values of the Keepalive timer and Hold timer.

By default, the value of a Keepalive timer is 60s and the value of a Hold timer is 180s.

Format

timer keepalive *keepalive-time* **hold** *hold-time* [**min-holdtime** *min-holdtime*]

undo timer keepalive *keepalive-time* **hold** *hold-time* [**min-holdtime** *min-holdtime*]

undo timer keepalive hold [**min-holdtime**]

Parameters

Parameter	Description	Value
keepalive *keepalive-time*	Specifies the Keepalive period.	The value is an integer that ranges from 0 to 21845, in seconds.
hold *hold-time*	Specifies the holdtime.	The value is an integer that can be 0, or ranges from 3 to 65535, in seconds.
min-holdtime *min-holdtime*	Specifies the minimum holdtime configured on the local device. **NOTE** The value of *min-holdtime* configured cannot exceed the value of *hold-time*.	The value is an integer that ranges from 20 to 65535, in seconds.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a connection is established between peers, the values of *keepalive-time* and *hold-time* are negotiated by the peers.

- The smaller of the *hold-time* values carried by Open messages of both peers is taken as the *hold-time* value.
- The smaller of one third of the *hold-time* value and the locally configured *keepalive-time* value is taken as the *keepalive-time* value.

If the local device establishes BGP peer relationships with many devices, it needs to process huge BGP messages. If *hold-time* negotiated among BGP peers is small, the timer may expire before the local device processes the Keepalive messages sent from other BGP peers. The peer relationships are then interrupted, and routes flap. To solve the preceding problem, you can configure an appropriate value for **min-holdtime** *min-holdtime* based on the CPU processing capability of the local device.

If the value of *min-holdtime* is changed, but the values of *keepalive-time* and *hold-time* negotiated between two BGP peers remain unchanged, the established peer relationship is not affected. Only when the local device attempts to re-establish a relationship with a remote device, the value of *min-holdtime* configured on the local device takes effect. The local device compares *min-holdtime* with *hold-time* sent from the remote device. If the value of *min-holdtime* exceeds that of *hold-time*, *hold-time* negotiation fails, and the peer relationship fails to be established.

NOTE

If *min-holdtime* is configured on the local device, and the value of *hold-time* sent from the remote device is 0, *hold-time* negotiation between the two devices succeeds. The negotiated value of *hold-time* is 0, and the peer relationship is established. The value 0 of *hold-time* indicates that the peer relationship never expires.

Precautions

The timers configured for a specific peer or peer group by using the **peer timer** command override the timers configured for all BGP peers by using the **timer** command.

If the value of a timer changes, the BGP peer relationship between devices is disconnected. This is because the devices need to re-negotiate the values of *keepalive-time* and *hold-time*. Therefore, exercise caution before changing the value of a timer.

Setting the Hold timer value to at least three times the Keepalive timer value is recommended. When setting the values of *keepalive-time* and *hold-time*, note the following points:

- The values of *keepalive-time* and *hold-time* cannot both be set to 0. This renders the BGP timers become invalid. This means that BGP is unable to detect link faults using the timers.
- The *hold-time* value cannot be significantly greater than the *keepalive-time* value. A setting of **timer keepalive 1 hold 65535**, for example, would be improper. If the holdtime is too long, link faults cannot be detected in a timely manner.

Example

On a BGP device, set the value of the Keepalive timer to 30s and the value of the Hold timer to 90s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] timer keepalive 30 hold 90
```

7.8.172 timer connect-retry

Function

The **timer connect-retry** command sets a global ConnectRetry interval.

The **undo timer connect-retry** command restores the default setting.

By default, the ConnectRetry interval is 32s.

Format

timer connect-retry *connect-retry-time*

undo timer connect-retry

Parameters

Parameter	Description	Value
connect-retry-time	Specifies a ConnectRetry interval.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When BGP initiates a TCP connection, the ConnectRetry timer is stopped if the TCP connection is established successfully. If the first attempt to establish a TCP connection fails, BGP tries again to establish the TCP connection after the ConnectRetry timer expires. The ConnectRetry interval can be adjusted as needed.

- The ConnectRetry interval can be reduced in order to lessen the time BGP waits to retry establishing a TCP connection after the first attempt fails.
- To suppress route flapping caused by constant peer flapping, the ConnectRetry interval can be increased to accelerate route convergence.

Precautions

A ConnectRetry interval can be configured globally, or on a particular peer or peer group. A ConnectRetry interval configured on a specific peer or peer group takes precedence over a global ConnectRetry interval.

If both the **peer** { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time* command and the **timer connect-retry** *connect-retry-time* command are run on a device, the configuration of the **peer** { *group-name* | *ipv4-address* | *ipv6-address* } **timer connect-retry** *connect-retry-time* command takes effect, but the configuration of the **timer connect-retry** *connect-retry-time* command does not.

Example

Set a global BGP ConnectRetry interval to 60s.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] timer connect-retry 60
```

7.8.173 undo synchronization (BGP)

Function

The **undo synchronization** command disables synchronization between BGP and an IGP.

By default, synchronization between BGP and an IGP is disabled.

Format

undo synchronization

Parameters

None

Views

BGP view, BGP-IPv4 unicast address family view, BGP-IPv4 multicast address family view, BGP-IPv6 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

You can run the **undo synchronization** command to disable synchronization between BGP and an IGP.

Example

Disable synchronization between BGP and an IGP.

```
<HUAWEI> system-view
```

```
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] undo synchronization
```

7.9 Routing Policy Configuration Commands

7.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.9.2 apply as-path

Function

The **apply as-path** command sets the action for changing the AS_Path attribute of BGP routes in a routing policy.

The **undo apply as-path** command restores the default setting.

By default, the action for changing the AS_Path attribute of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply as-path { { *as-number-plain* | *as-number-dot* } &<1-10> { **additive** | **overwrite** } | **none overwrite** }

undo apply as-path

Parameters

Parameter	Description	Value
as-number-dot	Specifies an AS number in dotted notation to be added to the AS_Path list or to replace the existing AS_Path list. A maximum of 10 AS numbers can be specified in one command.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.
additive	Adds the specified AS number to the original AS_Path attribute.	-
overwrite	Replaces the original AS_Path with the specified AS number.	-
none	Clears the original AS_Path list.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To change the AS_Path attribute of BGP routes BGP for selecting the optimal route, you can apply a routing policy containing the **apply as-path** command.

AS_Path is a private attribute of BGP and records all ASs that a route passes through from the local end to the destination address. Using the AS_Path attribute controls route selection and prevents routing loops. If multiple routes are destined for the same destination address, BGP compares the AS_Path lists of these routes and considers the route with the shortest AS_Path list as the optimal route.

After this command is configured, the AS_Path list for matched BGP routes will change. Assume that the original AS-Path is (30, 40, 50) and the BGP route matching condition is met. In this case:

- If the **apply as-path 60 70 80 additive** command is run, the AS-Path list is changed to (60, 70, 80, 30, 40, 50). This configuration change is generally used to make the BGP route not preferentially selected.
- If the **apply as-path 60 70 80 overwrite** command is run, the AS-Path list is changed to (60, 70, 80). There are many application scenarios for changing the AS-Path list, and the major application scenarios are as follows:
  - Hide the real path information of routes. For example, after the AS-Path list is changed to (60, 70, 80), the AS-Path information of the route (30, 40, 50) is lost.

  - Implement load balancing. For example, a router receives two routes with the same destination IP address 10.1.0.0/16. The AS_Path list of one route is (60, 70, 80) and that of the other route is (30, 40, 50). In this case, you can change the AS_Path list (30, 40, 50) to (60, 70, 80), and load balancing then may be implemented on the two routes.
  - Shorten the AS-Path list to prevent the route from being discarded. If the **as-path-limit** command is configured, whether the number of AS numbers in the AS-Path list of the incoming route exceeds the maximum value needs to be checked. If the number exceeds the maximum value, the route is discarded. Therefore, before receiving a route with a long AS-Path list, replace the AS-Path list with a shorter AS-Path list. For example, if the original AS-Path list is (60, 70, 80, 65001, 65002, 65003), run the **apply as-path 60 70 80 overwrite** command to change the AS-Path list to (60, 70, 80). In this manner, the length of the AS-Path is shortened, preventing the route from being discarded.
  - Shorten the AS-Path list to make the route to be preferentially selected and traffic to be directed to the local AS.
- If the **apply as-path none overwrite** command is run, the AS-Path list is changed to be vacant. In BGP route selection, if the AS-Path list is vacant, the length of the AS-Path list is considered as 0. Therefore, clearing the AS-Path list cannot only hide the real path information, but also make the route to be preferentially selected and traffic to be directed to the local AS because the AS-Path list is shortened.

Prerequisites

The **apply as-path** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects BGP route selection.

Running the apply as-path command changes the path through which network traffic passes. Use this command only when you are familiar with the network topology and impact of the command on services.

Example

Change the AS number in the original AS_Path attribute to 200, 10.10.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply as-path 200 10.10 additive
```

7.9.3 apply backup-interface

Function

The **apply backup-interface** command configures a backup outbound interface in a routing policy.

The **undo apply backup-interface** command restores the default setting.

By default, the backup outbound interface is not configured in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply backup-interface *interface-type interface-number*

undo apply backup-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the backup outbound interface.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply backup-interface** command is used in IP FRR scenarios to configure a backup outbound interface for a route. After IP FRR is enabled, data traffic can be quickly switched to the backup outbound interface if the primary link fails.

Prerequisites

if-match clauses can be used to configure matching rules such as IP prefix lists, and ACLs before a backup outbound interface is configured.

Follow-up Procedure

Reference a configured route-policy in the **ip frr (system view)** command or the **ip frr (VPN instance view)** command to configure IP FRR on a public network or VPN.

The **apply backup-interface** command is usually used together with the **apply backup-nexthop** command.

Precautions

For P2P links, a backup next hop is not necessary. For non-P2P links, a backup next hop is necessary.

Example

Configure the backup outbound interface and the backup next hop in the route-policy named **ip_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] apply backup-interface vlanif10
[HUAWEI-route-policy] apply backup-nexthop 192.168.20.2
```

Delete the configured backup outbound interface from the route-policy named **ip_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] undo apply backup-interface
```

7.9.4 apply backup-nexthop

Function

The **apply backup-nexthop** command configures a backup next hop in a routing policy.

The **undo apply backup-nexthop** command deletes the configured backup next hop.

By default, the backup next hop is not configured in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply backup-nexthop { *ipv4-address* | **auto** }

undo apply backup-nexthop

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IP address of a backup next hop.	It is in dotted decimal notation.
auto	Automatically searches for the backup next hop.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply backup-nexthop** command is used to configure a backup next hop for a route in IP FRR and VPN FRR scenarios. After IP FRR is enabled, data traffic can be quickly switched to the backup next hop if the primary link fails.

Prerequisites

if-match clauses can be used to set matching rules such as interfaces, IP prefix lists, and ACLs before a backup next hop is configured.

Follow-up Procedure

The configured route-policy can be used in the **ip frr (system view)** command or the **ip frr (VPN instance view)** command that is run to configure IP FRR for a public or private network. It can also be used in the **vpn frr** command that is run to enable VPN FRR.

In a VPN FRR scenario, you only need to run the **apply backup-nexthop** command to configure a backup next hop.

In an IP FRR scenario, you need to run both the **apply backup-nexthop** and **apply backup-interface** commands.

Precautions

For P2P links, a backup next hop is not necessary. For non-P2P links, a backup next hop is necessary.

NOTE

Example

Configure the backup interface and the backup next hop 192.168.20.2 in the route-policy named **ip_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] apply backup-interface vlanif10
[HUAWEI-route-policy] apply backup-nexthop 192.168.20.2
```

Delete the configured backup next hop from the route-policy named **ip_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] undo apply backup-nexthop
```

7.9.5 apply behavior

Function

The **apply behavior** command configures a QoS traffic behavior for routes.

The **undo apply behavior** command restores the default setting.

By default, no QoS traffic behavior is configured.

Format

apply behavior *behavior-name*

undo apply behavior

Parameters

Parameter	Description	Value
behavior-name	Specifies the name of a QoS traffic behavior.	The value is a string of 1 to 31 case-sensitive characters without spaces, and must start with a letter.

Views

Route-policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large and complex network is deployed, traffic flows of different types, such as voice, video, and data, need to be managed separately, with different bandwidth and delays assigned to these traffic flows. In this case, class-based QoS needs to be configured and complex traffic classification needs to be performed. The **apply behavior** command is used to associate filtered route with a specific traffic behavior.

Prerequisites

Before running the **apply behavior** *behavior-name* command, you need to create a traffic behavior.

Meanwhile, certain matching conditions need to be configured to classify routes, such as the AS-Path lost, community attribute list, address prefix list, and route cost.

Precautions

The **apply behavior** command is mutually exclusive with the **apply ip-precedence** command and the **apply qos-local-id** command, and only one of these commands can be configured on a node of a routing policy. For example, if the **apply behavior** command is configured in the view created by the **route-policy test permit node 10** command, configuring the **apply qos-local-id** command replaces **apply behavior** command.

Example

Configure the behavior named **example** in the system view, and then apply this QoS traffic behavior in the route-policy view.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior example
[HUAWEI-behavior-example] quit
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] apply behavior example
```

7.9.6 apply comm-filter delete

Function

The **apply comm-filter delete** command sets the action for deleting community attributes of a specified community filter in a routing policy.

The **undo apply comm-filter** command restores the default setting.

By default, the action for deleting community attributes of a specified community filter is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply comm-filter { *basic-comm-filter-number* | *adv-comm-filter-number* | *comm-filter-name* } **delete**

undo apply comm-filter

Parameters

Parameter	Description	Value
basic-comm-filter-number	Specifies the number of a basic community filter.	The value is an integer ranging from 1 to 99.
adv-comm-filter-number	Specifies the number of an advanced community filter.	The value is an integer ranging from 100 to 199.
comm-filter-name	Specifies the name of a community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To delete the community attributes, you can run the **ip community-filter** command several times to configure community attributes one by one, and apply the routing policy containing the **apply comm-filter delete** command to delete these community attributes.

The community attribute is a private attribute of BGP. The **apply comm-filter delete** command takes effect only for BGP routes.

Prerequisites

The **apply comm-filter delete** command can be used only after the **route-policy** command is used.

Precautions

After routes meet the filtering conditions, the specified community attributes of these routes are deleted.

1. When the delete operation is configured on a specified community attribute list, only one community attribute can be configured for the specified community attribute list. To delete multiple community attributes, you need to configure multiple community attribute lists. For example, if community attribute list 1 is used to delete 100:100 200:200 from the community attribute 100:100 200:200 carried in a route, you need to perform the following configurations on community attribute list 1:

   ```
   [HUAWEI] ip community-filter 1 permit 100:100
   [HUAWEI] ip community-filter 1 permit 200:200
   [HUAWEI] display ip community-filter
   Community filter Number: 1
   permit 100:100
   permit 200:200
   [HUAWEI] route-policy RP1 permit node 10
   [HUAWEI-route-policy] apply comm-filter 1 delete
   ```

   If multiple community attributes are configured in the same community filter, the **apply comm-filter delete** command cannot delete these community attributes. To delete the community attributes, you can run the **ip community-filter** command several times to configure community attributes one by one, and apply the routing policy containing the **apply comm-filter delete** command to delete these community attributes. For example, the following command cannot delete the community attribute 100:100 200:200 of the route:

   ```
   [HUAWEI] ip community-filter 1 permit 100:100 200:200
   [HUAWEI] display ip community-filter
   Community filter Number: 1
   permit 100:100 200:200
   [HUAWEI] route-policy RP1 permit node 10
   [HUAWEI-route-policy] apply comm-filter 1 delete
   ```

2. When the **apply community** and **apply comm-filter delete** commands are run on the same node in a routing policy, the system performs the delete operation before the set operation regardless of the sequence in which the two commands are run.

   ```
   [HUAWEI] display route-policy
   Route-policy : 123a
     permit : 10
   Match clauses:
   Apply clauses: a
   apply community 999:9 additive
   apply comm-filter 1 delete
   ```

   The following command output shows that community attribute 111:1 of the corresponding BGP route is deleted and community attribute 999:9 is added.

   ```
   [HUAWEI] display ip community-filter
   Community filter Number: 1
   permit 111:1
   permit 999:9
   ```

Example

Delete the specified BGP route community attributes 1:200, 2:200, and 3:200 from the community filter.

```
<HUAWEI> system-view
[HUAWEI] ip community-filter 1 permit 1:200
[HUAWEI] ip community-filter 1 permit 2:200
[HUAWEI] ip community-filter 1 permit 3:200
```

```
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] apply comm-filter 1 delete
```

7.9.7 apply community

Function

The **apply community** command sets the action for changing the community attribute of BGP routes in a routing policy.

The **undo apply community** command restores the default setting.

By default, the action for changing the community attribute of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply community none

apply community { *community-number* | *aa:nn* | **internet** | **no-advertise** | **no-export** | **no-export-subconfed** } &<1-32> [**additive**]

undo apply community

Parameters

Parameter	Description	Value
none	Indicates that all the community attributes of routes are deleted.	-

Parameter	Description	Value
community-number | *aa:nn*	Specifies the community number. A maximum of 32 community numbers can be configured in the **apply community** command. - If you do not configure any one of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 32 *community-number* and *aa:nn* together. - If you configure one of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 31 *community-number* and *aa:nn* together. - If you configure two of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 30*community-number* and *aa:nn* together. - If you configure three of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 29 *community-number* and *aa:nn* together. - If you configure all of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 28 *community-number* and *aa:nn* together.	The value of *community-number* is an integer ranging from 0 to 4294967295. The value of *aa* or *nn* ranges from 0 to 65535.
internet	Indicates that matching routes are sent to any peer. By default, all routes belong to the Internet community.	-
no-advertise	Indicates that matching routes are not sent to any peer. That is, after a router receives a route with this attribute, it does not advertise the route to other BGP peers.	-
no-export	Indicates that matching routes are sent to other sub-ASs but not to other ASs. That is, after a router receives a route with this attribute, it does not advertise the route outside the local AS.	-
no-export-subconfed	Indicates that matching routes are neither sent to other sub-ASs nor to other ASs. That is, after a router receives a route with this attribute, it does not advertise the route to other sub-ASs.	-
additive	Indicates that community attributes are added to matching routes.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To identify the BGP routes, you can apply a routing policy containing the **apply community** command to configure the community attribute of matched BGP routes.

The community attribute is a private attribute of BGP. It simplifies the application of routing policies and facilitates route maintenance and management. A community is a set of destination addresses with the same characteristics. These addresses have no physical boundary and are independent of their ASs. They share one or multiple community attributes, which can be changed or set by running the **apply community** command.

Prerequisites

The **apply community** command can be used only after the **route-policy** command is used.

Precautions

If the **apply community** command is configured in a routing policy, the community attributes of the BGP routes that match the routing policy are changed according to the configurations in the routing policy.

Assume that the original community attribute of a BGP route is 30. If this BGP route matches a certain routing policy, the AS number is replaced or added on the basis of the routing policy. For example:

- If the **apply community 100** command is run, the community attribute is changed to 100.
- If the **apply community 100 150** command is run, the community attribute is changed to 100, 150.
- If the **apply community 100 150 additive** command is run, the community attribute is changed to 30, 100, 150.
- If the **apply community none** command is run, the community attribute of the BGP route is deleted.

Example

Configure a routing policy named **setcommunity**, match the route with the AS_Path filter being 8, and change its community attribute to **no-export**.

```
<HUAWEI> system-view
[HUAWEI] route-policy setcommunity permit node 16
[HUAWEI-route-policy] if-match as-path-filter 8
[HUAWEI-route-policy] apply community no-export
```

7.9.8 apply cost

Function

The **apply cost** command sets the action for changing the cost of routes in a routing policy.

The **undo apply cost** command restores the default setting.

By default, the action for changing the cost of routes is not set in a routing policy.

Format

apply cost [**+** | **-**] *cost*

undo apply cost

Parameters

Parameter	Description	Value
+	Increases the route cost.	If the MED of BGP routes or cost of non-BGP routes is greater than the maximum value (4294967295) after the adjustment, 4294967295 takes effect.
-	Reduces the route cost.	If the MED of BGP routes or cost of non-BGP routes is less than the minimum value (0) after the adjustment, 0 takes effect.
cost	Specifies the route cost. To control route selection, you can adjust the route cost to prevent routing loops.	The value is an integer ranging from 0 to 4294967295.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the filtering conditions specified by **if-match** clauses are met, you can run the **apply cost** command to change the route MED or cost to control route selection. After setting the MED or cost, the MED or cost of the routes that are imported using the route-policy is changed accordingly.

Prerequisites

A route-policy has been configured by **route-policy**.

Configuration Impact

The costs of routes that match the route-policy are changed. BGP routes do not have costs, and instead, they have MEDs. If the **apply cost** command is run to configure an **apply** clause for a route-policy that is designed for BGP routes, the MEDs of BGP routes that match the route-policy are changed.

Precautions

The MEDs or costs of imported routes are independent of the route-policy after the **undo apply cost** command is used to cancel the route MED or cost.

Example

Define an **apply** clause to set the route cost to 120.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply cost 120
```

7.9.9 apply cost-type

Function

The **apply cost-type** command sets the action for changing the cost type of routes in a routing policy.

The **undo apply cost-type** command restores the default setting.

By default, the action for changing the cost type of routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply cost-type { **external** | **internal** | **type-1** | **type-2** }

undo apply cost-type

Parameters

Parameter	Description	Value
external	Sets the cost type of IS-IS external routes.	-
internal	Sets the cost type of IS-IS internal routes or sets the MED value of BGP routes as the IGP cost of the next hop.	-
type-1	Sets Type 1 external routes of OSPF.	-
type-2	Sets Type 2 external routes of OSPF.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply cost-type** { **external** | **internal** } command sets the cost type of IS-IS routes. The cost of an internal route imported to IS-IS remains unchanged and the cost of an external route imported to IS-IS is increased by 64.

NOTE

When the cost-style of an IS-IS device is wide, compatible, or wide-compatible, the cost types of external or internal are classified. When the cost-style of an IS-IS device is narrow or narrow-compatible, the imported route classifies the cost type of external or internal. In other words, the **apply cost-type** command is valid on IS-IS devices only in the narrow or narrow-compatible modes.

The **apply cost-type** { **type-1** | **type-2** } command modifies the type of OSPF routes. During route import, OSPF modifies the type but not the cost value of the original route. When OSPF advertises the imported route with the cost and type information to a peer, the peer device will recalculate the cost value of the imported route based on the received information.

When the filtering conditions specified by **if-match** clauses are met, you can change the cost type of routes to set the imported external routes all to Type-1 or all to Type-2 by using the **apply cost-type** command. After the cost type of the routes that match the route-policy is set, the cost type of the routes that are imported by using the route-policy is the set cost type.

Prerequisites

Before running the **apply cost-type** command, you need to configure a route-policy by **route-policy**.

Configuration Impact

After routes match the route-policy, the cost type of the routes is changed.

Precautions

Different operations are performed when the **apply cost-type internal** command is applied to IS-IS routes and BGP routes:

- When the **apply cost-type internal** command is applied to IS-IS routes:

  Routes are configured as IS-IS internal routes.

- When the **apply cost-type internal** command is applied to BGP routes:

  When a switch advertises a route learned from an IBGP peer to an EBGP peer, if the **apply cost-type internal** command is run, the switch sets the MED value of the route to be advertised to the EBGP peer as the IGP cost of the next hop of the route.

Example

Set the cost type to OSPF external Type-1.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply cost-type type-1
```

7.9.10 apply dampening

Function

The **apply dampening** command sets the action for changing the dampening parameters of EBGP routes in a routing policy.

The **undo apply dampening** command restores the default setting.

By default, the action for changing the dampening parameters of EBGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply dampening *half-life-reach reuse suppress ceiling*

undo apply dampening

Parameters

Parameter	Description	Value
half-life-reach	Specifies the half-life of a reachable route.	The value is an integer ranging from 1 to 45, in minutes.
reuse	Specifies the threshold for routes to be released from the dampening state. When the penalty value falls below the threshold, routes are reused.	The value is an integer ranging from 1 to 20000.
suppress	Specifies the threshold for routes to enter the dampening state. When the penalty value exceeds the threshold, routes are suppressed.	The value is an integer ranging from 1 to 20000. The configured value of *suppress* must be greater than the value of *reuse*.
ceiling	Specifies the upper limit of the penalty value of routes.	The value is an integer ranging from 1001 to 20000. The configured value of *ceiling* must be greater than the value of *suppress*.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply dampening** command, which is mostly used in BGP, is used to prevent frequent route dampening from affecting routers on the network.

You can configure different route dampening parameters for different nodes in the same routing policy. When route flapping occurs, BGP can use different route dampening parameters to suppress the routes that match the routing policy.

Procedure

If the **apply dampening** command is run multiple times, the latest configuration overwrites the previous one.

Prerequisites

The **route-policy** command has been configured.

Precautions

The parameters in this command do not have default values and must be set. The values of *reuse*, *suppress*, and *ceiling* are listed in ascending order: *reuse* < *suppress* <*ceiling*. According to the formula, MaxSuppressTime = *half-life-reach* x 60 x (ln (*ceiling*/*reuse*)/ln (2)), routes are unsuppressed if the value of MaxSuppressTime is less than 1. Therefore, the value of the *ceiling*/*reuse* must be great enough so that the value of MaxSuppressTime can be equal to or greater than 1.

Example

Set dampening parameters for EBGP routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy aa permit node 10
[HUAWEI-route-policy] apply dampening 20 2000 10000 16000
```

7.9.11 apply extcommunity

Function

The **apply extcommunity** command sets the action for changing the extended community attribute of BGP routes in a routing policy.

The **undo apply extcommunity** command restores the default setting.

By default, the action for changing the extended community attribute of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply extcommunity { **rt** { *as-number:nn* | *4as-number:nn* | *ipv4-address:nn* } } &<1-16> [**additive**]

undo apply extcommunity

Parameters

Parameter	Description	Value
rt	Indicates the route-target extended community. A maximum of 16 route targets can be configured.	-
as-number	Specifies the AS number.	The value is an integer ranging from 0 to 65535.
4as-number	Specifies a 4-byte AS number.	A 4-byte AS number is divided into the following types: ● It is an integer ranging from 65536 to 4294967295. ● It is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 respectively
ipv4-address	Specifies the IPv4 address.	It is in dotted decimal notation.
nn	Specifies an integer.	● When the value of *as-number* is a 2-byte AS number, the value of *nn* ranges from 0 to 4294967295. ● When the value of *4as-number* is a 4-byte AS number, the value of *nn* ranges from 0 to 65535. ● For *ipv4-address*, the value of *nn* ranges from 0 to 65535.
additive	Indicates that existing community attributes can be added to routes.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When controlling inter-AS VPN route receiving and advertising, apply the routing policy that contains the **apply extcommunity** command to change the RT extended community attribute of matched routes. Currently, only the RT extended community attribute is supported. This command cannot specify an extended community attribute for public routes.

Prerequisites

The **apply extcommunity** command can be used only after the **route-policy** command is used.

Precautions

When the routing policy that contains the action is used in the BGP view, BGP IPv4 unicast address view, or BGP IPv6 unicast address view, the action does not take effect.

When a routing policy takes effect, it affects inter-AS VPN route receiving and advertising.

If the keyword **additive** is not set in the **apply extcommunity** command, the original extended community attribute is replaced.

Example

Add 100:2, 10.1.1.1:22, 100.100:100 to the VPN route-target extended community attribute of BGP.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply extcommunity rt 100:2 rt 10.1.1.1:22 rt 100.100:100 additive
```

7.9.12 apply ip-address next-hop (Route-Policy view)

Function

The **apply ip-address next-hop** command sets the action for changing the next hop address of BGP routes in a routing policy.

The **undo apply ip-address next-hop** command restores the default setting.

By default, the action for changing the next hop address of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply ip-address next-hop { *ipv4-address* | **peer-address** }

undo apply ip-address next-hop { *ipv4-address* | **peer-address** }

Parameters

Parameter	Description	Value
ipv4-address	Specifies the next hop address.	It is in dotted decimal notation.
peer-address	Sets the next hop address to the local address when the **apply** clause is used by an export policy. Sets the next hop address to the peer address when the **apply** clause is used by an import policy.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To change the next hop address of BGP routes for selecting the optimal route, you can apply a routing policy containing the **apply ip-address next-hop** command.

The next hop address of a BGP route is set using the policy in the following situations:

- IBGP: Configure the import or export policy for the IBGP peer. If the next hop address configured in the routing policy is unreachable, the IBGP peer adds the corresponding route to the BGP routing table. However, this route is invalid.
- EBGP: Configure the import policy for the EBGP peer. If an export policy is configured, the route destined for the EBGP peer is discarded because the next hop address is unreachable.

Prerequisites

The **apply ip-address next-hop** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects BGP route selection.

When a routing policy is specified in the **import-route** and **network** commands, the **apply ip-address next-hop** clause in the routing policy does not take effect.

The command sets a next hop IP address for the routes that match the relevant route-policy, which may change the service forwarding path. Therefore, exercise caution when running this command.

Example

Define an **apply** clause to set the next hop address as 192.168.1.8.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply ip-address next-hop 192.168.1.8
```

7.9.13 apply ip-precedence

Function

The **apply ip-precedence** command sets the QoS parameter *ip-precedence* for routes.

The **undo apply ip-precedence** command restores the configuration.

By default, no IP preference is set.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply ip-precedence *ip-precedence*

undo apply ip-precedence

Parameters

Parameter	Description	Value
ip-precedence	IP precedence	The value can be a preference value or a keyword: - The value is an integer ranging from 0 to 7. - The preference keyword can be Routine, Priority, Immediate, Flash, Flash-override, Critical, Internet, or Network. Table 7-193 shows the relationship between preference values and keywords.

Table 7-193 Relationship between preference values and keywords

Value	Keyword
0	Routine
1	Priority
2	Immediate
3	Flash
4	Flash-override
5	Critical
6	Internet
7	Network

Views

Route-policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving routes, a BGP route receiver matches the attributes of the BGP routes based on the import route-policy, sets the IP precedence, delivers the BGP routes together with the associated QoS parameters, and applies QoS traffic policies to the classified data. In this case, the BGP route receiver can apply QoS policies to the data sent to the destination network segment based on the IP precedence. This applies QoS policies in BGP.

Prerequisites

The **apply ip-precedence** command can be used only after the **route-policy** command is used.

Configuration Impact

If a route matches a route-policy, you can change the value of the Precedence field in the IP header. The Precedence field is the first three bits of the Type of Service (ToS) field in the IP header.

Precautions

If an integer is used to specify *ip-precedence*, the preference is saved as an integer in the configuration file. If a keyword is used to specify *ip-precedence*, the preference is saved as a keyword in the configuration file.

Example

Set the IP precedence in the route-policy named **test**.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] apply ip-precedence internet
```

7.9.14 apply ipv6 backup-interface

Function

The **apply ipv6 backup-interface** command configures a backup outbound interface in a routing policy.

The **undo apply ipv6 backup-interface** command restores the default setting.

By default, the backup outbound interface is not configured in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply ipv6 backup-interface *interface-type interface-number*

undo apply ipv6 backup-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the backup outbound interface.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply ipv6 backup-interface** command is used in IPv6 FRR scenarios to configure a backup outbound interface for a route. After IPv6 FRR is enabled, data traffic can be quickly switched to the backup outbound interface if the primary link fails.

Prerequisites

if-match clauses can be used to configure matching rules such as IPv6 prefix lists, and ACLs before a backup outbound interface is configured.

Follow-up Procedure

Reference a configured route-policy in the **ipv6 frr (system view)** command or the **ipv6 frr (VPN instance view)** command to configure IPv6 FRR on a public network or VPN.

The **apply ipv6 backup-interface** command is usually used together with the **apply ipv6 backup-nexthop** command.

Precautions

For P2P links, a backup next hop is not necessary. For non-P2P links, a backup next hop is necessary.

Example

Configure the backup outbound interface and the backup next hop in the route-policy named **ipv6_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ipv6_frr_rp permit node 10
[HUAWEI-route-policy] apply ipv6 backup-interface vlanif10
[HUAWEI-route-policy] apply ipv6 backup-nexthop 2001:db8:1::1
```

Delete the configured backup outbound interface from the route-policy named **ipv6_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ipv6_frr_rp permit node 10
[HUAWEI-route-policy] undo apply ipv6 backup-interface
```

7.9.15 apply ipv6 backup-nexthop

Function

The **apply ipv6 backup-nexthop** command configures a backup next hop in a routing policy.

The **undo apply ipv6 backup-nexthop** command deletes the configured backup next hop.

By default, the backup next hop is not configured in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply ipv6 backup-nexthop { *ipv6-address* | **auto** }

undo ipv6 apply backup-nexthop

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a backup next hop.	The address is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
auto	Automatically searches for the backup next hop.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply ipv6 backup-nexthop** command is used to configure a backup next hop for a route in IPv6 FRR and VPN FRR scenarios. After IPv6 FRR is enabled, data traffic can be quickly switched to the backup next hop if the primary link fails.

Prerequisites

if-match clauses can be used to set matching rules such as interfaces, IPv6 prefix lists, and ACLs before a backup next hop is configured.

Follow-up Procedure

The configured route-policy can be used in the **ipv6 frr (system view)** command or the **ipv6 frr (VPN instance view)** command that is run to configure IPv6 FRR for a public or private network. It can also be used in the **vpn frr** command that is run to enable VPN FRR.

In a VPN FRR scenario, you only need to run the **apply ipv6 backup-nexthop** command to configure a backup next hop.

In an IPv6 FRR scenario, you need to run both the **apply ipv6 backup-nexthop** and **apply ipv6 backup-interface** commands.

Precautions

For P2P links, a backup next hop is not necessary. For non-P2P links, a backup next hop is necessary.

Example

Configure the backup interface and the backup next hop in the route-policy named **ipv6_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] apply ipv6 backup-interface vlanif10
[HUAWEI-route-policy] apply ipv6 backup-nexthop 2001:db8:1::1
```

Delete the configured backup next hop from the route-policy named **ipv6_frr_rp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy ipv6_frr_rp permit node 10
[HUAWEI-route-policy] undo apply ipv6 backup-nexthop
```

7.9.16 apply ipv6 next-hop

Function

The **apply ipv6 next-hop** command sets the action for changing an IPv6 next hop address of a BGP route in a route-policy.

The **undo apply ipv6 next-hop** command restores the default setting.

By default, the action for changing the IPv6 next hop addresses of BGP routes are not configured in a route-policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply ipv6 next-hop { **peer-address** | *ipv6-address* }

undo apply ipv6 next-hop { **peer-address** | *ipv6-address* }

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 next hop address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
peer-address	Specifies the peer address as the next hop.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply ipv6 next-hop** command configures an IPv6 next hop address for a BGP route.

In BGP, the next hop address of a route can be set through the route-policy in the following situations:

- IBGP

  For an IBGP peer, the configured inbound and outbound policies can take effect. If the next hop address configured in the policy is unreachable, the IBGP peer still adds the route to the BGP routing table, but the route is not valid.

- EBGP

  For an EBGP peer, when the policy is used to modify the next hop address of a route, the inbound policy is configured. If the outbound policy is configured, the route is discarded because its next hop is unreachable.

Prerequisites

The **apply ipv6 next-hop** command can be used only after the **route-policy** command is used.

Configuration Impact

After a BGP route matches a route-policy, you can change the IPv6 next hop address of the BGP route.

Precautions

When a route-policy is being applied in the **import-route** and **network** commands, the **apply ipv6 next-hop** clause in the route-policy does not take effect.

Example

Set FC00:0:0:6::1 as the next hop address.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply ipv6 next-hop fc00:0:0:6::1
```

7.9.17 apply isis

Function

The **apply isis** command sets the action for changing the level of routes imported to IS-IS in a routing policy.

The **undo apply isis** command restores the default setting.

By default, the action for changing the level of routes imported to IS-IS is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply isis { **level-1** \| **level-1-2** \| **level-2** }

undo apply isis

Parameters

Parameter	Description	Value
level-1	Indicates IS-IS Level-1 routes.	-
level-1-2	Indicates IS-IS Level-1 and Level-2 routes.	-
level-2	Indicates IS-IS Level-2 routes.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A large number of external routes can be imported to IS-IS, which causes extra burdens on IS-IS-enabled devices. To solve this problem, run the **apply isis** command to set the level of the routes to be imported to IS-IS.

Prerequisites

The **apply isis** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects route receiving and advertising in IS-IS.

Example

Set the level of the routes imported to IS-IS.

```
<HUAWEI> system-view
```

```
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply isis level-1
```

7.9.18 apply local-preference

Function

The **apply local-preference** command sets the action for changing the local preference of BGP routes in a routing policy.

The **undo apply local-preference** command restores the default setting.

By default, the action for changing the local preference of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply local-preference *preference*

undo apply local-preference

Parameters

Parameter	Description	Value
preference	Specifies the local preference of BGP routes.	The value is an integer ranging from 0 to 4294967295.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Local-Pref attribute is a private attribute of BGP. The **apply local-preference** command sets only the local preference for BGP routes. The Local_Pref attribute is used to determine the optimal route when traffic leaves an AS, and its default value is 100. When a BGP router obtains multiple routes to the same destination address but with different next hops through IBGP peers, the route with the largest Local_Pref value is selected.

Prerequisites

After a BGP route matches a routing policy, you can change the local preference of the BGP route.

Precautions

- When a routing policy takes effect, it affects BGP route selection.
- The Local_Pref attribute applies to the routing within an AS rather than be advertised to the outside of the AS. In this case, the **apply local-preference** command does not take effect when EBGP neighbor relationships are set up.
- After the **apply local-preference** command is run in a route-policy or its configuration is changed, route updates are triggered.

Example

Set the local preference of BGP routes to 130.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply local-preference 130
```

7.9.19 apply mpls-label

Function

The **apply mpls-label** command sets the action for allocating MPLS labels to public routes in a routing policy.

The **undo apply mpls-label** command restores the default setting.

By default, the action for allocating MPLS labels to public routes is not set in a routing policy.

NOTE

Only the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H support this command.

Format

apply mpls-label

undo apply mpls-label

Usage Guidelines

Usage Scenario

In the scenario where inter-AS VPN Option C or Carrier Support Carrier (CSC) is deployed, you can use the **apply mpls-label** command to allocate labels to public routes.

Prerequisites

The **apply mpls-label** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it allocates MPLS labels to public routes.

Example

Assign MPLS labels to the routes that match the routing policy.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply mpls-label
```

7.9.20 apply origin

Function

The **apply origin** command sets the action for changing the Origin attribute of BGP routes in a routing policy.

The **undo apply origin** command restores the default setting.

By default, the action for changing the Origin attribute of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply origin { **egp** { *as-number-plain* | *as-number-dot* } | **igp** | **incomplete** }

undo apply origin

Parameters

Parameter	Description	Value
egp *as-number-plain*	Sets the origin of BGP routes as EGP. The parameter *as-number-plain* specifies the Integral AS number of an external route. An AS number uniquely identifies an AS. *as-number-plain* is required when you need to change the origin of BGP routes as EGP. EGP has the secondary highest priority. The Origin attribute of the routes obtained through EGP is EGP.	The value is an integer ranging from 1 to 4294967295.
egp *as-number-dot*	Sets the origin of BGP routes as EGP. The parameter *as-number-dot* specifies the AS number in dotted notation of an external route. An AS number uniquely identifies an AS. *as-number-dot* is required when you need to change the origin of BGP routes as EGP. EGP has the secondary highest priority. The Origin attribute of the routes obtained through EGP is EGP.	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.
igp	Sets the origin of BGP routes as IGP. IGP has the highest priority. The Origin attribute of the routes obtained through an IGP of the AS that originates the routes, such as the routes imported to the BGP routing table through the **network** command, is IGP.	-

Parameter	Description	Value
incomplete	Sets the origin code of BGP routes as unknown. Incomplete has the lowest priority. The Origin attribute of the routes learned through other methods, such as the routes imported by BGP through the **import-route** command, is Incomplete.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To change the Origin attribute of routes for selecting the optimal route, you can apply a routing policy containing the **apply origin** command. The Origin attribute is a private attribute of BGP and defines the origin of a route.

Prerequisites

The **apply origin** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects BGP route selection.

Example

Set the origin of BGP routes to IGP.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply origin igp
```

7.9.21 apply ospf

Function

The **apply ospf** command sets the action performed for configuring an OSPF area to which the route is imported in a routing policy.

The **undo apply ospf** command restores the default setting.

By default, the action performed for configuring an OSPF area to which the route is imported is not set in a routing policy.

Format

apply ospf { **backbone** | **stub-area** }

undo apply ospf

Parameters

Parameter	Description	Value
backbone	Imports routes to the OSPF backbone area.	-
stub-area	Imports routes to an OSPF NSSA.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **apply ospf** command can be used to specify the OSPF backbone area or NSSA area to which routes are imported. This can prevent OSPF from importing too many external routes, which brings heavy burden on OSPF devices.

Prerequisites

The **apply ospf** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, routes are imported to the specified OSPF area.

Example

Import routes to the OSPF backbone area.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply ospf backbone
```

7.9.22 apply preference

Function

The **apply preference** command sets the action for changing the preference of routes in a routing policy.

The **undo apply preference** command restores the default setting.

By default, the action for changing the preference of routes is not set in a routing policy.

Format

apply preference *preference*

undo apply preference

Parameters

Parameter	Description	Value
preference	Specifies the route precedence. Route sharing and route selection are difficult because multiple routing protocols can run on the device at the same time; therefore, a default preference needs to be specified for each routing protocol. When different protocols discover multiple routes to the same destination, the route discovered by the protocol with a higher preference is selected to forward IP packets. The smaller the preference value, the higher the preference.	The value is an integer ranging from 1 to 255.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To change the preference of routes for selecting the optimal route, you can apply a routing policy containing the **apply preference** command.

Prerequisites

The **apply preference** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects route selection.

Example

Set the preference for routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply preference 90
```

7.9.23 apply preferred-value

Function

The **apply preferred-value** command sets the action for changing the preferred value of BGP routes in a routing policy.

The **undo apply preferred-value** command restores the default setting.

By default, the action for changing the preferred value of BGP routes is not set in a routing policy.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply preferred-value *preferred-value*

undo apply preferred-value

Parameters

Parameter	Description	Value
preferred-value	Specifies the preferred value of BGP routes. In route selection, the BGP route with the largest preferred value is preferred.	The value is an integer ranging from 0 to 65535.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To change the preferred value of BGP routes for selecting the optimal route, you can apply a routing policy containing the **apply preferred-value** command.

Prerequisites

The **apply preferred-value** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effect, it affects BGP route selection.

The preferred value of a route indicates the weight of the route in BGP routing. The preferred value is not a standard RFC-defined attribute and is valid only on local devices. The preferred value is inapplicable to export policies of BGP.

Example

Set the preferred value for BGP routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply preferred-value 66
```

7.9.24 apply qos-local-id

Function

The **apply qos-local-id** command sets the QoS local ID.

The **undo apply qos-local-id** command cancels the configuration.

By default, no QoS local ID is set.

Format

apply qos-local-id *qos-local-id*

undo apply qos-local-id

Parameters

Parameter	Description	Value
qos-local-id	Specifies the QoS local ID.	The value is an integer ranging from 1 to 4095.

Views

Route-policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The QoS local ID is a local identifier of QoS. In actual applications, you can set the QoS local ID in the route-policy, and add the command that matches the QoS local ID in the QoS policy. The QoS local ID set in the route-policy is delivered to the FIB table. During packet forwarding, the system obtains the QoS local ID from the FIB table and applies the related QoS policy according to the QoS local ID.

Configuration Impact

The **apply qos-local-id** command is mutually exclusive with the **apply behavior** and **apply ip-precedence** commands, and only one of these commands can be configured on a node of a routing policy. For example, if the **apply qos-local-id** command is configured in the view created by the **route-policy test permit node 10** command, configuring the **apply ip-precedence** command replaces **apply qos-local-id** command.

Example

Set the QoS local ID in the route-policy named **test**.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] apply qos-local-id 10
```

7.9.25 apply tag

Function

The **apply tag** command sets the action for changing the tag of routes in a routing policy.

The **undo apply tag** command restores the default setting.

By default, the action for changing the tag of routes is not set in a routing policy.

Format

apply tag *tag*

undo apply tag

Parameters

Parameter	Description	Value
tag	Specifies the tag of routes. Routes can be tagged as required. You can set the same tag for the same type of route. Routes can be flexibly controlled and managed through tags in the routing policy.	The value is an integer ranging from 0 to 4294967295.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To identify the routes, you can apply a routing policy containing the **apply tag** command to add the same tag to the matched routes.

Prerequisites

The **apply tag** command can be used only after the **route-policy** command is used.

Precautions

When a routing policy takes effects, routes will be matched by routing policies related to the tag.

BGP routes do not support tags. The **apply tag** command sets the tag for only IGP routes.

Example

Set the tag of routes to 100.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] apply tag 100
```

7.9.26 apply traffic-index

Function

The **apply traffic-index** command sets the BGP traffic index.

The **undo apply traffic-index** command cancels the configuration.

By default, no BGP traffic index is set.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

apply traffic-index *traffic-index*

undo apply traffic-index

Parameters

Parameter	Description	Value
traffic-index	Specifies the index of BGP traffic.	The value is an integer ranging from 1 to 64.

Views

Route-policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BGP accounting uses different BGP traffic indexes in BGP community attributes to identify routes and charge the traffic accordingly.

The sending end of BGP routes can set attributes for BGP routes by using the route-policy. The receiving end of BGP routes can set the BGP traffic index for BGP routes according to the BGP community filter, BGP AS_Path filter, ACL, and IP prefix list. The BGP traffic index together with routing information is delivered to the FIB table. After BGP accounting is enabled on an interface, the traffic-index-based traffic collection table can be generated for the interface.

During packet forwarding, traffic statistics can be collected according to the traffic index on each interface. Traffic statistics can be collected according to either the destination address in the inbound direction or the source address in the outbound direction.

Prerequisites

The **route-policy** command has been run.

Example

Configure the BGP traffic index.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] apply traffic-index 10
```

7.9.27 description (Route-Policy view)

Function

The **description** command configures the description of a route-policy.

The **undo description** command deletes the description of a route-policy.

By default, no description is configured for the route-policy.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of a route-policy.	The description is a string of 1 to 80 case-sensitive characters that can contain spaces.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **description** command can be used to configure a description for a created route-policy. If many route-policies have been configured, configuring descriptions for the policies will facilitate policy management.

Prerequisites

A route-policy has been created by using **route-policy** command.

Example

Configure the description of the route-policy named **temp**.

```
<HUAWEI> system-view
[HUAWEI] route-policy temp permit node 10
[HUAWEI-route-policy] description This policy-name is temp
```

7.9.28 display ip as-path-filter

Function

display ip as-path-filter command displays the configuration of the AS_Path filter.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

display ip as-path-filter [*as-path-filter-number* | *as-path-filter-name*]

Parameters

Parameter	Description	Value
as-path-filter-number	Displays the configuration of an AS_Path filter with a specified number.	It is an integer that ranges from 1 to 256.
as-path-filter-name	Displays the configuration of an AS_Path filter with a specified name.	The name is a string of 1 to 51 characters without any space. It is case-sensitive.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The AS-Path attribute is a BGP-specific attribute. An AS-Path filter is used to filter BGP routes.

You can run the **display ip as-path-filter** command to:

- View detailed information about a configured AS path filter.
- Check whether an AS-Path filter is deleted successfully after running the **undo ip as-path-filter** command.

Precautions

The **display ip as-path-filter** command:

- Displays the configuration information about a specified AS-Path filter, if the number or name of the AS-Path filter is specified.
- Displays the configuration information about all AS-Path filters, if neither the number nor name of the AS-Path filter is specified.
- Does not display any information, if the AS-Path filter does not exist in the system or the AS-Path filter that is queried does not exist.

Example

Display the configured AS_Path filter.

```
<HUAWEI> display ip as-path-filter
As path filter number: 1
         permit    1.1 100,200
As path filter name: abc
         deny      2.2 200,400
```

Table 7-194 Description of the display ip as-path-filter command output

Item	Description
As path filter number	AS-Path filter number.
As path filter name	AS-Path filter name.
permit	Matching mode is permit.
1.1 100,200	Content of the regular expression.
deny	Matching mode is deny.

7.9.29 display ip community-filter

Function

The **display ip community-filter** command displays the configuration of the community filter.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

display ip community-filter [*basic-comm-filter-num* | *adv-comm-filter-num* | *comm-filter-name*]

Parameters

Parameter	Description	Value
basic-comm-filter-num	Displays the configuration of a basic community filter with a specified number.	The value is an integer ranging from 1 to 99.
adv-comm-filter-num	Displays the configuration of an advanced community filter with a specified number.	The value is an integer ranging from 100 to 199.
comm-filter-name	Displays the configuration of a community filter with a specified name.	The name is a string of 1 to 51 characters. The string cannot be all numerals.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The community attribute is a BGP-specific attribute. A community filter is used to filter BGP routes.

You can run the **display ip community-filter** command to:

- View detailed information about a configured community filter.
- Check whether a community filter is successfully deleted after running the **undo ip community-filter** command.

Precautions

The **display ip community-filter** command:

- Displays the configuration information about a specified community filter, if the number or name of the community filter is specified.
- Displays the configuration information about all community filters, if neither the number nor name of the community filter is specified.
- Does not display any information, if the community filter does not exist in the system or the community filter that is queried does not exist.

Example

Display all community filters.

```
<HUAWEI> display ip community-filter
Community filter Number: 10
         deny  no-export
Community filter Number: 110
         permit 110:110
Named Community basic filter: aa (ListID = 200)
         permit  1 internet
Named Community advanced filter: bb (ListID = 700)
         permit ^20
```

Table 7-195 Description of the display ip community-filter command output

Item	Description
Community filter Number	Indicates the number of a community filter.
permit	Indicates that the matching mode is permit.
deny	Indicates that the matching mode is deny.
Named Community basic filter	Indicates the name of a basic community filter.
Named Community advanced filter	Indicates the name of an advanced community filter.

7.9.30 display ip extcommunity-filter

Function

display ip extcommunity-filter command displays the configuration of the extended community filter.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

display ip extcommunity-filter [*basic-extcomm-filter-num* | *advanced-extcomm-filter-num* | *extcomm-filter-name*]

Parameters

Parameter	Description	Value
basic-extcomm-filter-num	Specifies the basic extended community filter number.	It is an integer that ranges from 1 to 199.
advanced-extcomm-filter-num	Specifies the advanced extended community filter number.	It is an integer that ranges from 200 to 399.
extcomm-filter-name	Displays the configuration of an extended community filter with a specified name.	The name is a string of 1 to 51 characters without any space. It is case-sensitive.

Views

Usage Guidelines

Usage Scenario

The extended community attribute is a BGP-specific attribute. An extended community filter is used to filter VPN routes.

You can run the **display ip extcommunity-filter** command to:

- View detailed information about a configured extended community filter.

- Check whether an extended community filter is successfully deleted after running the **undo ip excommunity-filter** command.

Precautions

The **display ip extcommunity-filter** command:

- Displays the configuration information about a specified extended community filter, if the number or name of the extended community filter is specified.
- Displays the configuration information about all extended community filters, if neither the number nor name of the extended community filter is specified.
- Does not display any information, if the extended community filter does not exist in the system or the extended community filter that is queried does not exist.

Example

Display information about the extended community filter.

```
<HUAWEI> display ip extcommunity-filter
Extended Community filter Number 10
         permit rt : 100:10
Extended Community filter Number 280
         permit rt 100:65
Extended Community filter basic filter: bas-abc
         permit rt : 200:10
Extended Community filter advanced filter: adv-abc
         deny 1.1.1.1:10
```

Table 7-196 Description of the display ip extcommunity-filter command output

Item	Description
Extended Community filter Number	Indicates the number of an extended community filter.
Extended Community filter basic filter	Basic extended community filter name.
Extended Community filter advanced filter	Advanced extended community filter name.
permit	Indicates that the matching mode is permit.
deny	Indicates that the matching mode is deny.
rt	Indicates the extended community attribute of the specified RT.

7.9.31 display ip ip-prefix

Function

The **display ip ip-prefix** command displays the configuration of IPv4 prefix lists.

Format

display ip ip-prefix [*ip-prefix-name*]

Parameters

Parameter	Description	Value
ip-prefix-name	Displays the configuration of an IP prefix list with a specified name.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

An IPv4 prefix list is used to filter IPv4 addresses. To achieve the following purposes, run the **display ip ip-prefix** command:

- View detailed configuration of a configured IPv4 prefix list.
- Check whether an IPv4 prefix list is deleted after running the **undo ip ip-prefix** command.
- View the number of routes that do or do not match the route-policy in an IPv4 prefix list.

Precautions

The **display ip ip-prefix** command:

- Displays the configuration of a specified IPv4 prefix list if the name of the IPv4 prefix list is specified.
- Displays the configuration of all IPv4 prefix lists if no IPv4 prefix list name is specified.
- Does not display information if no IPv4 prefix list exists in the system or the queried IPv4 prefix list does not exist.

Before collecting the number of routes that do or do not match the route-policy in an IPv4 prefix list within a certain period, run the **reset ip ip-prefix** command to clear existing statistics.

NOTE

If **The specified filter list does not exist** is displayed in the command output, the specified IPv4 prefix list failed to be configured. To re-configure it, run the **ip ip-prefix** command in the system view.

Example

Display the configuration of the IP prefix list named **p1**.

```
<HUAWEI> display ip ip-prefix p1
Prefix-list pl
Permitted 0
  Description prefixok
Denied 0
        index: 10      permit  192.168.0.0/16          ge  17  le  18
```

Table 7-197 Description of the display ip ip-prefix command output

Item	Description
Prefix-list	Name of an IPv4 prefix list.
Permitted	Number of routes that match a route-policy.
Description	Description of an IPv4 prefix list. This field is displayed only after a description is configured using the **ip ip-prefix** *ip-prefix-name* **description** *text* command.
Denied	Number of routes that do not match the route-policy.
index	Index of the entry in the IPv4 prefix list.
permit	Contents of the entry in the IPv4 prefix list.
ge 17	The mask is greater than or equal to 17.
le 18	The mask is less than or equal to 18.

7.9.32 display ip ipv6-prefix

Function

display ip ipv6-prefix displays the configuration of IPv6 prefix lists.

Format

display ip ipv6-prefix [*ipv6-prefix-name*]

Parameters

Parameter	Description	Value
ipv6-prefix-name	Displays the configuration of an IP prefix list with a specified name. If *ipv6-prefix-name* is not specified, the configuration of all the configured IPv6 prefix lists is displayed.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

An IPv6 prefix list is used to filter IPv6 addresses. To achieve the following purposes, run the **display ip ipv6-prefix** command:

- View detailed configuration of a configured IPv6 prefix list.
- Check whether an IPv6 prefix list is deleted after running the **undo ip ipv6-prefix** command.
- View the number of routes that do or do not match the route-policy in an IPv6 prefix list.

Precautions

The **display ip ipv6-prefix** command:

- Displays the configuration of a specified IPv6 prefix list if the name of the IPv6 prefix list is specified.
- Displays the configuration of all IPv6 prefix lists if no IPv6 prefix list name is specified.
- Does not display information if no IPv6 prefix list exists in the system or the queried IPv6 prefix list does not exist.

Before collecting the number of routes that do or do not match the route-policy in an IPv6 prefix list within a certain period, run the **reset ip ipv6-prefix** command to clear existing statistics.

Example

Display the configuration of all the IPv6 prefix lists.

```
<HUAWEI> display ip ipv6-prefix
 Prefix-list6 abc
 Description prefixok
 Permitted 0
 Denied 0
 index:   10          permit  ::/0
 index:   20          permit  ::/1           ge  1   le  128
```

Table 7-198 Description of the display ip ipv6-prefix command output

Item	Description
Prefix-list6	Name of an IPv6 prefix list.
Description	Description of an IPv6 prefix list. This field is displayed only after a description is configured using the **ip ipv6-prefix** *ipv6-prefix-name* **description** *text* command.

Item	Description
Permitted	Number of routes that match a route-policy.
Denied	Number of routes that do not match a route-policy.
index	Index of the entry in the IPv6 prefix list.
permit	Contents of the entry in the IPv6 prefix list.
ge	Greater than or equal to.
le	Less than or equal to.

7.9.33 display ip rd-filter

Function

The **display ip rd-filter** command displays the configuration of the route distinguisher (RD) filter.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

display ip rd-filter [*rd-filter-number*]

Parameters

Parameter	Description	Value
rd-filter-number	Displays the configuration of an RD filter with a specified number.	The value is an integer ranging from 1 to 255.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The RD attribute is carried in VPN routes. An RD filter is used to filter VPN routes.

You can run the **display ip rd-filter** command to:

- View detailed information about a configured RD filter.
- Check whether an RD filter is successfully deleted after running the **undo ip rd-filter** command.

Precautions

The **display ip rd-filter** command:

- Displays the configuration information about a specified RD filter, if the number of an RD filter is specified.
- Displays the configuration information about all RD filters, if the number of no RD filter is specified.
- Does not display any information, if the RD filter does not exist in the system or the RD filter that is queried does not exist.

Example

Display the configured RD filter.

```
<HUAWEI> display ip rd-filter
Route Distinguisher Filter 1
       permit 10.1.1.1:1 10.2.2.2:* 100:1 200:*
Route Distinguisher Filter 2
       deny 1:1 2:2
       permit 1:* 2:*
```

Table 7-199 Description of the display ip rd-filter command output

Item	Description
Route Distinguisher Filter	Number of the RD filter
permit	Matching mode: permit
deny	Matching mode: deny

7.9.34 display route-policy

Function

The **display route-policy** command displays the configuration of the route-policy.

Format

display route-policy [*route-policy-name*]

Parameters

Parameter	Description	Value
route-policy-name	Displays the configuration of a route-policy with a specified name.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display route-policy** command to check detailed configuration of a route-policy.

Example

Display the configuration of the route-policy named **policy1**.

```
<HUAWEI> display route-policy policy1
Route-policy : policy1
  permit : 10 (matched counts: 2)
    Match clauses :
       if-match acl 2000
    Apply clauses :
       apply cost 100
       apply tag 100
```

Table 7-200 Description of the display route-policy command output

Item	Description
Route-policy	Name of the routing policy
permit	Matching mode and node index of the routing policy
matched counts: 2	Number of nodes that routes are matched in a routing policy
Match clauses	Matching condition list
Apply clauses	Apply clause list

7.9.35 goto next-node

Function

The **goto next-node** command further matches routes against a specified node after the routes match the current node.

The **undo goto next-node** command restores the default configuration.

By default, if a route matches the current node, it matches the route-policy and is no longer matched against other nodes.

Product	Support
S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, S6730-S, and S6730S-S	Not supported

Format

goto next-node [*node*]

undo goto next-node

Parameters

Parameter	Description	Value
node	Specifies the index of a node against which routes are further matched.	The value is an integer ranging from 1 to 65535 and must be greater than the index of the current node.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The relationship among the matching rules of nodes in the same route-policy is OR. Specifically, if a route matches a node, it matches the route-policy and is no longer matched against other nodes. If you want the route to be matched against two or more nodes, run the **goto next-node** command so that the route is further matched against a specified node after the route matches the current node.

- If *node* is not specified in the command, the route will be further matched against the next node of the current node by default.
- If the node specified in the command does not exist, the route will be further matched against the next node of the specified node by default. If the next node of the specified node does not exist either, the route fails to match the route-policy, and no **apply** clause will be applied to the route.

Precautions

- If the **goto next-node** command is run in the route-policy view and a route matches all the specified nodes, the **apply** clauses of these nodes will be applied to the route.
- If the route fails to match one node, the route is matched against the next node until it succeeds in matching a node, and then the **apply** clauses of the nodes that the route matches will be applied to the route. If the route fails to match all nodes, no **apply** clauses will be applied to the route.
- In the same route-policy, a maximum of 50 nodes can be specified using the command.
- In the same route-policy, if this command is configured to match routes against multiple nodes, a maximum of 10 AS numbers, 16 RT extended community attributes, 16 color extended community attributes, and 36 community attributes can be added to the routes that match the nodes; if multiple community filters are used in the same route-policy to delete community attributes from the routes that match filtering conditions, only the first community filter takes effect.

Example

Configure a route-policy named **test** to further match routes against node 20 after the routes match node 10.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] if-match tag 123
[HUAWEI-route-policy] apply cost 10
[HUAWEI-route-policy] goto next-node 20
```

7.9.36 if-match acl (Route-Policy view)

Function

The **if-match acl** command sets a matching rule that is based on the Access Control List (ACL).

The **undo if-match acl** command deletes the matching rule based on the specified ACL.

By default, no matching rule based on the ACL is configured.

Format

if-match acl { *acl-number* | *acl-name* }

undo if-match acl { *acl-number* | *acl-name* }

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl-name	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match acl** command to set a matching rule based on the ACL to match IPv4 prefixes.

Prerequisites

The **if-match acl** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes using the ACL. Routes that match the ACL will be checked by other **if-match** clauses of this node. Routes that do not match the ACL will be checked by the next node.

An ACL name is a character string that starts with a letter. For example, **2a** is an invalid ACL name.

The **if-match acl** command and the **if-match ip-prefix** command are mutually exclusive. If you run the **if-match ip-prefix** command after running the **if-match acl** command, the configuration of the **if-match ip-prefix** command overrides the configuration of the **if-match acl** command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Set a matching rule that is based on ACL 2000.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match acl 2000
```

7.9.37 if-match as-path-filter

Function

The **if-match as-path-filter** command creates a matching rule based on the AS_Path filter.

The **undo if-match as-path-filter** command deletes a matching rule based on the specified AS_Path filter.

By default, no matching rule based on the AS_Path filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

if-match as-path-filter { *as-path-filter-number* &<1-16> | *as-path-filter-name* }

undo if-match as-path-filter [*as-path-filter-number* &<1-16> | *as-path-filter-name*]

Parameters

Parameter	Description	Value
as-path-filter-number	Specifies the number of an AS_Path filter. A maximum of 16 AS_Path filters can be specified.	The value is an integer ranging from 1 to 256.

Parameter	Description	Value
as-path-filter-name	Specifies the name of the AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The value cannot contain only numerals. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The AS_Path attribute is the private attribute of BGP. The **if-match as-path-filter** command is applicable to only BGP routes. The **ip as-path-filter** command must be used to define an AS_Path filter so that the matching rule based on this AS_Path filter can take effect. For example:

- If the **if-match as-path-filter 1** command is used but AS_Path filter 1 is not configured, all routes are permitted, that is, all routes match the matching rule.
- If the **if-match as-path-filter 1** command after the **ip as-path-filter 1 permit *20** command is used, the BGP routes with the AS_Path attribute being 20 are permitted.

Multiple **if-match as-path-filter** clauses can be specified. The relationship between **if-match as-path-filter** clauses is "OR". The relationship between **if-match** clauses is "AND".

Prerequisites

Before running the **if-match as-path-filter** command, run the **ip as-path-filter** command to configure an AS_Path filter.

Precautions

The routing policy matches routes using the AS-Path filter. Routes that match the AS-Path filter will be checked by other **if-match** clauses of this node. Routes that do not match the AS-Path filter will be checked by the next node.

A maximum of 16 AS_Path filters can be specified. The relationship between these AS_Path filters is OR. Specifically, if a route matches one of these AS_Path filters, it matches the matching rules of the command.

Creating an AS_Path filter before it is referenced is recommended. By default, nonexistent AS_Path filters cannot be referenced using the command. If the **route-**

policy nonexistent-config-check disable command is run in the system view and a nonexistent AS_Path filter is referenced using the current command, all routes match the AS_Path filter.

Example

Configure AS_Path filter 2 to permit AS200 and AS300. Create a routing policy named **test**, and define AS_Path filter 2 in an **if-match** clause for node 10 of the routing policy.

```
<HUAWEI> system-view
[HUAWEI] ip as-path-filter 2 permit _200_300
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] if-match as-path-filter 2
```

7.9.38 if-match community-filter

Function

The **if-match community-filter** command creates a matching rule based on the community filter.

The **undo if-match community-filter** command deletes the matching rule based on the specified community filter.

By default, no matching rule based on the community filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

if-match community-filter { *basic-comm-filter-num* [**whole-match**] | *adv-comm-filter-num* } &<1-16>

if-match community-filter *comm-filter-name* [**whole-match**]

undo if-match community-filter [*basic-comm-filter-num* | *adv-comm-filter-num*] &<1-16>

undo if-match community-filter *comm-filter-name*

Parameters

Parameter	Description	Value
basic-comm-filter-num	Specifies the number of a basic community filter.	The value is an integer ranging from 1 to 99.
adv-comm-filter-num	Specifies the number of an advanced community filter.	The value is an integer ranging from 100 to 199.
comm-filter-name	Specifies the name of a community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
whole-match	Indicates complete matching. That is, all the communities in the command must be matched. Complete matching is valid only for the basic community filter.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The community attribute is a private attribute of BGP. The **if-match community-filter** command is applicable to only BGP routes. The **ip community-filter** command must be used to define a community filter so that the matching rule based on this community filter can take effect. For example:

- If the **if-match community-filter 1** command is used but community filter 1 is not configured, all routes are permitted, that is, all routes can match the matching rule.
- If the **if-match community-filter 1** command is used after the **ip community-filter 1 permit 1:1** command is used, the BGP routes with the community attribute being 1:1 are permitted.

Multiple **if-match community-filter** clauses can be specified. The relationship between **if-match community-filter** clauses is "OR". The relationship between **if-match** clauses is "AND".

Prerequisites

Before using the **if-match community-filter** command, you must use the **ip community-filter** command to configure a community filter.

The **if-match community-filter** command can be used only after a routing policy is configured.

Precautions

The routing policy matches routes using the community filter. Routes that match the community filter will be checked by other **if-match** clauses of this node. Routes that do not match the community filter will be checked by the next node.

A maximum of 16 community filters can be configured in the **if-match community-filter** command. The relationship between these community-filters is OR. Specifically, if a route matches one of these community-filters, it matches the matching rules of the command.

The parameter **whole-match** is valid only for its front community filter number. If multiple community filters are specified in the **if-match community-filter** command and packets are required to completely match each filter, you need to specify the parameter **whole-match** behind each community filter and it is valid to only the basic community filter.

The name of a community filter cannot be all numerals.

Creating a community attribute filter before it is referenced is recommended. By default, nonexistent community attribute filters cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent community attribute filter is referenced using the current command, all routes match the community filter.

Example

Set a matching rule that is based on the community filter 1.

```
<HUAWEI> system-view
[HUAWEI] ip community-filter 1 permit 100:200
[HUAWEI] route-policy test permit node 10
[HUAWEI-route-policy] if-match community-filter 1
```

Set the complete matching rule for community attribute filters 1 and 2.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 11
[HUAWEI-route-policy] if-match community-filter 1 whole-match 2 whole-match
```

Set a matching rule that is based on the community filter named **aa**.

```
<HUAWEI> system-view
[HUAWEI] route-policy test permit node 12
[HUAWEI-route-policy] if-match community-filter aa
```

7.9.39 if-match cost

Function

The **if-match cost** command creates a matching rule based on the route cost.

The **undo if-match cost** command deletes the matching rule based on the specified route cost.

By default, no matching rule based on the route cost is configured.

Format

if-match cost { *cost* | **greater-equal** *greater-equal-value* [**less-equal** *less-equal-value*] | **less-equal** *less-equal-value* }

undo if-match cost

Parameters

Parameter	Description	Value
cost	Specifies the route cost. Route costs can be changed to prevent routing loops.	The value is an integer ranging from 0 to 4294967295.
greater-equal *greater-equal-value*	Specifies the minimum value of route cost.	The value is an integer ranging from 0 to 4294967294.
less-equal *less-equal-value*	Specifies the maximum value of route cost. *less-equal-value* is demanded to be greater than *greater-equal-value*.	The value is an integer ranging from 1 to 4294967295.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **if-match cost** command to configure a node to filter routes based on the route costs. After such a matching rule is configured, you can apply the **apply** clauses to change the attributes of the routes that match the matching rule.

Prerequisites

The **if-match cost** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on the route cost. Routes that match the route cost will be checked by other **if-match** clauses of this node. Routes that do not match the route cost will be checked by the next node.

Example

Match the route with the cost 8.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match cost 8
```

7.9.40 if-match extcommunity-filter

Function

The **if-match extcommunity-filter** command sets a matching rule that is based on the extended community filter.

The **undo if-match extcommunity-filter** command deletes the matching rule based on the specified extended community filter.

By default, no matching rule based on the extended community filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

if-match extcommunity-filter { { *basic-extcomm-filter-num* | *adv-extcomm-filter-num* } &<1-16> | *extcomm-filter-name* }

undo if-match extcommunity-filter [[*basic-extcomm-filter-num* | *adv-extcomm-filter-num*] &<1-16> | *extcomm-filter-name*]

Parameters

Parameter	Description	Value
basic-extcomm-filter-num	Specifies the number of a basic extended community filter.	It is an integer ranging from 1 to 199.
adv-extcomm-filter-num	Specifies the number of an advanced extended community filter.	It is an integer ranging from 200 to 399.

Parameter	Description	Value
extcomm-filter-name	Specifies the name of an extended community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The extended community attributes help flexibly control the routing policy. You can use the **if-match extcommunity-filter** command to configure a node to filter routes based on the extended community filter.

The **if-match extcommunity-filter** command is applicable to only BGP routes and must work in conjunction with the **ip extcommunity-filter** command. For example:

- If the **if-match extcommunity-filter 1** command is used but the extended community filter 1 is not configured, all routes are permitted, that is, all routes can match the matching rule.
- If the **if-match extcommunity-filter 1** command is used after the **ip extcommunity-filter 1 permit rt 1:1** command is used, the BGP routes with the extended community attribute being 1:1 are permitted.

Multiple **if-match extcommunity-filter** clauses can be specified. The relationship between **if-match extcommunity-filter** clauses is "OR". The relationship between **if-match** clauses is "AND".

Prerequisites

Before using the **if-match extcommunity-filter** command, you must use the **ip extcommunity-filter** command to configure an extended community filter.

Precautions

The routing policy matches routes using the extended community filter. Routes that match the extended community filter will be checked by other **if-match** clauses of this node. Routes that do not match the extended community filter will be checked by the next node.

A maximum of 16 extended community filters can be configured in the **if-match extcommunity-filter** command. The relationship between these extended community filters is OR. Specifically, if a route matches one of these extended community filters, it matches the matching rules of the command.

Example

Define a rule to match the routes of the specified extended community filter.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match extcommunity-filter 100
```

7.9.41 if-match interface

Function

The **if-match interface** command creates a matching rule based on the outbound interface.

The **undo if-match interface** command deletes the matching rule based on the specified outbound interface.

By default, no matching rule based on the outbound interface is configured.

Format

if-match interface { *interface-type interface-number* } &<1-16>

undo if-match interface [*interface-type interface-number*] &<1-16>

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the outbound interface. A maximum of 16 outbound interfaces can be specified in the **if-match interface** command.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **if-match interface** command is used to filter routes based on the outbound interfaces.

A maximum of 16 outbound interfaces can be configured in this command.

If a node contains multiple **if-match interface** clauses, the relationship between the **if-match interface** clauses is OR. If a node contains both **if-match interface** clauses and other **if-match** clauses with different matching rules, the relationship between the **if-match interface** clauses and other **if-match** clauses is AND. For example, if a node contains **if-match interface GE0/0/1**, **if-match interface GE0/0/2**, and **if-match acl 2000** clauses, **if-match interface GE0/0/1** and **if-match interface GE0/0/2** are ORed, whereas **if-match interface GE0/0/1** and **if-match acl 2000** are ANDed.

Prerequisites

The **if-match interface** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on outbound interface information. Routes that match the outbound interface information will be checked by other **if-match** clauses of this node. Routes that do not match the outbound interface information will be checked by the next node.

Example

Define a rule to match the routes with the outbound interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match interface vlanif 100
```

7.9.42 if-match ip

Function

The **if-match ip** command creates a matching rule based on IP information.

The **undo if-match ip** command deletes the matching rule based on specified IP information.

By default, no matching rule based on IP information is configured.

Format

if-match ip { **next-hop** | **route-source** | **group-address** } { **acl** { *acl-number* | *acl-name* } | **ip-prefix** *ip-prefix-name* }

undo if-match ip { **next-hop** | **route-source** | **group-address** } [**acl** { *acl-number* | *acl-name* } | **ip-prefix** *ip-prefix-name*]

Parameters

Parameter	Description	Value
next-hop	Specifies the next hop address.	-
route-source	Specifies the source address of routes.	-
group-address	Indicates the IP address of the multicast group.	The value is in dotted decimal notation.

Parameter	Description	Value
acl	Indicates route filtering using the ACL.	-
acl-number	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl-name	Specifies the name of a basic ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list that is used to filter routes.	The value is a string of case-sensitive characters without space and ranges from 1 to 169.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An ACL or IP prefix must be configured before running the **if-match ip** command so that the matching rule can take effect. For example:

- If the **if-match ip next-hop ip-prefix aa** command is used but the IP prefix **aa** is not configured, all routes are permitted, that is, all routes match the matching rule. This rule also applies to ACL.
- If the **if-match ip next-hop ip-prefix aa** and **ip ip-prefix aa permit 10.1.1.1 32** commands are used, the routes with the next hop being 10.1.1.1 is permitted. This rule also applies to ACL.

Prerequisites

The **if-match ip** command can be used only after the **route-policy** command is used.

Before running the **if-match ip** command, configure an **ACL** or an **IP prefix**.

Precautions

- The routing policy matches routes based on the next hop address or source address. Routes that match the next hop address or source address will be checked by other **if-match** clauses of this node. Routes that do not match the next hop address or source address will be checked by the next node.
- If the next hop address or source address of a route to be filtered is 0.0.0.0, by default, the system considers the mask length as 0 and matches the route.

If the next hop address or source address of a route to be filtered is not 0.0.0.0, by default, the system considers the mask length as 32 and matches the route.

- When you run the **rule** command to configure a filtering rule in an ACL, only the **source** and **time-range** parameters are valid for the filtering rule.
- Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes match the ACL.
- Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes match the IP prefix list.

Example

Set an IP prefix list named **p1** to filter routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match ip next-hop ip-prefix p1
```

Set a rule that source addresses of routes match ACL 2000 to filter routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match ip route-source acl 2000
```

7.9.43 if-match ip-prefix

Function

The **if-match ip-prefix** command creates a matching rule based on the IP prefix list.

The **undo if-match ip-prefix** command deletes the matching rule based on the specified IP prefix list.

By default, no matching rule based on the IP prefix list is configured in the routing policy.

Format

if-match ip-prefix *ip-prefix-name*

undo if-match ip-prefix *ip-prefix-name*

Parameters

Parameter	Description	Value
ip-prefix-name	Specifies the name of an IP address prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The routing policy matches routes using the IP prefix list. Routes are either permitted or denied.

The **ip ip-prefix** command must be used so that the matching rule can take effect. For example:

- If the **if-match ip-prefix aa** command is used but the IP prefix **aa** is not configured, all routes are permitted, that is, all routes match the matching rule.
- If the **if-match ip-prefix aa** and **ip ip-prefix aa permit 10.1.1.1 32** commands are used, the routes with the IP prefix being 10.1.1.1 and mask being 32 are permitted.

Prerequisites

The **if-match ip-prefix** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on IP prefix information. Routes that match the IP prefix information will be checked by other **if-match** clauses of this node. Routes that do not match the IP prefix information will be checked by the next node.

The **if-match acl** and **if-match ip-prefix** commands cannot be used together in the same node of a routing policy, because the latest configuration will override the previous one.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes match the IP prefix list.

Example

Set an IP prefix list named **p1** to filter routes.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match ip-prefix p1
```

7.9.44 if-match ipv6

Function

The **if-match ipv6** command creates a matching rule based on IPv6 information.

The **undo if-match ipv6** command deletes a specified matching rule based on IPv6 information.

By default, no matching rule based on IPv6 information is configured in a routing policy.

Format

if-match ipv6 { **address** | **next-hop** | **route-source** } **prefix-list** *ipv6-prefix-name*

undo if-match ipv6 { **address** | **next-hop** | **route-source** } **prefix-list** *ipv6-prefix-name*

Parameters

Parameter	Description	Value
address	Matches the destination addresses of IPv6 routes.	-
next-hop	Matches the next hops of IPv6 routes. **NOTE** The S500 series switches do not support this parameter.	-
route-source	Matches the source addresses of the advertised IPv6 routes.	-
prefix-list	Indicates the IP prefix list.	-
ipv6-prefix-name	Specifies the name of the IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Route-policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ip ipv6-prefix** command must be used to configure an IPv6 prefix so that the matching rule (based on the destination addresses, next hop addresses, or source addresses of IPv6 routes) configured using the **if-match ipv6** command can take effect. If the **ip ipv6-prefix** command is not configured, all routes are permitted.

Prerequisites

The **if-match ipv6** command can be configured only after the **route-policy** command is configured.

Before running the **if-match ipv6** command, you must run the **ip ipv6-prefix** command to configure an IPv6 prefix.

Precautions

- When you filter routes based on the destination addresses, next hop addresses, or source addresses of IPv6 routes, the routes that match the matching rule are permitted and the routes that do not match the matching rule are denied.
- If the next hop address or source address of a route to be filtered is 0::0, by default, the system matches the route and considers that its mask length is 0.

  If the next hop address or source address of a route to be filtered is not 0::0, by default, the system matches the route and considers that its mask length is 128.
- Creating an IPv6 prefix list before it is referenced is recommended. If a nonexistent IPv6 prefix list is referenced using the command, all routes match the IPv6 prefix list.

Example

Define an if-match clause to match the related IPv6 routing information.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match ipv6 address prefix-list p1
[HUAWEI-route-policy] if-match ipv6 next-hop prefix-list p1
[HUAWEI-route-policy] if-match ipv6 route-source prefix-list p1
```

7.9.45 if-match mpls-label

Function

The **if-match mpls-label** command creates a matching rule based on the MPLS label.

The **undo if-match mpls-label** command deletes the matching rule based on the specified MPLS label.

By default, no matching rule based on the MPLS label is configured.

NOTE

Only the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H support this command.

Format

if-match mpls-label

undo if-match mpls-label

Parameters

None

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the scenario where inter-AS VPN Option C or Carrier Support Carrier (CSC) is deployed, you can use the **if-match mpls-label** command to allocate labels to public routes.

Prerequisites

The **if-match mpls-label** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on the MPLS label. Routes that match the MPLS label will be checked by other **if-match** clauses of this node. Routes that do not match the MPLS label will be checked by the next node.

Example

Assign MPLS labels to the routes that match the routing policy.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match mpls-label
```

7.9.46 if-match rd-filter

Function

The **if-match rd-filter** command creates a matching rule based on the RD filter.

The **undo if-match rd-filter** command deletes the matching rule based on the specified RD filter.

By default, no matching rule based on the RD filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

if-match rd-filter *rd-filter-number*

undo if-match rd-filter

Parameters

Parameter	Description	Value
rd-filter-number	Specifies the number of an RD filter.	The value is an integer ranging from 1 to 255.

Views

Route-policy view, Tunnel selector view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **if-match rd-filter** command and the **ip rd-filter** command work together to filter routes based on RD attributes. For example:

- If **if-match rd-filter 1** is configured, but **rd-filter 1** is not configured, then all current routes will be permitted.
- If **if-match rd-filter 1** is configured, and **ip rd-filter 1 permit 1:1** has been configured, then routes with RD 1:1 will be permitted.

Prerequisites

The **if-match rd-filter** command must be run after the **route-policy** command is run.

Precautions

The routing policy matches routes using the RD filter. Routes that match the RD filter will be checked by other **if-match** clauses of this node. Routes that do not match the RD filter will be checked by the next node.

Example

Define a matching rule to match an RD filter.

```
<HUAWEI> system-view
[HUAWEI] route-policy abc permit node 10
[HUAWEI-route-policy] if-match rd-filter 1
```

7.9.47 if-match route-type

Function

The **if-match route-type** command sets a matching rule that is based on the route type.

The **undo if-match route-type** command deletes the matching rule based on the specified route type.

By default, no matching rule based on the route type is configured.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

if-match route-type { **external-type1** | **external-type1or2** | **external-type2** | **internal** | **is-is-level-1** | **is-is-level-2** | **nssa-external-type1** | **nssa-external-type1or2** | **nssa-external-type2** }

undo if-match route-type { **external-type1** | **external-type1or2** | **external-type2** | **internal** | **is-is-level-1** | **is-is-level-2** | **nssa-external-type1** | **nssa-external-type1or2** | **nssa-external-type2** }

Parameters

Parameter	Description	Value
external-type1	Indicates OSPF external Type 1 routes.	-
external-type1or2	Indicates OSPF external routes.	-
external-type2	Indicates OSPF external Type 2 routes.	-
internal	Indicates internal routes, including OSPF inter-area routes and intra-area routes.	-
is-is-level-1	Indicates IS-IS Level-1 routes.	-
is-is-level-2	Indicates IS-IS Level-2 routes.	-
nssa-external-type1	Indicates NSSA external Type 1 routes.	-
nssa-external-type1or2	Indicates NSSA external routes.	-
nssa-external-type2	Indicates NSSA external Type 2 routes.	-

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match route-type** command to filter OSPF or IS-IS routes based on the route type.

Multiple **if-match route-type** clauses can be specified. The relationship between **if-match route-type** clauses is "OR". The relationship between **if-match** clauses is "AND".

Prerequisites

The **if-match route-type** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on the route type. Routes that match the route type will be checked by other **if-match** clauses of this node. Routes that do not match the route type will be checked by the next node.

For the same node in a routing policy, if two **if-match route-type** clauses are the same, the latter **if-match route-type** will not override the previous **if-match route-type**. After the latter clause is configured, both clauses take effect simultaneously. The relationship between **if-match route-type** clauses is "OR". That is, the actions defined by **apply** clauses can be performed on a route as long as the route meets one of the matching rules. For example, if both the **if-match route-type is-is-level-1** and **if-match route-type external-type1or2** commands are configured on the same node of a route policy, both IS-IS Level-1 routes and OSPF external routes can match the route policy.

NOTE

external-type1or2 refers to **external-type1** or **external-type2**. For the same node in a route policy, configuring both the **if-match route-type external-type1** and **if-match route-type external-type2** is equivalent to configuring the **if-match route-type external-type1or2** command. The two operations generate the same configuration file.

Similarly, **nssa-external-type1or2** refers to **nssa-external-type1** or **nssa-external-type2**. For the same node in a route policy, configuring both the **if-match route-type nssa-external-type1** and **if-match route-type nssa-external-type2** commands is equivalent to configuring the **if-match route-type nssa-external-type1or2** command. The two operations generate the same configuration file.

Example

Define a rule to match the routes of the specified type.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match route-type nssa-external-type1
```

7.9.48 if-match tag

Function

The **if-match tag** command sets a matching rule that is based on the route tag.

The **undo if-match tag** command deletes the matching rule based on the specified route tag.

By default, no matching rule based on the route tag is configured.

Format

if-match tag *tag*

undo if-match tag

Parameters

Parameter	Description	Value
tag	Indicates the tag value. Route tags classify routes as required. The same type of routes has the same tags. Routes are managed and controlled based on the tag by using the routing policy.	The value is an integer ranging from 0 to 4294967295.

Views

Route-Policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match tag** command to filter routes based on the tags.

Prerequisites

The **if-match tag** command can be used only after the **route-policy** command is used.

Precautions

The routing policy matches routes based on the route tag. Routes that match the route tag will be checked by other **if-match** clauses of this node. Routes that do not match the route tag will be checked by the next node.

Example

Define a rule to match the OSPF routes with the tag value 8.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy permit node 10
[HUAWEI-route-policy] if-match tag 8
```

7.9.49 ip as-path-filter

Function

The **ip as-path-filter** command creates an AS_Path filter.

The **undo ip as-path-filter** command deletes a specified AS_Path filter.

By default, no AS_Path filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

ip as-path-filter { *as-path-filter-number* | *as-path-filter-name* } { **deny** | **permit** } *regular-expression*

undo ip as-path-filter { *as-path-filter-number* | *as-path-filter-name* } [{ **deny** | **permit** } *regular-expression*]

Parameters

Parameter	Description	Value
as-path-filter-number	Specifies the number of an AS_Path filter.	The value is an integer ranging from 1 to 256.
as-path-filter-name	Specifies the name of an AS_Path filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The string cannot be all numerals. When double quotation marks are used around the string, spaces are allowed in the string.
deny	Sets the matching mode of the AS_Path filter to deny.	-
permit	Sets the matching mode of the AS_Path filter to permit.	-
regular-expression	Specifies the AS_Path regular expression.	The value is a string of 1 to 255 characters, with spaces supported.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An AS_Path filter uses the regular expression to define matching rules. After an AS_Path filter is set, the RM module immediately instructs each protocol to apply the filter by default.

The AS_Path attribute is a private attribute of BGP, and is used to filter BGP routes.

- The filter can be directly applied by using a command such as **peer as-path-filter**.
- The filter can be used as a matching condition of a routing policy by using a command such as **if-match as-path-filter zz**.

Configuration Impact

Multiple rules (permit or deny) can be specified in a filter.

By default, AS_Path filters work in **deny** mode. If all matching rules in a filter are configured to work in **deny** mode, all routes are denied by the filter; to prevent this problem, configure one matching rule in **permit** mode after one or multiple matching rules in **deny** mode so that the routes except for those denied by preceding matching rules are permitted by the filter.

Before you run the **undo ip as-path-filter** command to delete an AS_Path filter that is referenced by another command, delete the reference configuration.

Follow-up Procedure

To view detailed configurations of the AS_Path filter, run the **display ip as-path-filter** command.

Example

Create the AS_Path filter with the sequence number being 1, and permit routes that begin with 10 in the AS_Path to pass.

```
<HUAWEI> system-view
[HUAWEI] ip as-path-filter 1 permit ^10_
```

Create the AS_Path filter 2, and permit routes that contain 20 in the AS_Path to pass through.

```
<HUAWEI> system-view
[HUAWEI] ip as-path-filter 2 permit _20_
```

Create the AS_Path filter 3, and prohibit routes that contain 30 in the AS_Path from passing through.

```
<HUAWEI> system-view
```

```
[HUAWEI] ip as-path-filter 3 deny _30_
[HUAWEI] ip as-path-filter 3 permit .*
```

7.9.50 ip community-filter

Function

The **ip community-filter** command creates a community filter.

The **undo ip community-filter** command deletes a community filter.

By default, no community filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

ip community-filter { **basic** *comm-filter-name* | *basic-comm-filter-num* } { **permit** | **deny** } [*community-number* | *aa:nn* | **internet** | **no-export-subconfed** | **no-advertise** | **no-export**] &<1-20>

ip community-filter { **advanced** *comm-filter-name* | *adv-comm-filter-num* } { **permit** | **deny** } *regular-expression*

undo ip community-filter { **basic** *comm-filter-name* | *basic-comm-filter-num* } [**permit** | **deny**] [*community-number* | *aa:nn* | **internet** | **no-export-subconfed** | **no-advertise** | **no-export**] &<1-20>

undo ip community-filter { **advanced** *comm-filter-name* | *adv-comm-filter-num* } [**permit** | **deny**] [*regular-expression*]

Parameters

Parameter	Description	Value
basic *comm-filter-name*	Specifies the name of a basic community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
basic-comm-filter-num	Specifies the number of a basic community filter.	The value is an integer ranging from 1 to 99.
deny	Sets the matching mode of the community filter to deny.	-
permit	Sets the matching mode of the community filter to permit.	-
community-number	Specifies the community number.	The value is an integer ranging from 0 to 4294967295.

Parameter	Description	Value
aa:nn	Specifies the community number. You can configure a maximum of 20 community numbers once. ● If you do not configure any one of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 20 *community-number* and *aa:nn* together. ● If you configure one of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 19 *community-number* and *aa:nn* together. ● If you configure two of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 18 *community-number* and *aa:nn* together. ● If you configure three of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 17 *community-number* and *aa:nn* together. ● If you configure all of **internet**, **no-export-subconfed**, **no-advertise**, and **no-export**, you can specify 16 *community-number* and *aa:nn* together.	*aa* and *nn* are integers ranging from 0 to 65535.
internet	Indicates that the matching routes can be sent to any peer.	-
no-export-subconfed	Indicates that routes are not advertised outside an AS. If an AS confederation is used, routes are not advertised to any other sub-ASs in the AS confederation.	-
no-advertise	Indicates that routes are not advertised to other peers.	-
no-export	Indicates that routes are not advertised outside an AS. If an AS confederation is used, routes are not advertised outside the AS confederation, but to other sub-ASs.	-

Parameter	Description	Value
advanced *comm-filter-name*	Specifies the name of an advanced community filter.	The value is a string of 1 to 51 case-sensitive characters. The string cannot be all digits. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.
adv-comm-filter-num	Specifies the number of an advanced community filter.	The value is an integer ranging from 100 to 199.
regular-expression	Specifies the regular expression used to match the community information.	The value is a string of 1 to 255 case-sensitive characters, with spaces supported.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The community attribute is a private attribute of BGP, and can be used only to filter BGP routes. The community attribute can be used as a matching rule of a routing policy by using the **ip community-filter** and **if-match community-filter** commands together.

Precautions

Only the community number or known community attribute can be specified for a basic community filter. The regular expression can be used as a matching rule in an advanced community filter.

- The **ip community-filter basic** *comm-filter-name* command or the **ip community-filter** *basic-comm-filter-num* command can be used to configure a basic community filter. **basic** *comm-filter-name* specifies the name of a basic community filter, and the name cannot be all digits. A maximum of 20 community numbers can be configured in one command. *basic-comm-filter-num* specifies only the basic community filter with the number ranging from 1 to 99. A maximum of 20 community numbers can be configured in one command.

- The **ip community-filter advanced** *comm-filter-name* command or the **ip community-filter** *adv-comm-filter-num* command can be used to configure an advanced community filter. **advanced** *comm-filter-name* specifies the name of an advanced community filter, and the name cannot be all digits. *adv-comm-filter-num* specifies only the advanced community filter with the number ranging from 100 to 199.

The relationship between the rules of the community filter is "AND". This is different from the route distinguisher (RD) filter. This is because each route has only one RD but can have multiple communities.

For example, the community filters in the following formats have different matching results:

Format 1:

```
ip community-filter 1 permit 100:1 200:1 300:1
```

Format 2:

```
ip community-filter 1 permit 100:1
ip community-filter 1 permit 200:1 300:1
```

In the preceding configuration of the community filter, the community defined in each rule must be a sub-set of route communities so that the rule can be matched.

The RD filters in the following formats have the same matching results:

Format 1:

```
ip rd-filter 100 permit 100:1 200:1 2.2.2.2:1 3.3.3.3:1
```

Format 2:

```
ip rd-filter 100 permit 100:1 200:1
ip rd-filter 100 permit 2.2.2.2:1
ip rd-filter 100 permit 3.3.3.3:1
```

The **apply comm-filter delete** command run in the Route-Policy view deletes the specified community attribute from routes. An **ip community-filter** command can be used to specify community attributes but one such command specifies only one community attribute each time. To delete more than one community attribute, run the **ip community-filter** command multiple times. If multiple community attributes are specified in one filter, none of them can be deleted. For information about examples, see **apply comm-filter delete**.

By default, Community filters work in **deny** mode. If all matching rules in a filter are configured to work in **deny** mode, all routes are denied by the filter; to prevent this problem, configure one matching rule in **permit** mode after one or multiple matching rules in **deny** mode so that the routes except for those denied by preceding matching rules are permitted by the filter.

Before you run the **undo ip community-filter** command to delete a community attribute filter that is referenced by another command, delete the reference configuration.

Follow-up Procedure

By default, the Route Management (RM) module will instruct all protocols to apply this community filter. To delay the effective time, run the **route-policy-change notify-delay** command.

Run the **display ip community-filter** command to view detailed configuration for the community filter.

Example

Configure a basic community filter of which the sequence number is 1 to prevent matching routes from being advertised to any peer.

```
<HUAWEI> system-view
[HUAWEI] ip community-filter 1 deny internet
```

Configure an advanced community filter of which the sequence number is 100 to permit all the routes that match the AS 65001.

```
<HUAWEI> system-view
[HUAWEI] ip community-filter advanced 100 permit 65001:[0-9]+
```

7.9.51 ip extcommunity-filter

Function

The **ip extcommunity-filter** command creates an extended community filter.

The **undo ip extcommunity-filter** command deletes an extended community filter.

By default, no extended community filter is configured.

Product	Support

Format

ip extcommunity-filter { *basic-extcomm-filter-num* | **basic** *basic-extcomm-filter-name* } { **deny** | **permit** } { **rt** { *as-number:nn* | *4as-number:nn* | *ipv4-address.nn* } } &<1-16>

ip extcommunity-filter { *advanced-extcomm-filter-num* | **advanced** *advanced-extcomm-filter-name* } { **deny** | **permit** } *regular-expression*

undo ip extcommunity-filter { *basic-extcomm-filter-num* | **basic** *basic-extcomm-filter-name* } [{ **deny** | **permit** } { **rt** { *as-number:nn* | *4as-number:nn* | *ipv4-address.nn* } } &<1-16>]

undo ip extcommunity-filter { *advanced-extcomm-filter-num* | **advanced** *advanced-extcomm-filter-name* } [*regular-expression*]

Parameters

Parameter	Description	Value
deny	Sets the matching mode of the extended community filter to deny.	-
permit	Sets the matching mode of the extended community filter to permit.	-
rt	Sets the extended community filter type to RT.	-
as-number	Specifies the AS number.	The value is an integer ranging from 0 to 65535.
4as-number	Specifies a 4-byte AS number.	A 4-byte AS number is divided into the following types: ● It is an integer ranging from 65536 to 4294967295. ● It is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535.
ipv4-address	Specifies an IPv4 address.	The value is in dotted decimal notation.
nn	Specifies an integer.	● When the value of *as-number* is a 2-byte AS number, the value of *nn* ranges from 0 to 4294967295. ● When the value of *4as-number* is a 4-byte AS number, the value of *nn* ranges from 0 to 65535. ● For *ipv4-address*, the value of *nn* ranges from 0 to 65535.
basic-extcomm-filter-num	Specifies the number of a basic extended community filter.	The value is an integer ranging from 1 to 199.

Parameter	Description	Value
basic *basic-extcomm-filter-name*	Specifies the name of a basic extended community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The value cannot contain only numerals. When double quotation marks are used around the string, spaces are allowed in the string.
advanced-extcomm-filter-num	Specifies the number of an advanced extended community filter.	The value is an integer ranging from 200 to 399.
advanced *advanced-extcomm-filter-name*	Specifies the name of an advanced extended community filter.	The name is a string of 1 to 51 case-sensitive characters without spaces. The value cannot contain only numerals. When double quotation marks are used around the string, spaces are allowed in the string.
regular-expression	Specifies the regular expression used to match the extended community information.	It is a string of 1 to 255 space-tolerant characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An extended community filter can be used as a matching condition of a route-policy by using a command such as **if-match extcommunity-filter zz**.

Only the extended community number can be specified for a basic extended community filter. The regular expression can be used as a matching rule in an advanced extended community filter.

- The **ip extcommunity-filter basic** *extcomm-filter-name* command or the **ip extcommunity-filter** *basic-extcomm-filter-num* command can be used to configure a basic extended community filter. **basic** *extcomm-filter-name* specifies the name of a basic extended community filter, and the name cannot be all digits. *basic-extcomm-filter-num* specifies only the basic extended community filter with the number ranging from 1 to 199. A maximum of 16 extended community numbers can be configured using one command.

- The **ip extcommunity-filter advanced** *extcomm-filter-name* command or the **ip extcommunity-filter** *adv-extcomm-filter-num* command can be used to configure an advanced extended community filter. **advanced** *extcomm-filter-name* specifies the name of an advanced extended community filter, and the name cannot be all digits. *adv-extcomm-filter-num* specifies only the advanced extended community filter with the number ranging from 200 to 399.

The relationship between the rules of the extended community filter is "OR".

For example, the extended community filters in the following formats have the same matching results:

Format 1:

```
ip extcommunity-filter 1 permit rt 100:1 200:1 300:1
```

Format 2:

```
ip extcommunity-filter 1 permit rt 100:1
ip extcommunity-filter 1 permit rt 200:1 300:1
```

After the extended community filter is configured, if the policy application delay is set by using the **route-policy-change notify-delay** command, the Route Management (RM) module will instruct each protocol to apply this filter after the delay expires. By default, the RM module instructs each protocol to immediately apply this filter.

The **undo ip extcommunity-filter** command is used to delete a specified extended community filter.

The **display ip extcommunity-filter** command is used to display the detailed configurations of the extended community filter.

Configuration Impact

The **ip extcommunity-filter** command is used to filter routes based on the RT attributes of the routes. The routes that pass the filtering are permitted to pass through and the routes that fail to pass the filtering are denied.

Precautions

The extended community attributes of a route include VPN-target and Site-of-Origin (SoO). Only VPN-target, however, is supported by the policy.

By default, extended community filters work in **deny** mode. If all matching rules in a filter are configured to work in **deny** mode, all routes are denied by the filter; to prevent this problem, configure one matching rule in **permit** mode after one or multiple matching rules in **deny** mode so that the routes except for those denied by preceding matching rules are permitted by the filter.

Example

Configure an RT extended community filter of which the sequence number is 1.

```
<HUAWEI> system-view
[HUAWEI] ip extcommunity-filter 1 deny rt 200:200
```

7.9.52 ip ip-prefix

Function

The **ip ip-prefix** command creates an IPv4 prefix list or an entry in an IPv4 prefix list.

The **undo ip ip-prefix** command deletes an IPv4 prefix list or an entry from an IPv4 prefix list.

By default, no IPv4 prefix list is created.

Format

ip ip-prefix *ip-prefix-name* [**index** *index-number*] { **permit** | **deny** } *ipv4-address mask-length* [**match-network**] [**greater-equal** *greater-equal-value*] [**less-equal** *less-equal-value*]

undo ip ip-prefix *ip-prefix-name* [**index** *index-number*]

ip ip-prefix *ip-prefix-name* **description** *text*

undo ip ip-prefix *ip-prefix-name* **description** [*text*]

Parameters

Parameter	Description	Value
ip-prefix-name	Specifies the name of an IPv4 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
index *index-number*	Specifies the sequence number of an entry in the IPv4 prefix list.	The value is an integer that ranges from 1 to 4294967295. By default, the sequence number increases by 10 according to the configuration order, and the first sequence number is 10. **NOTE** A maximum of 65535 entries can be configured in an IP prefix list.

Parameter	Description	Value
permit	Specifies the matching mode of the IP prefix list as permit. In permit mode, if the IP address to be filtered is within the defined prefix range, the IP address matches the routing policy and does not continue to match the next entry. Otherwise, the IP address continues to match the next entry.	-
deny	Specifies the matching mode of the IP prefix list as deny. In deny mode, if the IP address to be filtered is within the defined prefix range, the IP address fails to match the routing policy and cannot match the next entry. Otherwise, the IP address continues to match the next entry.	-
ipv4-address	Specifies an IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
match-network	Matches the network address. The **match-network** parameter can be configured only when the IP address generated after *ipv4-address* is ANDed with *mask-length* is 0.0.0.0. This parameter is mainly used to match routes with a specified network address. For example, the **ip ip-prefix prefix1 permit 0.0.0.0 8** command filters all routes with mask length 8, while the **ip ip-prefix prefix1 permit 0.0.0.0 8 match-network** command filters all routes to the IP address range from 0.0.0.1 to 0.255.255.255.	-
greater-equal *greater-equal-value*	Specifies the lower threshold of the mask length. If **greater-equal** *greater-equal-value* and **less-equal** *less-equal-value* are not specified, the value of *mask-length* is the mask length.	*greater-equal-value* must meet the following requirement: *mask-length* ≤ *greater-equal-value* ≤ *less-equal-value* ≤ 32. If **greater-equal** is configured, the mask ranges from *greater-equal-value* to 32.

Parameter	Description	Value
less-equal *less-equal-value*	Specifies the upper threshold of the mask length. If **greater-equal** *greater-equal-value* and **less-equal** *less-equal-value* are not specified, the value of *mask-length* is the mask length.	*less-equal-value* must meet the following requirement: *mask-length* ≤ *greater-equal-value* ≤ *less-equal-value* ≤ 32. If **less-equal** is configured, the mask ranges from *mask-length* to *less-equal-value*.
description *text*	Specifies the description of the IP prefix list.	The value is a string of 1 to 80 case-sensitive characters without spaces. If the string is enclosed within double quotation marks ("), the string can contain spaces.

Usage Guidelines

Usage Scenario

An IP prefix list can be used as a filter or as matching conditions of a routing policy when it is used together with the **if-match** command.

Each entry in an IP prefix list can be used as a filtering rule. When a route to be filtered matches an entry, whether the route matches the IP prefix list is determined by the matching mode. A route to be filtered matches an entry or entries based on the following rules:

- Sequential matching: The route has to match the entries in the IP prefix list in ascending order of their *index-number* values. Therefore, specifying *index-number* in a required sequence is recommended.
- One-time matching: If a route matches one entry, the route matches the IP prefix list and will not be matched against the next entry.
- Matching failure by default: If a route fails to match any of the entries, it fails to match the IP prefix list.

The following example shows how different IP prefix lists take effect on the routes 1.1.1.1/24, 1.1.1.1/32, 1.1.1.1/26, 2.2.2.2/24, and 1.1.1.2/16.

Table 7-201 Matching results of IP prefix lists

Case	Commands	Matching result	Note
1	`ip ip-prefix aa index 10 permit 1.1.1.1 24`	Only the route 1.1.1.1/24 is permitted, and the other routes are denied.	This is a single-node accurate matching case, which indicates that only the route whose destination IP address and mask are the same as those specified by the entry meets the matching conditions. In addition, **permit** is configured as the matching mode. Therefore, the route 1.1.1.1/24 is permitted, and other routes are denied because they fail to meet the matching conditions.
2	`ip ip-prefix aa index 10 deny 1.1.1.1 24`	All routes are denied.	This is also a single-node accurate matching case. **deny** is configured as the matching mode. Therefore, the route 1.1.1.1/24 is denied, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
3	`ip ip-prefix aa index 10 permit 1.1.1.1 24 less-equal 32`	The routes 1.1.1.1/24, 1.1.1.1/32, and 1.1.1.1/26 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, and **less-equal** is set to 32. Therefore, the routes with 1.1.1.0 as the prefix and the mask ranging from 24 to 32 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
4	`ip ip-prefix aa index 10 permit 1.1.1.0 24 greater-equal 24 less-equal 32`	The routes 1.1.1.1/24, 1.1.1.1/32, and 1.1.1.1/26 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, **greater-equal** is set to 24, and **less-equal** is set to 32. Therefore, the routes with 1.1.1.0 as the prefix and the mask ranging from 24 to 32 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions. This case is similar to case 3 in terms of the matching result.

Case	Commands	Matching result	Note
5	`ip ip-prefix aa index 10 permit 1.1.1.1 24 greater-equal 26`	The routes 1.1.1.1/32 and 1.1.1.1/26 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, and **greater-equal** is set to 26. Therefore, the routes with 1.1.1.0 as the prefix and the mask ranging from 26 to 32 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
6	`ip ip-prefix aa index 10 permit 1.1.1.1 24 greater-equal 26 less-equal 32`	The routes 1.1.1.1/32 and 1.1.1.1/26 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, **greater-equal** is set to 26, and **less-equal** is set to 32. Therefore, the routes with 1.1.1.0 as the prefix and the mask ranging from 26 to 32 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions. This case is similar to case 5 in terms of the matching result.
7	`ip ip-prefix aa index 10 deny 1.1.1.1 24` `ip ip-prefix aa index 20 permit 1.1.1.1 32`	The route 1.1.1.1/32 is permitted, and the other routes are denied.	This is a multi-node accurate matching case. **deny** is configured as the matching mode of the matching entry indexed 10, and therefore the route 1.1.1.1/24 is denied by the matching entry indexed 10 based on the rule of one-time matching. The route 1.1.1.1/32 fails to match the matching conditions, and it is then matched against the entry indexed 20 for which **permit** is configured as the matching mode. Consequently, the route 1.1.1.1/32 matches the matching conditions of the entry indexed 20. The other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.

Case	Commands	Matching result	Note
8	`ip ip-prefix aa index 10 permit 0.0.0.0 8 less-equal 32`	The routes 1.1.1.1/24, 1.1.1.1/32, 1.1.1.1/26, 2.2.2.2/24, and 1.1.1.2/16 are all permitted.	If the IP prefix is 0.0.0.0 and you specify a mask and a mask length range after this IP prefix, all routes with the mask length within the specified mask length range are denied or permitted, regardless of the mask. The mask length range is from 8 to 32, 0.0.0.0 is specified as the IP address, and **permit** is configured as the matching mode. Therefore, all routes with the mask length within the range are permitted.
9	`ip ip-prefix aa index 10 deny 0.0.0.0 24 less-equal 32` `ip ip-prefix aa index 20 permit 0.0.0.0 0 less-equal 32`	The route 1.1.1.2/16 is permitted, and the other routes are denied.	Note: For the entry indexed 10, the mask length range is from 24 to 32, 0.0.0.0 is specified as the IP address, and **deny** is configured as the matching mode. Therefore, all routes with the mask length within the range are denied, and the route 1.1.1.2/16 that fails to match its matching conditions is then matched against the entry indexed 20. For the entry indexed 20, the mask length range is from 0 to 32, 0.0.0.0 is specified as the IP address, and **permit** is configured as the matching mode. Therefore, the route 1.1.1.2/16 is permitted by the entry indexed 20.
9	`ip ip-prefix aa index 10 deny 2.2.2.2 24` `ip ip-prefix aa index 20 permit 0.0.0.0 0 less-equal 32`	All routes except the route 2.2.2.2/24 are permitted.	For the entry indexed 10, **deny** is configured as the matching mode. Therefore, the route 2.2.2.2/24 that matches its matching conditions is denied, and the other routes that fail to match the matching conditions are then matched against the entry indexed 20. For the entry indexed 20, the mask length range is from 0 to 32, 0.0.0.0 is specified as the IP address, and **permit** is configured as the matching mode. Therefore, all routes except the route 2.2.2.2/24 are permitted by the entry indexed 20.

Configuration Impact

If you create an entry whose *index-number* has existed in the same IP prefix list but has different filtering rules, the new entry overwrites the existing one.

Precautions

- Because of the matching failure by default, if one or more than one entry with **deny** as the matching mode is created, create an entry using the **ip ip-prefix** *ip-prefix-name* [**index** *index-number*] **permit 0.0.0.0 0 less-equal 32** command so that all IPv4 routes may match the IP prefix list.
- If *ipv4-address mask-length* is specified as **0.0.0.0 0**, only default routes are matched.
- If *ipv4-address mask-length* is set to **0.0.0.0 0 less-equal 32**, all routes are matched.
- Before you run the **undo ip ip-prefix** command to delete an IP prefix list that is referenced by another command, delete the reference configuration.
- After a configuration is delivered, the device checks the validity of the parameters in the configuration and processes these parameters. After the processing, the generated configuration is the result of the AND calculation between the specified *ipv4-address* and *mask-length*. For example, if the specified *ipv4-address* and *mask-length* are 1.1.1.1 and 24, respectively, the generated configuration is 1.1.1.0 24.

  If the *ipv4-address* in the generated configuration is 0.0.0.0, the configuration matches all IPv4 addresses. In this case, routes are filtered based on the following rules.

  NOTE

  If the specified *ipv4-address* is not 0.0.0.0, the *mask-length* must not be 0.

Table 7-202 Route filtering rules

Whether *greater-equal* and *less-equal* Exist in the Post-Processing Configuration	**Condition**	**Matching Result**	**Example**

Neither *greater-equal* nor *less-equal* exists.	The post-processing *ipv4-address* and *mask-length* are 0.0.0.0 and X (non-0 value), respectively.	Matches all routes with the mask length of X.	Pre-processing:
			`ip ip-prefix aa index 10 permit 0.0.1.1 16`
			Post-processing:
			`ip ip-prefix aa index 10 permit 0.0.0.0 16`
			Matching result: The routes with the mask length of 16 are permitted.

greater-equal exists, but *less-equal* does not.	The post-processing *ipv4-address* and *mask-length* are 0.0.0.0 and X (non-0 value), respectively.	Matches all the routes whose mask length is within the range from *greater-equal* to 32.	Pre-processing:
			`ip ip-prefix aa index 10 permit 0.0.1.1 16 greater-equal 20`
			Post-processing:
			`ip ip-prefix aa index 10 permit 0.0.0.0 16 greater-equal 20 less-equal 32`
			Matching result: The routes whose mask length is within the range from 20 to 32 are permitted.

greater-equal does not exist, but *less-equal* does.	The post-processing *ipv4-address* and *mask-length* are 0.0.0.0 and X (non-0 value), respectively.	Matches all the routes whose mask length is within the range from X to *less-equal*.	Pre-processing:
			`ip ip-prefix aa index 10 permit 0.0.1.1 16 less-equal 30`
			Post-processing:
			`ip ip-prefix aa index 10 permit 0.0.0.0 16 greater-equal 16 less-equal 30`
			Matching result: The routes whose mask length is within the range from 16 to 30 are permitted.

Whether *greater-equal* and *less-equal* Exist in the Post-Processing Configuration	Condition	Matching Result	Example

Both *greater-equal* and *less-equal* exist.	The post-processing *ipv4-address* and *mask-length* are 0.0.0.0 and X (non-0 value), respectively.	Matches all the routes whose mask length is within the range from *greater-equal* to *less-equal*.	Pre-processing:
			`ip ip-prefix aa index 10 permit 0.0.1.1 16 greater-equal 20 less-equal 30`
			Post-processing:
			`ip ip-prefix aa index 10 permit 0.0.0.0 16 greater-equal 20 less-equal 30`
			Matching result: The routes whose mask length is within the range from 20 to 30 are permitted.

Follow-up Procedure

In a scenario in which a routing policy is being modified, after an IP prefix is configured, the RM module notifies protocols of applying the changed routing policy immediately by default. However, in some cases, multiple commands need to be run to modify a routing policy. If other commands need to be run after an IP prefix is configured, protocols may apply the routing policy whose modification is not complete yet. To solve this problem, run the **route-policy-change notify-delay** command to configure a delay for protocols to apply the changed routing policy.

Example

Configure the IP prefix list named **p1** to permit only the routes with the mask length ranging from 17 to 18 on the network segment 10.0.0.0/8.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix p1 permit 10.0.0.0 8 greater-equal 17 less-equal 18
```

Configure the IP prefix list named **p3** to deny the routes to the IP address ranging from 0.0.0.1 to 0.255.255.255.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix p3 index 10 deny 0.0.0.0 8 match-network
[HUAWEI] ip ip-prefix p3 index 20 permit 0.0.0.0 0 less-equal 32
```

7.9.53 ip ipv6-prefix

Function

The **ip ipv6-prefix** command configures an IPv6 prefix list or an entry in an IPv6 prefix list.

The **undo ip ipv6-prefix** command deletes an IPv6 prefix list or an entry from an IPv6 prefix list.

By default, no IPv6 prefix list is created.

Format

ip ipv6-prefix *ipv6-prefix-name* [**index** *index-number*] { **deny** | **permit** } *ipv6-address prefix-length* [**match-network**] [**greater-equal** *greater-equal-value*] [**less-equal** *less-equal-value*]

undo ip ipv6-prefix *ipv6-prefix-name* [**index** *index-number*]

ip ipv6-prefix *ipv6-prefix-name* **description** *text*

undo ip ipv6-prefix *ipv6-prefix-name* **description** [*text*]

Parameters

Parameter	Description	Value
ipv6-prefix-name	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
index *index-number*	Specifies the sequence number of an entry in the IPv6 prefix list.	The value is an integer that ranges from 1 to 4294967295. By default, the sequence number increases by 10 according to the configuration order, and the first sequence number is 10. **NOTE** A maximum of 65535 entries can be configured in an IPv6 prefix list.

Parameter	Description	Value
permit	Specifies the matching mode of the IPv6 prefix list as permit. In permit mode, if the IPv6 address to be filtered is within the defined prefix range, the IPv6 address matches the routing policy and does not continue to match the next entry. Otherwise, the IPv6 address continues to match the next entry.	-
deny	Specifies the matching mode of the IPv6 prefix list as deny. In deny mode, if the IPv6 address to be filtered is within the defined prefix range, the IPv6 address fails to match the routing policy and cannot match the next entry. Otherwise, the IPv6 address continues to match the next entry.	-
ipv6-address	Specifies the IPv6 prefix range in the form of an IPv6 address. If :: is specified, the address 0::0 is matched.	-
prefix-length	Specifies the IPv6 prefix range using the mask length.	The value is an integer that ranges from 0 to 128. If ::0 less-equal 128 is used, all IPv6 addresses are matched.
match-network	Matches the network address. The **match-network** parameter can be configured only when the IP address generated after *ipv6-address* is ANDed with *prefix-length* is ::. For example, the **ip ipv6-prefix prefix1 permit :: 96** command filters all IPv6 routes with mask length 96, while the **ip ipv6-prefix prefix1 permit :: 96 match-network** command filters all routes to the IPv6 address range from ::1 to ::FFFF:FFFF.	-
greater-equal *greater-equal-value*	Specifies the lower threshold of the mask length.	*greater-equal-value* must meet the following requirement: *prefix-length* ≤ *greater-equal-value* ≤ *less-equal-value* ≤ 128.

Parameter	Description	Value
less-equal *less-equal-value*	Specifies the upper threshold of the mask length.	*less-equal-value* must meet the following requirement: *prefix-length* ≤ *greater-equal-value* ≤ *less-equal-value* ≤ 128.
description *text*	Specifies the description of the IPv6 prefix list.	The value is a string of 1 to 80 case-sensitive characters without spaces. If the string is enclosed within double quotation marks ("), the string can contain spaces.

2: Configuration level

Usage Guidelines

Usage Scenario

The IPv6 prefix list can be used by the protocols as a prefix filter, or used with the **if-match ipv6** command as a matching condition of routing policies.

Each entry in the IPv6 prefix list can be considered as a filter rule. When a route to be filtered matches one of the entries, the route can be determined whether it is permitted the IPv6 prefix list based on the matching mode. Entries in the IPv6 prefix list can be matched with routes to be filtered based on the following rules:

- Sequence match: Each entry in the IP prefix list is matched in ascending order of the index number. When setting index numbers for entries, you can arrange your expected matching order.
- Unique match: When the route to be filtered matches one entry, the route stops to match the other entries.
- Default deny: By default, if routes to be filtered do not match any entry in the IP prefix list, the routes are denied by IP prefix list.

The following example shows how different IPv6 prefix lists take effect on the routes 1::1/96, 1::1/128, 1::1/100, 2::2/96, and 1::2/64.

Table 7-203 Matching results of IPv6 prefix lists

Case	Commands	Matching result	Note
1	`ip ipv6-prefix aa index 10 permit 1::1 96`	Only the route 1::1/96 is permitted, and the other routes are denied.	This is a single-node accurate matching case, which indicates that only the route whose destination IPv6 address and mask are the same as those specified by the entry meets the matching conditions. In addition, **permit** is configured as the matching mode. Therefore, the route 1::1/96 is permitted, and other routes are denied because they fail to meet the matching conditions.
2	`ip ipv6-prefix aa index 10 deny 1::1 96`	All routes are denied.	This is also a single-node accurate matching case. **deny** is configured as the matching mode. Therefore, the route 1::1/96 is denied, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
3	`ip ipv6-prefix aa index 10 permit 1::1 96 less-equal 128`	The routes 1::1/96, 1::1/128, and 1::1/100 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, and **less-equal** is set to 128. Therefore, the routes with 1::1 as the prefix and the mask ranging from 96 to 128 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
4	`ip ipv6-prefix aa index 10 permit 1::1 96 greater-equal 96 less-equal 128`	The routes 1::1/96, 1::1/128, and 1::1/100 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, **greater-equal** is set to 96, and **less-equal** is set to 128. Therefore, the routes with 1::1 as the prefix and the mask ranging from 96 to 128 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions. This case is similar to case 3 in terms of the matching result.

Case	Commands	Matching result	Note
5	ip ipv6-prefix aa index 10 permit 1::1 96 greater-equal 100	The routes 1::1/128 and 1::1/100 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, and **greater-equal** is set to 100. Therefore, the routes with 1::1 as the prefix and the mask ranging from 100 to 128 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.
6	ip ipv6-prefix aa index 10 permit 1::1 96 greater-equal 100 less-equal 128	The routes 1::1/128 and 1::1/100 are permitted, and the other routes are denied.	This is also a single-node accurate matching case. **permit** is configured as the matching mode, **greater-equal** is set to 100, and **less-equal** is set to 128. Therefore, the routes with 1::1 as the prefix and the mask ranging from 100 to 128 can be permitted, and the other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions. This case is similar to case 5 in terms of the matching result.
7	ip ipv6-prefix aa index 10 deny 1::1 96 ip ipv6-prefix aa index 20 permit 1::1 128	The route 1::1/128 is permitted, and the other routes are denied.	This is a multi-node accurate matching case. **deny** is configured as the matching mode of the matching entry indexed 10, and therefore the route 1::1/96 is denied by the matching entry indexed 10 based on the rule of one-time matching. The route 1::1/128 fails to match the matching conditions, and it is then matched against the entry indexed 20 for which **permit** is configured as the matching mode. Consequently, the route 1::1/128 matches the matching conditions of the entry indexed 20. The other routes are denied based on the rule of matching failure by default because they fail to meet the matching conditions.

Case	Commands	Matching result	Note
8	`ip ipv6-prefix aa index 10 permit :: 64 less-equal 128`	The routes 1::1/96, 1::1/128, 1::1/100, 2::2/96, and 1::2/64 are all permitted.	If the IPv6 prefix is :: and you specify a mask and a mask length range after this IPv6 prefix, all routes with the mask length within the specified mask length range are denied or permitted, regardless of the mask. The mask length range is from 64 to 128, :: is specified as the IPv6 address, and **permit** is configured as the matching mode. Therefore, all routes with the mask length within the range are permitted.
9	`ip ipv6-prefix aa index 10 deny :: 96 less-equal 128` `ip ipv6-prefix aa index 20 permit :: 0 less-equal 128`	The route 1::2/64 is permitted, and the other routes are denied.	For the entry indexed 10, the mask length range is from 96 to 128, :: is specified as the IPv6 address, and **deny** is configured as the matching mode. Therefore, all routes with the mask length within the range are denied, and the route 1::2/64 that fails to match its matching conditions is then matched against the entry indexed 20. For the entry indexed 20, the mask length range is from 0 to 128, :: is specified as the IPv6 address, and **permit** is configured as the matching mode. Therefore, the route 1::2/64 is permitted by the entry indexed 20.
10	`ip ipv6-prefix aa index 10 deny 2::2 96` `ip ipv6-prefix aa index 20 permit :: 0 less-equal 128`	All routes except the route 2::2/96 are permitted.	Note: For the entry indexed 10, **deny** is configured as the matching mode. Therefore, the route 2::2/96 that matches its matching conditions is denied, and the other routes that fail to match the matching conditions are then matched against the entry indexed 20. For the entry indexed 20, the mask length range is from 0 to 128, :: is specified as the IPv6 address, and **permit** is configured as the matching mode. Therefore, all routes except the route 2::2/96 are permitted by the entry indexed 20.

Configuration Impact

If you create an entry whose index number is the same as an existing entry in the IPv6 prefix list, the created entry will replace the existing entry.

Precautions

- The IPv6 prefix list adopts default deny as the matching mode. If you have created one or multiple entries in **deny** mode, but no entry in the **permit** mode, you must create an entry **permit :: 0 less-equal 128** to permit IPv6 routes which do not match the entries in **deny** mode.
- If you specify *ipv6-address prefix-length* to be :: 0, only IPv6 default routes are matched.
- If *ipv6-address prefix-length* is set to **:: 0 less-equal 128**, all routes will be matched.
- Before you run the **undo ip ipv6-prefix** command to delete an IPv6 prefix list that is referenced by another command, delete the reference configuration.
- After a configuration is delivered, the device checks the validity of the parameters in the configuration and processes these parameters. After the processing, the generated configuration is the result of the AND calculation between the specified *ipv6-address* and *prefix-length*. For example, if the specified *ipv6-address* and *prefix-length* are 1::1 and 64, respectively, the generated configuration is 1:: 64.

  If the *ipv6-address* in the generated configuration is ::, the configuration matches all IPv6 addresses. In this case, routes are filtered based on the following rules.

  NOTE

  If the specified *ipv6-address* is not ::, the *prefix-length* must not be 0.

Table 7-204 Route filtering rules

Whether *greater-equal* and *less-equal* Exist in the Post-Processing Configuration	**Condition**	**Matching Result**	**Example**

Neither *greater-equal* nor *less-equal* exists.	The post-processing *ipv6-address* and *prefix-length* are :: and X (non-0 value), respectively.	Matches all IPv6 routes with the prefix length of X.	Pre-processing:
			`ip ipv6-prefix aa index 10 permit ::1:1 96`
			Post-processing:
			`ip ipv6-prefix aa index 10 permit :: 96`
			Matching result: The IPv6 routes with the prefix length of 96 are permitted.

greater-equal exists, but *less-equal* does not.	The post-processing *ipv6-address* and *prefix-length* are :: and X (non-0 value), respectively.	Matches all the IPv6 routes whose prefix length is within the range from *greater-equal* to 128.	Pre-processing:
			`ip ipv6-prefix aa index 10 permit ::1:1 96 greater-equal 120`
			Post-processing:
			`ip ipv6-prefix aa index 10 permit :: 96 greater-equal 120 less-equal 128`
			Matching result: The IPv6 routes whose prefix length is within the range from 120 to 128 are permitted.

greater-equal does not exist, but *less-equal* does.	The post-processing *ipv6-address* and *prefix-length* are :: and X (non-0 value), respectively.	Matches all the IPv6 routes whose prefix length is within the range from X to *less-equal*.	Pre-processing:
			`ip ipv6-prefix aa index 10 permit ::1:1 96 less-equal 120`
			Post-processing:
			`ip ipv6-prefix aa index 10 permit :: 96 greater-equal 96 less-equal 120`
			Matching result: The IPv6 routes whose prefix length is within the range from 96 to 120 are permitted.

Whether *greater-equal* and *less-equal* Exist in the Post-Processing Configuration	Condition	Matching Result	Example

Both *greater-equal* and *less-equal* exist.	The post-processing *ipv6-address* and *prefix-length* are :: and X (non-0 value), respectively.	Matches all the IPv6 routes whose prefix length is within the range from *greater-equal* to *less-equal*.	Pre-processing:
			`ip ipv6-prefix aa index 10 permit ::1:1 96 greater-equal 120 less-equal 124`
			Post-processing:
			`ip ipv6-prefix aa index 10 permit :: 96 greater-equal 120 less-equal 124`
			Matching result: The IPv6 routes whose prefix length is within the range from 120 to 124 are permitted.

Follow-up Procedure

In a scenario in which a used routing policy is being modified, after you configure the IPv6 prefix list, RM immediately notifies the protocols of re-applying the routing policy. However, you must run several commands to modify the routing policy. To prevent the protocols from repeatedly re-applying the routing policy which is being modified, you can run the **route-policy-change notify-delay** command to configure delay time for re-applying the routing policy, after you configure the IPv6 prefix list.

Example

Permit the routes with the mask length ranging from 32 to 64 bits.

```
<HUAWEI> system-view
[HUAWEI] ip ipv6-prefix abc permit :: 0 greater-equal 32 less-equal 64
```

Deny the routes with the IP prefix FC00:0:0:D00::/32 and with the prefix longer than 32 bits, and permit the other IPv6 routes.

```
<HUAWEI> system-view
[HUAWEI] ip ipv6-prefix abc deny fc00:0:0:d00:: 32 less-equal 128
[HUAWEI] ip ipv6-prefix abc permit :: 0 less-equal 128
```

Configure the IPv6 prefix list named **p3** to deny the routes to the IPv6 address ranging from ::1 to ::FFFF:FFFF.

```
<HUAWEI> system-view
[HUAWEI] ip ipv6-prefix p3 index 10 deny :: 96 match-network
```

```
[HUAWEI] ip ipv6-prefix p3 index 20 permit :: 0 less-equal 128
```

7.9.54 ip rd-filter

Function

The **ip rd-filter** command creates an RD filter.

The **undo ip rd-filter** command deletes an RD filter.

By default, no RD filter is configured.

Product	Support
S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported.
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported.

Format

ip rd-filter *rd-filter-number* { **deny** | **permit** } *route-distinguisher* &<1-10>

undo ip rd-filter *rd-filter-number* [{ **deny** | **permit** } *route-distinguisher* &<1-10>]

Parameters

Parameter	Description	Value
rd-filter-number	Specifies the number of an RD filter.	The value is an integer ranging from 1 to 255.
permit	Permits a route to match the rules if its RD matches the rules.	-
deny	Denied a route if its RD matches the rules.	-

Parameter	Description	Value
route-distinguisher	Specifies the RD to aa:nn or ipv4-address:nn. You can set a maximum of 10 RDs. The switch support RDs in the following formats: ● ipv4-address:nn, such as 10.1.1.1:200 ● aa:nn, such as 100:1 ● aa.aa:nn, such as 100.100:1 ● ipv4-address:* in the wildcard format, such as 10.1.1.1:*, indicating that the RD begins with 10.1.1.1 ● aa:* in the wildcard format, such as 100:*, indicating that the RD begins with 100 ● aa.aa:* in the wildcard format, such as 100.100:*, indicating that the RD begins with 100.100	● The IPv4 address is in dotted decimal notation. ● The *nn* in ipv4-address:nn is an integer ranging from 0 to 65535. ● In aa:nn, the *aa* is an integer ranging from 0 to 65535, and *nn* is an integer ranging from 0 to 4294967295. ● The *aa* and *nn* in aa:*, aa.aa:*, and aa.aa:nn are both integers ranging from 0 to 65535.

2: Configuration level

Usage Guidelines

The **ip rd-filter** command is used together with the **if-match rd-filter** command. First use the **ip rd-filter** command to configure an RD filter, and use the **if-match rd-filter** command to configure a matching rule based on the RD filter in a routing policy. The routing policy is used to filter routes that are received and advertised.

The RD filter has the following rules:

- If the RD filter is not configured but is used to filter routes, the matching result is **permit**.

  For example, the RD filter 100 is not configured but is used by the routing policy:

  ```
  route-policy test permit node 10
  if-match rd-filter 100
  ```

  When the routing policy is used to filter routes, the routes match this **if-match** clause, and the routes match the node 10 in the routing policy named **test**.

- If the RD filter is configured but the RD of routes does not match any RD defined in the RD filter, the default matching result is **deny**.

  For example, the RD of routes is 100:1, and the configuration of the RD filter is as follows:

  ```
  ip rd-filter 100 permit 10.1.1.1:100
  ```

  When the RD filter is used to filter routes, the matching result is **deny**.
- The relationship between the rules of the RD filter is "OR". This is different from the community filter. This is because each route has only one RD but can have multiple communities.

  For example, the RD filters in the following formats have the same matching results:

  Format 1:

  ```
  ip rd-filter 100 permit 100:1 200:1 10.2.2.2:1 10.3.3.3:1
  ```

  Format 2:

  ```
  ip rd-filter 100 permit 100:1 200:1
  ip rd-filter 100 permit 10.2.2.2:1
  ip rd-filter 100 permit 10.3.3.3:1
  ```

  The community filters in the following formats have different matching results:

  Format 1:

  ```
  ip community-filter 1 permit 100:1 200:1 300:1
  ```

  Format 2:

  ```
  ip community-filter 1 permit 100:1
  ip community-filter 1 permit 200:1 300:1
  ```

  In the preceding configuration of the community filter, the community defined in each rule must be a sub-set of route communities so that the rule can be matched.
- Routes are filtered according to the configuration order of multiple rules. For example:

  ```
  ip rd-filter 100 deny 200:1 10.5.5.5:1
  ip rd-filter 100 permit 200:* 10.5.5.5:*
  ```

  In this situation, the route with the RD 200:1 or 5.5.5.5:1 is denied. If the configuration order of multiple rules is reversed as follows:

  ```
  ip rd-filter 100 permit 200:* 10.5.5.5:*
  ip rd-filter 100 deny 200:1 10.5.5.5:1
  ```

  In this situation, the route with the RD 200:1 or 10.5.5.5:1 is permitted.
- Each RD filter can be configured with a maximum of 255 rules.

Example

Configure an RD filter.

```
<HUAWEI> system-view
[HUAWEI] ip rd-filter 1 permit 100:1
```

7.9.55 reset ip ip-prefix

Function

The **reset ip ip-prefix** command resets the statistics of the specified IPv4 prefix list.

Format

reset ip ip-prefix [*ip-prefix-name*]

Parameters

Parameter	Description	Value
ip-prefix-name	Specifies the name of an IPv4 prefix list. If *ip-prefix-name* is not specified, you can reset the statistics of all the IPv4 prefix lists.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

User view

2: Configuration level

Usage Guidelines

Usage Scenario

The IPv4 prefix list can be used to filter IPv4 addresses. When filtering IPv4 addresses, the system records the numbers of prefixes that are permitted and denied by the IPv4 prefix list. You can run the **display ip ip-prefix** command to view the numbers.

To view the number of IPv4 prefixes that are permitted and denied by the IPv4 prefix list, run the **reset ip ip-prefix** command to clear statistics about permitted and denied routes in the IPv4 prefix list, and then run the **display ip ip-prefix** command to display the number of IPv4 prefixes since the previous operation.

Configuration Impact

The **reset ip ip-prefix** command clears statistics about the IPv4 prefix list. After that, the previous statistics cannot be shown.

Precautions

The **reset ip ip-prefix** command:

- Clears statistics in a specified IPv4 prefix list, if the name of the IPv4 prefix list is specified using *ip-prefix-name*.
- Clears statistics in all IPv4 prefix lists, if the name of the IPv4 prefix list is not specified using *ip-prefix-name*.

Example

Reset the statistics of the specified IPv4 prefix list.

```
<HUAWEI> reset ip ip-prefix abc
```

7.9.56 reset ip ipv6-prefix

Function

The **reset ip ipv6-prefix** command resets the timer of a specified IPv6 prefix list.

Format

reset ip ipv6-prefix [*ipv6-prefix-name*]

Parameters

Parameter	Description	Value
ipv6-prefix-name	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Usage Scenario

The IPv6 prefix list can be used to filter IPv6 addresses. When filtering IPv6 addresses, the system records the numbers of prefixes that are permitted and denied by the IPv6 prefix list. You can run the **display ip ipv6-prefix** command to view the numbers.

To view the number of IPv6 prefixes that are permitted and denied by the IPv6 prefix list, run the **reset ip ipv6-prefix** command to clear statistics about permitted and denied routes in the IPv6 prefix list, and then run the **display ip ipv6-prefix** command to display the number of IPv6 prefixes since the previous operation.

Configuration Impact

The **reset ip ipv6-prefix** command clears statistics about the IPv6 prefix list. After that, the previous statistics cannot be shown.

Precautions

The **reset ip ipv6-prefix** command:

- Clears statistics in a specified IPv6 prefix list, if the name of the IPv6 prefix list is specified using *ipv6-prefix-name*.
- Clears statistics in all IPv6 prefix lists, if the name of the IPv6 prefix list is not specified using *ipv6-prefix-name*.

Example

Resets the timer of the IPv6 prefix list named **abc**.

```
<HUAWEI> reset ip ipv6-prefix abc
```

7.9.57 reset route-policy counters

Function

The **reset route-policy counters** command resets route-policy counters.

Format

reset route-policy *route-policy-name* **counters**

Parameters

Parameter	Description	Value
route-policy-name	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The route-policy is used to filter routes and set the attributes of a route that matches a route-policy. When a route-policy filters routes, the system records the number of routes that match the route-policy nodes. You can run the **display route-policy** to view the numbers.

The **reset route-policy counters** command clears the number of routes which match or do not match the route-policy. You can run both the **reset route-policy counters** command and the **display route-policy** command to instruct whether to record the number of routes matching a specified route-policy.

Configuration Impact

The **reset route-policy counters** command clears the number of routes which match or do not match the route-policy. After that, the number cannot be restored.

Example

Reset the counters of a route-policy named **policy1**.

```
<HUAWEI> reset route-policy policy1 counters
```

7.9.58 route-policy

Function

The **route-policy** command creates a routing policy and displays the Route-Policy view.

The **undo route-policy** command deletes a specified routing policy.

By default, no routing policy is configured.

Format

route-policy *route-policy-name* { **permit** | **deny** } **node** *node*

undo route-policy *route-policy-name* [**node** *node*]

Parameters

Parameter	Description	Value
route-policy-name	Specifies the name of a routing policy. If the routing policy does no exist, create a routing policy and enter its Route-Policy view. If the routing policy exists, enter its Route-Policy view.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
permit	Specifies the matching mode of the routing policy as permit. In permit mode, a route matches all the **if-match** clauses, the route matches the routing policy and the actions defined by the **apply** clause are performed on the route. Otherwise, the route continues to match the next entry.	-
deny	Specifies the matching mode of the routing policy as deny. In deny mode, if a route matches all the **if-match** clauses, the route fails to match the routing policy and cannot match the next node.	-
node *node*	Specifies the index of the node in the routing policy. When the routing policy is used to filter routes, the node with the smaller value of *node* is matched first.	The value is an integer ranging from 0 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A routing policy is used to filter routes and set route attributes for the routes that match the routing policy. A routing policy consists of multiple nodes. One node can be configured with multiple **if-match** and **apply** clauses.

The **if-match** clauses define matching rules for this node, and the **apply** clauses define behaviors for the routes that match the rules. The relationship between **if-match** clauses is "AND". That is, a route must match all the **if-match** clauses. The relationship between the nodes of a routing policy is "OR". That is, if a route matches one node, the route matches the routing policy. If the route does not match any node, the route fails to match the routing policy.

Procedure

After a routing policy is created, the system prompts "Info: New Sequence of this List !" and displays the Route-Policy view. The system displays no prompt when a routing policy is deleted.

Precautions

After a route-policy is configured, by default, the RM immediately notifies each protocol to apply the route-policy to filter routes. To delay applying a route-policy, you need to run the **route-policy-change notify-delay** command to set the delay for applying the route-policy.

You can run the **display route-policy** command to view the number of routes that match and do not match the route-policy.

A *route-policy-name* must have been configured using the **route-policy** command before the *route-policy-name* is referenced by another command.

Before you run the **undo route-policy** command to delete a route-policy that is referenced by another command, delete the reference configuration.

If an **if-match** clause of a route-policy defines an **ip-prefix**-based filtering rule, the filtering rule applies to IPv4 prefixes, not to IPv6 prefixes, and IPv6 prefixes match the filtering rule by default. If IPv6 prefixes also need to be filtered, add an **ipv6-prefix**-based **if-match** clause. Similarly, if an **if-match** clause of a route-policy defines an **ipv6-prefix**-based filtering rule, the filtering rule applies to IPv6 prefixes, not to IPv4 prefixes, and IPv4 prefixes match the filtering rule by default. If IPv4 prefixes also need to be filtered, add an **ip-prefix**-based **if-match** clause.

The configuration of a peer takes precedence over that of the peer group to which the peer belongs. That is, when a routing policy is used to control BGP route advertisement or receiving, the priority of this configuration on a BGP peer is higher than that of the configuration on the peer group.

Example

Configure the routing policy named **policy1** whose node number is 10 and the matching mode is **permit**.

```
<HUAWEI> system-view
[HUAWEI] route-policy policy1 permit node 10
[HUAWEI-route-policy]
```

7.9.59 route-policy-change notify-delay

Function

The **route-policy-change notify-delay** command sets the delay before the RM to notify each protocol of applying a new policy after the original route-policy changes.

The **undo route-policy-change notify-delay** command restores the default setting.

By default, this command is not configured, and the delay time is 0s.

Format

route-policy-change notify-delay *delay-time*

undo route-policy-change notify-delay

Parameters

Parameter	Description	Value
delay-time	Specifies the delay for applying a new policy after the original route-policy changes.	The value is an integer ranging from 1 to 180, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The switch process the changes of a route-policy according to the following rules.

After the configuration of a route-policy changes, by default, the RM immediately notifies the protocol of performing related operations. To delay processing the changes of the route-policy, you can run the **route-policy-change notify-delay** command to set the delay for change processing. The new policy is applied after the timer expires:

- If the configuration of the route-policy changes again within the delay, the RM resets the timer.
- If the new policy is configured for BGP, the **refresh bgp all** command can be used within the delay set by the **route-policy-change notify-delay** command to trigger BGP to immediately use the new policy.

The following commands are related to the timer:

- **route-policy**
- **ip ip-prefix**
- **ip ipv6-prefix**
- **ip as-path-filter**
- **ip community-filter**
- **ip extcommunity-filter**
- **ip rd-filter**
- **acl**

Example

Set the delay before the RM to notify each protocol of applying a new policy after the original route-policy changes.

```
<HUAWEI> system-view
[HUAWEI] route-policy-change notify-delay 20
```

7.9.60 route-policy nonexistent-config-check

Function

The **route-policy nonexistent-config-check** command controls whether the system allows a nonexistent route-policy to be specified in a command.

The **undo route-policy nonexistent-config-check disable** command forbids a nonexistent route-policy to be specified in a command.

By default, the system does not allow a nonexistent route-policy to be specified in a command.

Format

route-policy nonexistent-config-check { **disable** | **enable** }

undo route-policy nonexistent-config-check disable

Parameters

Parameter	Description	Value
disable	Indicates that the system allows a nonexistent route-policy to be specified in a command.	-
enable	Indicates that the system does not allow a nonexistent route-policy to be specified in a command.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, if you specify a nonexistent route-policy in a command, the command does not take effect. To enable the system to allow a nonexistent route-policy to be specified in a command, run the **route-policy nonexistent-config-check disable** command.

Example

Enable the system to allow a nonexistent route-policy to be specified in a command.

```
<HUAWEI> system-view
[HUAWEI] route-policy nonexistent-config-check disable
```

7.10 IP Routing Table Management Commands

7.10.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.10.2 arp vlink-direct-route advertise

Function

The **arp vlink-direct-route advertise** command configures the advertisement of IPv4 ARP Vlink direct routes.

The **undo arp vlink-direct-route advertise** command cancels advertising IPv4 ARP Vlink direct routes.

By default, a device does not advertise IPv4 ARP Vlink direct routes.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

arp vlink-direct-route advertise [**route-policy** *route-policy-name*]

undo arp vlink-direct-route advertise

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of the route-policy used to filter IPv4 ARP Vlink direct routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view, VPN instance view, VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, IPv4 ARP Vlink direct routes are only used to guide local traffic forwarding. To control the routing table size and maintain routing table stability, devices are prohibited from importing these direct routes into dynamic routing protocols for advertisement. In some situations, however, devices need to perform operations based on specific routes. For example, a device needs to direct remote traffic for different users using different export policies. Subsequently, the device needs to import IPv4 ARP Vlink direct routes into dynamic routing protocols and advertises them to the remote end.

If you only need to visit several users, you can specify the **route-policy** *route-policy-name* parameter to filter IPv4 ARP Vlink direct routes to be advertised. This operation can control the routing table size and implement precise control over data traffic.

Configuration Impact

After you specify the **route-policy** *route-policy-name* parameter to filter the IPv4 ARP Vlink direct routes to be advertised, only the routes that match the specified route-policy are advertised.

Follow-up Procedure

IPv4 ARP Vlink direct routes need to be imported into the routing tables of dynamic routing protocols on the device running dynamic routing protocols before being advertised by dynamic routing protocols.

Precautions

You need to run the **route-policy** command to configure a route-policy. If the specified route-policy does not exist, IPv4 ARP Vlink direct routes cannot be filtered.

Example

Configure the advertisement of IPv4 ARP Vlink direct routes and configure a route-policy **policy1** to allow route 10.1.1.4/32 to be advertised.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix prefix1 permit 10.1.1.4 32
[HUAWEI] route-policy policy1 permit node 10
[HUAWEI-route-policy] if-match ip-prefix prefix1
[HUAWEI-route-policy] quit
[HUAWEI] arp vlink-direct-route advertise route-policy policy1
```

7.10.3 display fib

Function

The **display fib** command displays information about the FIB table.

Format

display fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] [**verbose**]

Parameters

Parameter	Description	Value
slot-id	Displays information about the FIB table with a specified slot ID.	The value is an integer and the value range depends on the device configuration.
vpn-instance *vpn-instance-name*	Displays information about the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.
verbose	Displays detailed information about the FIB table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display fib** command displays information about the FIB table. Each row represents a route.

NOTE

If there are lots of routes, using wildcard (|, **begin**, **exclude**, **include**, *regular-expression*) to display information or details lasts a long time. You can press Ctrl+C to terminate information display.

Example

Display brief information about the FIB table.

```
<HUAWEI> display fib
Route Flags: G - Gateway Route, H - Host Route,    U - Up Route
           S - Static Route,  D - Dynamic Route, B - Black Hole Route
           L - Vlink Route
------------------------------------------------------------------------------
 FIB Table:
 Total number of Routes : 5

Destination/Mask   Nexthop         Flag  TimeStamp     Interface      TunnelID
192.168.150.111/32 127.0.0.1       HU    t[117]        InLoop0        0x0
127.0.0.1/32       127.0.0.1       HU    t[54]         InLoop0        0x0
127.0.0.0/8        127.0.0.1       U     t[54]         InLoop0        0x0
192.168.150.0/24   192.168.150.111 U     t[117]        MEth0/0/1      0x0
0.0.0.0/0          192.168.150.1   GSU   t[117]        MEth0/0/1      0x0
```

Display information starting from the line that contains 169.254.0.0

```
<HUAWEI> display fib | begin 10.254.0.0
Destination/Mask  Nexthop   Flag  TimeStamp  Interface   TunnelID
10.254.0.0/16    10.2.1.1   U     t[0]       Vlanif10     0x0
10.12.0.0/16     10.2.1.1   U     t[0]       Vlanif10     0x0
127.0.0.0/8      127.0.0.1  U     t[0]       InLoop0      0x0
```

Display all lines that contain Vlanif10.

```
<HUAWEI> display fib | include Vlanif10
Destination/Mask  Nexthop   Flag  TimeStamp  Interface  TunnelID
10.254.0.0/16    10.2.1.1   U     t[0]       Vlanif10    0x0
10.12.0.0/16     10.2.1.1   U     t[0]       Vlanif10    0x0
```

Display all lines that do not include 192.168.150.0.

```
<HUAWEI> display fib | exclude 192.168.150.0

Destination/Mask   Nexthop         Flag  TimeStamp     Interface      TunnelID
192.168.150.111/32 127.0.0.1       HU    t[117]        InLoop0        0x0
127.0.0.1/32       127.0.0.1       HU    t[54]         InLoop0        0x0
127.0.0.0/8        127.0.0.1       U     t[54]         InLoop0        0x0
0.0.0.0/0          192.168.150.1   GSU   t[117]        MEth0/0/1      0x0
```

Table 7-205 Description of the display fib command output

Item	Description
Route Flags	Flag of a route.
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.

Item	Description
Flag	Current flag, which is the combination of G, H, U, S, D, B and L. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S (static route): indicates that the route is manually configured. ● D (dynamic route): indicates that the route is generated based on the routing algorithm. ● B (blackhole route): indicates that the next hop is a null interface. ● L: indicates a Vlink route.
TimeStamp	Timestamp, which indicates the time equal to FIB entry generation time minus system startup time.
Interface	Outbound interface to the destination address.
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0x0, packets matching the entry are forwarded through the MPLS tunnel. If the value is 0x0, packets matching the entry are not forwarded through the MPLS tunnel.

Display detailed information about the FIB table.

```
<HUAWEI> display fib verbose
Route Flags: G - Gateway Route, H - Host Route,    U - Up Route
             S - Static Route,  D - Dynamic Route, B - Black Hole Route

Table 7-206 Description of the display fib verbose command output

Item	Description
Destination	Destination address.
Mask	Mask.
Nexthop	Next hop.
OutIf	Outbound interface.

Item	Description
LocalAddr	Local IP address.
LocalMask	Mask of the local IP address.
Flags	Current flag, which is the combination of G, H, U, S, D, and B. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S (static route): indicates that the route is manually configured. ● D (dynamic route): indicates that the route is generated based on the routing algorithm. ● B (blackhole route): indicates that the next hop is a null interface. ● L: indicates a Vlink route.
Age	Lifetime of a route, in seconds.
ATIndex	Index of the virtual link connecting the local end and the gateway.
Slot	Slot ID of the outbound interface.
LspFwdFlag	Forwarding flag of an LSP.
LspToken	Forwarding ID of an LSP.
InLabel	Inner tag of a VPN LSP.
OriginAs	Original AS number.
BGPNextHop	Address of the BGP next hop.
PeerAs	Neighbor AS number.
QosInfo	QoS information.
OriginQos	Original QoS information.
NexthopBak	Backup of the next hop.
OutIfBak	Backup of the outbound interface.
VlanId	VLAN ID.
BgpKey	Key value of the BGP route.
BgpKeyBak	Backup key value of the BGP route.

7.10.4 display fib acl

Function

The **display fib acl** command displays information about FIB entries that match a specified ACL rule.

Format

display fib [**vpn-instance** *vpn-instance-name*] **acl** *acl-number* [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.
acl-number	Displays information about the FIB table with a specified ACL rule.	The value is an integer that ranges from 2000 to 2999.
verbose	Displays detailed information about the FIB table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display fib acl** command to check information about FIB entries that match a specified ACL rule.

Example

Display FIB entries that match an ACL rule.

```
<HUAWEI> display fib acl 2010
Route Entry matched by access-list 2010
 Summary Counts: 1
Destination/Mask Nexthop  Flag TimeStamp Interface     TunnelID
127.0.0.0/8      127.0.0.1 U    t[0]      InLoop0       0x0
```

Table 7-207 Description of the display fib acl command output

Item	Description
Route Entry matched by access-list	FIB entries that match an ACL rule.
Summary Counts	Total number of the FIB entries.
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.
Flag	Current flag, which is the combination of G, H, U, S, D, B and T. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S: indicates a static route. ● D: indicates a dynamic route. ● B (blackhole route): indicates that the next hop is a null interface. ● T: indicates ingress TOKEN_SETBYLSPM nodes.
TimeStamp	Timestamp, which indicates the lifetime of an entry, in seconds.
Interface	Outbound interface to the destination address.
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0, packets matching the entry are forwarded through the MPLS tunnel. If the value is 0, packets matching the entry are not forwarded through the MPLS tunnel.

7.10.5 display fib interface

Function

The **display fib interface** command displays information about FIB entries with a specified outbound interface.

Format

display fib [**vpn-instance** *vpn-instance-name*] **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.
interface-type interface-number	Specifies the type and number of the outbound interface to a specified destination address.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display fib interface** command to check information about FIB entries with a specified outbound interface.

Example

Display FIB entries with a specified outbound interface.

```
<HUAWEI> display fib interface vlanif10
Destination/Mask   Nexthop    Flag TimeStamp   Interface       TunnelID
10.1.1.0/24        10.1.1.2    U    t[115]     Vlanif10           0x0
```

Table 7-208 Description of the display fib interface command output

Item	Description
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.

Item	Description
Flag	Current flag, which is the combination of G, H, U, S, D, and B. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S: indicates a static route. ● D: indicates a dynamic route. ● B (blackhole route): indicates that the next hop is a null interface.
TimeStamp	Timestamp, which indicates the lifetime of an entry, in seconds.
Interface	Outbound interface to the destination address.
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0, packets matching the entry are forwarded through the MPLS tunnel. If the value is 0, packets matching the entry are not forwarded through the MPLS tunnel.

7.10.6 display fib ip-prefix

Function

The **display fib ip-prefix** command displays information about the FIB table.

Format

display fib [**vpn-instance** *vpn-instance-name*] **ip-prefix** *prefix-name* [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
prefix-name	Specifies the name of an IP prefix list.	The value is a string of 1 to 169 characters.
verbose	Displays detailed information about the FIB table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command displays FIB entries that match a specified IP prefix list.

If 0 FIB entries match, the command output displays that zero FIB entries match.

If the name of an IP prefix list is not found, all FIB entries are displayed.

Example

Display FIB entries matching the IP prefix list **abc0**.

```
<HUAWEI> display fib ip-prefix abc0
Route Entry matched by prefix-list abc0
 Summary Counts: 4
Destination/Mask  Nexthop  Flag  TimeStamp  Interface   TunnelID
127.0.0.0/8       127.0.0.1 U     t[0]       InLoop0       0x0
127.0.0.1/32      127.0.0.1 U      t[0]       InLoop0       0x0
172.16.0.0/8      10.1.1.1  SU     t[0]       Vlanif10      0x0
172.16.0.0/15     10.1.1.1  SU     t[0]       Vlanif10      0x0
```

Table 7-209 Description of the display fib ip-prefix command output

Item	Description
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.

Item	Description
Flag	Current flag, which is the combination of G, H, U, S, D, and B. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S: indicates a static route. ● D: indicates a dynamic route. ● B (blackhole route): indicates that the next hop is a null interface.
TimeStamp	Timestamp, which indicates the lifetime of an entry, in seconds.
Interface	Outbound interface to the destination address.
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0, packets matching the entry are forwarded through the tunnel. If the value is 0, packets matching the entry are not forwarded through the tunnel.

7.10.7 display fib longer

Function

The **display fib longer** command displays FIB entries that match a specified parameter.

The **display fib** [*slot-id*] *destination-address* command displays FIB entries that match a specified destination IP address. If the specified destination IP address matches an FIB entry in the natural mask range, all the subnets are displayed. Otherwise, FIB entries are displayed based on the longest matching principle.

The **display fib** [*slot-id*] *destination-address destination-mask* command displays FIB entries that accurately match the destination address and mask.

The **display fib** [*slot-id*] *destination-address* **longer** command displays all FIB entries that match destination IP addresses in the natural mask range.

The **display fib** [*slot-id*] *destination-address* destination-mask **longer** command displays all FIB entries that match destination IP addresses in a specified mask range.

The **display fib** [*slot-id*] *destination-address1 destination-mask1 destination-address2 destination-mask2* command displays FIB entries that match destination

IP addresses in the range of *destination-address1 destination-mask1* to *destination-address2 destination-mask2*.

If *slot-id* is specified, FIB entries on the device are displayed.

Format

display fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] *destination-address1* [*destination-mask1*] [**longer**] [**verbose**]

display fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] *destination-address1* *destination-mask1* *destination-address2* *destination-mask2* [**verbose**]

Parameters

Parameter	Description	Value
slot-id	Displays information about the FIB table with a specified slot ID.	The value is an integer and the value range depends on the device configuration.
vpn-instance *vpn-instance-name*	Displays information about the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.
destination-address1	Indicates destination IP address 1.	The value is in dotted decimal notation.
destination-mask1	Indicates subnet mask 1.	The value is in dotted decimal notation or an integer that ranges from 0 to 32.
destination-address2	Indicates destination IP address 2.	The value is in dotted decimal notation.
destination-mask2	Indicates subnet mask 2.	The value is in dotted decimal notation or an integer that ranges from 0 to 32.
longer	Displays FIB entries matching a specified network segment or mask.	-
verbose	Displays detailed information about the FIB table.	-

1: Monitoring level

Usage Guidelines

You can run the **display fib longer** command to check FIB entries that match a specified condition.

Example

Display FIB entries that match destination address 172.16.0.0 in the natural mask range or based on the longest match principle.

```
<HUAWEI> display fib 172.16.0.0
  Route Entry Count: 1
Destination/Mask  Nexthop  Flag  TimeStamp  Interface  TunnelID
172.16.0.0/16     10.1.1.1 U     t[0]       Vlanif10     0x0
```

Display the FIB entries with the destination addresses in the range of 172.16.0.0/16 to 172.16.0.6/16.

```
<HUAWEI> display fib 172.16.0.0 255.255.0.0 172.16.0.6 255.255.0.0
  Route Entry Count: 1
Destination/Mask  Nexthop  Flag  TimeStamp  Interface  TunnelID
172.16.0.1/8      10.1.1.1  U     t[0]       Vlanif10     0x0
```

Table 7-210 Description of the display fib longer command output

Item	Description
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.
Flag	Current flag, which is the combination of G, H, U, S, D, and B. • G (gateway route): indicates that the next hop is a gateway. • H (host route): indicates that the route is a host route. • U (available route): indicates that the route status is Up. • S: indicates a static route. • D: indicates a dynamic route. • B (blackhole route): indicates that the next hop is a null interface.
TimeStamp	Timestamp, which indicates the lifetime of an entry, in seconds.
Interface	Outbound interface to the destination address.

Item	Description
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0, packets matching the entry are forwarded through the tunnel. If the value is 0, packets matching the entry are not forwarded through the tunnel.

7.10.8 display fib next-hop

Function

The **display fib next-hop** command displays FIB entries that match a specified next-hop IP address.

Format

display fib [**vpn-instance** *vpn-instance-name*] **next-hop** *ip-address*

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about the FIB table of a specified VPN instance.	The value must be an existing VPN instance name.
ip-address	Specifies the next-hop IP address.	The value is in dotted decimal notation.

1: Monitoring level

Usage Guidelines

You can run the **display fib next-hop** command to check FIB entries that match a specified next-hop IP address.

Example

Display FIB entries that match a specified next-hop IP address.

```
<HUAWEI> display fib next-hop 10.1.1.1
Destination/Mask   Nexthop         Flag TimeStamp     Interface      TunnelID
```

```
10.1.1.1/32        10.1.1.1        HU   t[115]       Vlanif10         0x0
```

Table 7-211 Description of the display fib next-hop command output

Item	Description
Destination/Mask	Destination address or mask length.
Nexthop	Next hop.
Flag	Current flag, which is the combination of G, H, U, S, D, and B. ● G (gateway route): indicates that the next hop is a gateway. ● H (host route): indicates that the route is a host route. ● U (available route): indicates that the route status is Up. ● S: indicates a static route. ● D: indicates a dynamic route. ● B (blackhole route): indicates that the next hop is a null interface.
TimeStamp	Timestamp, which indicates the lifetime of an entry, in seconds.
Interface	Outbound interface to the destination address.
TunnelID	Index of a forwarding entry. It is used in packet forwarding between the upstream and downstream boards. If the value is not 0, packets matching the entry are forwarded through the MPLS tunnel. If the value is 0, packets matching the entry are not forwarded through the MPLS tunnel.

7.10.9 display fib statistics

Function

The **display fib statistics** command displays the total number of IPv4 FIB entries.

Format

display fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] **statistics**

Parameters

Parameter	Description	Value
slot-id	Displays status information about a specified IPv4 FIB module.	The value is an integer and the value range depends on the device configuration.
vpn-instance *vpn-instance-name*	Specifies the name of an IPv4 VPN instance.	The value must be an existing VPN instance name.

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display fib statistics** command to check the total number of IPv4 FIB entries.

Example

Display the total number of IPv4 FIB entries.

```
<HUAWEI> display fib statistics
Route Entry Count : 30
Route Prefix Count : 30
```

Table 7-212 Description of the display fib statistics command output

Item	Description
Route Entry Count	Total number of FIB entries.
Route Prefix Count	Total number of route prefix entries.

7.10.10 display fib statistics all

Function

The **display fib statistics all** command displays IPv4 FIB entry statistics.

Format

display fib [*slot-id*] **statistics all**

Parameters

Parameter	Description	Value
slot-id	Specifies the slot ID of the switch on which IPv4 FIB entry statistics are displayed.	The value is an integer and the value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When running the **display fib statistics all** command, you can view the IPv4 FIB route prefix capacity and the number of IPv4 FIB forwarding entries on the device.

Example

Display statistics about IPv4 FIB entries on the switch in slot 0.

```
<HUAWEI> display fib 0 statistics all
IPv4 FIB Route Prefix Capacity : 320000
IPv4 FIB Total Route Prefix Count :2 ; Entry Count : 2
IPv4 FIB Public Route Prefix Count :2 ; Entry Count : 2
IPv4 FIB VPN-instance vpna Route Prefix Count :0 ; Entry Count : 0
```

Table 7-213 Description of the display fib statistics all command output

Item	Description
IPv4 FIB Route Prefix Capacity:	IPv4 FIB route prefix capacity on the local switch.
IPv4 FIB Total Route Prefix Count: Entry Count:	Total number of IPv4 FIB route prefixes and forwarding entries on the local switch.
IPv4 FIB Public Route Prefix Count: Entry Count:	Total number of IPv4 route prefixes and forwarding entries on a public network.
IPv4 FIB VPN-instance vpna Route Prefix Count: Entry Count:	Total number of route prefixes and forwarding entries of IPv4 VPN instance **vpna**.

7.10.11 display ip routing-table

Function

The **display ip routing-table** command displays information about an IPv4 routing table.

Format

display ip routing-table [**vpn-instance** *vpn-instance-name*] [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] *ip-address* [*mask* | *mask-length*] [**longer-match**] [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] *ip-address* { *mask* | *mask-length* } **nexthop** *nexthop-address* [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] *ip-address1* { *mask1* | *mask-length1* } *ip-address2* { *mask2* | *mask-length2* } [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] **acl** { *acl-number* | *acl-name* } [**verbose**]

display ip routing-table [**vpn-instance** *vpn-instance-name*] **ip-prefix** *ip-prefix-name* [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance of an enabled IPv4 address family.	The value must be an existing VPN instance name.
verbose	Displays detailed information about active routes and inactive routes. If this keyword is not specified, only brief information about active routes is displayed.	-
ip-address	Displays the routes with the specified destination address.	The value is in dotted decimal notation.
nexthop *nexthop-address*	Displays the routes with the specified next-hop address.	The value is in dotted decimal notation.
longer-match	Displays the routes with the specified destination address and mask.	-

Parameter	Description	Value
mask	Specifies the mask of the destination IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the destination IP address.	The value is an integer that ranges from 0 to 32.
ip-address1	Specifies the start IP address in an IP address range. *ip-address1* and *ip-address2* determine an IP address range. Only the routes in the IP address range are displayed.	The value is in dotted decimal notation.
ip-address2	Specifies the end IP address in an IP address range. *ip-address1* and *ip-address2* determine an IP address range. Only the routes in the IP address range are displayed.	The value is in dotted decimal notation.
mask1	Specifies the subnet mask of the start IP address.	The value is in dotted decimal notation.
mask-length1	Specifies the mask length of the start IP address.	The value is an integer that ranges from 0 to 32.
mask2	Specifies the subnet mask of the end IP address.	The value is in dotted decimal notation.
mask-length2	Specifies the mask length of the end IP address.	The value is an integer that ranges from 0 to 32.
acl *acl-number*	Displays the routes that match the ACL with the specified ACL number. If the specified ACL does not exist, information about all active routes is displayed.	The value is an integer that ranges from 2000 to 2999.
acl *acl-name*	Displays the routes that match the ACL with the specified ACL name. If the specified ACL does not exist, information about all active routes is displayed.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Displays the routes that match the specified IP prefix list. If the specified IP prefix list does not exist, information about all active routes is displayed.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the **verbose** keyword is not specified in the **display ip routing-table** command, each line in the command output indicates a route, including the destination address, mask length, protocol, preference, cost, flag, next hop, and outbound interface of the route.

NOTE

A recursive route is counted as one route regardless of how many outbound interfaces and next hops the route finds.

Matching rules vary with parameters in the command:

- If the **display ip routing-table** *ip-address* command is used, the routes that longest match the destination address are displayed.
- If the **display ip routing-table** *ip-address mask* command is used, the routes that accurately match the destination address and mask are displayed.
- If the **display ip routing-table** *ip-address* **longer-match** command is used, all the routes that match the IP address specified by the destination address and the natural mask are displayed.
- If the **display ip routing-table** *ip-address mask* **longer-match** command is used, all the routes that match the IP address specified by the destination address and the input mask are displayed.
- If the **display ip routing-table** *ip-address1 mask1 ip-address2 mask2* command is used, the routes whose destination address ranges from *ip-address1 mask1* to *ip-address2 mask2* are displayed.

Example

Display brief information about the current IPv4 routing table. The command output shows that there are two static routes with the same destination address 10.1.1.1/32 but different next hops.

```
<HUAWEI> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: Public
         Destinations : 5        Routes : 5

Destination/Mask    Proto   Pre  Cost      Flags NextHop         Interface

      10.1.1.1/32   Static  60   0           D   0.0.0.0         NULL0
                    Static  60   0           D   192.168.0.2     Vlanif100
      127.0.0.0/8   Direct  0    0           D   127.0.0.1       InLoopBack0
     127.0.0.1/32   Direct  0    0           D   127.0.0.1       InLoopBack0
  192.168.150.0/24  Direct  0    0           D   192.168.150.22  Vlanif4094
 192.168.150.22/32  Direct  0    0           D   127.0.0.1       Vlanif4094
```

Table 7-214 Description of the display ip routing-table command output

Item	Description
Route Flags	Flag of a route: ● R: indicates that the route is a recursive route. ● D: indicates that the route is delivered to the FIB table. ● T: indicates a route whose next hop belongs to a VPN instance.
Routing Tables: Public	The routing table is a public routing table. If the routing table is a private routing table, a private network name is displayed, for example, Routing Tables: ABC.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination/Mask	Address and mask length of the destination network or host.
Proto	Routing protocol that learns a route.
Pre	Preference of a route.
Cost	Cost of a route.
Flags	Route flags in the heading of the routing table.
NextHop	Next-hop address of a route.
Interface	Outbound interface through which the next hop of a route is reachable.

Display the summary of the routing table of the IPv4 VPN instance named **vpn1**.

```
<HUAWEI> display ip routing-table vpn-instance vpn1
Route Flags: R - relay, D - download to fib, T - to vpn-instance
```

```
------------------------------------------------------------------------------
Routing Table: vpn1
         Destinations : 3        Routes : 3

Destination/Mask    Proto  Pre  Cost      Flags NextHop         Interface

       10.1.1.0/24  Direct 0    0           D  10.1.1.1        Vlanif10
       10.1.1.1/32  Direct 0    0           D  127.0.0.1       Vlanif10
       10.5.5.0/24  Static 60   0          RD  10.1.1.2        Vlanif10
```

Table 7-215 Description of the display ip routing-table vpn-instance command output

Item	Description
Route Flags	Route flag: ● R: indicates a recursive route. ● D: indicates that the route is downloaded to the FIB table. ● T: indicates a route whose next hop belongs to a VPN instance.
Routing Tables: vpn1	VPN routing table named vpn1.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination/Mask	Address and mask length of the destination network or host.
Proto	Routing protocol.
Pre	Preference.
Cost	Route cost.
Flags	Route flag, that is, Route Flags in the heading of the routing table.
NextHop	Next hop.
Interface	Outbound interface through which the next hop is reachable.

Display brief information about the current routing table. Route 10.2.2.2/32 is a static route with next hop 10.1.1.1. This route is a recursive route and has two outbound interfaces because 10.1.1.1 has two outbound interfaces.

```
<HUAWEI> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: Public
         Destinations : 6        Routes : 7

   Destination/Mask  Proto   Pre  Cost Flags  NextHop     Interface

       10.1.1.1/32   Static  60   0      D    0.0.0.0     NULL0
                     Static  60   0      D    10.10.0.2  Vlanif100
```

```
      10.2.2.2/32   Static  60   0     RD   10.1.1.1     NULL0
                    Static  60   0     RD   10.1.1.1     Vlanif100
     10.10.0.0/24   Direct   0   0      D    10.10.0.1  Vlanif100
     10.10.0.1/32   Direct   0   0      D    127.0.0.1  Vlanif100
     127.0.0.0/8    Direct   0   0      D    127.0.0.1  InLoopBack0
     127.0.0.1/32   Direct   0   0      D    127.0.0.1  InLoopBack0
```

Display detailed information about the IPv4 routing table.

```
<HUAWEI> display ip routing-table verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------ Routing Tables: Public
         Destinations : 5        Routes : 5

Table 7-216 Description of the display ip routing-table verbose command output

Item	Description
Route Flags	Flag of a route: - R: indicates that the route is a recursive route. - D: indicates that the route is delivered to the FIB table. - T: indicates a route whose next hop belongs to a VPN instance.
Destinations	Total number of destination networks or hosts.
Routes	Total number of active routes and inactive routes.
Destination	Address and mask length of the destination network or host.
Protocol	Routing protocol of a route.
Process ID	Routing protocol process ID of a route.
Preference	Preference of a route.
Cost	Cost of a route.
NextHop	Next-hop address of a route.
Neighbour	Neighbor address of a route.
State	Status of a route: - Active: active route - Invalid: invalid route - Inactive: inactive route - NoAdv: route that cannot be advertised - Adv: route that can be advertised - Del: route to be deleted - Relied: route that recurses to an outbound interface and a next hop or that recurses to a tunnel - Stale: route that is marked Stale and used in GR
Age	Lifetime of a route.
Tag	Routing management tag. The value is an integer that ranges from 0 to 4294967295.

Item	Description
Priority	Convergence priority of route: ● low ● medium ● high ● critical
Label	Label allocated by MPLS.
QoSInfo	QoS information. The value 0x0 indicates that QoS information is empty.
IndirectID	ID of indirect next hop.
RelayNextHop	Recursive next-hop address.
Interface	Outbound interface.
TunnelID	Tunnel ID.
Flags	Route flags in the heading of the routing table.

7.10.12 display ip routing-table limit

Function

The **display ip routing-table limit** command displays the maximum number of routes and prefixes.

Format

display ip routing-table limit [**all-vpn-instance** | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
all-vpn-instance	Indicates all IPv4 VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of a IPv4 VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command displays limits on the number of IPv4 routes and prefixes.

- The **display ip routing-table limit** command displays limits on the number of IPv4 public routes and prefixes.
- The **display ip routing-table limit all-vpn-instance** command displays the limit on the number of routes and prefixes of all IPv4 VPN instances.
- The **display ip routing-table limit vpn-instance** *vpn-instance-name* command displays the limit on the number of routes and prefixes of a specified IPv4 VPN instance.

Example

Display the limits on the number of IPv4 public routes and prefixes.

```
<HUAWEI> display ip routing-table limit
Public Instance:
Limit-Object Limit-Type     Upper-Limit  Warning    Current    Log-Interval
Route         Default        -            -          9          5
Prefix        Default        -            -          9          5
```

Display limits on the numbers of routes and prefixes of all IPv4 VPN instances.

```
<HUAWEI> display ip routing-table limit all-vpn-instance
Limit-Object     Limit-Type    Upper-Limit     Warning     Current    Log-Interval
--------------------------------------------------------------------------------
VPN Instance Name: vpn1
Route            Simply-Alert   5000          -           4223      5
Prefix           Alert-Percent  1000          800         760       5
---------------------------------------------------------------------------------
VPN Instance Name: vpn2
Route            Alert-Percent  2000          1000        823       5
Prefix           Default        -             -           760       5
```

Display limits on the numbers of routes and prefixes of the IPv4 VPN instance named **vpn1**.

```
<HUAWEI> display ip routing-table limit vpn-instance vpn1
VPN Instance Name: vpn1
Limit-Object     Limit-Type     Upper-Limit    Warning    Current    Log-Interval
Route            Simply-Alert    5000          -          4223       5
Prefix           Alert-Percent   1000          800        760        5
```

Table 7-217 Description of the display ip routing-table limit command output

Item	Description
Limit-Object	Object whose total number is limited: ● Prefix ● Route

Item	Description
Limit-Type	Limit type for the routes and prefixes in the routing table: ● Simply-Alert: indicates that only alarms are generated when the number of routes or prefixes exceeds the upper limit. ● Alert-Percent: indicates the percentage of the alarm threshold of routes. ● Default: indicates that the number of routes or prefixes is not limited by default.
Upper-Limit	Upper limit of routes or prefixes in the current routing table.
Warning	Alarm threshold of routes or prefixes in the current routing table.
Current	Number of routes or prefixes in the current routing table.
Log-Interval	Frequency of displaying logs when the number of routes or prefixes in the current routing table exceeds the upper limit, in seconds. The default value is 5s.

7.10.13 display ip routing-table protocol

Function

The **display ip routing-table protocol** command displays routing information about a specified routing protocol.

Format

display ip routing-table [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance of an enabled IPv4 address family.	The value must be an existing VPN instance name.

Parameter	Description	Value
protocol	Displays routing information of a specified routing protocol.	The value may be **bgp, direct**, **isis, ospf, rip**, **static**, or **unr**. The specific value varies depending on the routing protocol supported by the device.
inactive	Displays brief information about inactive routes only.	-
verbose	Displays detailed information about active routes and inactive routes.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If neither **verbose** nor **inactive** is specified, brief information about all the routes of each routing protocol is displayed.

Example

Display brief information about all direct routes.

```
<HUAWEI> display ip routing-table protocol direct
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Public routing table : Direct
        Destinations : 4        Routes : 4

Direct routing table status : <Active>
        Destinations : 4        Routes : 4

Destination/Mask    Proto   Pre  Cost      Flags NextHop         Interface

   10.137.216.0/23  Direct  0    0           D   10.137.217.210  Vlanif100
 10.137.217.210/32  Direct  0    0           D   127.0.0.1       Vlanif100
      127.0.0.0/8   Direct  0    0           D   127.0.0.1       InLoopBack0
      127.0.0.1/32  Direct  0    0           D   127.0.0.1       InLoopBack0

Direct routing table status : <Inactive>
        Destinations : 0        Routes : 0
```

Table 7-218 Description of the display ip routing-table protocol command output

Item	Description
Route Flags	Flag of a route: - R: indicates that the route is a recursive route. - D: indicates that the route is delivered to the FIB table. - T: indicates a route whose next hop belongs to a VPN instance.
Public routing table	Contents of a public routing table.
Direct routing table status	Status of direct routes: - **Inactive**: inactive routes in the routing table - **Active**: active routes in the routing table
Destinations	Total number of destination addresses.
Routes	Total number of routes in the routing table.
Destination/Mask	Destination address or mask length.
Proto	Routing protocol of a route.
Pre	Routing protocol preference of a route.
Cost	Cost of a route.
Flags	Route flags in the heading of the routing table.
Nexthop	Next-hop address of a route.
Interface	Outbound interface of a route.

Display all the direct routes of the VPN instance named **vpn1**.

```
<HUAWEI> display ip routing-table vpn-instance vpn1 protocol direct
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
vpn4 routing table : Direct
         Destinations : 2          Routes : 2

Direct routing table status : <Active>
         Destinations : 2          Routes : 2

Destination/Mask    Proto  Pre  Cost     Flags NextHop         Interface

       10.1.1.0/24  Direct 0    0          D  10.1.1.1        Vlanif30
       10.1.1.1/32  Direct 0    0           D  127.0.0.1       Vlanif30

Direct routing table status : <Inactive>
         Destinations : 0          Routes : 0
```

Table 7-219 Description of the display ip routing-table vpn-instance protocol command output

Item	Description
Active	Active routes.
Inactive	Inactive routes.

7.10.14 display ip routing-table statistics

Function

The **display ip routing-table statistics** command displays statistics about routes in an IPv4 routing table.

Format

display ip routing-table [**vpn-instance** *vpn-instance-name* | **all-vpn-instance**] **statistics**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about routes in the routing table of a specified VPN instance. If neither **vpn-instance** *vpn-instance-name* nor **all-vpn-instance** is specified, statistics about routes in a public routing table are displayed.	The value must be an existing VPN instance name.
all-vpn-instance	Displays statistics about routes in the routing tables of all VPN instances. If neither **vpn-instance** *vpn-instance-name* nor **all-vpn-instance** is specified, statistics about routes in a public routing table are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Route statistics include:

- Total number of routes that are added or deleted through routing protocols
- Number of active or inactive routes that are labeled for deletion but are not deleted

Example

Display statistics about routes in an IPv4 routing table.

```
<HUAWEI> display ip routing-table statistics
Summary Prefixes: 9
Proto   total   active  added     deleted     freed
        routes  routes  routes     routes      routes
DIRECT   6        6      42          36         36
STATIC   3        3      21          18         18
RIP      0        0      0           0          0
OSPF     0        0      0           0          0
IS-IS    0        0      0           0          0
BGP      0        0      0           0          0
UNR      0        0      0           0          0
Total    9        9      63          54         54
```

Table 7-220 Description of the display ip routing-table statistics command output

Item	Description
Summary Prefixes	Total number of prefixes in the current routing table.
Proto	Routing protocol type
total routes	Total number of routes that a routing protocol learns in the routing table, including active and inactive routes.
active routes	Number of active routes that a routing protocol learns in the routing table.
added routes	Number of active and inactive routes that are added to the routing table through a routing protocol.
deleted routes	Number of routes to be deleted from the routing table.
freed routes	Number of routes that are permanently deleted from the routing table.

7.10.15 display ip routing-table time-range

Function

The **display ip routing-table time-range** command displays information about routes generated in a specified time range in an IP routing table.

Format

display ip routing-table [**vpn-instance** *vpn-instance-name*] **time-range** *min-age max-age* [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about routes generated in a specified time range in the IP routing table of the specified VPN instance. If you do not specify this parameter, the **display ip routing-table time-range** command displays information about routes generated in a specified time range in the public IP routing table.	The value must be an existing VPN instance name.
min-age	Specifies the end time of the period when routes are generated.	The value is in xxdxxhxxmxxs format. ● d indicates days. The value is an integer that ranges from 0 to 10000. ● h indicates hours. The value is an integer that ranges from 0 to 23. ● m indicates minutes. The value is an integer that ranges from 0 to 59. ● s indicates seconds. The value is an integer that ranges from 0 to 59. For example, you can enter 5d4h30m20s to specify 5 days, 4 hours, 30 minutes, and 20 seconds. **NOTE** If the value of d is 10000, the values of h, m, and s can only be 0.

Parameter	Description	Value
max-age	Specifies the start time of the period when routes are generated.	The value is in xxdxxhxxmxxs format. ● d indicates days. The value is an integer that ranges from 0 to 10000. ● h indicates hours. The value is an integer that ranges from 0 to 23. ● m indicates minutes. The value is an integer that ranges from 0 to 59. ● s indicates seconds. The value is an integer that ranges from 0 to 59. For example, you can enter 5d4h30m20s to specify 5 days, 4 hours, 30 minutes, and 20 seconds. **NOTE** If the value of d is 10000, the values of h, m, and s can only be 0.
verbose	Displays detailed information about active and inactive routes. If you do not specify this parameter, the **display ip routing-table time-range** command displays only brief information about active routes.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If route flapping occurs on a network, you can run the **display ip routing-table time-range** command and specify a small time range for the command. You can then find the flapping route rapidly and accelerate fault location.

Precautions

max-age must be larger than *min-age*. Otherwise, the **display ip routing-table time-range** command does not display any information.

If *max-age* is larger than *min-age* but no route was generated within this time range, the **display ip routing-table time-range** command displays only the table heading.

Example

Display information about public network routes generated in the last 20 minutes.

```
<HUAWEI> display ip routing-table time-range 0 20m
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: Public
        Destinations : 2        Routes : 2

Destination/Mask    Proto   Pre  Cost      Flags NextHop         Interface

      10.3.3.3/32  Direct  0    0           D   127.0.0.1       LoopBack1
      10.4.4.0/24  Static  60   0           D   0.0.0.0         NULL0
```

Table 7-221 Description of the display ip routing-table time-range command output

Item	Description
Route Flags	Route flags: ● R: The route is a recursive route. ● D: The route is sent to the FIB table. ● T: Indicates a route whose next hop belongs to a VPN instance.
Routing Tables: Public	The routing table is a public routing table.
Destinations	Number of destination networks and hosts.
Routes	Number of routes.
Destination/Mask	Address and mask length of the destination network and host.
Proto	Protocol used to learn routes.
Pre	Route preference.
Cost	Route cost.
Flags	Route flags in the heading of the routing table.
NextHop	Next hop.
Interface	Outbound interface in a route with a reachable next hop.

Display detailed information about public network routes generated in the last 20 minutes.

```
<HUAWEI> display ip routing-table time-range 0 20m verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: Public
```

```
         Destinations : 3        Routes : 3

Destination: 10.3.3.3/32
     Protocol: Direct           Process ID: 0
   Preference: 0                      Cost: 0
      NextHop: 127.0.0.1         Neighbour: 0.0.0.0
        State: Active Adv              Age: 00h14m06s
          Tag: 0                  Priority: high

        State: Invalid Adv Relied      Age: 00h01m38s
          Tag: 0                  Priority: medium
        Label: NULL                QoSInfo: 0x0
   IndirectID: 0x80000002
 RelayNextHop: 0.0.0.0           Interface: NULL0
     TunnelID: 0x0                   Flags: R
```

Table 7-222 Description of the display ip routing-table time-range verbose command output

Item	Description
Process ID	Process ID of the routing protocol.
Preference	Route preference.
Cost	Route cost.
NextHop	Next hop.
Neighbour	IP address of a neighbor. 0.0.0.0 indicates that the route is generated by a local device.

Item	Description
State	Route status: - Active: an active route - Invalid: an invalid route - Inactive: an inactive route - NoAdv: a route that cannot be advertised - Adv: a route that can be advertised - Del: a route to be deleted - Relied: a route that recurses to the next hop and outbound interface or that recurses to a tunnel - Stale: a route with the Stale flag and used in GR
Age	Time after the route is generated.
Tag	Administrative tag of the route. The value is an integer that ranges from 0 to 4294967295.
Priority	Convergence priority of the route: - low: The convergence priority of a route is low. - medium: The convergence priority of a route is medium. - high: The convergence priority of a route is high. - critical: The convergence priority of a route is critical.
Label	Label allocated by MPLS.
QoSInfo	QoS information. 0x0 indicates QoS information is empty.
IndirectID	ID of the indirect next hop.
RelayNextHop	Recursive next hop.
Interface	Recursive outbound interface.
Tunnel ID	Tunnel ID: - The value 0x0 indicates that the route does not use a tunnel or the tunnel fails to be set up. - If the value is not 0x0, the route recurses to a tunnel.

Item	Description
Flags	Route flags in the heading of the routing table.

7.10.16 display ipv6 fib

Function

The **display ipv6 fib** command displays FIB entries on the device.

Format

display ipv6 fib [*slot-id*] **statistics** [**all**]

display ipv6 fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] **statistics**

display ipv6 fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] [*ipv6-address* [*prefix-length*]] [**verbose**]

display ipv6 fib [*slot-id*] [**vpn-instance** *vpn-instance-name*] **verbose statistics**

Parameters

Parameter	Description	Value
slot-id	Specifies the slot ID.	-
ipv6-address	Specifies the prefix of an IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
statistics	Displays the statistics of FIB entries.	-
all	Displays all FIB entries.	-
vpn-instance *vpn-instance-name*	Displays FIB entries of the specified VPN instance.	The value must be an existing VPN instance name.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 1 to 128.
verbose	Displays detailed information about FIB entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ipv6 fib** command to check IPv6 FIB entries on the device.

Example

Display all FIB entries on the device.

```
<HUAWEI> display ipv6 fib
 IPv6 FIB Table:
 Total number of Routes : 1

Destination:  ::1                               PrefixLength : 128
Nexthop    :  ::1                               Flag         : HU
Interface  :  InLoopBack0                           Tunnel ID    : 0x0
TimeStamp  :  2008-11-03 13:47:52
```

Table 7-223 Description of the display ipv6 fib command output

Item	Description
Total number of Routes	Number of IPv6 routes.
Destination	Destination IPv6 address of a route.
PrefixLength	Prefix length of the destination IPv6 address.
Nexthop	Next-hop router that forwards packets to the destination address.
Flag	Description of route characteristics using S/U/G/H/B/D: ● S: static ● U: Up ● G: gateway ● H: host ● B. blackhole ● D: dynamic
Tunnel ID	ID of the tunnel. If packets are forwarded to the next hop using MPLS forwarding, the tunnel ID of the packets cannot be 0. If packets are forwarded using IP forwarding, the tunnel ID of the packets is 0.
TimeStamp	Time taken to generate a route in the FIB table.
Interface	Outbound interface through which packets are forwarded.

7.10.17 display ipv6 routing-table

Function

The **display ipv6 routing-table** command displays information about an IPv6 routing table.

Format

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] [**verbose** | **brief**]

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] *ipv6-address* [*prefix-length*] [**longer-match**] [**verbose** | **brief**]

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] *ipv6-address1* [*prefix-length1*] *ipv6-address2 prefix-length2* [**verbose** | **brief**]

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **acl** { *acl6-number* | *acl6-name* } [**verbose** | **brief**]

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **ipv6-prefix** *ipv6-prefix-name* [**verbose** | **brief**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance of an enabled IPv6 address family.	The value must be an existing VPN instance name.
verbose	Displays detailed information about all the routes in the current routing table, including active and inactive routes.	-
brief	Displays brief information about active routes in the current routing table.	-
ipv6-address	Displays the routes with the specified IPv6 destination address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 destination address.	The value is an integer that ranges from 0 to 128.
longer-match	Displays the routes with the specified destination address and mask.	-

Parameter	Description	Value
ipv6-address1	Specifies the start IPv6 address in an IP address range. *ipv6-address1* and *ipv6-address2* determine an IP address range. Only the routes in the IP address range are displayed.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
ipv6-address2	Specifies the end IPv6 address in an IP address range. *ipv6-address1* and *ipv6-address2* determine an IP address range. Only the routes in the IP address range are displayed.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length1	Specifies the mask length of the start IPv6 address.	The value is an integer that ranges from 0 to 128.
prefix-length2	Specifies the mask length of the end IPv6 address.	The value is an integer that ranges from 0 to 128.
acl *acl6-number*	Displays the routes that match the ACL6 with the specified ACL number. If the specified ACL6 does not exist, information about all active routes is displayed.	The value is an integer that ranges from 2000 to 2999.
acl *acl6-name*	Displays the routes that match the ACL6 with the specified ACL name. If the specified ACL6 does not exist, information about all active routes is displayed.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ipv6-prefix *ipv6-prefix-name*	Displays the routes that match the specified IPv6 prefix list. If the specified IPv6 prefix list does not exist, information about all active routes is displayed.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the **verbose** keyword is not specified, the command output includes the destination address, prefix length, protocol type, preference, cost, next hop, outbound interface, tunnel ID, flag, and status of a route.

NOTE

A recursive route is counted as one route regardless of how many outbound interfaces and next hops the route finds.

Example

Display brief information about the current IPv6 routing table.

```
<HUAWEI> display ipv6 routing-table
Routing Table : Public
         Destinations : 4        Routes : 4

 Destination  : ::1                          PrefixLength : 128
 NextHop      : ::1                          Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : InLoopBack0                  Flags        : D

 Destination  : FC00:0:0:112::               PrefixLength : 64
 NextHop      : FC00:0:0:112::2              Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : Vlanif10                     Flags        : D

 Destination  : FC00:0:0:112::2              PrefixLength : 128
 NextHop      : ::1                          Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : Vlanif10                     Flags        : D

 Destination  : FE80::                       PrefixLength : 10
 NextHop      : ::                           Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : NULL0                        Flags        : D
```

Table 7-224 Description of the display ipv6 routing-table command output

Item	Description
Routing Tables : Public	The routing table is a public routing table.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination	IP address of the destination network or host of a route.
PrefixLength	Prefix length of a route.
NextHop	Next-hop IPv6 address of a route.
Preference	Preference of a route.

Item	Description
Cost	Cost of a route.
Protocol	Routing protocol of a route.
RelayNextHop	Recursive next-hop address.
TunnelID	Tunnel ID. The value 0x0 indicates that no tunnel is used or the tunnel fails to be established.
Interface	Outbound interface through which the next hop of a route can be reached.
Flags	Flag of a route: ● R: The route is a recursive route. ● D: The route is delivered to the FIB table.

Display detailed information about the IPv6 routing table.

```
<HUAWEI> display ipv6 routing-table verbose
Routing Table : Public
         Destinations : 2        Routes : 2

 Destination  : ::1                          PrefixLength : 128

```

Table 7-225 Description of the display ipv6 routing-table verbose command output

Item	Description
Neighbour	IPv6 address of a neighbor interface.
ProcessID	Routing protocol process ID of a route.
Label	Label carried in a route.

Item	Description
State	Status of a route: - Active: active route - Invalid: invalid route - Inactive: inactive route - NoAdv: route that cannot be advertised - Adv: route that can be advertised - Del: route to be deleted - Relied: route that recurses to an outbound interface and a next hop or that recurses to a tunnel - Stale: route that is marked Stale and used in GR
Entry ID	ID of a routing entry in the routing table.
EntryFlags	Flag of a routing entry.
Reference Cnt	Number of times a route is referenced.
Tag	Routing management tag. The value is an integer that ranges from 0 to 4294967295.
Priority	Convergence priority of a route: - low - medium - high - critical
IndirectID	ID of indirect next hop.
Age	Time a route is generated.

Display brief information about the active routes that match ACL6 2000.

```
<HUAWEI> display ipv6 routing-table acl 2000
Routes Matched by Access list  2000  :
Summary Count : 2

 Destination  : ::1                              PrefixLength : 128

7.10.18 display ipv6 routing-table limit

Function

The **display ipv6 routing-table limit** command displays limits on the numbers of routes and prefixes.

Format

display ipv6 routing-table limit [**all-vpn-instance** | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
all-vpn-instance	Indicates all IPv6 VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of an IPv6 VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command displays limits on the number of IPv6 routes and prefixes.

- The **display ipv6 routing-table limit** command displays limits on the number of IPv6 public routes and prefixes.
- The **display ipv6 routing-table limit all-vpn-instance** command displays the limit on the number of routes and prefixes of all IPv6 VPN instances.
- The **display ipv6 routing-table limit vpn-instance** *vpn-instance-name* command displays the limit on the number of routes and prefixes of a specified IPv6 VPN instance.

Example

Display the limits on the number of IPv6 public routes and prefixes.

```
<HUAWEI> display ipv6 routing-table limit
Public Instance:
Limit-Object Limit-Type     Upper-Limit  Warning    Current    Log-Interval
Route         Default        -            -          1          5
Prefix        Default        -            -          1          5
```

Table 7-226 Description of the **display ipv6 routing-table limit** command output

Item	Description
Limit-Object	Indicates the object whose total number is limited: ● Prefix ● Route

Item	Description
Limit-Type	Indicates the limit mode for the routes and prefixes in the current routing table: ● Simply-Alert: indicates that only alarms are generated after the number of routes or prefixes exceeds the upper limit. ● Alert-Percent: indicates the percentage of the alarm threshold of routes. ● Default: indicates that the number of routes or prefixes is not limited by default.
Upper-Limit	Indicates the upper limit of routes or prefixes in the current routing table.
Warning	Indicates the alarm threshold of routes or prefixes in the current routing table.
Current	Indicates the number of routes or prefixes in the current routing table.
Log-Interval	Indicates the frequency of displaying logs when the number of routes or prefixes in the current routing table exceeds the upper limit, in seconds.

7.10.19 display ipv6 routing-table protocol

Function

The **display ipv6 routing-table protocol** command displays routing information about a specified IPv6 routing protocol.

Format

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose** | **brief**]

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance of an enabled IPv6 address family.	The value must be an existing VPN instance name.

Parameter	Description	Value
protocol	Displays routing information of a specified routing protocol.	The value may be **bgp, direct**, **isis, ospfv3, ripng**, **static**, or **unr**. The specific value varies depending on the routing protocol supported by the device.
inactive	Displays information about inactive routes. If this parameter is not specified, information about all active and inactive routes is displayed.	-
verbose	Displays detailed information about active and inactive routes. If this keyword is not specified, only brief information about active routes is displayed.	-
brief	Displays brief information about active and inactive routes.	-

1: Monitoring level

Usage Guidelines

You can run the **display ipv6 routing-table protocol** command to check routing information about a specified IPv6 routing protocol.

Example

Display brief information about all IPv6 direct routes.

```
<HUAWEI> display ipv6 routing-table protocol direct
Public Routing Table : Direct
Summary Count : 2

Direct Routing Table's Status : < Active >
Summary Count : 2

 Destination  : ::1                              PrefixLength : 128
 NextHop      : ::1                              Preference   : 0
 Cost         : 0                                Protocol     : Direct
 RelayNextHop : ::                               TunnelID     : 0x0
 Interface    : InLoopBack0                      Flags        : D
```

```
 Destination  : FE80::                          PrefixLength : 10
 NextHop      : ::                              Preference   : 0
 Cost         : 0                               Protocol     : Direct
 RelayNextHop : ::                              TunnelID     : 0x0
 Interface    : NULL0                           Flags        : D

Direct Routing Table's Status : < Inactive >
Summary Count : 0
```

Table 7-227 Description of the display ipv6 routing-table protocol command output

Item	Description
Public Routing Table	Contents of a public routing table: ● Direct: direct IPv6 route ● Static: static IPv6 route ● bgp: BGP4+ route ● ripng: RIPng route ● isis: IS-IS IPv6 route ● ospfv3: OSPFv3 route ● unr: user network route
Summary Count	Number of prefixes of routes.
Direct Routing Table's Status	Status of direct routes: ● active: information about active routes ● inactive: information about inactive routes
Destination	IP address of the destination network or host of a route.
PrefixLength	Prefix length of a route.
NextHop	Next-hop address of a route.
Preference	Routing protocol preference of a route.
Cost	Cost of a route.
Protocol	Routing protocol that learns a route.
RelayNextHop	Recursive next-hop address.
TunnelID	Tunnel ID. The value 0x0 indicates that no tunnel is used or the tunnel fails to be established.
Interface	Outbound interface through which the next hop of a route can be reached.
Flags	Flag of a route: ● R: The route is a recursive route. ● D: The route is delivered to the FIB table.

7.10.20 display ipv6 routing-table statistics

Function

The **display ipv6 routing-table statistics** command displays statistics about routes in an IPv6 routing table.

Format

display ipv6 routing-table [**vpn-instance** *vpn-instance-name* | **all-vpn-instance**] **statistics**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about routes in the routing table of a specified VPN instance. If neither *vpn-instance-name* nor **all-vpn-instance** is specified, statistics about routes in a public routing table are displayed.	The value must be an existing VPN instance name.
all-vpn-instance	Displays statistics about routes in the routing tables of all VPN instances. If neither *vpn-instance-name* nor **all-vpn-instance** is specified, statistics about routes in a public routing table are displayed.	-

Views

1: Monitoring level

Usage Guidelines

Route statistics include the total number of routes, number of added routes, and number of deleted routes.

Example

Display statistics about routes in an IPv6 routing table.

```
<HUAWEI> display ipv6 routing-table statistics
Summary Prefixes : 0
Protocol   route      active     added      deleted    freed
DIRECT     0          0          0          0          0
STATIC     0          0          0          0          0
RIPng      0          0          0          0          0
OSPFv3     0          0          0          0          0
```

```
IS-IS     0          0          0          0          0
BGP       0          0          0          0          0
UNR       0          0          0          0          0
Total     0          0          0          0          0
```

Table 7-228 Description of the display ipv6 routing-table statistics command output

Item	Description
Summary Prefixes	Total number of prefixes in the current routing table.
Protocol	Routing protocol type:
route	Total number of routes that a routing protocol learns in the routing table, including active and inactive routes.
active	Number of active routes of a routing protocol in the routing table.
added	Number of active and inactive routes that are added to the routing table through a routing protocol.
deleted	Number of routes that are deleted from the routing table.
freed	Number of routes that are permanently deleted from the routing table.

7.10.21 display ipv6 routing-table time-range

Function

The **display ipv6 routing-table time-range** command displays information about routes generated in a specified time range in an IPv6 routing table.

Format

display ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **time-range** *min-age max-age* [**verbose** | **brief**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about routes generated in a specified time range in the IPv6 routing table of the specified VPN instance. If this parameter is not specified, the **display ipv6 routing-table time-range** command displays information about routes generated in a specified time range in the public IPv6 routing table.	The value must be an existing VPN instance name.
min-age	Specifies the end time of the period when routes are generated.	The value is in xxdxxhxxmxxs format. - d indicates days. The value is an integer that ranges from 0 to 10000. - h indicates hours. The value is an integer that ranges from 0 to 23. - m indicates minutes. The value is an integer that ranges from 0 to 59. - s indicates seconds. The value is an integer that ranges from 0 to 59. For example, enter 5d4h30m20s to specify 5 days, 4 hours, 30 minutes, and 20 seconds. **NOTE** If the value of d is 10000, the values of h, m, and s can only be 0.

Parameter	Description	Value
max-age	Specifies the start time of the period when routes are generated.	The value is in xxdxxhxxmxxs format. - d indicates days. The value is an integer that ranges from 0 to 10000. - h indicates hours. The value is an integer that ranges from 0 to 23. - m indicates minutes. The value is an integer that ranges from 0 to 59. - s indicates seconds. The value is an integer that ranges from 0 to 59. For example, enter 5d4h30m20s to specify 5 days, 4 hours, 30 minutes, and 20 seconds. **NOTE** If the value of d is 10000, the values of h, m, and s can only be 0.
verbose	Displays detailed information about active and inactive routes. If this parameter is not specified, the **display ipv6 routing-table time-range** command displays only brief information about active routes.	-
brief	Displays brief information about active and inactive routes.	-

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If route flapping occurs on a network, to find the flapping route rapidly and accelerate fault location, run the **display ipv6 routing-table time-range** command and specify a small time range.

Precautions

max-age must be larger than *min-age*. Otherwise, the **display ipv6 routing-table time-range** command does not display any information.

If *max-age* is larger than *min-age* but no route is generated within this time range, the **display ipv6 routing-table time-range** command displays only the table heading.

Example

Display information about public network IPv6 routes generated in the last 2 hours, 20 minutes, and 10 seconds.

```
<Switch> display ipv6 routing-table time-range 0 2h20m10s
Routing Table : Public
         Destinations : 4        Routes : 4

 Destination  : ::1                          PrefixLength : 128
 NextHop      : ::1                          Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : InLoopBack0                  Flags        : D

 Destination  : FC00:0:0:1::1                PrefixLength : 128
 NextHop      : ::1                          Preference   : 0
 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : LoopBack2                    Flags        : D

 Destination  : FC00:0:0:1::2                PrefixLength : 128
 NextHop      : ::                           Preference   : 60
 Cost         : 0                            Protocol     : Static
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : NULL0                        Flags        : D

 Destination  : FE80::                       PrefixLength : 10

 Cost         : 0                            Protocol     : Direct
 RelayNextHop : ::                           TunnelID     : 0x0
 Interface    : NULL0                        Flags        : D
```

Table 7-229 Description of the display ipv6 routing-table time-range command output

Item	Description
Routing Tables: Public	The routing table is a public routing table.
Destinations	Number of destination networks or hosts.
Routes	Number of routes.
Destination	IP addresses of the destination network or host.
PrefixLength	Prefix length of a route.
NextHop	Next-hop IPv6 address.
Preference	Route preference.
Cost	Route cost.

Item	Description
Protocol	Name of the routing protocol.
RelayNextHop	Recursive next hop.
TunnelID	Tunnel ID: ● The value 0x0 indicates that the route does not use a tunnel or the tunnel fails to be set up. ● If the value is not 0x0, the route recurses to a tunnel.
Interface	Outbound interface through which the next hop of a route can be reached.
Flags	Route flag: ● R: The route is a recursive route. ● D: The route is delivered to the FIB table.

Display detailed information about public network routes generated in the last 20 minutes.

```
<Switch> display ipv6 routing-table time-range 0 20m verbose

Table 7-230 Description of the display ipv6 routing-table time-range verbose command output

Item	Description
Neighbour	IP address of a neighboring interface. :: indicates that the route is generated by a local device.
ProcessID	Process ID of the routing protocol.
Label	Label carried in a route.
State	Status of the route: • Active: an active route • Invalid: an invalid route • Inactive: an inactive route • NoAdv: a route that cannot be advertised • Adv: a route that can be advertised • Del: a route to be deleted • Relied: a route that recurses to the next hop and outbound interface or that recurses to a tunnel • Stale: a route with the Stale flag and used in GR
Entry ID	ID of a route in the routing table.
EntryFlags	Flag of a route.

Item	Description
Reference Cnt	Number of times the route is referenced.
Tag	Administrative tag of the route. The value is an integer that ranges from 0 to 4294967295.
Priority	Convergence priority of the route: ● low ● medium ● high ● critical
IndirectID	ID of the indirect next hop.
Age	Time when the route is generated.

7.10.22 display rm bfd-session

Function

The **display rm bfd-session** command displays the BFD session configuration in routing management (RM).

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

display rm bfd-session [**vpn-instance** *vpn-instance-name*] [**destination** *destination-address*] [**source** *source-address*] [**interface** *interface-type interface-number*] [**protocol** { **bgp** | **isis-l1** | **isis-l2** | **isis-l1l2** | **ospf** | **rip** | **pim** }]

display rm bfd-session all

Parameters

Parameter	Description	Value
all	Displays all the BFD session configurations in RM, including the BFD session configurations of the public and private networks. If **all** is not specified, only the BFD session configuration on the public network is displayed.	-
vpn-instance *vpn-instance-name*	Displays the configurations of BFD sessions of the specified VPN instance in RM.	The value must be an existing VPN instance name.
destination *destination-address*	Displays the configurations of BFD sessions with the specified destination address in RM.	The value is in dotted decimal notation.
source *source-address*	Displays the configurations of BFD sessions with the specified source address in RM.	The value is in dotted decimal notation.
interface *interface-type interface-number*	Displays the configurations of BFD sessions with the specified outbound interface type and number in RM.	-
protocol	Displays the configurations of BFD sessions of the specified routing protocol in RM: ● **bgp**: BGP ● **isis-l1**: IS-IS Level-1 ● **isis-l2**: IS-IS Level-2 ● **isis-l1l2**: IS-IS Level-1-2 ● **ospf**: OSPF ● **rip**: RIP ● **pim**: PIM	-

Views

Usage Guidelines

You can use this command to view the configuration of BFD sessions dynamically created by routing protocols. The command output includes the global BFD status, number of BFD sessions, and BFD session configuration, such as VPN instance, destination address, source address, interface, and status.

Example

Display the BFD configuration in RM.

```
<HUAWEI> display rm bfd-session vpn-instance vrf1 destination 10.8.1.2 source 10.8.1.1 interface
Vlanif10
BFD Global Status: ON
BFD Session Total Number: 1

BFD Session: 1
  Interface: Vlanif10    VRF Name: vrf1
  Destination     Source          Session-State Create-State
  10.8.1.2        10.8.1.1        Up            Established
  Route-Protocol  Rx-Interval(ms) Tx-Interval(ms) Multiplier
  BGP             1000            1000            5
```

Table 7-231 Description of the display rm bfd-session command output

Item	Description
BFD Global Status	Global BFD status: ● ON: BFD is enabled globally. ● OFF: BFD is disabled globally. To set the global BFD status, run the **bfd** command.
BFD Session Total Number	Total number of BFD sessions.
BFD Session	Number of the BFD session.
Interface	Local physical interface bound to the BFD session.
VRF Name	Name of a VPN instance to which the BFD session is bound to.
Destination	Peer IP address bound to the BFD session.
Source	Source IP address bound to the BFD session.
Session-State	Status of the BFD session: ● AdminDown: indicates that the BFD session is in AdminDown state when the **shutdown** command is run. ● Down: indicates that the BFD session in Down state. ● Init: indicates that the BFD session is in Init state. ● Up: indicates that the BFD session is in Up state.

Item	Description
Create-State	BFD session setup status in RM: - Creating: indicates that the routing protocol notifies RM of the session, but RM does not instruct BFD to set up a session. - Established: indicates that RM notifies BFD to set up a BFD session. You can view the Session-State field to check whether a BFD session is set up.
Route-Protocol	Routing protocol enabled with BFD: - BGP - IS-IS Level-1 - IS-IS Level-2 - IS-IS Level-1-2 - OSPF - RIP - PIM
Rx-Interval(ms)	Configured receiving interval, in milliseconds.
Tx-Interval(ms)	Configured sending interval, in milliseconds.
Multiplier	Configured local detection multiplier.

7.10.23 display rm interface

Function

The **display rm interface** command displays routing management (RM) information on an interface.

Format

display rm interface [*interface-type interface-number*]

display rm interface [**vpn-instance** *vpn-instance-name*] [**ip-address** *ip-address*]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays RM information on the specified interface.	-
vpn-instance *vpn-instance-name*	Displays RM information on the interface of the specified VPN instance.	The value must be an existing VPN instance name.
ip-address *ip-address*	Displays RM information on the interface with the specified destination address.	The value is in dotted decimal notation.

Table 7-232 Description of the display rm interface command output

Item	Description
Name	Name of the interface.
Physical IF Info	Physical interface information.
IfnetIndex	Network segment index of the interface.
State	Current interface status.
Hardware Address	MAC address of the interface.
Slot	Slot ID of the interface.
IntType	Type of the interface.
PriLog	Index of the primary logical interface.
MTU	Maximum transmission unit (MTU) of the interface.
Reference Count	Number of times the interface is referenced.
Bandwidth	Bandwidth of the interface.
Baudrate	Baud rate of the interface.
Delay	Link delay.
Reliability	Link reliability.
Load	Link load.
Quality	Link quality. Currently: ● 0: indicates the link quality is "GOOD". ● 4: indicates the link quality is "LOW".
LDP-ISIS sync capability	Whether synchronization between LDP and IS-IS is enabled: ● enabled: indicates that synchronization is enabled. ● disabled: indicates that synchronization is disabled.
LDP-OSPF sync capability	Whether synchronization between LDP and OSPF is enabled: ● enabled: indicates that synchronization is enabled. ● disabled: indicates that synchronization is disabled.
InstanceID	Instance ID.
Instance Name	Instance name.

Item	Description
Logical IF Info	Logical interface information.
PhyIndex	Physical interface index.
Logical Index	Logical interface index.
Dest	Destination address.
Mask	Mask of the destination address.
Age	Lifetime of the displayed information.

7.10.24 display rm ipv6 bfd-session

Function

The **display rm ipv6 bfd-session** command displays the configurations of BFD sessions in Route Management (RM).

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

display rm ipv6 bfd-session [**all** | [[**vpn-instance** *vpn-instance-name*] [**destination** *destination-address*] [**source** *source-address*] [**interface** *interface-type interface-number*] [**protocol** { **bgp** | **isis-l1** | **isis-l2** | **isis-l1l2** | **ospfv3** | **pim** }]]]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
destination *destination-address*	Specifies the remote destination address.	-
source *source-address*	Specifies the local source address.	-
interface *interface-type interface-number*	Specifies the type and number of an outbound interface.	-
protocol	Indicates a routing protocol. ● **bgp**: indicates the Border Gateway Protocol (BGP). ● **isis-l1**: indicates IS-IS Level-1. ● **isis-l2**: indicates IS-IS Level-2. ● **Isis-l1l2**: indicates IS-IS Level-1-2. ● **ospfv3**: indicates the Open Shortest Path First (OSPF) version 3 protocol. ● **pim**: indicates the Protocol Independent Multicast (PIM) protocol.	-
all	Displays all the configurations of BFD sessions in RM, including the BFD sessions of the public network and VPN. If **all** is not specified, only the configurations of BFD sessions in the public network are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the command to view the BFD sessions that are dynamically created by the routing protocol. The configurations include the global status of BFD, number of BFD sessions, and VPN instance, destination address, source address, interface, and session status of each BFD session. To modify the parameters of a BFD session, refer to the **bfd all-interfaces**, **ospfv3 bfd**, **isis ipv6 bfd**, and **peer bfd**.

Example

Display the configurations of BFD sessions in RM.

```
<HUAWEI> display rm ipv6 bfd-session vpn-instance a destination fc00:0:0::1 source fc00:0:0::2
interface GigabitEthernet0/0/1

BFD Global Status: ON
RM IPv6 BFD Session Total Number: 1
Destination: fc00:0:0::1
Source     : fc00:0:0::2
  Session-State      Local-Discr      Interface             VPN-Name
  Up                 8192             GigabitEthernet0/0/1  a
  Route-Protocol     Rx-Interval(ms)  Tx-Interval(ms)       Multiplier
  BGP                1000             1000                  7
```

Table 7-233 Description of the **display rm ipv6 bfd-session** command output

Item	Description
BFD Global Status	Global status of BFD: ● On: indicates that BFD is enabled globally. ● Off: indicates that BFD is disabled globally.
RM IPv6 BFD Session Total Number	Total number of BFD sessions.
Destination	Destination IP address bound to the BFD session.
Source	Source IP address bound to the BFD session.
Session-State	Current status of a BFD session: ● AdmDown: If the **shutdown (BFD session view)** command is used, the BFD session enters the AdmDown state. ● Down: the BFD session is in the Down state. ● Init: the BFD session is in the Init state. ● Up: the BFD session is in the Up state.
Local-Discr	Local discriminator of the BFD session. ● If the value is 0, it indicates that the RM is notified of the need to set up of a BFD session, but the RM has not instructed BFD to set up the session. ● If the value is not 0, it indicates that RM has instructed BFD to set up a BFD session. If you need to learn the establishment of the BFD session, you can view the Session-State.
Interface	Local physical interface bound to the BFD session.

Item	Description
Route-Protocol	Routing protocol enabled with BFD: ● BGP ● IS-IS Level-1 ● IS-IS Level-2 ● IS-IS Level-1-2 ● OSPFv3 ● PIM
Rx-Interval (ms)	Configured receiving interval in milliseconds.
Tx-Interval (ms)	Configured sending interval in milliseconds.
Multiplier	Configured local detection multiplier.
VPN-Name	Name of the VPN instance.

7.10.25 display rm ipv6 interface

Function

The **display rm ipv6 interface** command displays IPv6 routing management (RM) information on an interface.

Format

display rm ipv6 interface [*interface-type interface-number*]

display rm ipv6 interface [**vpn-instance** *vpn-instance-name*] [**ipv6-address** *ipv6-address*]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays IPv6 RM information on the specified interface.	-
vpn-instance *vpn-instance-name*	Displays IPv6 RM information in a specified VPN instance.	The value must be an existing VPN instance name.
ipv6-address *ipv6-address*	Displays IPv6 RM information with the specified destination IPv6 address.	The value is a 32-digit hexadecimal number, in the X:X:X:X:X:X:X:X format.

Views

Table 7-234 Description of the display rm ipv6 interface command output

Item	Description
Name	Name of an interface.
Physical IF Info	Physical interface information.

Item	Description
IfnetIndex	Network segment index of the interface.
State	Interface status.
IntType	Interface type.
Slot	Slot ID.
PriLog	Index of the primary logical interface.
MTU	Maximum transmission unit (MTU) of the interface.
Ref	Number of times the interface is referenced.
Bandwidth	Bandwidth of the interface.
Baudrate	Baud rate of the interface.
Delay	Link delay.
Reliability	Link reliability.
Load	Link load.
Age	Lifetime of the displayed information.
Logical IF Info	Logical interface information.
PhyIndex	Physical index.
LogiIndex	Logical index.
Dest	Destination IPv6 address.
Mask	Prefix length of the destination IPv6 address.

7.10.26 display router id

Function

The **display router id** command displays the configured router ID.

Format

display router id [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays the configured router ID of the specified VPN instance. If this parameter is not specified, the configured router ID of the public network is displayed.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Some dynamic routing protocols require a router ID to uniquely identify a device. If no router ID is specified when these routing protocols are enabled, the global router ID is used by default. You can run the **display router id** command to check the global router ID.

Example

Display the configured router ID.

```
<HUAWEI> display router id
RouterID:10.1.1.1
```

7.10.27 display route resource

Function

The **display route resource** command displays the total number of IPv4 and IPv6 route prefixes in the IP routing table on the device.

Format

display route resource

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display route resource** command displays the total number of IPv4 and IPv6 route prefixes in the IP routing table on the device.

Example

Display the total number of IPv4 and IPv6 route prefixes in the IP routing table on the device.

```
<HUAWEI> display route resource
 Total number of IPv4 Prefixes: 16
 Total number of IPv6 Prefixes: 13
```

Table 7-235 Description of the **display route resource** command output

Item	Description
Total number of IPv4 Prefixes	Current number of IPv4 route prefixes.
Total number of IPv6 Prefixes	Current number of IPv6 route prefixes.

7.10.28 ecmp load-balance

Function

The **ecmp load-balance** command sets the ECMP load balancing mode.

The **undo ecmp load-balance** command deletes the configured ECMP load balancing mode.

By default, ECMP load balancing is performed on packets based on the source IP address, destination IP address, transport-layer source port number and destination port number.

Product	Support
S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730S-H, S6730-H, S6730-S, and S6730S-S	Supported
SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735S-H, S5736-S and S6720S-S	Not supported

Format

ecmp load-balance sip [**dip**] [**port**]

undo ecmp load-balance sip [**dip**] [**port**]

Parameters

Parameter	Description	Value
sip	Configures ECMP load balancing based on the source IP address.	-
dip	Configures ECMP load balancing based on the destination IP address.	-
port	Configures ECMP load balancing based on the transport-layer source port number and destination port number.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If you run the **ecmp load-balance** command in the system view multiple times, only the latest configuration takes effect.

Example

Configure ECMP load balancing based on the source IP address.

```
<HUAWEI> system-view
[HUAWEI] ecmp load-balance sip
```

7.10.29 ecmp load-balance diffluence

Function

The **ecmp load-balance diffluence** command configures ECMP-based distribution of packets with the same source address and destination address.

The **undo ecmp load-balance diffluence** command cancels ECMP-based distribution of packets with the same source address and destination address.

By default, ECMP-based distribution of packets with the same source address and destination address is not configured.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ecmp load-balance diffluence

undo ecmp load-balance diffluence

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to analyzing the unidirectional traffic of the two communication parties, a packet analysis device needs to analyze traffic between the two communication parties so that the traffic information can be fully analyzed. In this case, the packets of the two communication parties need to be distributed to the same traffic distribution server. The traffic distribution device is required to support the algorithm based on the same source and destination in the specific forwarding procedure. Identical source and destination indicates that bidirectional data packets of a network connection must be sent out from the same outbound interface. To configure ECMP-based traffic distribution of packets with the same source addresses and destination addresses, run the **ecmp load-balance diffluence** command.

Precautions

This function may cause uneven load balancing among IPv4 and IPv6 routes.

In a VXLAN scenario, ECMP-based distribution of packets with the same source address and destination address does not take effect; instead, the configured ECMP load balancing mode takes effect..

Example

Configure ECMP-based distribution of packets with the same source addresses and destination addresses.

```
<HUAWEI> system-view
[HUAWEI] ecmp load-balance diffluence
```

7.10.30 ecmp local-preference disable

Function

The **ecmp local-preference disable** command disables ECMP local preferential forwarding.

The **undo ecmp local-preference disable** command enables ECMP local preferential forwarding.

By default, ECMP local preferential forwarding is enabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ecmp local-preference disable

undo ecmp local-preference disable

Parameters

None

Views

System view

Default Level

2: Configuration level

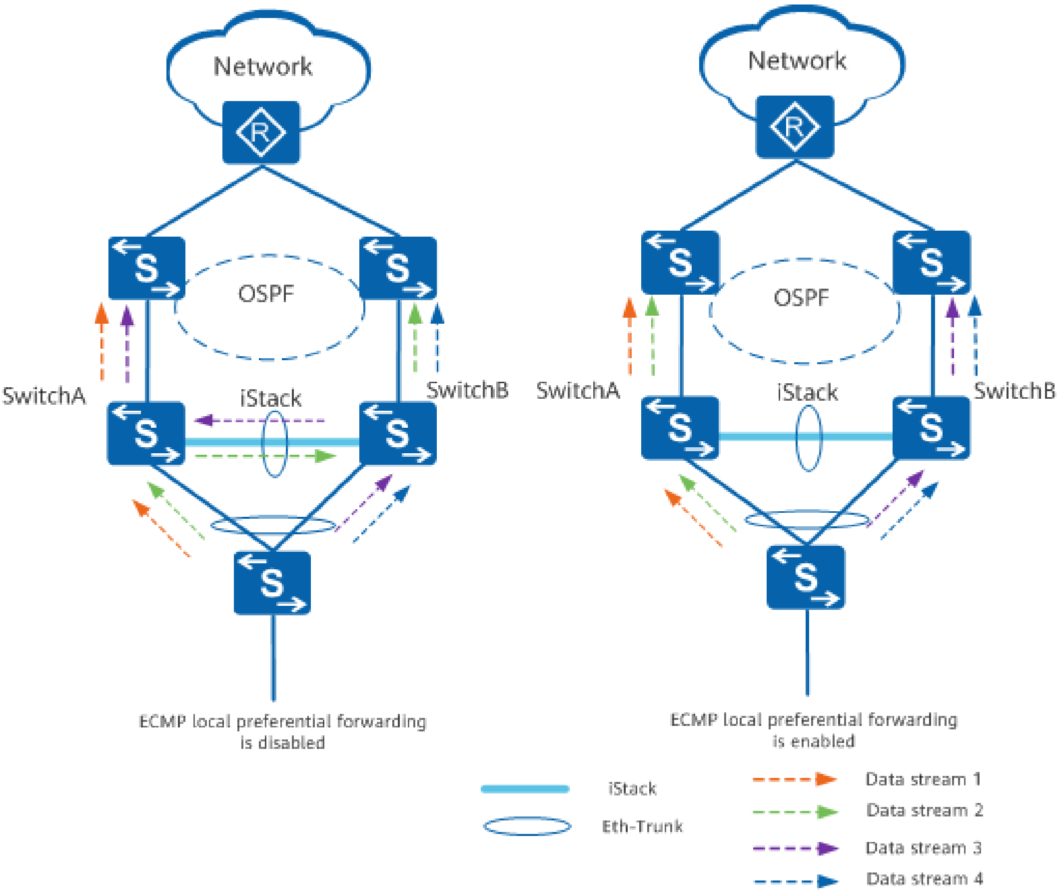
Usage Guidelines

Usage Scenario

Generally, you can use an Eth-Trunk or equal-cost routes to implement traffic load balancing. In a stack, when an inter-chassis Eth-Trunk is unavailable, you can use equal-cost routes for traffic load balancing. Because traffic will be forwarded between member switches, during a stack switchover, traffic switching depends on route convergence, causing some traffic to be lost. In this case, use ECMP local preferential forwarding to improve route convergence performance during a stack switchover and reduce traffic loss. In ECMP local preferential forwarding, traffic reaching the local switch is preferentially forwarded through a local interface. If the local outbound interface fails, traffic is forwarded through an interface on another member switch.

In **Figure 7-4**, SwitchA and SwitchB set up a stack and implement ECMP load balancing with upstream devices. If local preferential forwarding is not configured, traffic reaching SwitchA is load balanced based on ECMP, and some traffic is forwarded through stack cables and sent out from a physical interface on SwitchB. After local preferential forwarding is configured, traffic reaching SwitchA is forwarded through a local physical interface instead of a physical interface on SwitchB.

Figure 7-4 ECMP local preferential forwarding



Configuration Impact

After ECMP local preferential forwarding is enabled in a stack, traffic entering from the local device is preferentially forwarded through a local interface. Therefore, even load balancing of the traffic cannot be guaranteed. To address this issue, you can run the **ecmp local-preference disable** command to disable ECMP local preferential forwarding.

Precautions

- Only a stack supports ECMP local preferential forwarding.
- After the system software of a switch is upgraded to V200R010C00 or later, the **ecmp local-preference disable** configuration is automatically generated.
- Enabling or disabling ECMP local preferential forwarding takes effect immediately for newly added routes and takes effect for existing routes only after these routes are re-advertised.
- ECMP local preferential forwarding does not take effect in the following scenarios:
  - No ARP or ND entry for the next hop of a route is found.
  - The next hop of a route is a blackhole.
  - The next-hop outbound interface of a route is an Eth-Trunk interface.

Example

Disable ECMP local preferential forwarding.

```
<HUAWEI> system-view
[HUAWEI] ecmp local-preference disable
Warning: The operation will take effect only on routing tables generated later.
```

7.10.31 fib regularly-refresh

Function

The **fib regularly-refresh** command configures the entire FIB entry update interval, FIB entry update interval per cycle, and the number of FIB entries updated per cycle.

The **undo fib regularly-refresh** command restores the default entire FIB entry update interval, FIB entry update interval per cycle, and the number of FIB entries updated per cycle.

By default, the FIB entry update interval per cycle is 1 second, and the number of FIB entries updated per cycle is 50. The entire FIB entry update interval is 1 minute on the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H, and is fixed to 1440 minutes on other devices.

Format

fib regularly-refresh { **interval** *interval* [**entry-number** *entry-number*] | **entry-number** *entry-number* | **cycle-interval** *cycle-interval* }

undo fib regularly-refresh { **interval** *interval* [**entry-number** *entry-number*] | **entry-number** *entry-number* | **cycle-interval** *cycle-interval* }

Parameters

Parameter	Description	Value
interval *interval*	Specifies an interval at which FIB entries are refreshed.	The value is an integer ranging from 1 to 300, in seconds.

Parameter	Description	Value
entry-number *entry-number*	Specifies the number of FIB entries refreshed per circle.	The value is an integer ranging from 20 to 2000.
cycle-interval *cycle-interval*	Specifies the entire interval at which FIB entries are updated.	The value is an integer ranging from 1 to 1440, in minutes. **NOTE** This parameter is supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Regular FIB entry updating occupies system resources, including CPU and memory resources. A longer update interval and a smaller number of updated entries result in less impact on other services. You can flexibly configure the update interval and the number of entries to be updated based on system resources.

To allow underlying data to be forwarded in real-time and effective ways, you can configure a device to update FIB entries in cycles. The *cycle-interval* parameter specifies the interval for FIB entry update per cycle. Note that the *cycle-interval*, *interval*, and *entry-number* parameters together determine the FIB entry update process. As an example, assume that a device has 500 FIB entries.

- If *interval* is set to 1 second, *entry-number* is set to 50, and *cycle-interval* is set to 1 minute, the 500 FIB entries are updated in 10 cycles (with 50 FIB entries updated in each cycle), and the entry update can be completed within 10s (1s for each cycle). The device stays idle from 10s to 1 minute (entire FIB entry update interval).
- If *interval* is set to 10 seconds, *entry-number* is set to 50, and *cycle-interval* is set to 1 minute, the 500 FIB entries are still updated in 10 cycles, taking a total of 100 seconds. In this case, the update period exceeds 1 minute, and the device cycles update from the next minute (a total of 2 minutes at this point). That is, the device updates FIB entries at an interval of 2 minutes.

Prerequisites

Regular FIB entry updating has been enabled using the **undo fib regularly-refresh disable** command in the system view. This function is enabled by default.

Example

Set an interval at which FIB entries are updated to 5 seconds and the number of FIB entries updated per circle to 200.

```
<HUAWEI> system-view
[HUAWEI] fib regularly-refresh interval 5 entry-number 200
```

7.10.32 fib regularly-refresh disable

Function

The **fib regularly-refresh disable** command disables the FIB entry update function.

The **undo fib regularly-refresh disable** command enables the FIB entry update function.

By default, the FIB entry update function is enabled.

Format

fib regularly-refresh disable

undo fib regularly-refresh disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a device starts FIB entry update 30 minutes after a device is powered on, and the update is performed regularly at an interval of 1 minute. Updating FIB entries occupy system resources. To avoid a high CPU usage within a short period, run the **fib regularly-refresh** { **interval** *interval* [**entry-number** *entry-number*] | **entry-number** *entry-number* | **cycle-interval** *cycle-interval* } command to set the entire FIB entry update interval or the FIB entry update interval per cycle to a larger value or reduce the number of FIB entries updated per cycle. If the CPU usage problem still persists, run the **fib regularly-refresh disable** command to disable the FIB entry update function.

Precautions

Disabling the FIB entry update function may cause a failure to rectify certain hardware faults in time. Exercise caution when running the **fib regularly-refresh disable** command.

Example

Disable the FIB from being refreshed.

```
<HUAWEI> system-view
[HUAWEI] fib regularly-refresh disable
```

7.10.33 fib threshold-alarm

Function

The **fib threshold-alarm** command enables the alarm function for IPv4 route prefix usage and sets the alarm threshold.

The **undo fib threshold-alarm** command restores the default alarm threshold.

By default, the alarm function for IPv4 route prefix usage is enabled. The upper alarm threshold is 85% and the lower alarm threshold is 75%.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

fib threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo fib threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold for IPv4 route prefix usage.	The value is an integer that ranges from 1 to 100, in percentage.

Parameter	Description	Value
lower-limit *lower-limit-value*	Sets the lower alarm threshold for IPv4 route prefix usage.	The value is an integer that ranges from 1 to 100, in percentage.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Overload of the IPv4 route prefix usage will cause entries unable to be delivered and result in a forwarding failure.

- When the upper alarm threshold for IPv4 route prefix usage is smaller than 100%, an alarm is generated when the resource usage exceeds the upper alarm threshold or reaches 100%.
- When the upper alarm threshold for IPv4 route prefix usage is set to 100%, an alarm is generated when the resource usage reaches 100%.

Precautions

In versions earlier than V200R019C00SPC300, the upper alarm threshold for the IPv4 route prefix usage can be greater than or equal to the lower alarm threshold. In V200R019C00SPC300 and later versions, the upper alarm threshold for the IPv4 route prefix usage must be greater than the lower alarm threshold. If the upper alarm threshold for the IPv4 route prefix usage is configured to be equal to the lower alarm threshold on a switch running a version earlier than V200R019C00SPC300, the configuration will be lost after the switch is upgraded to V200R019C00SPC300 or a later version, and the upper and lower alarm thresholds will be restored to the default settings.

Example

Enable the alarm function for IPv4 route prefix usage and set the upper and lower alarm thresholds to 85% and 60% respectively.

```
<HUAWEI> system-view
[HUAWEI] fib threshold-alarm upper-limit 85 lower-limit 60
```

7.10.34 fib trap lpm-fail enable

Function

The **fib trap lpm-fail enable** command enables the trap function for the event that FIB entries fail to be delivered.

The **undo fib trap lpm-fail enable** command disables the trap function for the event that FIB entries fail to be delivered.

By default, the trap function is enabled for the event that FIB entries fail to be delivered.

NOTE

Only the S5735S-H, S5736-S and S6720S-S support this command.

Format

fib trap lpm-fail enable

undo fib trap lpm-fail enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

FIB entries may fail to be delivered because of an LPM algorithm error. For fault location, you can run the **fib trap lpm-fail enable** command to enable the trap function for the event that FIB entries fail to be delivered and check trap function. After this trap function is disabled, no trap is generated when FIB entries fail to be delivered because of an LPM algorithm error.

Precautions

Traps are generated for the event that FIB entries fail to be delivered only when this trap function is enabled. To set the trap interval, run the **fib trap lpm-fail interval** command. To set the maximum number of traps generated in a trap interval, run the **fib trap lpm-fail history** command.

Example

Enable the trap function for the event that FIB entries fail to be delivered because of an LPM algorithm error.

```
<HUAWEI> system-view
[HUAWEI] fib trap lpm-fail enable
```

7.10.35 fib trap lpm-fail history

Function

The **fib trap lpm-fail history** command sets the maximum number of traps generated when FIB entries fail to be delivered.

The **undo fib trap lpm-fail history** command restores the default maximum number of traps generated when FIB entries fail to be delivered.

By default, a maximum of 10 traps are generated each time FIB entries fail to be delivered.

NOTE

Only the S5735S-H, S5736-S and S6720S-S support this command.

Format

fib trap lpm-fail history *history-number*

undo fib trap lpm-fail history

Parameters

Parameter	Description	Value
history-number	Sets the maximum number of traps generated each time FIB entries fail to be delivered.	The value is an integer that ranges from 10 to 30.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

FIB entries may fail to be delivered because of an LPM algorithm error. By default, a maximum of 10 traps are generated each time FIB entries fail to be delivered. To change the maximum number of traps generated each time FIB entries fail to be delivered, run the **fib trap lpm-fail history** *history-number* command.

Example

Set the maximum number of traps generated each time FIB entries fail to be delivered to 30.

```
<HUAWEI> system-view
```

```
[HUAWEI] fib trap lpm-fail history 30
```

7.10.36 fib trap lpm-fail interval

Function

The **fib trap lpm-fail interval** command sets the interval for generating traps when FIB entries fail to be delivered.

The **undo fib trap lpm-fail interval** command restores the default interval for generating traps when FIB entries fail to be delivered.

By default, traps are generated at an interval of 60s when FIB entries fail to be delivered.

NOTE

Only the S5735S-H, S5736-S and S6720S-S support this command.

Format

fib trap lpm-fail interval *interval-number*

undo fib trap lpm-fail interval

Parameters

Parameter	Description	Value
interval-number	Sets the interval for generating traps.	The value is an integer that ranges from 30 to 3600, in seconds. The default value is 60.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

FIB entries may fail to be delivered because of an LPM algorithm error. By default, traps are generated at an interval of 60s when FIB entries fail to be delivered because of an LPM algorithm error. To change the interval, run the **fib trap lpm-fail interval** *interval-number* command.

Example

Set the interval for generating traps when FIB entries fail to be delivered to 90s.

```
<HUAWEI> system-view
[HUAWEI] fib trap lpm-fail interval 90
```

7.10.37 ip frr (system view)

Function

The **ip frr** command enables IP FRR for public routes.

The **undo ip frr** command disables IP FRR for public routes.

By default, IP FRR is disabled for public routes.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ip frr route-policy *route-policy-name*

undo ip frr [**all**]

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Enables IP FRR for public routes matching the specified route-policy.	The value must be an existing route-policy.
all	Disables IP FRR for all public and private routes. If this parameter is not specified, IP FRR is disabled for all public routes.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the development of the network, services such as audio, online video, and finance have more requirements for real time. Generally, active/standby links are deployed on the network to ensure service stability.

However, under traditional forwarding modes, when multiple routes to the same destination exist, switch selects the optimal route, which is delivered to FIB table to direct data forwarding. When the optimal link is faulty, switch waits for the completion of route convergence, then selects another optimal route, and then deliver the route to the FIB table. Then the service is recovered. This process leads to a long-time service interruption and cannot meet service requirements.

Using the **ip frr** command, you can enable IP FRR of the public network. IP FRR can specify a backup next hop and a backup interface and set backup forwarding information for IPv4 routes. When the active link is faulty, the system can switch the traffic immediately to the backup link. This process is irrelevant to route convergence and therefore services are interrupted for short time.

Pre-configuration Tasks

The **ip frr** command should be used with the **apply backup-interface** command and the **apply backup-nexthop** command. It is required to use the **route-policy** command to create route-policy at first, in which the **apply backup-interface** command and the **apply backup-nexthop** command are used to set a backup outbound interface and a backup next hop for IPv4 route of the public network.

Precautions

Only one policy can be used at one time. New configuration will replace the previous one if another policy is configured. Configuration in the system view and that in the VPN instance IPv4 address family view will not interfere each other.

Using the **undo ip frr all** command, IP FRR of all the public network and the private networks is disabled. Use it with caution.

Example

Specify a backup outbound interface and a backup next hop in route-policy **ip_frr_rp** and enable IP FRR for public routes in the system view.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] apply backup-interface vlanif 100
[HUAWEI-route-policy] apply backup-nexthop 192.168.20.2
[HUAWEI-route-policy] quit
[HUAWEI] ip frr route-policy ip_frr_rp
```

7.10.38 ip prefix-limit

Function

The **ip prefix-limit** command configures a limit on the number of IPv4 public route prefixes.

The **undo ip prefix-limit** command restores the default configuration.

By default, the maximum number of IPv4 public route prefixes is not limited.

Format

ip prefix-limit *number* { *alert-percent* [**route-unchanged**] | **simply-alert** }

undo ip prefix-limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of IPv4 public route prefixes.	The value is an integer, and the minimum value is 1. The maximum number is determined by the license file.
alert-percent	Specifies the percentage of the maximum number of IPv4 public route prefixes. If you specify *alert-percent* in the command, when the number of IPv4 public route prefixes exceeds the value calculated by (*number* x *alert-percent*) / 100, an alarm is generated. Additional IPv4 public route prefixes can still be added to the routing table until the number of IPv4 public route prefixes reaches *number*. Subsequent route prefixes are discarded.	The value is an integer ranging from 1 to 100.
route-unchanged	Indicates that the routing table remains unchanged. If you decrease *alert-percent* after the number of IPv4 public route prefixes exceeds *number*, whether the routing table remains unchanged is determined by **route-unchanged**. • If you specify **route-unchanged** in the command, the routing table remains unchanged. • If you do not specify **route-unchanged** in the command, the system deletes the routes from the routing table and re-adds routes. By default, the system deletes the routes from the routing table and re-adds routes.	-

Parameter	Description	Value
simply-alert	Indicates the following function: If you specify *simply-alert* in the command, new IPv4 public route prefixes can still be added to the routing table and only an alarm is generated after the number of IPv4 public route prefixes exceeds *number*. However, when the total number of private and public route prefixes reaches the limit on the number of unicast route prefixes specified in the PAF file, subsequent IPv4 public route prefixes are discarded.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the switch imports a large number of routes, system performance may be affected when processing services because the routes consume a lot of system resources. To improve system security and reliability, you can run the **ip prefix-limit** command to configure a limit on the number of IPv4 public route prefixes. When the number of IPv4 public route prefixes exceeds the limit, an alarm is generated, prompting you to check whether unneeded IPv4 public route prefixes exist.

Configuration Impact

After the **ip prefix-limit** command is run, the switch may discard unneeded IPv4 public route prefixes.

- If the number of IPv4 public route prefixes exceeds the value calculated from *number* x *alert-percent*/100, an alarm (RM_1.3.6.1.4.1.2011.5.25.145.19.1.3 hwPublicIpv4PrefixThresholdExceed) is generated.
- If the number of IPv4 public route prefixes exceeds *number*, an alarm (RM_1.3.6.1.4.1.2011.5.25.145.19.1.1 hwPublicIpv4PrefixExceed) is generated.
- If the number of IPv4 public route prefixes falls below the value calculated from (*number* x (*alert-percent* – 5))/100, a clear alarm (RM_1.3.6.1.4.1.2011.5.25.145.19.1.4 hwPublicIpv4PrefixThresholdExceedClear) is generated.
- If the number of IPv4 public route prefixes exceeds *number*, a clear alarm (RM_1.3.6.1.4.1.2011.5.25.145.19.1.2 hwPublicIpv4PrefixExceedClear) is generated.

Precautions

If you run the **ip prefix-limit** command for several times, the last configuration overrides previous configurations.

After the number of IPv4 public route prefixes exceeds the limit, note the following rules:

- If you run the **ip prefix-limit** command to increase *number* or the **undo ip prefix-limit** command to delete the limit, the switch relearns IPv4 public route prefixes.
- Direct and static routes can still be added to the IP routing table.

Example

Configure **simply-alert** so that only an alarm is generated when the switch imports more than 10000 IPv4 public route prefixes.

```
<HUAWEI> system-view
[HUAWEI] ip prefix-limit 10000 simply-alert
```

7.10.39 ip prefix-limit log-interval

Function

The **ip prefix-limit log-interval** command configures an interval at which logs are generated after the number of IPv4 public route prefixes exceeds the limit.

The **undo ip prefix-limit log-interval** command restores the default configuration.

By default, the system generates logs at an interval of 5s after the number of IPv4 public route prefixes exceeds the limit.

Format

ip prefix-limit log-interval *interval*

undo ip prefix-limit log-interval

Parameters

Parameter	Description	Value
interval	Specifies an interval at which logs are generated after the number of IPv4 public route prefixes exceeds the limit.	The value is an integer ranging from 1 to 60, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The system generates logs at an interval of 5s after the number of IPv4 public route prefixes exceeds the limit. You can run the **ip prefix-limit log-interval** command to set a larger value for the interval to decrease the frequency at which these logs are generated.

The maximum number of IPv4 public route prefixes supported by the routing table can be adjusted using the **ip prefix-limit** command.

Precautions

If a log is generated to record the event that the number of IPv4 public route prefixes reaches the limit, no more routes can be added to the routing table, and subsequent routes are discarded.

Example

Set the interval at which logs are generated after the number of IPv4 public route prefixes exceeds the limit to 30s.

```
<HUAWEI> system-view
[HUAWEI] ip prefix-limit log-interval 30
```

7.10.40 ip route recursive-lookup default-route protocol

Function

The **ip route recursive-lookup default-route protocol** command sets specified routes to recurse to the default route.

The **undo ip route prefix-priority-scheduler protocol** command cancels specified routes from recursing to the default route.

By default, routes cannot recurse to the default route.

Format

ip route recursive-lookup default-route protocol { **static** | **bgp** | **msr** }

undo ip route recursive-lookup default-route protocol { **static** | **bgp** | **msr** }

NOTE

- Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **bgp** parameter.
- Only the S5720-LI, S5720S-LI, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **msr** parameter.

Parameters

Parameter	Description	Value
static	Static route	-
bgp	BGP Route	-
msr	Multicast Static Route	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traffic cannot be transmitted along static, BGP, or multicast static routes with an unreachable next hop. In this situation, route recursion is required. Run the **ip route recursive-lookup default-route protocol** command to recurse these routes to the default route.

Precautions

After route recursion, the actual forwarding route may change.

Example

Set static routes to recurse to the default route.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup default-route protocol static
```

7.10.41 ip route trace unicast-route-change disable

Function

The **ip route trace unicast-route-change disable** command disables recording of unicast route changes.

The **undo ip route trace unicast-route-change disable** command enables recording of unicast route changes.

By default, recording of unicast route changes is enabled.

Format

ip route trace unicast-route-change disable

undo ip route trace unicast-route-change disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If recording of unicast route changes is enabled, information about changes in direct, static, OSPF, IS-IS, and BGP routes that are delivered to the routing table is recorded.

Example

Disable recording of unicast route changes.

```
<HUAWEI> system-view
[HUAWEI] ip route trace unicast-route-change disable
```

7.10.42 ipv6 fib-loadbalance-type hash-based

Function

The **ipv6 fib-loadbalance-type hash-based** command configures packets sent from a specified source to a specified destination to be forwarded using the same route.

The **undo ipv6 fib-loadbalance-type hash-based** command restores the default configuration.

By default, flow-based load balancing is used.

Format

ipv6 fib-loadbalance-type hash-based

undo ipv6 fib-loadbalance-type hash-based

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

This command configures packets sent from a specified source to a specified destination to be forwarded using the same route. This command takes effect only when the FIB cache fails.

Example

Configure packets sent from a specified source to a specified destination to be forwarded using the same route.

```
<HUAWEI> system-view
[HUAWEI] ipv6 fib-loadbalance-type hash-based
```

7.10.43 ipv6 fib regularly-refresh

Function

The **ipv6 fib regularly-refresh** command configures the entire IPv6 FIB entry update interval, IPv6 FIB entry update interval per cycle, and the number of IPv6 FIB entries updated per cycle.

The **undo ipv6 fib regularly-refresh** command restores the default entire IPv6 FIB entry update interval, IPv6 FIB entry update interval per cycle, and the number of IPv6 FIB entries updated per cycle.

By default, the IPv6 FIB entry update interval per cycle is 1 second, and the number of IPv6 FIB entries updated per cycle is 50. The entire IPv6 FIB entry update interval is 1 minute on the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H, and is fixed to 1440 minutes on other devices.

Format

ipv6 fib regularly-refresh { **interval** *interval* | **entry-number** *entry-number* | **cycle-interval** *cycle-interval* }

undo ipv6 fib regularly-refresh { **interval** *interval* | **entry-number** *entry-number* | **cycle-interval** *cycle-interval* }

Parameters

Parameter	Description	Value
interval *interval*	Specifies an interval at which IPv6 FIB entries are refreshed.	The value is an integer ranging from 1 to 300, in seconds.

Parameter	Description	Value
entry-number *entry-number*	Specifies the number of IPv6 FIB entries refreshed per circle.	The value is an integer ranging from 20 to 2000.
cycle-interval *cycle-interval*	Specifies the entire interval at which IPv6 FIB entries are updated.	The value is an integer ranging from 1 to 1440, in minutes. **NOTE** This parameter is supported only by the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Regular IPv6 FIB entry updating occupies system resources, including CPU and memory resources. A longer update interval and a smaller number of updated entries result in less impact on other services. You can flexibly configure the update interval and the number of entries to be updated based on system resources.

To allow underlying data to be forwarded in real-time and effective ways, you can configure a device to update IPv6 FIB entries in cycles. The *cycle-interval* parameter specifies the interval for IPv6 FIB entry update per cycle. Note that the *cycle-interval*, *interval*, and *entry-number* parameters together determine the IPv6 FIB entry update process. As an example, assume that a device has 500 IPv6 FIB entries.

- If *interval* is set to 1 second, *entry-number* is set to 50, and *cycle-interval* is set to 1 minute, the 500 FIB entries are updated in 10 cycles (with 50 FIB entries updated in each cycle), and the entry update can be completed within 10s (1s for each cycle). The device stays idle from 10s to 1 minute (entire FIB entry update interval).
- If *interval* is set to 10 seconds, *entry-number* is set to 50, and *cycle-interval* is set to 1 minute, the 500 FIB entries are still updated in 10 cycles, taking a total of 100 seconds. In this case, the update period exceeds 1 minute, and the device cycles update from the next minute (a total of 2 minutes at this point). That is, the device updates FIB entries at an interval of 2 minutes.

Prerequisites

Regular IPv6 FIB entry updating has been enabled using the **undo ipv6 fib regularly-refresh disable** command in the system view. This function is enabled by default.

Example

Set an interval at which IPv6 FIB entries are updated to 5 seconds and the number of FIB entries updated per circle to 200.

```
<HUAWEI> system-view
[HUAWEI] ipv6 fib regularly-refresh interval 5 entry-number 200
```

7.10.44 ipv6 fib regularly-refresh disable

Function

The **ipv6 fib regularly-refresh disable** command disables IPv6 FIB regularly-refresh.

The **undo ipv6 fib regularly-refresh disable** command enables IPv6 FIB regularly-refresh.

By default, IPv6 FIB regularly-refresh is enabled.

Format

ipv6 fib regularly-refresh disable

undo ipv6 fib regularly-refresh disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During peak hours, refreshing the IPv6 FIB can cause over-high CPU usage and affect service reliability. To resolve this problem, run the **ipv6 fib regularly-refresh disable** command to disable IPv6 FIB regularly-refresh. After the CPU usage restores to a normal state, run the **undo ipv6 fib regularly-refresh disable** command to restore IPv6 FIB regularly-refresh.

Precautions

Disabling IPv6 FIB regularly-refresh may prevent the rectification of certain hardware forwarding entry faults. Exercise caution when running the **ipv6 fib regularly-refresh disable** command.

Example

Disable IPv6 FIB regularly-refresh.

```
<HUAWEI> system-view
[HUAWEI] ipv6 fib regularly-refresh disable
Warning: This operation will disable the function of the FIB regularly refresh,Confirm?[Y/N]:y
Info: The function of the FIB regularly refresh is disabled.
```

7.10.45 ipv6 prefix-limit

Function

The **ipv6 prefix-limit** command configures a limit on the number of IPv6 public route prefixes.

The **undo ipv6 prefix-limit** command restores the default configuration.

By default, the maximum number of IPv6 public route prefixes is not limited.

Format

ipv6 prefix-limit *number* { *alert-percent* [**route-unchanged**] | **simply-alert** }

undo ipv6 prefix-limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of IPv6 public route prefixes.	The value is an integer, and the minimum value is 1. The maximum number is determined by the license file.
alert-percent	Specifies the percentage of the maximum number of IPv6 public route prefixes. If you specify *alert-percent* in the command, when the number of IPv6 public route prefixes exceeds the value calculated by (*number* x *alert-percent*) / 100, an alarm is generated. Additional IPv6 public route prefixes can still be added to the routing table until the number of IPv6 public route prefixes reaches *number*. Subsequent route prefixes are discarded.	The value is an integer ranging from 1 to 100.

Parameter	Description	Value
route-unchanged	Indicates that the routing table remains unchanged. If you decrease *alert-percent* after the number of IPv6 public route prefixes exceeds *number*, whether the routing table remains unchanged is determined by **route-unchanged**. ● If you specify **route-unchanged** in the command, the routing table remains unchanged. ● If you do not specify **route-unchanged** in the command, the system deletes the routes from the routing table and re-adds routes. By default, the system deletes the routes from the routing table and re-adds routes.	-
simply-alert	Indicates the following function: If you specify *simply-alert* in the command, new IPv6 public route prefixes can still be added to the routing table and only an alarm is generated after the number of IPv6 public route prefixes exceeds *number*. However, when the total number of private and public route prefixes reaches the limit on the number of unicast route prefixes specified in the PAF file, subsequent IPv6 public route prefixes are discarded.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the switch imports a large number of routes, system performance may be affected when processing services because the routes consume a lot of system resources. To improve system security and reliability, you can run the **ipv6 prefix-limit** command to configure a limit on the number of IPv6 public route prefixes. When the number of IPv6 public route prefixes exceeds the limit, an alarm is generated, prompting you to check whether unneeded IPv6 public route prefixes exist.

Configuration Impact

After the **ipv6 prefix-limit** command is run, the switch may discard unneeded IPv6 public route prefixes.

Precautions

If you run the **ipv6 prefix-limit** command for several times, the last configuration overrides previous configurations.

After the number of IPv6 public route prefixes exceeds the limit, note the following rules:

- If you run the **ipv6 prefix-limit** command to increase *number* or the **undo ipv6 prefix-limit** command to delete the limit, the switch relearns IPv6 public route prefixes.
- Direct and static routes can still be added to the IPv6 routing table.

Example

Configure **simply-alert** so that only an alarm is generated when the switch imports more than 10000 IPv6 public route prefixes.

```
<HUAWEI> system-view
[HUAWEI] ipv6 prefix-limit 10000 simply-alert
```

7.10.46 ipv6 prefix-limit log-interval

Function

The **ipv6 prefix-limit log-interval** command configures an interval at which logs are generated after the number of IPv6 public route prefixes exceeds the limit.

The **undo ipv6 prefix-limit log-interval** command restores the default configuration.

By default, the system generates logs at an interval of 5s after the number of IPv6 public route prefixes exceeds the limit.

Format

ipv6 prefix-limit log-interval *interval*

undo ipv6 prefix-limit log-interval

Parameters

Parameter	Description	Value
interval	Specifies an interval at which logs are generated after the number of IPv6 public route prefixes exceeds the limit.	The value is an integer ranging from 1 to 60, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The system generates logs at an interval of 5s after the number of IPv6 public route prefixes exceeds the limit. You can run the **ip prefix-limit log-interval** command to set a larger value for the interval to decrease the frequency at which these logs are generated.

The maximum number of IPv6 public route prefixes supported by the routing table can be adjusted using the **ipv6 prefix-limit** command.

Precautions

If a log is generated to record the event that the number of IPv6 public route prefixes reaches the limit, no more routes can be added to the routing table, and subsequent routes are discarded.

Example

Set the interval at which logs are generated after the number of IPv6 public route prefixes exceeds the limit to 30s.

```
<HUAWEI> system-view
[HUAWEI] ipv6 prefix-limit log-interval 30
```

7.10.47 ipv6 frr (system view)

Function

The **ipv6 frr** command enables IPv6 FRR for public routes.

The **undo ipv6 frr** command disables IPv6 FRR for public routes.

By default, IPv6 FRR is disabled for public routes.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ipv6 frr route-policy *route-policy-name*

undo ipv6 frr [**all**]

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Enables IPv6 FRR for public routes matching the specified route-policy.	The value must be an existing route-policy.
all	Disables IPv6 FRR for all public and private routes. If this parameter is not specified, IPv6 FRR is disabled for all public routes.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the development of the network, services such as audio, online video, and finance have more requirements for real time. Generally, active/standby links are deployed on the network to ensure service stability.

However, under traditional forwarding modes, when multiple routes to the same destination exist, switch selects the optimal route, which is delivered to FIB table to direct data forwarding. When the optimal link is faulty, switch waits for the completion of route convergence, then selects another optimal route, and then deliver the route to the FIB table. Then the service is recovered. This process leads to a long-time service interruption and cannot meet service requirements.

Using the **ipv6 frr** command, you can enable IPv6 FRR of the public network. IPv6 FRR can specify a backup next hop and a backup interface and set backup forwarding information for IPv6 routes. When the active link is faulty, the system can switch the traffic immediately to the backup link. This process is irrelevant to route convergence and therefore services are interrupted for short time.

Pre-configuration Tasks

The **ipv6 frr** command should be used with the **apply ipv6 backup-interface** command and the **apply ipv6 backup-nexthop** command. It is required to use the **route-policy** command to create route-policy at first, in which the **apply ipv6 backup-interface** command and the **apply ipv6 backup-nexthop** command are used to set a backup outbound interface and a backup next hop for IPv6 route of the public network.

Precautions

Only one policy can be used at one time. New configuration will replace the previous one if another policy is configured. Configuration in the system view and that in the VPN instance IPv6 address family view will not interfere each other.

Using the **undo ipv6 frr all** command, IPv6 FRR of all the public network and the private networks is disabled. Use it with caution.

Example

Specify a backup outbound interface and a backup next hop in route-policy **ipv6_frr_rp** and enable IPv6 FRR for public routes in the system view.

```
<HUAWEI> system-view
[HUAWEI] route-policy ipv6_frr_rp permit node 10
[HUAWEI-route-policy] apply ipv6 backup-interface vlanif 100
[HUAWEI-route-policy] apply ipv6 backup-nexthop 2001:db8:1::1
[HUAWEI-route-policy] quit
[HUAWEI] ipv6 frr route-policy ipv6_frr_rp
```

7.10.48 l3-forward-entry aging

Function

The **l3-forward-entry aging enable** command enables the l3-forward-entry aging function.

The **undo l3-forward-entry aging enable** command disables the l3-forward-entry aging function.

By default, the l3-forward-entry aging function is disabled.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Format

l3-forward-entry aging enable

undo l3-forward-entry aging enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **l3-forward-entry aging enable** command must be used together with the **l3-forward-entry regularly-check** command. After the l3-forward-entry aging function is enabled, the system reads the periodic l3-forward-entry check result everyday between 2 am and 5 am. When residual Layer 3 forwarding entries exist for more than 48 hours, the system triggers resource recycling and entry deletion.

Example

Enable the l3-forward-entry aging function.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry aging enable
```

Disable the l3-forward-entry aging function.

```
<HUAWEI> system-view
[HUAWEI] undo l3-forward-entry aging enable
```

7.10.49 l3-forward-entry regularly-check

Function

The **l3-forward-entry regularly-check** command enables periodic l3-forward-entry check and sets the periodic l3-forward-entry check interval, scanning time for each round of check, and number of entries checked in each round of check.

The **undo l3-forward-entry regularly-check** command restores the default settings of periodic l3-forward-entry check.

By default, periodic l3-forward-entry check is enabled, the periodic l3-forward-entry check interval is 1 minute, the scanning time for each round of check is 1 second, and the number of entries checked in each round of check is 200.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

l3-forward-entry regularly-check { **enable** | **cycle-interval** *cycle-interval-value* | **interval** *interval-value* | **entry-number** *number* }

undo l3-forward-entry regularly-check { **enable** | **cycle-interval** | **interval** | **entry-number** }

Parameters

Parameter	Description	Value
enable	Enables periodic l3-forward-entry check	-
cycle-interval *cycle-interval-value*	Sets the periodic l3-forward-entry check interval.	The value is an integer that ranges from 1 to 1440, in minutes.
interval *interval-value*	Sets the scanning time for each round of l3-forward-entry check.	The value is an integer that ranges from 1 to 300, in seconds.
entry-number *number*	Sets the number of entries checked in each round of check.	The value is an integer that ranges from 20 to 2000.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After periodic l3-forward-entry check is configured, the device periodically checks l3-forward-entries to ensure realtime and valid bottom-layer forwarded data and records the check result. The check result can help locate problems of Layer 3 forwarding software resource leak and residual Layer 3 forwarding hardware entries.

The three parameters, *cycle-interval*, *interval*, and *entry-number*, together determine the periodic l3-forward-entry check process. For example, the device has a total of 2,000 l3-forward-entries:

- If the three parameters use their default values, that is, 2,000 entries need to be checked in 10 rounds of check and can be checked within 10 seconds (with the scanning time of each round of check as 1 second), the system is idle during the period between 10 seconds to 1 minutes (periodic check interval).
- If *cycle-interval* is set to 1 minute, *interval* is set to 10 seconds, and *entry-number* uses the default value, 2,000 entries still need to be updated for 10 rounds of check, and a total of 100 seconds is required to finish updating these entries. Then the update time will exceed 1 minute, so the device needs to start periodic update within the next 1 minute. In this situation, periodic update is performed at an interval of 2 minutes.

Precautions

Periodic l3-forward-entry check occupies system resources, including CPU and memory resources. A longer check interval and fewer entries indicate a smaller impact on other services. You can flexibly configure the l3-forward-entry check interval and number of checked entries based on system resources.

Example

Enable periodic l3-forward-entry check.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry regularly-check enable
```

Set the periodic l3-forward-entry check interval to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry regularly-check cycle-interval 10
```

Set the scanning time for each round of l3-forward-entry check to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry regularly-check interval 5
```

Set the number of entries checked in each round of check to 500.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry regularly-check entry-number 500
```

Disable periodic l3-forward-entry check.

```
<HUAWEI> system-view
[HUAWEI] undo l3-forward-entry regularly-check enable
```

7.10.50 l3-forward-entry self-healing enable

Function

The **l3-forward-entry self-healing enable** command enables l3-forward-entry self-healing.

The **undo l3-forward-entry self-healing enable** command disables l3-forward-entry self-healing.

By default, the l3-forward-entry self-healing function is disabled.

Product	Support

Format

l3-forward-entry self-healing enable

undo l3-forward-entry self-healing enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After the **l3-forward-entry regularly-check** command is configured on a switch, the switch periodically checks l3-forward-entries to ensure real-time and effective forwarding of data at the bottom layer. In this situation, if the **l3-forward-entry self-healing enable** command is configured to enable l3-forward-entry self-healing, the switch can repair l3-forward-entries for self-healing based on the check result to ensure correct packet forwarding.

Example

Enable l3-forward-entry self-healing.

```
<HUAWEI> system-view
[HUAWEI] l3-forward-entry self-healing enable
```

7.10.51 l3-interface regularly-refresh

Function

The **l3-interface regularly-refresh** command enables periodic l3-interface entry update and configures the periodic l3-interface entry update interval, scanning time for each round of update, and number of entries updated in each round of update.

The **undo l3-interface regularly-refresh** command restores the default configuration.

By default, periodic l3-interface entry update is enabled, the periodic l3-interface entry update interval is 1 minute, the scanning time for each round of update is 1 second, and the number of entries updated in each round of update is 50.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

l3-interface regularly-refresh { **enable** | **cycle-interval** *cycle-interval-value* | **scan-interval** *scan-interval-value* | **entry-number** *entry-number* }

undo l3-interface regularly-refresh { **enable** | **cycle-interval** | **scan-interval** | **entry-number** }

Parameters

Parameter	Description	Value
enable	Enables periodic l3-interface entry update.	-
cycle-interval *cycle-interval-value*	Sets the periodic l3-interface entry update interval.	The value is an integer that ranges from 1 to 1440, in minutes.

Parameter	Description	Value
scan-interval *scan-interval-value*	Sets the scanning time for each round of l3-interface entry update.	The value is an integer that ranges from 1 to 300, in seconds.
entry-number *entry-number*	Sets the number of entries updated in each round of l3-interface entry update.	The value is an integer that ranges from 1 to 100.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the periodic l3-interface entry update function is configured on a switch, the switch periodically updates l3-interface entries to ensure real-time and effective forwarding of data at the bottom layer and records revision information.

The three parameters, *cycle-interval*, *scan-interval*, and *entry-number*, together determine the periodic l3-interface entry update process. For example, the switch has a total of 500 l3-interface entries:

- If the three parameters retain their default values, that is, 500 entries need to be updated in 10 rounds and can be checked within 10 second (with the scanning time of each round of update as 1 second), the system is idle during the period between 10 seconds to 1 minute (periodic update interval).
- If *cycle-interval* is set to 1 minute, *scan-interval* is set to 10 seconds, and *entry-number* retains the default value, 500 entries still need to be updated for 10 rounds, and a total of 100 seconds is required to finish updating these entries. Then the update time will exceed 1 minute, so the switch needs to start periodic update within the next 1 minute. In this situation, periodic update is performed at an interval of 2 minutes.

Precautions

Periodic l3-interface entry update occupies system resources, including CPU and memory resources. A longer check interval and fewer entries indicate a smaller impact on other services. Flexibly configure the l3-interface entry update interval and number of l3-interface entries updated each time based on system resources.

Example

Enable periodic l3-interface entry update.

```
<HUAWEI> system-view
[HUAWEI] l3-interface regularly-refresh enable
```

Set the periodic l3-interface entry update interval to 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] l3-interface regularly-refresh cycle-interval 10
```

Set the scanning time for each round of l3-interface entry update to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] l3-interface regularly-refresh scan-interval 5
```

Set the number of entries checked in each round of update to 100.

```
<HUAWEI> system-view
[HUAWEI] l3-interface regularly-refresh entry-number 100
```

Disable periodic l3-interface entry update.

```
<HUAWEI> system-view
[HUAWEI] undo l3-interface regularly-refresh enable
```

7.10.52 l3-interface periodic-refresh disable

Function

The **l3-interface periodic-refresh disable** command disables the function of updating l3-interface entries every 10 hours.

The **undo l3-interface periodic-refresh disable** command enables the function of updating l3-interface entries every 10 hours.

By default, l3-interface entries are updated every 10 hours.

Format

l3-interface periodic-refresh disable

undo l3-interface periodic-refresh disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a device updates l3-interface entries every 10 hours. To reduce the load on the device, you can run this command to disable the device from updating l3-interface entries every 10 hours.

Precautions

To disable all functions of periodically updating l3-interface entries on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, you need to run both the **l3-interface periodic-refresh disable** and **undo l3-interface regularly-refresh** commands.

Example

Disable the function of updating l3-interface entries every 10 hours.

```
<HUAWEI> system-view
[HUAWEI] l3-interface periodic-refresh disable
```

7.10.53 refresh fib

Function

The **refresh fib** command delivers IPv4 FIB policies and forwarding entries.

Format

refresh fib slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID of a switch that needs to update IPv4 FIB policies.	The value is determined based on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the IPv4 FIB policy changes, you must run the **refresh fib** command to update the switch to make the configuration take effect.

After the **refresh fib** command is executed, you can view the FIB table to check whether the update succeeds.

Precautions

If the FIB module is in overload state and the switch works in overload suspension mode, the IPv4 and IPv6 modules need to be updated.

Example

Refresh IPv4 FIB module on the switch in slot 2.

```
<HUAWEI> system-view
[HUAWEI] refresh fib slot 2
```

7.10.54 refresh ipv6 fib

Function

The **refresh ipv6 fib** command delivers IPv6 FIB policies and forwarding entries.

Format

refresh ipv6 fib slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the slot ID of a switch that needs to update IPv6 FIB policies.	The value is determined based on the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After the IPv6 FIB policy changes, you must run the **refresh ipv6 fib** command to update the switch to make the configuration take effect.

After the **refresh ipv6 fib** command is executed, you can view the FIB table to check whether the update succeeds.

NOTE

If the FIB module is in overload state and the switch works in overload suspension mode, the IPv4 and IPv6 modules need to be updated.

Example

Update the IPv6 FIB module on the switch in slot 2.

```
<HUAWEI> system-view
[HUAWEI] refresh ipv6 fib slot 2
```

7.10.55 reset ip routing-table statistics protocol

Function

The **reset ip routing-table statistics protocol** command clears route statistics in an IPv4 routing table.

Format

reset ip routing-table statistics protocol [**vpn-instance** *vpn-instance-name*] { **all** | *protocol* }

reset ip routing-table all-vpn-instance statistics protocol { **all** | *protocol* }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears route statistics in an IPv4 routing table of the specified VPN instance. If this parameter is not specified, route statistics in an IPv4 routing table of the public network are cleared.	The value must be an existing VPN instance name.
all	Clear route statistics of all routing protocols in an IPv4 routing table.	-
protocol	Clears route statistics of the specified routing protocol in an IPv4 routing table. This parameter can be the following keywords. For details, see the routing protocols supported by the device: **direct**, **bgp**, **isis**, **ospf**, **rip**, **static**, and **unr**.	-
all-vpn-instance	Clears the statistics in the IPv4 routing tables of all VPN instances.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use this command to clear route statistics in an IPv4 routing table, including statistics about the routes added, deleted, and released by each routing protocol. Subsequently, the system can re-collect route statistics of each routing protocol again to monitor route changes and locate network faults.

Precautions

IPv4 route statistics cannot be restored after being cleared. Exercise caution when you use this command.

Example

Clear route statistics of all routing protocols in an IPv4 routing table.

```
<HUAWEI> reset ip routing-table statistics protocol all
```

7.10.56 reset ipv6 routing-table statistics protocol

Function

The **reset ipv6 routing-table statistics protocol** command clears route statistics in an IPv6 routing table.

Format

reset ipv6 routing-table [**vpn-instance** *vpn-instance-name*] **statistics protocol** { **all** | *protocol* }

reset ipv6 routing-table all-vpn-instance statistics protocol { **all** | *protocol* }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of an IPv6 VPN instance.	The value must be an existing VPN instance name.
all	Clear route statistics of all routing protocols in an IPv6 routing table.	-
protocol	Clears route statistics of the specified routing protocol in an IPv6 routing table.	The value may be **bgp, direct**, **isis, ospfv3, ripng**, **static**, or **unr**. The specific value varies depending on the routing protocol supported by the device.
all-vpn-instance	Clears the statistics in the IPv6 routing tables of all VPN instances.	-

Views

User view

2: Configuration level

Usage Guidelines

Usage Scenario

You can use this command to clear route statistics of each routing protocol in an IPv6 routing table. Subsequently, the switch can re-collect route statistics of each routing protocol to monitor route changes and locate network faults.

Precautions

IPv6 route statistics cannot be restored after being cleared. Exercise caution when you use this command.

Example

Clear route statistics of all routing protocols in an IPv6 routing table.

```
<HUAWEI> reset ipv6 routing-table statistics protocol all
```

7.10.57 router id

Function

The **router id** command sets the global router ID.

The **undo router id** command deletes the configured global router ID.

By default, the global router ID is 0.0.0.0 when no IPv4 interface address is configured.

Format

router id *router-id*

undo router id

Parameters

Parameter	Description	Value
router-id	Sets a router ID in the IPv4 address format.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A router ID is a 32-bit integer used to uniquely identify a device that uses a specific dynamic routing protocol for route exchange. A router ID uses the same format as an IP address. Router IDs are classified into global router IDs of devices and router IDs of dynamic routing protocols.

The rules for selecting a global router ID are as follows:

1. If you set the global router ID using the **router id** command, the configured router ID is used.
2. If no global router ID is set, the router selects a router ID based on IP addresses of current interfaces:
   - If there are loopback interfaces that have IP addresses configured, the device selects the largest IP address among loopback interface addresses as the global router ID.
   - If no loopback interface is configured or loopback interfaces do not have IP addresses configured, the device selects the largest IP address among interface addresses as the global router ID without considering the Up/Down state of interfaces.

   NOTE

   The global router ID is reselected only when the interface address that is selected as the global router ID is deleted or changed. The global router ID is not reselected in any of the following situations:

   - The interface is Down.
   - A loopback interface is configured when the IP address of a non-loopback interface is selected as the router ID.
   - A larger interface address is configured later.

   You can run the **display router id** command to view the global router ID.
3. Each VPN instance selects the router ID from the IP addresses of the interfaces in the VPN instance based on rules 1 and 2.

After the global router ID is changed, manually run the **reset** command for each routing protocol to make the new global router ID take effect.

Precautions

When a device is being initialized and there is no interface address on the device, the first configured IP address on the device, which may be a loopback interface address or another interface address, will become the global router ID of the device. This global router ID remains unchanged even if there is a larger interface IP address on the device.

The IP address of the interface whose configuration is restored the first is used as the global router ID after the restart.

NOTE

To enhance network reliability, configure the address of a loopback interface as the global router ID.

Example

Set the global router ID to 10.10.10.1.

```
<HUAWEI> system-view
[HUAWEI] router id 10.10.10.1
```

7.10.58 route low-priority enable

Function

The **route low-priority enable** command sets the priority of routes on the forwarding plane to be lower than the ARP/ND priority.

The **undo route low-priority enable** command sets the priority of routes on the forwarding plane to be higher than the ARP/ND priority.

By default, on a device running a version earlier than V200R019C00SPC210, the priority of routes (excluding BGP routes and blackhole routes) on the forwarding plane is lower than the ARP/ND priority. On a device running V200R019C00SPC210 or later, the priority of routes on the forwarding plane is higher than the ARP/ND priority.

Format

route low-priority enable

undo route low-priority enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The control plane and forwarding plane of the routing system are separated and cooperate with each other to forward data. The control plane learns and exchanges routing protocols, calculates routes, generates routing entries, and delivers the entries to the forwarding plane for packet forwarding. The forwarding plane receives and sends packets, encapsulates and decapsulates packets, queries routing entries, and forwards packets.

If the control plane has host routes and ARP entries with the same destination IP address as the host routes, the forwarding plane forwards packets based on the routes because the route priority on the control plane is higher than the ARP/ND priority. On the forwarding plane, packets are forwarded based on routes or ARP/ND entries, depending on which ones have higher priority. For example, if the route priority on the forwarding plane is lower than the ARP/ND priority, packets are forwarded based on ARP/ND entries. In this case, if the outbound interface of an ARP/ND entry is different from that of a route, for example, the outbound interface is manually specified in a static ARP entry, different forwarding behaviors will be performed.

Therefore, you need to run the **route low-priority enable** command to adjust the route priority on the forwarding plane to control whether packets are forwarded based on routes or ARP/ND entries.

Precautions

- In actual deployment, if there is no special requirement, to ensure consistent forwarding behaviors on the forwarding plane and control plane, it is recommended that the route priority on the forwarding plane be higher than the ARP/ND priority.
- This command takes effect only for newly generated routes. For existing routes, you need to run the **refresh fib** and **refresh ipv6 fib** commands to manually refresh routes after running this command. During route refresh, path switching may cause temporary traffic interruptions.
- In an upgrade scenario, after a device running V200R019C00SPC200 or an earlier version is upgraded to V200R019C00SPC210 or a later version, the route priority on the forwarding plane remains unchanged. That is, the route priority on the forwarding plane is lower than the ARP/ND priority. This conflicts with the default setting on switches running V200R019C00SPC210 or a later version. This is because the route priority on the forwarding plane is higher than the ARP/ND priority on these switches by default. To resolve the conflict, the **route low-priority enable** command is automatically generated in the configuration file of a switch.

Example

Set the route priority on the forwarding plane to be higher than the ARP/ND priority.

```
<HUAWEI> system-view
[HUAWEI] undo route low-priority enable
```

7.11 PBR Configuration Commands

7.11.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.11.2 redirect ip-multihop

Function

The **redirect ip-multihop** command configures an action of redirecting packets to multiple next hop IP addresses in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, an action of redirecting packets to multiple next hop IP addresses is not configured in a traffic behavior.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

redirect [**vpn-instance** *vpn-instance-name*] **ip-multihop** { **nexthop** *ip-address* } &<2-4>

redirect [**vpn-instance** *vpn-instance-name*] **ip-multihop** *acl-ip-pool-name*

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
nexthop *ip-address*	Specifies the IP address of the next hop.	The value is in dotted decimal notation and in X.X.X.X format.
acl-ip-pool-name	Specifies the name of an ACL IP address pool.	The ACL IP address pool name must exist.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple next hop IP addresses are specified, the device redirects packets through equal-cost routes in load balancing mode.

If the outbound interface corresponding to a next hop IP address becomes Down or a route changes, the device switches traffic to the outbound interface corresponding to an available next hop. If the specified next hops are unavailable, the device forwards the packets to the original destination.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to multiple next hop IP addresses.

Precautions

- In a traffic behavior, the **redirect ip-multihop** command cannot be used together with any of the following commands: **remark 8021p**, **add-tag vlan-id**, **remark cvlan-id** and **remark vlan-id**.
- A traffic policy containing the redirection action can be only used globally, on an interface, or in a VLAN in the inbound direction.
- If you configure only two identical IP addresses when executing the **redirect ip-multihop** command, the system displays the following error message:
  ```
  Error: Redirect ip-multihop should configure at least two address.
  ```
- If the device has no ARP entry matching the specified next hop IP address, the **redirect ip-multihop** command can be used but redirection does not take effect. The device still forwards packets to the original destination until the device has the corresponding ARP entry.

Example

Configure three next hop IP addresses in the traffic behavior **b1**: 10.1.42.1, 10.2.12.3, and 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect ip-multihop nexthop 10.1.42.1 nexthop 10.2.12.3 nexthop 10.1.1.2
```

In the traffic behavior **b2**, configure the action of redirecting packets to five next hop IP addresses in the ACL IP address pool **abc**.

```
<HUAWEI> system-view
[HUAWEI] acl ip-pool abc
[HUAWEI-acl-ip-pool-abc] ip address 192.168.10.1 32
[HUAWEI-acl-ip-pool-abc] ip address 192.168.20.1 32
[HUAWEI-acl-ip-pool-abc] ip address 192.168.30.1 32
[HUAWEI-acl-ip-pool-abc] ip address 192.168.40.1 32
[HUAWEI-acl-ip-pool-abc] ip address 192.168.50.1 32
[HUAWEI-acl-ip-pool-abc] quit
[HUAWEI] traffic behavior b2
[HUAWEI-behavior-b2] redirect ip-multihop abc
```

7.11.3 redirect ip-nexthop

Function

The **redirect ip-nexthop** command configures the action of redirecting packets to a next-hop IP address in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, the action of redirecting packets to a next-hop IP address is not configured in a traffic behavior.

Format

redirect [**remote**] [**vpn-instance** *vpn-instance-name*] **ip-nexthop** { *ip-address* [**track-nqa** *admin-name test-name*] } &<1-4> [**forced** | **low-precedence**] *

undo redirect

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vpn-instance** *vpn-instance-name* and **low-precedence**.

Parameters

Parameter	Description	Value
remote	Redirects packets to a remote next hop.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ip-address	Specifies a next-hop IP address.	The value is in dotted decimal notation and in X.X.X.X format.
track-nqa	Specifies an NQA test instance.	-
admin-name	Specifies the administrator of an NQA test instance.	The value is a string of 1 to 32 case-sensitive characters, excluding question marks (?), hyphens (-), and a single or consecutive quotation marks (").

Parameter	Description	Value
test-name	Specifies the name of an NQA test instance.	The value is a string of 1 to 32 case-sensitive characters, excluding question marks (?), hyphens (-), and a single or consecutive quotation marks (").
forced	Specifies that packets are discarded if the next hop is unavailable.	-
low-precedence	Specifies a low-priority next hop. **NOTE** If this parameter is specified, redirection-based PBR has a lower priority than routes generated through dynamic routing protocols or statically configured routes. If this parameter is not specified, the former has a higher priority than the latter. In enhanced-ipv4 or ipv4-ipv6 6:1 resource assignment mode, the S6720-EI does not support redirection to low-priority next hops. You can run the **display resource-mode configuration** command to view the resource assignment mode on the device, and run the **assign resource-mode** { **enhanced-mac** | **enhanced-arp** | **enhanced-ipv4** | **ipv4-ipv6 6:1** } [**slot** *slot-id* | **all**] command to change the resource assignment mode.	-

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple next-hop IP addresses are configured, the device redirects packets in active/standby mode. A maximum of four next-hop IP addresses can be configured in a traffic behavior. The device determines the primary and backup paths according to the sequence in which next-hop IP addresses are configured. The next-hop IP address that is configured first has the highest priority and this next hop is used as the primary path. Other next hops are used as backup paths. When the primary link becomes Down, a next hop with a higher priority is used as the primary link.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to a next-hop IP address.

Precautions

- In a traffic behavior, the **redirect ip-nexthop** command cannot be used together with any of the following commands: **remark 8021p**, **add-tag vlan-id**, **remark cvlan-id** and **remark vlan-id**.
- A traffic policy containing the redirection action can be applied globally, as well as on an interface and in a VLAN in the inbound direction.
- If no ARP entry matches the next-hop address on the device, the device triggers ARP learning. If the ARP entry cannot be learned, redirection does not take effect and packets are forwarded along the original path.
- In V200R021C00SPC600 and later versions, when the action of redirecting packets to a remote next hop, the configuration does not take effect if the next-hop address is reachable only through tunnel forwarding.

Example

Configure the action of redirecting packets to next hop 10.0.0.1 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect ip-nexthop 10.0.0.1
```

7.11.4 redirect ipv6-multihop

Function

The **redirect ipv6-multihop** command configures an action of redirecting packets to multiple next hop IPv6 addresses in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, an action of redirecting packets to multiple next hop IPv6 addresses is not configured in a traffic behavior.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

redirect [**vpn-instance** *vpn-instance-name*] **ipv6-multihop** *acl6-ip-pool-name*

undo redirect

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv6-address	Specifies a next hop IPv6 address.	The address is a 32-digit hexadecimal number, in X:X:X:X:X:X:X:X format.
link-local *link-local-address*	Specifies a link-local address. The prefix of the specified IPv6 address must match FE80::/10.	The address is a 32-digit hexadecimal number, in X:X:X:X:X:X:X:X format.
interface *interface-type interface-number*	Specifies the interface corresponding to the link-local address. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Parameter	Description	Value
acl6-ip-pool-name	Specifies the name of the ACL IPv6 address pool to be created.	The value is a string of 1 to 32 case-sensitive characters without spaces and starting with a letter.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple next hop IPv6 addresses are specified, the device redirects packets through equal-cost routes in load balancing mode.

If the outbound interface corresponding to a next hop IPv6 address becomes Down or a route changes, the device switches traffic to the outbound interface corresponding to an available next hop. If the specified next hops are unavailable, the device forwards the packets to the original destination.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to multihop IPv6 addresses.

Precautions

- In a traffic behavior, the **redirect ipv6-multithop** command cannot be used together with any of the following commands: **remark 8021p**, **add-tag vlan-id**, **remark cvlan-id** and **remark vlan-id**.
- When the next hop IPv6 address is a local-link address, you must configure a VLANIF interface. The address is only valid in the VLAN corresponding to the VLANIF interface.
- The traffic policy that contains the redirection action can only be applied to the system, an interface, or a VLAN.
- When running the **redirect ipv6-multithop** command to configure multiple next hop IPv6 addresses, you can specify 2 to 4 next hop IPv6 addresses. When configuring multiple next hop IPv6 addresses through an ACL IPv6-POOL, you can specify a maximum of 64 next hop IPv6 addresses. To create and configure an ACL IPv6-POOL, run the **acl ipv6 ip-pool** and **ipv6 address (ACL IPv6-POOL view)** commands.
- If the device does not match the neighbor entry corresponding to the next hop IPv6 address, the device sends NS packets to check whether the neighbor

is reachable. If the neighbor is unreachable, packets are forwarded based on the original path and redirection does not take effect.

- If you run the **redirect ipv6-multithop** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure two next hop IPv6 addresses in the traffic behavior **b1**: FC00:0:0:2000::1 and FC00:0:0:3000::1.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect ipv6-multihop fc00:0:0:2000::1 fc00:0:0:3000::1
```

In the traffic behavior **b2**, configure an action of redirecting packets to five next hop IPv6 addresses in the ACL IPv6-POOL **abc**.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 ip-pool abc
[HUAWEI-acl6-ip-pool-abc] ipv6 address 2001:db8::1 128
[HUAWEI-acl6-ip-pool-abc] ipv6 address 2001:db8::2 128
[HUAWEI-acl6-ip-pool-abc] ipv6 address 2001:db8::3 128
[HUAWEI-acl6-ip-pool-abc] ipv6 address 2001:db8::4 128
[HUAWEI-acl6-ip-pool-abc] ipv6 address 2001:db8::5 128
[HUAWEI-acl6-ip-pool-abc] quit
[HUAWEI] traffic behavior b2
[HUAWEI-behavior-b2] redirect ipv6-multihop abc
```

7.11.5 redirect ipv6-nexthop

Function

The **redirect ipv6-nexthop** command configures the action of redirecting packets to a next-hop IPv6 address in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, the action of redirecting packets to a next-hop IPv6 address is not configured in a traffic behavior.

Format

redirect [**remote**] [**vpn-instance** *vpn-instance-name*] **ipv6-nexthop** { *ipv6-address* | **link-local** *link-local-address* **interface** *interface-type interface-number* } & <1-4> [**forced**]

undo redirect

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **vpn-instance** *vpn-instance-name* parameter.

Parameters

Parameter	Description	Value
remote	Redirects packets to a remote next hop.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
ipv6-address	Specifies a next-hop IPv6 address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
link-local *link-local-address*	Specifies a link-local IPv6 address. The prefix of the specified IPv6 address must match FE80::/10.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface *interface-type interface-number*	Specifies the interface corresponding to the link-local address. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
forced	Indicates that packets are discarded if the next hop is unavailable.	-

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure the action of redirecting packets to a specified next-hop IPv6 address in a traffic behavior to implement PBR.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing the action of redirecting packets to a next-hop IPv6 address.

Precautions

- In a traffic behavior, the **redirect ipv6-nexthop** command cannot be used together with any of the following commands: **remark 8021p**, **add-tag vlan-id**, **remark cvlan-id** and **remark vlan-id**.
- If no neighbor entry matches the next-hop IPv6 address, the device sends NS packets to check whether the neighbor is reachable. If the neighbor is unreachable, redirection does not take effect and packets are forwarded along the original path.
- If multiple next-hop IPv6 addresses are configured, the device redirects packets in active/standby mode. A maximum of four next-hop IPv6 addresses can be configured in a traffic behavior. The device determines the primary and backup paths according to the sequence in which next-hop IPv6 addresses are configured. The next-hop IPv6 address that is configured first has the highest priority and this next hop is used as the primary path. Other next hops are used as backup paths. When the primary link becomes Down, a next hop with a higher priority is used as the primary link.
- When the next-hop IPv6 address is a local-link address, you must configure a VLANIF interface. The address is valid only in the VLAN corresponding to the VLANIF interface.
- If you run the **redirect ipv6-nexthop** command in the same traffic classifier view multiple times, only the latest configuration takes effect.
- In V200R021C00SPC600 and later versions, when the action of redirecting packets to a remote next hop, the configuration does not take effect if the next-hop address is reachable only through tunnel forwarding.

Example

Configure the action of redirecting packets to the next-hop IPv6 address FC00:0:0:2001::1 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect ipv6-nexthop fc00:0:0:2001::1
```

7.12 Route Monitoring Group Configuration Commands

7.12.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.12.2 display ip route-monitor-group

Function

The **display ip route-monitor-group** command displays information about a route monitoring group or all route monitoring groups.

Format

display ip route-monitor-group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Displays information about a specified route monitoring group. If *group-name* is specified, detailed information about the specified route monitoring group is displayed. If *group-name* is not specified, a summary of all route monitoring groups is displayed.	The value is a string of 1 to 31 case-sensitive characters.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a route monitoring group is configured, you can run the **display ip route-monitor-group** command to check information about the route monitoring group, such as the status and information about routes in the route monitoring group.

Example

Display brief information about all route monitoring groups.

```
<HUAWEI> display ip route-monitor-group
 Route monitor group number : 1
 Route monitor group              State
 uplink                           Enable
```

Display detailed information about the route monitoring group **uplink**.

```
<HUAWEI> display ip route-monitor-group uplink
route monitor group uplink
 State         : Enabled
-------------------------------------------------------
 route monitor group tracking route number : 1
-------------------------------------------------------
```

```
VPN name      : Public
Destination  : 10.2.2.2
Mask          : 255.255.255.255
State         : Inactive
```

Table 7-236 Description of the **display ip route-monitor-group** command output

Item	Description
Route monitor group number	Number of route monitor groups.
Route monitor group	Name of a route monitoring group.
State	Status of a route monitoring group: ● Enabled: The route monitoring group is enabled. ● Disabled: The route monitoring group is disabled. ● Up: The route monitoring group is Up. ● Down: The route monitoring group is Down. You can run the **monitor enable** command to enable a route monitoring group.
route monitor group tracking route number	Number of routes in a route monitoring group.
VPN name	VPN instance to which routes belongs. The value **Public** indicates a public network.
Destination	Destination IP address of a route.
Mask	Mask of the destination IP address of a route.
State	Status of a route: ● Active ● Inactive

7.12.3 display ip route-monitor-group track-route

Function

The **display ip route-monitor-group track-route** command displays information about all route monitoring groups to which a specified route is added.

Format

display ip route-monitor-group track-route [**vpn-instance** *vpn-instance-name*] *dest-address* { *mask* | *mask-length* }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the VPN instance to which a route belongs. If this parameter is specified, information about all route monitoring groups to which a VPN route in the VPN instance is added is displayed. If this parameter is not specified, information about all route monitoring groups to which a public network route is added is displayed.	The value is a string of 1 to 31 case-sensitive characters without spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
dest-address	Specifies the destination IP address of a route.	The value is in dotted decimal notation.
mask	Specifies the mask of the destination IP address of a route.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the destination IP address of a route.	The value is an integer in the range from 0 to 32.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A route can be added to multiple route monitoring groups to monitor the route status change. You can run the **display ip route-monitor-group track-route** command to display information about all route monitoring groups to which a specified route is added.

Example

Display information about all route monitoring groups to which the route to 192.168.1.0/24 is added.

```
<HUAWEI> display ip route-monitor-group track-route 192.168.1.0 24
 Route monitor group              State
 uplink                           Enabled
```

Table 7-237 Description of the **display ip route-monitor-group track-route** command output

Item	Description
Route monitor group	Name of a route monitoring group.
State	Status of a route monitoring group: - Enabled: The route monitoring group is enabled. - Disabled: The route monitoring group is disabled. - Up: The route monitoring group is Up. - Down: The route monitoring group is Down. You can run the **monitor enable** command to enable a route monitoring group.

7.12.4 ip route-monitor-group

Function

The **ip route-monitor-group** command creates a route monitoring group and displays the view of this route monitoring group, or displays the view of an existing route monitoring group.

The **undo ip route-monitor-group** command deletes a route monitoring group.

By default, no route monitoring group is created on a switch.

Format

ip route-monitor-group *group-name*

undo ip route-monitor-group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a route monitoring group.	The value is a string of 1 to 31 case-sensitive characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

All network-side routes of the same type can be added to the same route monitoring group, which monitors a certain number of routes. In a hot standby scenario, you can add network-side routes to a route monitoring group and associate access-side service modules with it so that the service modules can perform active/standby link switchovers upon route changes in the group. This mechanism prevents network congestion and packet loss.

Follow-up Procedure

Run the **track ip route** command to add a route to the route monitoring group.

Example

Create a route monitoring group named **uplink**.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink]
```

7.12.5 monitor enable

Function

The **monitor enable** command enables a route monitoring group.

The **undo monitor enable** command disables a route monitoring group.

By default, a route monitoring group is disabled.

Format

monitor enable

undo monitor enable

Parameters

None

Views

Route monitoring group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A route monitoring group can monitor status changes of network-side routes. After the routes to be monitored are added to a route monitoring group, run the

monitor enable command to enable the route monitoring group so that it can take effect immediately.

When a large number of routes are being added to or deleted from a route monitoring group, the status of the route monitoring group changes frequently, which in turn leads to service flapping of the service modules associated with the route monitoring group. To prevent such service flapping, run the **undo monitor enable** command to disable the route monitoring group so that it is dissociated from all service modules. After the routes are added or deleted, run the **monitor enable** command to re-associate the route monitoring group with all service modules.

Prerequisites

A route has been added to the route monitoring group using the **track ip route** command.

Example

Enable the route monitoring group **uplink**.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink] track ip route 10.1.1.0 24
[HUAWEI-route-monitor-group-uplink] monitor enable
```

7.12.6 operator and

Function

The **operator and** command sets the status of routes in a route monitoring group to be of the AND relationship.

The **undo operator and** command restores the default configuration.

By default, the status of routes in a route monitoring group is of the OR relationship.

Format

operator and

undo operator and

Parameters

None

Views

Route monitoring group view

Default Level

2: Configuration level

Usage Guidelines

You can run the **operator and** command to set the status of routes in a route monitoring group to be of the AND relationship. That is, the status of the route monitoring group is Up only when all routes in the route monitoring group are Up. The status of the monitoring group is Down as long as one route in the group is Down. By default, the status of routes in a route monitoring group is of the OR relationship. That is, the status of the route monitoring group is Up as long as one route in the group is Up. The status of the monitoring group is Down only when all routes in the group are Down.

Example

Set the status of routes in a route monitoring group to be of the AND relationship.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink] operator and
```

7.12.7 trigger-down-delay

Function

The **trigger-down-delay** command configures a delay after which the route management (RM) module instructs the associated service modules to perform link switchovers.

The **undo trigger-down-delay** command restores the default configuration.

By default, the delay is 0s.

Format

trigger-down-delay *delay-value*

undo trigger-down-delay [*delay-value*]

Parameters

Parameter	Description	Value
delay-value	Specifies a delay after which the RM module instructs the associated service modules to perform link switchovers.	The value is an integer in the range from 0 to 1000, in seconds.

Views

Route monitoring group view

Default Level

2: Configuration level

Usage Guidelines

In a hot standby scenario, service modules can be associated with a route monitoring group to trigger link switchovers. When the status of the route monitoring group goes Down, the RM module instructs the associated service modules to perform link switchovers. In addition, the RM module re-delivers routes to the forwarding table and establishes forwarding entries for the routes, which takes some time. Packet loss may occur if the RM module instructs the associated service modules to perform link switchovers immediately. To resolve this problem, run the **trigger-down-delay** command to configure a delay after which the RM module instructs the associated service modules to perform link switchovers.

Example

Set the delay to 10s after which the RM module instructs the associated service modules to perform link switchovers.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink] trigger-down-delay 10
```

7.12.8 trigger-up-delay

Function

The **trigger-up-delay** command configures a delay after which the RM module instructs the associated service modules to perform link switchbacks.

The **undo trigger-up-delay** command restores the default configuration.

By default, the delay is 5s.

Format

trigger-up-delay *delay-value*

undo trigger-up-delay

Parameters

Parameter	Description	Value
delay-value	Specifies a delay after which the RM module instructs the associated service modules to perform link switchbacks.	The value is an integer in the range from 0 to 1000, in seconds.

Views

Route monitoring group view

Default Level

2: Configuration level

Usage Guidelines

In a hot standby scenario, service modules can be associated with a route monitoring group to trigger link switchovers. When the status of the route monitoring group goes Up, the RM module instructs the associated service modules to perform link switchbacks. In addition, the RM module re-delivers routes to the forwarding table and establishes forwarding entries for the routes, which takes some time. Packet loss may occur if the RM module instructs the associated service modules to perform link switchovers immediately. To resolve this problem, run the **trigger-up-delay** command to configure a delay after which the RM module instructs the associated service modules to perform link switchbacks.

Example

Set the delay to 10s after which the RM module instructs the associated service modules to perform link switchbacks.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink] trigger-up-delay 10
```

7.12.9 track ip route

Function

The **track ip route** command adds a route to a route monitoring group.

The **undo track ip route** command deletes a route from a route monitoring group.

By default, no route is added to a route monitoring group.

Format

track ip route [**vpn-instance** *vpn-instance-name*] *dest-address* { *mask* | *mask-length* }

undo track ip route [**vpn-instance** *vpn-instance-name*] *dest-address* { *mask* | *mask-length* }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the VPN instance to which a route belongs. If this parameter is specified, a VPN route in the VPN instance is added to the route monitoring group. If this parameter is not specified, a public network route is added to the route monitoring group.	The value is a string of 1 to 31 case-sensitive characters without spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
dest-address	Specifies the destination IP address of a route.	The value is in dotted decimal notation.
mask	Specifies the mask of the destination IP address of a route.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the destination IP address of a route.	The value is an integer in the range from 0 to 32.

Views

Route monitoring group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A route monitoring group can monitor the status of its member routes to prevent network congestion and packet loss. You can run the **track ip route** command to add a route to be monitored to a route monitoring group. All network-side routes of the same type can be added to the same route monitoring group.

Follow-up Procedure

Run the **monitor enable** command to enable the route monitoring group.

Precautions

A maximum of 16 routes can be added to a route monitoring group. A route can be added to multiple route monitoring groups.

Example

Add the route to 10.1.1.0/24 to the route monitoring group **uplink**.

```
<HUAWEI> system-view
[HUAWEI] ip route-monitor-group uplink
[HUAWEI-route-monitor-group-uplink] track ip route 10.1.1.0 24
```

S6700	Supported.

NOTE

Only S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the IGMP multi-instance feature.

8.1.2 display default-parameter igmp

Function

The **display default-parameter igmp** command displays default IGMP configurations.

Format

display default-parameter igmp

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays default IGMP parameter settings even if IGMP parameters have been modified. Therefore, you can use this command to check which parameters have been modified.

Example

Display default IGMP configurations.

```
<HUAWEI> display default-parameter igmp
  IGMP View Default Configurations:
```

```
---------------------------------
Lastmember-queryinterval: 1 s
Max-response-time: 10 s
Require-router-alert: disabled
Robust-count: 2
Send-router-alert: enabled
Ssm-mapping: disabled
Timer other-querier-present: 125 s
Timer query: 60 s

Interface View Default Configurations:
--------------------------------------
Group-policy: disabled
Lastmember-queryinterval: 1 s
Lastmember-query time: 2 s
Max-response-time: 10 s
Other-querier-present-timer-expiry: off
Prompt-leave: disabled
Require-router-alert: disabled
Robust-count: 2
Send-router-alert: enabled
Ssm-mapping: disabled
Startup-query-timer-expiry: off
Static-group: disabled
Timer other-querier-present: 125 s
Timer query: 60 s
Version: 2
Ip-source-policy: disabled
```

Table 8-1 Description of the **display default-parameter igmp** command output

Item	Description
IGMP View Default Configurations	Default configurations in the IGMP view. The default configurations take effect globally.
Lastmember-queryinterval	Interval for sending IGMP Group-Specific Query messages. This parameter is configured using the **lastmember-queryinterval (IGMP view)** command in the IGMP view or the **igmp lastmember-queryinterval** command in the interface view.
Max-response-time	Maximum response time for IGMP Query messages. This parameter is configured using the **max-response-time (IGMP view)** command in the IGMP view or the **igmp max-response-time** command in the interface view.
Require-router-alert	Whether the device checks for the Router-Alert option in the received IGMP message. This parameter is configured using the **require-router-alert (IGMP view)** command in the IGMP view or the **igmp require-router-alert** command in the interface view.
Robust-count	Robustness variable of an IGMP querier. This parameter is configured using the **robust-count (IGMP view)** command in the IGMP view or the **igmp robust-count** command in the interface view.

Item	Description
Send-router-alert	Whether the IGMP messages sent from the device carry the Router-Alert option. This parameter is configured using the **send-router-alert (IGMP view)** command in the IGMP view or the **igmp send-router-alert** command.
Ssm-mapping	Status of the SSM mapping function. The value can be: ● enabled: This function is enabled. ● disabled: This function is disabled. SSM mapping can be configured using the **igmp ssm-mapping enable** command.
Timer other-querier-present	Length of the other querier present timer. This parameter is configured using the **timer other-querier-present (IGMP view)** command in the IGMP view or the **igmp timer other-querier-present** command in the interface view.
Timer query	Interval for sending IGMP General Query messages. This parameter is configured using the **timer query (IGMP view)** command in the IGMP view or the **igmp timer query** command in the interface view.
Interface View Default Configurations	Default configurations in the interface view. The configurations take effect only for IGMP-enabled interfaces.
Group-policy	Whether a multicast group policy is configured. The value can be: ● enabled: A multicast group policy is configured. ● disabled: No multicast group policy is configured. A multicast group policy is configured using the **igmp group-policy** command.
Lastmember-query time	Last member query time, calculated using the following formula: Last member query time = Last member query interval x Robustness variable The last member query time is not defined in IGMPv1.

Item	Description
Other-querier-present-timer-expiry	Status of the other querier present timer: ● off: The interface considers itself a querier and no other queriers exist. ● on: The interface no longer considers itself a querier and another querier exists.
Prompt-leave	Status of the fast leave function. The value can be: ● enabled: This function is enabled. ● disabled: This function is disabled. This function is configured using the **igmp prompt-leave** command.
Startup-query-timer-expiry	Startup query interval of the querier. The interface sends Query messages at this interval when it starts to function as a querier. The value is expressed in seconds and is 1/4 of the query interval (Timer query). The value **off** indicates that the interface has not started to send Query messages as a querier. The startup query timer is enabled only when the interface starts as a querier.
Static-group	Whether static multicast groups are configured. The value can be: ● enabled: Static multicast groups are configured. ● disabled: No static multicast groups are configured. A static multicast group is configured using the **igmp static-group** command.
Version	IGMP version number. IGMP has three versions: IGMPv1, IGMPv2, and IGMPv3, which is configured using the **igmp version** command.
Ip-source-policy	Status of IGMP Report/Leave message filtering based on host addresses. The value can be: ● enabled: This function is enabled. ● disabled: This function is disabled. This function is configured using the **igmp ip-source-policy** command.

8.1.3 display igmp control-message counters

Function

The **display igmp control-message counters** command displays statistics about IGMP control messages.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters** [**interface** *interface-type interface-number*] [**message-type** { **query** | **report** }]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays IGMP message statistics in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays IGMP message statistics in all instances.	-
interface *interface-type interface-number*	Displays IGMP message statistics on a specified interface. If this parameter is not specified, the command displays IGMP message statistics on all interfaces.	-
message-type	Indicates the IGMP message type. If this parameter is not specified, the command displays statistics about all types of IGMP messages.	-
query	Displays statistics about Query messages received by the interface. Query messages are sent from a querier.	-
report	Displays statistics about Report messages received by the interface. Report messages are sent by hosts to join a multicast group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the number of IGMP control messages sent and received on the device.

Example

Display statistics about the IGMP messages sent and received by VLANIF100.

```
<HUAWEI> display igmp control-message counters interface vlanif 100
Interface message counter information
 Vlanif100(192.168.2.1):
 Message Type              Sent       Valid      Invalid    Ignore
 -----------------------------------------------------------------

Table 8-2 Description of the **display igmp control-message counters interface vlanif 100** command output

Item	Description
Interface message counter information	IGMP packet information on an interface.
Vlanif100(192.168.2.1)	Type, number, and IP address of the interface.
Message Type	Type of IGMP messages.
Sent	Number of IGMP messages sent from the interface.
Valid	Number of valid IGMP messages received by the interface.
Invalid	Number of wrong IGMP messages received by the interface.
Ignore	Number of received IGMP messages ignored by the interface.
General Query	Number of IGMP General Query messages.

Item	Description
Group Query	Number of IGMP Group-Specific Query messages.
Source Group Query	Number of IGMP Group-and-Source-Specific Query messages.
Report ASM	Number of IGMPv1 and IGMPv2 Report messages with multicast group addresses in the ASM group address range.
Report SSM	Number of IGMPv1 and IGMPv2 Report messages with multicast group addresses in the SSM group address range.
LEAVE ASM	Number of IGMPv2 Leave messages with multicast group addresses in the ASM group address range.
LEAVE SSM	Number of IGMPv2 Leave messages with multicast group addresses in the SSM group address range.
ISIN Report	Number of IGMPv3 IS_IN Report messages.
ISEX Report	Number of IGMPv3 IS_EX Report messages.
TOIN Report	Number of IGMPv3 TO_IN Report messages.
TOEX Report	Number of IGMPv3 TO_EX Report messages.
ALLOW Report	Number of IGMPv3 ALLOW Report messages.
BLOCK Report	Number of IGMPv3 BLOCK Report messages.
Source Records Total	Number of multicast sources carried in IGMPv3 messages.
Others	Number of invalid and ignored IGMP messages of unknown types.

8.1.4 display igmp explicit-tracking

Function

The **display igmp explicit-tracking** command displays explicit (S, G) entries of IGMPv3 hosts, that is, (S, G) entries that IGMPv3 hosts have joined in Include mode.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **explicit-tracking** [**interface** *interface-type interface-number* [**host-address** *host-address* | **group** *group-address* **source** *source-address*]]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about IGMPv3 hosts that join a specified multicast source in INCLUDE mode in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMPv3 hosts that join a specified multicast source in INCLUDE mode in all instances.	-
interface *interface-type interface-number*	Displays information about IGMPv3 hosts that join a specified multicast source in INCLUDE mode on a specified interface.	-
host-address *host-address*	Specifies the address of an IGMP host.	The address is in dotted decimal notation.
group *group-address*	Specifies the address of a multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
source *source-address*	Specifies the address of a multicast source.	The address is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to view information about IGMPv3 hosts that have dynamically joined specified sources/groups in Include mode.

Example

Display information about the IGMPv3 hosts that have joined specified source/group in Include mode.

```
<HUAWEI> display igmp explicit-tracking
Explicit-tracking information
 Total 1 host, 2 entries

 Vlanif100(192.168.0.12)
  0001.Host: 192.168.0.28
       Uptime: 00:02:47
```

```
    Expires: 00:01:33
    (S, G) List:
      Group: 232.1.1.1
          Source: 10.12.12.12
            Uptime: 00:02:47
            Time since last refresh: 00:02:47
          Source: 10.13.13.13
            Uptime: 00:02:47
            Time since last refresh: 00:02:47
```

Table 8-3 Description of the **display igmp explicit-tracking** command output

Item	Description
Explicit-tracking information	IGMP host information.
Total 1 host, 2 entries	There is one IGMP host and two (S, G) entries.
Vlanif100(192.168.0.12)	Interface connected to IGMPv3 hosts that have joined a group with source addresses specified in Include mode.
Host	IGMP host address.
Uptime	Running time since an IGMP host joins a multicast group. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Amount of time left before an IGMP host times out. After the IGMP host expires, it is deleted from the IGMP member host list. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
(S, G) List	List of multicast sources and groups an IGMP host has joined.
Group	Multicast group address.
Source	Multicast source address.

Item	Description
Time since last refresh	Amount of time since an IGMP host last joins a group. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.

8.1.5 display igmp group

Function

The **display igmp group** command displays information about IGMP groups that hosts have dynamically joined by sending IGMP Report messages.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address* | **interface** *interface-type interface-number*]* [**verbose**]

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [**interface** *interface-type interface-number*] **entry-number**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about IGMP groups in a VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMP groups in all instances.	-
group-address	Displays information about the IGMP group with a specified group address.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
interface *interface-type interface-number*	Displays information about the IGMP group on the specified interface.	-

Parameter	Description	Value
verbose	Displays detailed information about IGMP groups. If the parameter is not specified, the command displays only the summary of IGMP groups.	-
entry-number	Displays statistics about IGMP multicast groups that hosts dynamically join.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If a host wants to receive multicast data for a multicast group, the host must join the multicast group in either of the following modes:

- Dynamic mode: After you run the **igmp enable** command to enable IGMP on the interface connected to the network segment on which the host resides, the host can dynamically join the multicast group.
- Static mode: After you run the **igmp static-group** command to enable IGMP on the interface connected to the network segment on which the host resides, the host can statically join the multicast group.

To monitor the status of the multicast group or locate a fault in a dynamically joined multicast group, run the **display igmp group** command. This command displays information about the multicast group that hosts have dynamically joined.

Example

Display information about dynamic IGMP groups.

```
<HUAWEI> display igmp group
Interface group report information of VPN-Instance: public net
 Vlanif100(10.1.6.2):
  Total 1 IGMP Group reported
   Group Address   Last Reporter   Uptime      Expires
   225.1.1.2       10.1.6.10       00:02:04    00:01:17
```

Display detailed information about dynamic IGMP groups.

```
<HUAWEI> display igmp group verbose
Interface group report information of VPN-Instance: public net
 Limited entry of this VPN-Instance: -
 Vlanif100(10.1.6.2):
  Total entry on this interface: 1
  Limited entry on this interface: -
```

```
 Total 1 IGMP Group reported
  Group: 225.1.1.2
    Uptime: 00:03:59
    Expires: off
    Last reporter: 10.1.6.10
    Last-member-query-counter: 0
    Last-member-query-timer-expiry: off
    Group mode: include
    Version1-host-present-timer-expiry: off
    Version2-host-present-timer-expiry: off
    Source list:
      Source: 192.168.232.1
         Uptime: 00:51:07
         Expires: 00:02:05
         Last-member-query-counter: 0
         Last-member-query-timer-expiry: off
```

Display statistics about IGMP multicast groups that hosts dynamically join.

```
<HUAWEI> display igmp group entry-number
Interface group report information of VPN-Instance: public net
  Total 4 IGMP Groups reported
 Vlanif200(10.36.1.10):
  Total 2 IGMP Groups reported
 Vlanif100(10.0.0.4):
  Total 2 IGMP Groups reported
```

Table 8-4 Description of the **display igmp group command** output

Item	Description
Interface group report information of VPN-Instance	VPN instance to which IGMP groups on an interface belong. **public net** indicates the public network instance.
Group Address	Address of a multicast group.
Last Reporter	Link-local address of the last host that sends a Multicast Listener Report message. **NOTE** When a host joins a multicast group through a sub-interface for QinQ or Dot1q VLAN tag termination, the Last Reporter field displays the address of the multicast proxy. By default, the address of the multicast proxy is 192.168.0.1.
Limited entry of this VPN-Instance	Maximum number of IGMP entries that can be created for this instance.
Vlanif100(10.1.6.2)	Interface type and interface number (IP address).
Total entry on this interface	Total number of IGMP entries on the current interface.
Limited entry on this interface	Maximum number of IGMP entries that the current interface can create.
Total 1 IGMP Group reported	Number of IGMP groups that the current interface has dynamically joined.

Item	Description
Group	Address of a multicast group.
Uptime	Amount of time since a multicast group is created. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Time left before a group will be deleted from the IGMP group table. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days. "off" indicates that the group will never be aged out.
Last-member-query-counter	Number of times the querier will send Group-Specific Query messages after receiving a Leave message. The counter value decreases by 1 every time the querier sends a Group-Specific Query message. This parameter is configured using the **igmp robust-count** command. The value 0 indicates that the querier does not send Group-Specific Query messages after receiving a Leave message.
Last-member-query-timer-expiry	Length of the last member query timer. The timer starts only when a Leave message is received from a group member. The timer value is configured using the **igmp lastmember-queryinterval** command. The value **off** indicates that the last member query timer has not started.

Item	Description
Group mode	Multicast group record type, which can be Include or Exclude. It is displayed only when the interface is running IGMPv3.
Version1-host-present-timer-expiry	Timeout interval of IGMPv1 hosts. IGMPv1 does not define the Leave message; therefore, memberships of IGMPv1 hosts are aged using a timer. The device starts the timer when receiving a Report message from an IGMPv1 host. The timer value is calculated using the following formula: IGMPv1 timeout interval = General group query interval x Robustness variable + Maximum response time for Query messages The general group query interval is configured using the **igmp timer query** command. The robustness variable is configured using the **igmp robust-count** command. The maximum response time for Query messages is configured using the **igmp max-response-time** command. The value **off** indicates that the device has not received any Report messages from IGMPv1 hosts.
Version2-host-present-timer-expiry	Timeout interval of IGMPv2 hosts. It is displayed only when the interface is running IGMPv3. The value **off** indicates that the device has not received any Report messages from IGMPv2 hosts.
Source list	List of multicast sources. It is displayed only when the interface has IGMPv3 receiver hosts attached.
Source	IP address of a multicast source.

8.1.6 display igmp group ssm-mapping

Function

The **display igmp group ssm-mapping** command displays information about multicast group entries established with SSM mapping.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address* | **interface** *interface-type interface-number*]* **ssm-mapping** [**verbose**]

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group ssm-mapping** [**interface** *interface-type interface-number*] **entry-number**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays group entries established with SSM mapping in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays group entries established with SSM mapping in all instances.	-
group-address	Displays information about the specified multicast group entries established with SSM mapping. If this parameter is not specified, the command displays information about all multicast group entries established with SSM mapping.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
interface *interface-type interface-number*	Displays information about multicast group entries established with SSM mapping on the specified interface. If this parameter is not specified, the command displays information about multicast group entries established with SSM mapping on all interfaces.	-
verbose	Displays detailed information about group membership established with SSM mapping. If the parameter is not specified, the command displays only the summary of group membership established with SSM mapping.	-
entry-number	Displays statistics about IGMP multicast groups established with SSM mapping.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display igmp group ssm-mapping** command to view information about multicast group entries that are established with SSM mapping. SSM mapping entries are configured using the **ssm-mapping** command.

Example

Display summary of all multicast group entries established with SSM mapping.

```
<HUAWEI> display igmp group ssm-mapping

IGMP SSM mapping interface group report information of VPN-Instance: public net
 Limited entry of this VPN-Instance: -
 Vlanif100(192.168.101.1):
  Total 1 IGMP SSM-Mapping Group reported
   Group Address   Last Reporter   Uptime      Expires
   232.0.0.1       192.168.101.2   00:00:02    00:02:08
```

Display detailed information about all multicast group entries established with SSM mapping.

```
<HUAWEI> display igmp group ssm-mapping verbose
Interface group report information of VPN-Instance: public net
 Limited entry of this VPN-Instance: -
 Vlanif100(192.168.101.1):
  Total entry on this interface: 1
  Limited entries on this interface: -
  Total 1 IGMP SSM-Mapping Group reported
   Group: 232.0.0.1
     Uptime: 00:00:15
     Expires: 00:01:55
     Last reporter: 192.168.101.2
     Last-member-query-counter: 0
     Last-member-query-timer-expiry: off
     Group mode: exclude
     Version1-host-present-timer-expiry: off
     Version2-host-present-timer-expiry: 00:01:55
```

Display detailed information about IGMP multicast groups established with SSM mapping.

```
<HUAWEI> display igmp group ssm-mapping entry-number
Interface group report information of VPN-Instance: public net
  Total 4 IGMP SSM-Mapping Groups reported
 Vlanif200(10.36.1.10):
  Total 2 IGMP SSM-Mapping Groups reported
 Vlanif100(10.0.0.4):
  Total 2 IGMP SSM-Mapping Groups reported
```

Table 8-5 Description of the **display igmp group ssm-mapping** command output

Item	Description
IGMP SSM mapping interface group report information of VPN-Instance	VPN instance to which IGMP groups on an interface belong. **public net** indicates the public network instance.

Item	Description
Group Address	Group address.
Last Reporter	Link-local address of the last host that sends a Multicast Listener Report message.
Limited entry of this VPN-Instance	Maximum number of entries that can be generated in the VPN instance.
Vlanif100(192.168.101.1)	Interface type and interface number (IP address).
Interface group report information of VPN-Instance	VPN instance to which IGMP groups on an interface belong.
Total entry on this interface	Total number of entries generated on the interface.
Limited entries on this interface	Maximum number of entries that can be generated on the interface.
Total 1 IGMP SSM-Mapping Group reported	Number of IGMP Report messages with SSM group addresses received on the interface.
Group	Group address.
Uptime	Amount of time since the last Report message is received. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Timeout period of a group. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Last-member-query-counter	Number of times Group-Specific Query messages are sent.

Item	Description
Last-member-query-timer-expiry	Length of the last member query timer. The timer starts only when a Leave message is received from a group member. The timer value is configured using the **igmp lastmember-queryinterval** command. The value **off** indicates that the last member query timer has not started.
Group mode	Filter mode of a group, which can be Include or Exclude. It is displayed only when the interface is running IGMPv3.
Version1-host-present-timer-expiry	Timeout interval of IGMPv1 hosts. IGMPv1 does not define the Leave message; therefore, memberships of IGMPv1 hosts are aged using a timer. The device starts the timer when receiving a Report message from an IGMPv1 host. The timer value is calculated using the following formula: IGMPv1 timeout interval = General group query interval x Robustness variable + Maximum response time for Query messages The general group query interval is configured using the **igmp timer query** command. The robustness variable is configured using the **igmp robust-count** command. The maximum response time for Query messages is configured using the **igmp max-response-time** command. The value **off** indicates that the device has not received any Report messages from IGMPv1 hosts.
Version2-host-present-timer-expiry	Timeout interval of IGMPv2 hosts. It is displayed only when the interface is running IGMPv3. The value **off** indicates that the device has not received any Report messages from IGMPv2 hosts.

8.1.7 display igmp group static

Function

The **display igmp group static** command displays information about static IGMP entries.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address*] **static** [**up** | **down**] [**verbose**]

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address* | **interface** *interface-type interface-number*]* **static** [**verbose**]

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address*] **static interface-number**

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group static interface** *interface-type interface-number* **entry-number**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about static IGMP entries in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about static IGMP entries in all instances.	-
group-address	Displays information about static IGMP entries of a specified group. If this parameter is not specified, the command displays static IGMP entries of all groups.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
up | **down**	Displays information about interfaces in Up or Down state. If this parameter is not specified, the command displays all interfaces in IGMP entries.	-
verbose	Displays detailed interface list in a static IGMP group. If the parameter is not specified, the command displays only summary of static IGMP entries.	-
interface-number	Displays the number of interfaces in a static IGMP group.	-
interface *interface-type interface-number*	Displays information about the static IGMP groups on a specified interface. *interface-type interface-number* specifies the type and number of an interface.	-

Parameter	Description	Value
entry-number	Displays the number of static IGMP groups on an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays information about static IGMP entries configured using the **igmp static-group** command.

Example

Display information about all static IGMP entries.

```
<HUAWEI> display igmp group static
Static join group information
 Total 2 entries, Total 2 active entries
  Group Address   Source Address  Interface         State     Expires
  225.1.1.1       10.1.1.1        Vlanif10          UP        never
  225.1.1.2       10.1.1.1        Vlanif20          UP        never
```

Table 8-6 Description of the **display igmp group static** command output

Item	Description
Static join group information	information about static IGMP groups.
Total 2 entries, Total 2 active entries	Number of static IGMP entries and active IGMP entries on the interface.
Group Address	Multicast group address.
Source Address	Multicast source address.
Interface	Interface type and number.
State	Status of an interface, which can be: ● UP: The interface is operating normally. ● DOWN: An error occurs on the physical link of the interface.
Expires	Amount of time left before a group entry times out. If this field displays **never**, the corresponding multicast group is a static group and will never age out.

Display detailed information about static IGMP entries.

```
<HUAWEI> display igmp group static verbose
Static join group information
 Total 2 entries
  00001.(*, 225.1.1.1)
      Total List of 1 joined interface
      1.Vlanif10
          State:            UP
          Reference Count:   1
          Multicast Boundary:NO
          Outgoing Interface:YES
  00002.(*, 225.1.1.2)
      Total List of 1 joined interface
      1.Vlanif20
          State:            UP
          Reference Count:   1
          Multicast Boundary:NO
          Outgoing Interface:YES
```

Table 8-7 Description of the display igmp group static verbose command output

Item	Description
Static join group information	information about static IGMP groups.
Total 2 entries	Number of static IGMP entries on the interface.
00001.(*, 225.1.1.1)	(*, G) entry ID.
Total List of 1 joined interface	Downstream interface list of the (*, G) entry.
1.Vlanif10	Interface type and interface number.
State	Status of an interface, which can be: ● UP: The interface is operating normally. ● DOWN: An error occurs on the physical link of the interface.
Reference Count	Number of the IGMP entry on the current interface is referenced.
Multicast Boundary	Whether the multicast forwarding boundary is configured: ● YES ● NO This function is configured using the **multicast boundary** *group-address* { *mask* | *mask-length* } command.
Outgoing Interface	Whether downstream interfaces exist: ● YES ● NO

Display lists of Up interfaces in static IGMP entries.

```
<HUAWEI> display igmp group static up
Static join group information
 Total 4 entries
  00001.(*,225.1.1.1)
      Total List of 2 joined interfaces
      Total Matched 2 interfaces

      2.Vlanif20
  00002.(*,225.1.1.2)
      Total List of 2 joined interfaces
      Total Matched 2 interfaces
      1.Vlanif10
      2.Vlanif20
```

Table 8-8 Description of the display igmp group static up command output

Item	Description
Total List of 2 joined interfaces	Number of interfaces in a static group.
Total Matched 2 interfaces	List of Up interfaces in a static group.

Display information about IGMP groups statically configured on VLANIF100.

```
<HUAWEI> display igmp group interface vlanif 100 static
Static join group information
 Total 2 entries
 Specified interface state:UP
 Total 2 entries matched
   Group Address   Source Address  Expires
   226.0.0.1       10.0.5.120      never
   226.0.0.2       0.0.0.0         never
```

Table 8-9 Description of the display igmp group interface vlanif 100 static command output

Item	Description
Static join group information	information about static IGMP groups.
Total 2 entries	Number of static IGMP entries on the interface.
Specified interface state	Status of an interface, which can be: ● UP: The interface is operating normally. ● DOWN: An error occurs on the physical link of the interface.
Total 2 entries matched	Number of IGMP groups that meet the query conditions.
Group Address	Multicast group address.
Source Address	Multicast source address.

Item	Description
Expires	Amount of time left before a group entry times out. If this field displays **never**, the corresponding multicast group is a static group and will never age out.

8.1.8 display igmp interface

Function

The **display igmp interface** command displays information about IGMP interfaces.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**]**interface** [*interface-type interface-number* | **up** | **down**] [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about IGMP interfaces in a VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMP interfaces in all instances.	-
interface-type interface-number	Displays information about a specified IGMP interface. If this parameter is not specified, the command displays information about all IGMP interfaces.	-
up	Displays information about the IGMP interfaces with the IP protocol in Up state and the IGMP protocol in Active state.	-
down	Displays information about the IGMP interfaces with the IP protocol in Down state and the IGMP protocol in Inactive state.	-
verbose	Displays detailed information about IGMP interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the IGMP configuration and running information on an interface, run the **display igmp interface** command. This command displays IGMP information only when IGMP is enabled on the interface.

Example

Display the IGMP configuration and running information on VLANIF100.

```
<HUAWEI> display igmp interface vlanif 100
Interface information of VPN-Instance: public net
 Vlanif100(192.168.1.2):
   IGMP is enabled
   Current IGMP version is 2
   IGMP state: up
   IGMP group policy: none
   IGMP limit: -
   Value of query interval for IGMP (negotiated): -
   Value of query interval for IGMP (configured): 60 s
   Value of other querier timeout for IGMP: 0 s
   Value of maximum query response time for IGMP: 10 s
   Querier for IGMP: 192.168.1.2 (this router)
  Total 1 IGMP Group reported
```

Display IGMP parameters on all interfaces.

```
<HUAWEI> display igmp interface verbose
Interface information of VPN-Instance: public net
 Vlanif100(192.168.1.2):
   IGMP is enabled
   Current IGMP version is 2
   IGMP state: up
   IGMP group policy: none
   IGMP limit: -
   Value of query interval for IGMP (negotiated): -
   Value of query interval for IGMP (configured): 60 s
   Value of other querier timeout for IGMP: 0 s
   Value of maximum query response time for IGMP: 10 s
   Value of last member query time: 2 s
   Value of last member query interval: 1 s
   Value of startup query interval: 15 s
   Value of startup query count: 2
   General query timer expiry (hours:minutes:seconds): 00:00:44
   Querier for IGMP: 192.168.1.2 (this router)
   IGMP activity: 1 joins, 0 leaves
   Robustness (negotiated): -
   Robustness (configured): 2
   Require-router-alert: disabled
   Send-router-alert: enabled
   Ip-source-policy: disabled
   Query Ip-source-policy: disabled
   Prompt-leave: disabled
   SSM-Mapping: enabled
   Startup-query-timer-expiry: off
   Other-querier-present-timer-expiry: off
```

```
 TTL-check: disabled
Total 1 IGMP Group reported
```

Table 8-10 Description of the **display igmp interface** command output

Item	Description
Interface information of VPN-Instance	VPN instance to which IGMP interface information belongs. **public net** indicates the public network instance.
Vlanif100(192.168.1.2)	Interface type and interface number (IP address).
IGMP is enabled	IGMP has been enabled on an interface. IGMP can be enabled on an interface using the **igmp enable** command.
Current IGMP version is 2	IGMP version running on an interface. IGMP has three versions: IGMPv1, IGMPv2, and IGMPv3. This parameter is configured using the **igmp version** command.
IGMP state	Status of an IGMP interface, which can be up or down.
IGMP group policy	Number of the ACL used in an IGMP group policy, which is used to control the number of groups that an interface can join. The ACL is specified by using the **igmp group-policy** command. The value **none** indicates that no ACL is applied to the interface.
IGMP limit	Maximum number of IGMP group memberships that the current interface can maintain. This parameter is configured using the **igmp limit** command.
Value of query interval for IGMP (negotiated)	Interval negotiated by non-queriers for sending Query messages. The negotiated value is only supported by IGMPv3.
Value of query interval for IGMP (configured)	Configured interval for sending IGMP Query messages. This parameter is configured using the **igmp timer query** command.
Value of other querier timeout for IGMP	Length of the other querier present timer. This parameter is configured using the **igmp timer other-querier-present** command. The value is 0 on the interface that functions as the querier.

Item	Description
Value of maximum query response time for IGMP	Maximum response time carried by an IGMP Query message. This parameter is configured using the **igmp max-response-time** command.
Value of last member query time	Last member query time, calculated using the following formula: Last member query time = Last member query interval x Robustness variable The last member query time is not defined in IGMPv1.
Value of last member query interval	Interval for sending Group-Specific Query messages. The value is configured using the **igmp lastmember-queryinterval** command. This interval is not defined in IGMPv1.
Value of startup query interval	Startup query interval of the querier. The interface sends Query messages at this interval when it starts to function as a querier. The value is 1/4 of the query interval configured using the **igmp timer query** command. The startup query interval is not defined in IGMPv1.
Value of startup query count	Number of query messages the querier interface sends at startup. The value is configured using the **igmp robust-count** command. The startup query count is not defined in IGMPv1.
General query timer expiry (hours:minutes:seconds)	Timeout interval of a general query timer.
Querier for IGMP	Link-local address of the IGMP querier. In IGMPv1, the querier is selected based on the multicast routing protocol. In IGMPv2, the multicast switch with the smallest IP address functions as the querier on the shared network segment.
IGMP activity: 1 joins, 0 leaves	Active group memberships on an interface. ● joins: indicates the number of IGMP groups that the interface has joined. When the interface joins a new group, the value increases by 1. When the interface leaves a group, the value remains unchanged. ● leaves: indicates the number of groups that the interface has left. When the interface leaves a group, the value increases by 1.

Item	Description
Robustness (negotiated)	Robustness variable negotiated by non-queriers. The negotiated value is only supported by IGMPv3.
Robustness (configured)	Robustness variable configured on an interface. This parameter is configured using the **igmp robust-count** command.
Require-router-alert	Whether the switch discards IGMP packets that do not contain the Router-Alert option in IP packet headers. ● enable: The switch discards IGMP packets that do not contain the Router-Alert option in IP packet headers. ● disable: The switch does not discard IGMP packets that do not contain the Router-Alert option in IP packet headers. This function is configured using the **igmp require-router-alert** command.
Send-router-alert	Whether the switch sends IGMP packets with the Router-Alert option. ● enabled: The switch sends IGMP packets with the Router-Alert option. ● disabled: The switch sends IGMP packets without the Router-Alert option. This function is configured using the **igmp send-router-alert** command.
Ip-source-policy	Whether to filter IGMP Report/Leave messages based on host addresses. ● enabled: The switch filters IGMP Report/ Leave messages based on host addresses. ● disabled: The switch does not filter IGMP Report/Leave messages based on host addresses. This function is configured using the **igmp ip-source-policy** command.
Query Ip-source-policy	Whether to filter IGMP Query messages based on source addresses. ● enabled: The switch filters IGMP Query messages based on source addresses. ● disabled: The switch does not filter IGMP Query messages based on source addresses. This function is configured using the **igmp query ip-source-policy** command.

Item	Description
Prompt-leave	Whether fast leave is enabled. - enabled: Fast leave is enabled. - disabled: Fast leave is disabled. This function is configured using the **igmp prompt-leave** command.
SSM-Mapping	Whether SSM mapping is enabled. - enabled: SSM mapping is enabled. - disabled: SSM mapping is disabled. This function is enabled using the **igmp ssm-mapping enable** command.
Startup-query-timer-expiry	Interval at which the interface sends Query messages when it starts to function as a querier. The value is 1/4 of Timer query. The value **off** indicates that the interface has not started to send Query messages. The startup query timer is enabled only when the interface starts as a querier.
Other-querier-present-timer-expiry	Status of the other querier present timer: - off: The interface considers itself a querier and no other queriers exist. - on: The interface no longer considers itself a querier and another querier exists.
TTL-check	Whether the function to check the TTL values in received IGMP Report, Leave, and Query messages is enabled: - enabled - disabled This function is configured using the **igmp ttl-check** command.
Total 1 IGMP Group reported	Indicates the number of IGMP groups that the interface dynamically joins.

8.1.9 display igmp invalid-packet

Function

The **display igmp invalid-packet** command displays statistics and details about invalid IGMP packets received by the switch.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet** [**interface** *interface-type interface-number* | **message-type** { **leave** | **query** | **report** }] *

display igmp invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about invalid IGMP messages received in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays statistics about invalid IGMP messages received in all VPN instances.	-
interface *interface-type interface-number*	Displays statistics about invalid IGMP messages received on a specified interface. If this parameter is not specified, the command displays statistics about IGMP messages received on all interfaces.	-
message-type	Displays statistics about invalid IGMP messages of a specific type.	-
leave	Displays statistics about invalid Leave messages.	-
query	Displays statistics about invalid Query messages.	-
report	Displays statistics about invalid Report messages.	-
packet-number	Displays details about a specified number of invalid, recently received IGMP messages.	The value is an integer that ranges from 1 to 100. By default, details about all invalid, currently stored IGMP messages are displayed.
verbose	Displays details about invalid IGMP messages.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display igmp invalid-packet** command to view statistics and details about invalid IGMP messages for fault location and rectification.

If IGMP entries fail to be generated on a multicast network, you can run the **display igmp invalid-packet** command to check whether devices have received invalid IGMP messages. If the command output contains statistics about invalid IGMP messages, run the **display igmp invalid-packet** [*packet-number*] **verbose** command to view details about invalid IGMP messages to locate faults.

You can run the following commands to view information about specific invalid IGMP messages:

- Run the **display igmp invalid-packet interface** *interface-type interface-number* command to view statistics about invalid IGMP messages received by a specified interface.
- Run the **display igmp invalid-packet** *packet-number* **verbose** command to view details about invalid, recently received IGMP messages. Currently, the command output can contain details about a maximum of 100 invalid IGMP messages.

Example

Display statistics about invalid IGMP messages received by the switch.

```
<HUAWEI> display igmp invalid-packet

         Statistics of invalid packets for public net:
-------------------------------------------------------------------
IGMP Query invalid packet:
Unwanted Source List    : 1000        Zero Max Resp Code      : 0
Fault Length            : 1000        Invalid Multicast Group : 0
Bad Checksum            : 0

IGMP Report invalid packet:
Fault Length            : 0           Invalid Multicast Group : 0
Invalid Multicast Source: 0           Bad Checksum            : 0
Illegal Report Type     : 0

IGMP Leave invalid packet:
Invalid Multicast Group : 0           Bad Checksum            : 0
-------------------------------------------------------------------
```

Table 8-11 Description of the **display igmp invalid-packet** command output

Item	Description
Statistics of invalid packets for public net	Statistics of invalid IGMP messages in public network.
IGMP Query invalid packet	Number of invalid IGMP Query messages.
Unwanted Source List	Number of messages with unwanted source lists.

Item	Description
Zero Max Resp Code	Number of messages whose Max Resp Code field is 0.
Fault Length	Number of messages with invalid lengths.
Invalid Multicast Group	Number of messages with invalid group addresses.
Bad Checksum	Number of messages with checksum errors.
IGMP Report invalid packet	Number of invalid IGMP Report messages.
Invalid Multicast Source	Number of messages with invalid multicast source addresses.
Illegal Report Type	Number of IGMP Report messages of invalid types.
IGMP Leave invalid packet	Number of invalid IGMP Leave messages.

Display details of one invalid recently received IGMP message.

```
<HUAWEI> display igmp invalid-packet 1 verbose
      Detailed information of invalid packets
-----------------------------------------------------
Packet information (Index 6):
-----------------------------------------------------
Interface           :  Vlanif100
Time                :  2010-06-09 11:03:51 UTC-08:00
Message Length      :  24
Invalid Type        :  Invalid Multicast Group
0000: 16 3c 00 00 01 34 04 04
-----------------------------------------------------
```

Table 8-12 Description of the **display igmp invalid-packet 1 verbose** command output

Item	Description
Detailed information of invalid packets	Details about the invalid IGMP message.
Packet information (Index 6)	Sequence number of the invalid IGMP message, which is numbered in the opposite order in which the message is received.
Interface	Interface receiving invalid IGMP messages.

Item	Description
Time	Time when the invalid IGMP message is received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is configured using the **clock timezone** command; DST indicates that the daylight saving time is configured using **clock daylight-saving-time** command.
Message Length	Length of the invalid IGMP message.
Invalid Type	Type of the invalid IGMP message.
0000: 16 3c 00 00 01 34 04 04	Contents of the invalid IGMP message.

8.1.10 display igmp proxy group

Function

The **display igmp proxy group** command displays information about IGMP proxy groups.

Format

display igmp proxy [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** [*group-address*] [**interface** *interface-type interface-number*] [**verbose**]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about IGMP proxy groups in a specific VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMP proxy groups in all VPN instances.	-

Parameter	Description	Value
group-address	Specifies a multicast group address. If you specify *group-address* in this command, the command displays information about a specified multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
interface *interface-type interface-number*	Displays information about IGMP proxy groups in the specified instances.	-
verbose	Displays detailed information about IGMP proxy groups. If you specify **verbose** in this command, the command displays status parameters of IGMP groups.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the status of an IGMP proxy group or find out the cause of a fault in an IGMP proxy group, run the **display igmp proxy group** command.

Example

Display information about IGMP proxy groups.

```
<HUAWEI> display igmp proxy group
Interface group report information
    Vlanif100(10.1.6.2):
     Total 2 IGMP proxy Groups
      Group Address   Filter mode
      225.1.1.1       exclude
      225.1.1.2       include
```

Display details of IGMP proxy groups.

```
<HUAWEI> display igmp proxy group verbose
Interface group report information
       Vlanif100(10.1.6.2):
        Total 2 IGMP proxy Groups
        Group: 225.1.1.1
          Filter mode: exclude
          Query Response Expiry: 00:00:02
          Source list (total 1 source)
             Source: 2.1.1.1
        Group: 225.1.1.2
          Filter mode: include
          Query Response Expiry: off
          Source list (total 1 source)
             Source: 2.1.1.2
```

Table 8-13 Description of the **display igmp proxy group** command output

Item	Description
Interface group report information	-
Vlanif100(10.1.6.2)	Interface type and interface number (IP address).
Total 2 IGMP proxy Groups	Total two IGMP proxy groups on an interface.
Group Address	Multicast group address.
Filter mode	Filter mode of a group, which can be exclude or include.
Query Response Expiry	Amount of time before the query response time expires.
Source list (total 1 source)	Multicast source list (number of sources in the source list).
Source	Multicast source address.
Group	Multicast group address.

8.1.11 display igmp proxy interface

Function

The **display igmp proxy interface** command displays information about IGMP proxy interfaces.

Format

display igmp proxy [**vpn-instance** *vpn-instance-name* | **all-instance**] **interface** [*interface-type interface-number*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about IGMP proxy interfaces in a specific VPN instance. If neither **vpn-instance** nor **all-instance** is specified, the command displays only IGMP proxy interfaces in the public network instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMP proxy interfaces in all VPN instances.	-
interface-type interface-number	Displays information about IGMP proxy interfaces in a specific interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the status of an IGMP proxy interface or find out the cause of a fault in an IGMP proxy interface, run the **display igmp proxy interface** command.

Example

Display information about IGMP proxy interfaces.

```
<HUAWEI> display igmp proxy interface
Interface information of VPN-Instance: public net
 Vlanif100(192.168.1.2):
   IGMP proxy is enabled
   Current IGMP proxy version (negotiated) is 2
   Current IGMP proxy version (configured) is 2
   IGMP proxy state: up
   Value of query interval for IGMP (negotiated): 60 s
   Value of query interval for IGMP (configured): 60 s
   Value of querier present timeout for IGMPv1: off
   Value of querier present timeout for IGMPv2: 168 s
   Value of querier present timeout for IGMPv3: 124 s
   General query response expiry: off
   Querier for IGMP: 192.168.1.1
   Robustness (negotiated): 3
   Robustness (configured): 3
   Require-router-alert: disabled
   Send-router-alert: enabled
   Ip-source-policy: disabled
   Query ip-source-policy: 2000
   TTL-check: disabled
```

Table 8-14 Description of the **display igmp proxy interface** command output

Item	Description
Interface information of VPN-Instance: public net	VPN instance to which IGMP proxy interface information belongs. **public net** indicates the public network instance.
Vlanif100(192.168.1.2)	Interface type and interface number (IP address).
IGMP proxy is enabled	IGMP proxy is enabled on the interface.
Current IGMP proxy version (negotiated) is	Negotiated IGMP version on the IGMP proxy interface .
Current IGMP proxy version (configured) is	Configured IGMP version on the IGMP proxy interface.
IGMP proxy state	Status of the IGMP proxy interface, which can be Up or Down.
Value of query interval for IGMP (negotiated)	Query interval negotiated between the query interval configured on the IGMP proxy interface and the query interval carried in a Query message, in seconds. Only IGMPv3 Query messages carry this field. This field takes effect only in IGMPv3.
Value of query interval for IGMP (configured)	Interval at which the IGMP proxy interface sends IGMP Query messages, in seconds.
Value of querier present timeout for IGMPv1	Timeout period of an IGMPv1 querier.
Value of querier present timeout for IGMPv2	Timeout period of an IGMPv2 querier.
Value of querier present timeout for IGMPv3	Timeout period of an IGMPv3 querier.
General query response expiry	Timeout period of a general group query timer.
Querier for IGMP	Address of an IGMP querier. In IGMPv1, a querier is selected based on a multicast routing protocol; in IGMPv2 and IGMPv3, the switch with the lowest IP address acts as the querier on the shared network segment. If no querier exists, this field is displayed as "-".
Robustness (negotiated)	Robustness variable negotiated between the robustness variable configured on an IGMP proxy interface and the robustness variable carried in a Query message. This field takes effect only in IGMPv3.

Item	Description
Robustness (configured)	Robustness variable configured on the IGMP proxy interface.
Require-router-alert	Whether the switch discards IGMP packets that do not contain the Router-Alert option in IP packet headers. ● enable: The switch discards IGMP packets that do not contain the Router-Alert option in IP packet headers. ● disable: The switch does not discard IGMP packets that do not contain the Router-Alert option in IP packet headers. This function is configured using the **igmp require-router-alert** command.
Send-router-alert	Whether the switch sends IGMP packets with the Router-Alert option. ● enabled: The switch sends IGMP packets with the Router-Alert option. ● disabled: The switch sends IGMP packets without the Router-Alert option. This function is configured using the **igmp send-router-alert** command.
Ip-source-policy	Whether to filter IGMP Report/Leave messages based on host addresses. ● enabled: The switch filters IGMP Report/Leave messages based on host addresses. ● disabled: The switch does not filter IGMP Report/Leave messages based on host addresses. This function is configured using the **igmp ip-source-policy** command.
Query ip-source-policy	Whether to filter IGMP Query messages based on source addresses. ● enabled: The switch filters IGMP Query messages based on source addresses. ● disabled: The switch does not filter IGMP Query messages based on source addresses. This function is configured using the **igmp query ip-source-policy** command.

Item	Description
TTL-check	Whether the function to check the TTL values in received IGMP Report, Leave, and Query messages is enabled: - enabled - disabled This function is configured using the **igmp ttl-check** command.

8.1.12 display igmp proxy routing-table

Function

The **display igmp proxy routing-table** command displays information about an IGMP proxy routing table.

Format

display igmp proxy [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table** [*group-address* [**mask** { *group-mask-length* | *group-mask* }] | *source-address* [**mask** { *source-mask-length* | *source-mask* }] | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **none** } | **incoming-interface** *interface-type interface-number* | **flags** *flag-value* | **fsm**] * [**outgoing-interface-number** [*number*]]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about an IGMP proxy routing table in a specific VPN instance. If you specify neither **vpn-instance** nor **all-instance** in this command, the command displays only the IGMP proxy routing table in the public network instance.	The value must be an existing VPN instance name.
all-instance	Displays information about IGMP proxy routing tables in all VPN instances.	-

Parameter	Description	Value
group-address	Displays information about the routing entry of a specified group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
mask	Indicates the mask of a multicast group address or a source address.	-
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
group-mask	Specifies the mask of a multicast group address.	The value is in dotted decimal notation.
source-address	Displays the routing entry for a multicast source.	The value is in dotted decimal notation.
source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 32.
source-mask	Specifies the mask of a multicast source address.	The value is in dotted decimal notation.
outgoing-interface	Displays the routing entries with a specific interface as the outbound interface.	-
include	Displays the routing entries of which the downstream interface list has a specific interface.	-
exclude	Displays the routing entries of which the downstream interface list does not have a specific interface.	-
match	Displays the routing entries of which the downstream interface list has only a specific interface.	-
interface-type interface-number	Specifies the type and number of an interface.	-

Parameter	Description	Value
none	Displays the routing entries with an empty downstream interface list.	-
incoming-interface	Displays the routing entries with a specific interface as the inbound interface.	-
flags *flag-value*	Indicates an IGMP proxy routing entry with a specific type. *flag-value* specifies the flag of a routing entry. If you specify **flags** *flag-value* in this command, the command displays IGMP proxy routing entries with the flag.	*flag-value* can be act, del, join, none, niif, sgjoin, wcjoin, upchg, or wc. For information about each value, see the flag-value field description in the **display pim routing-table** command output.
fsm	Displays detailed information about a finite state machine (FSM).	-
outgoing-interface-number	Displays the number of downstream interfaces in an IGMP proxy routing entry.	-
number	Specifies the number of downstream interfaces in an entry to be queried.	The value is an integer that ranges from 0 to 2048.

1: Monitoring level

Usage Guidelines

To find information about an IGMP proxy routing table, run the **display igmp proxy routing-table** command. You can specify different parameters in this command to view specific routing information. This command helps you find specific routes and locate faults.

Example

Display details of an FSM in an IGMP proxy routing table.

```
<HUAWEI> display igmp proxy routing-table fsm
Routing table
```

```
Total 1 (*, G) entry; 1 (S, G) entry

 (*, 225.1.1.1)
     Flag: WC, UpTime: 6d:10h
     Upstream interface: Vlanif100
     Downstream interface(s) information:
     Total number of downstreams: 1
         1: Vlanif200
             Protocol: igmp, UpTime: 17:27:13
             IGMP querier: 10.1.1.1(this router)
             IGMP state: EXCLUDE

     FSM information for non-downstream interfaces: None

 (10.3.3.100, 225.1.1.1)
     Flag: JOIN ACT, UpTime: 6d:17h
     Upstream interface: GigabitEthernetVlanif100
     Downstream interface(s) information:
     Total number of downstreams: 1
         1: Vlanif200
             Protocol: igmp, UpTime: 17:27:13
             IGMP querier: 10.1.1.1(this router)
             IGMP state: NI

     FSM information for non-downstream interfaces: None
```

Table 8-15 Description of the **display igmp proxy routing-table fsm** command output

Item	Description
Routing table	-
Total 1 (*, G) entry; 1 (S, G) entry	Total number of (*, G) and (S, G) entries in the IGMP proxy routing table.
(*, 225.1.1.1)	(*, G) or (S, G) entry in the IGMP proxy routing table.
Flag	Flag of a (*, G) or an (S, G) entry in the IGMP proxy routing table.
UpTime	Amount of time since a (*, G) or an (S, G) entry is created.
Upstream interface	Upstream interface of a (*, G) or an (S, G) entry.
Downstream interface(s) information	Information about downstream interfaces.
Total number of downstreams	Total number of downstream interfaces.
Vlanif200	Name of a downstream interface.
Protocol	Protocol of a downstream interface.

Item	Description
UpTime	Amount of time a downstream interface has been in Up state, expressed in hh:mm:ss format. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
IGMP querier	Address of an IGMP querier
IGMP state	IGMP status on a downstream interface: ● NI: indicates that an (S, G) entry inherits the downstream interfaces of a (*, G) entry. ● BLOCK: indicates that the interface does not forward traffic based on an (S, G) entry. ● INCLUDE: indicates that the interface needs to join the specified group and source. ● EXCLUDE: indicates that the interface does not join the specified group and source.
FSM information for non-downstream interfaces	Interfaces that do not forward multicast data packets matching (*, G) or (S, G) entries.

8.1.13 display igmp routing-table

Function

The **display igmp routing-table** command displays the IGMP routing table.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table** [*group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }]] * [**static**] [**outgoing-interface-number** [*number*]]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays IGMP routing information in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays IGMP routing information in all instances.	-
group-address	Displays IGMP routing information of a specified multicast group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Indicates the mask of a multicast group address or a multicast source address.	-
group-mask	Specifies the mask of a multicast group address.	It is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Displays IGMP routing information of a specified multicast source.	It is in dotted decimal notation.
source-mask	Specifies the mask of a multicast source address.	It is in dotted decimal notation.
source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 32.
static	Displays static IGMP routing entries.	-
outgoing-interface-number	Displays the number of the outbound interfaces in IGMP routing entries.	-
number	Specifies the number of outbound interfaces. If this parameter is specified, the command displays the specified number of outbound interfaces.	The value is an integer that ranges from 1 to 2048.

Default Level

1: Monitoring level

Usage Guidelines

The **display igmp routing-table** command provides IGMP routing information. You can specify different parameters to view specific IGMP routing information and locate faults.

NOTE

This command provides output information only when PIM is not enabled on the IGMP-capable interface.

Example

Display the IGMP routing table.

```
<HUAWEI> display igmp routing-table
Routing table
 Total 2 entries

 00001. (10.10.10.10, 232.1.1.3)
       List of 1 downstream interface in include mode
        Vlanif100 (10.20.20.1),
                   Protocol: SSM-MAP

 00002. (*, 225.1.1.1)
       List of 1 downstream interface
        Vlanif100 (10.20.20.1),
                   Protocol: IGMP
```

Table 8-16 Description of the **display igmp routing-table** command output

Item	Description
Routing table	IGMP routing table.
Total 2 entries	Total number of IGMP routing entries.
00001. (10.10.10.10, 232.1.1.3)	Entry 00001. (S, G) indicates that data is transmitted from S to G. (*, G) indicates that data is transmitted from any source to G.
List of 1 downstream interface in include mode	List of the downstream interfaces that join the multicast group in INCLUDE mode.
Vlanif100 (10.20.20.1)	Interface type and interface number (IP address).
Protocol	Protocol type, including: ● SSM-MAP: Entries are generated using SSM mapping. ● IGMP: Entries are generated using IGMP. ● STATIC: Entries are generated by configuring static IGMP groups.

8.1.14 display igmp ssm-mapping

Function

The **display igmp ssm-mapping** command displays configuration of IGMP SSM mapping.

Format

display igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **ssm-mapping** { **group** [*group-address*] | **interface** [*interface-type interface-number*] }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays SSM mapping entries in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays SSM mapping entries in all instances.	-
group [*group-address*]	Displays the SSM mapping entries of a specified group. If *group-address* is not specified, the command displays SSM mapping entries of all groups.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
interface [*interface-type interface-number*]	Displays whether SSM mapping is enabled on a specified interface. If *interface-type interface-number* is not specified, the command displays all the interfaces that are in Up state and have SSM mapping enabled.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays mapping between multicast groups and multicast sources configured using the **ssm-mapping** command. You can also use this command to check the SSM mapping configuration on an interface. To enable SSM mapping on an interface, run the **igmp ssm-mapping enable** command in the interface view.

Example

Display SSM mapping entries of all the multicast sources and multicast groups.

```
<HUAWEI> display igmp ssm-mapping group
IGMP SSM-Mapping conversion table
 Total 2 entries    2 entries matched

 00001. (10.1.0.2, 225.1.1.0/24)

 00002. (10.1.0.2, 239.255.255.0/24)

 Total 2 entries matched
```

Table 8-17 Description of the **display igmp ssm-mapping group** command output

Item	Description
IGMP SSM-Mapping conversion table	IGMP SSM mapping table.
Total 2 entries 2 entries matched	Total number of SSM mapping entries and total number of entries matching the query conditions.
00001. (10.1.0.2, 225.1.1.0/24) 00002. (10.1.0.2, 239.255.255.0/24)	Number of an (S, G) entry.
Total 2 entries matched	Number of SSM mapping entries matching the query conditions.

Display whether IGMP SSM mapping is enabled on VLANIF100.

```
<HUAWEI> display igmp ssm-mapping interface vlanif 100
IGMP SSM-Mapping is enabled
```

Table 8-18 Description of the display igmp ssm-mapping interface vlanif 100 command output

Item	Description
IGMP SSM-Mapping is enabled	SSM mapping is enabled on the interface.

8.1.15 igmp

Function

The **igmp** command displays the IGMP view.

The **undo igmp** command deletes all configurations in the IGMP view.

Format

igmp [**vpn-instance** *vpn-instance-name*]

undo igmp [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Global IGMP parameters must be configured in the IGMP view.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

NOTE

Running the **undo igmp** command in the system view may interrupt IGMP services and deletes all global IGMP configurations of the public network instance. To restore the IGMP function, you have to re-run the deleted commands.

Example

Enter the IGMP view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp]
```

8.1.16 igmp enable

Function

The **igmp enable** command enables IGMP on an interface.

The **undo igmp enable** command disables IGMP on an interface.

By default, IGMP is disabled on an interface.

Format

igmp enable

undo igmp enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

User hosts and Layer 3 multicast devices directly connected to user network segments must run IGMP. A multicast device can process IGMP messages sent from user hosts only after IGMP is enabled on the interfaces connected to user network segments.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

If IGMPv1 is run on an interface, you must enable **pim dm** or **pim sm**. This is because IGMPv1 does not the querier election. In IGMPv1, the querier is specified by Protocol Independent Multicast (PIM).

If IGMPv2/v3 is run on an interface, **pim dm** or **pim sm** is recommended. Although IGMPv2/v3 supports the querier election, enabling PIM improves the system stability.

Precautions

- If PIM and IGMP need to be enabled on the same interface, enable PIM, and then IGMP.
- If IGMP parameters are configured on an interface, the parameter settings take effect only after IGMP is enabled.
- Running the **igmp enable** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

- When Layer 2 and Layer 3 multicast are both deployed, pay attention to the following points:
  - If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable IGMP on the corresponding VLANIF interface first, and then enable IGMP snooping in the VLAN. If IGMP snooping is enabled in the VLAN first, IGMP cannot be enabled on the VLANIF interface.
  - If Layer 2 and Layer 3 multicast are both configured in a VLAN, you must delete the Layer 2 multicast configuration before you can modify or delete the Layer 3 multicast configuration. This means that you must disable IGMP snooping in the VLAN first, then modify or disable the IGMP and PIM (IPv4) configuration in the VLANIF interface view, and finally enable IGMP snooping in the VLAN. Otherwise, the Layer 3 multicast configuration cannot be modified or deleted on the corresponding VLANIF interface.
  - If a VLANIF interface is shut down in the VLANIF interface view, Layer 2 multicast in the corresponding VLAN becomes ineffective accordingly. To make Layer 2 multicast effective, you must disable IGMP snooping in the VLAN first, then disable IGMP and PIM (IPv4) in the VLANIF interface view, and finally enable IGMP snooping in the VLAN.
  - When both Layer 2 and Layer 3 multicast services are configured, traffic is forwarded based on Layer 3 multicast forwarding entries instead of Layer 2 multicast forwarding entries. This means that Layer 2 multicast provides physical outbound interfaces for Layer 3 multicast, implementing accurate forwarding of multicast data. In addition, the maximum number of Layer 3 multicast forwarding entries depends on the maximum number of Layer 2 multicast forwarding entries.

Example

Enable IGMP on VLANIF100 connected to a user network segment.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp enable
```

Enable IGMP on GE0/0/1 connected to a user network segment.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp enable
```

8.1.17 igmp global limit

Function

The **igmp global limit** command sets the maximum number of IGMP entries that can be created on the switch.

The **undo igmp global limit** command deletes the configured maximum number of IGMP entries.

The following lists the maximum number of IGMP entries allowed on each model by default:

- S5720-LI, S5720S-LI: 1022
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5735S-H, S5736-S, S6720S-S: 1536
- S6730-S, S6730S-S: 4096
- S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H: 8192

Format

igmp global limit *number*

undo igmp global limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of IGMP entries that can be created on the switch.	The value is an integer that ranges from 1 to *The maximum number of IGMP entries allowed by default*. **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of IGMP entries reaches the limit, the system does not create any new IGMP entries. To enable the switch to create new IGMP entries, delete unnecessary entries or increase the limit. Alternatively, you can configure static IGMP entries or source-groups.

The number of IGMP entries is counted as follows:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.

- Each (*, G) entry established with SSM mapping is counted as one entry.

Precautions

You can also run the **limit (IGMP view)** command in the IGMP view to set the maximum number of IGMP group memberships in the system. If both the **igmp global limit** and **limit (IGMP view)** commands are run, the smaller value takes effect.

Example

Set the maximum number of IGMP entries that can be created on the switch to 248.

```
<HUAWEI> system-view
[HUAWEI] igmp global limit 248
```

8.1.18 igmp group-policy

Function

The **igmp group-policy** command configures an IGMP group policy on an interface to limit the range of multicast groups that the hosts can join.

The **undo igmp group-policy** command deletes the IGMP group policy.

By default, no IGMP group policy is configured on an interface, and the hosts can join any multicast groups.

Format

igmp group-policy *acl-number* [**1** | **2** | **3**]

undo igmp group-policy

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL or an advanced ACL. The ACL defines a multicast group range.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
1	Sets the range of multicast groups that IGMPv1 hosts can join.	-
2	Sets the range of multicast groups that IGMPv2 hosts can join.	-
3	Sets the range of multicast groups that IGMPv3 hosts can join.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To control the multicast groups that hosts on the network attached to an interface can join, specify an ACL in the **igmp group-policy** command on the interface. This configuration improves security of the IGMP application. You can also use this command to prevent the switch from receiving Join messages for specified groups.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- Before running the **igmp group-policy** command, run the **acl** command to configure the ACL that you want to apply to the group policy to limit the range of multicast groups that hosts connected to the interface can join.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that an interface can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that an interface can join.
- After the **igmp group-policy** command is executed on an interface:
  - The interface filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The interface discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.

Example

Create ACL 2005, and configure a rule that allows hosts to receive data of multicast group 225.1.1.1. Configure an IGMP group policy on VLANIF100 and

reference ACL 2005 to allow hosts connected to the interface to join only multicast group 225.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2005
[HUAWEI-acl-basic-2005] rule permit source 225.1.1.1 0
[HUAWEI-acl-basic-2005] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp group-policy 2005
```

Create ACL 2005, and configure a rule that allows hosts to receive data of multicast group 225.1.1.1. Configure an IGMP group policy on GE0/0/1 and reference ACL 2005 to allow hosts connected to the interface to join only multicast group 225.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2005
[HUAWEI-acl-basic-2005] rule permit source 225.1.1.1 0
[HUAWEI-acl-basic-2005] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp group-policy 2005
```

8.1.19 igmp ip-source-policy

Function

The **igmp ip-source-policy** command enables filtering of IGMP Report/Leave messages based on source addresses.

The **undo igmp ip-source-policy** command disables filtering of IGMP Report/Leave messages based on source addresses.

By default, the switch does not filter IGMP Report/Leave messages based on source addresses.

Format

igmp ip-source-policy [*basic-acl-number*]

undo igmp ip-source-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of a basic ACL, which defines the range of source addresses.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGMP runs on member hosts and their directly connected multicast devices. A multicast device processes all received Report/Leave messages. For security purposes, you can configure the multicast device to filter Report/Leave messages received on an interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

IGMP Report/Leave messages are encapsulated in IP packets. The **igmp ip-source-policy** command configures the switch to check the source address in the IP header of each received Report/Leave message. The switch filters Report/Leave messages based on the following rules (if ACL rules are not configured):

- If the source IP address of a Report/Leave message is 0.0.0.0 or on the same network segment as the IP address of the inbound interface, the switch processes the Report/Leave message.
- If the source IP address of a Report/Leave message is on a different network segment than the IP address of the inbound interface, the switch discards the Report/Leave message.

If you have specified an ACL rule, the interface filters out the IGMP Report/Leave messages whose source addresses do not match the ACL rule.

The **igmp ip-source-policy** command works with the **acl** command. For a numbered ACL, you can configure the source address of IGMP messages by specifying the **source** parameter in the **rule** command in the basic ACL view.

Example

Enable filtering of IGMP Report/Leave messages based on source addresses on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp ip-source-policy
```

Configure VLANIF100 to accept the IGMP Report/Leave messages with the source address 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.10.1.1 0
[HUAWEI-acl-basic-2001] quit
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp ip-source-policy 2001
```

Enable filtering of IGMP Report/Leave messages based on source addresses on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp ip-source-policy
```

8.1.20 igmp lastmember-queryinterval

Function

The **igmp lastmember-queryinterval** command configures interval at which an IGMP querier interface sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages after receiving IGMP Leave messages from hosts.

The **undo igmp lastmember-queryinterval** command restores the default value.

By default, the interval at which an IGMP querier interface sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages is 1s.

Format

igmp lastmember-queryinterval *interval*

undo igmp lastmember-queryinterval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which an IGMP querier sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages.	The value is an integer that ranges from 1 to 5, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a querier receives a Leave message for a group, the querier periodically sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages to check for other members in the group. The **igmp lastmember-queryinterval** command sets the interval at which the querier sends Last Member Query messages. The querier stops forwarding multicast data to the group if it receives no Report message from the group within the period specified by *interval* x *robust-value*. Here, *robust-value* is the robustness variable configured using the **igmp robust-count** or **robust-count** command.

If the querier receives at least one more Report message from the group within the specified period, the querier continues maintaining memberships of the group. Otherwise, the querier considers that the last member has left the group and no longer maintains memberships of the group.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The **igmp lastmember-queryinterval** command is valid only when the IGMP querier runs IGMPv2 or IGMPv3.
- The **igmp lastmember-queryinterval** command has the same function as the **lastmember-queryinterval** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

Set the interval for sending IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages to 3 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp lastmember-queryinterval 3
```

Set the interval for sending IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages to 3 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp lastmember-queryinterval 3
```

8.1.21 igmp limit

Function

The **igmp limit** command sets the maximum number of IGMP group memberships allowed on an interface.

The **undo igmp limit** command restores the maximum number of IGMP group memberships allowed on an interface to the default value.

The following lists the maximum number of IGMP group memberships allowed on an interface of each model by default:

- S5720-LI, S5720S-LI: 1022
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5735S-H, S5736-S, S6720S-S: 1536
- S6730-S, S6730S-S, S5731-H, S5731S-H, S5732-H, S6730-H, S6730S-H: 2048
- S6720S-EI, S6735-S, S6720-EI: 4096

Format

igmp limit *number* [**except** *acl-number*]

undo igmp limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of IGMP group memberships allowed on an interface.	The value is an integer that ranges from 1 to *The maximum number of IGMP group memberships allowed on an interface by default.* **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.
except	Specifies the range of multicast groups whose IGMP entries are not limited by the IGMP limit.	-

Parameter	Description	Value
acl-number	Specifies a basic ACL or an advanced ACL.	The value is an integer. The basic ACL number ranges from 2000 to 2999. A basic ACL filters group addresses only. The advanced ACL number ranges from 3000 to 3999. An advanced ACL filters (S, G) entries as well as group addresses.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of IGMP entries reaches the limit, the system does not create any IGMP entries. To allow the switch to create more IGMP entries, delete useless entries or increase the limit. Alternatively, you can configure static IGMP entries.

The number of IGMP entries is counted as follows:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.
- Each (*, G) entry for SSM mapping is counted as one entry.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

If **except** is not specified in the command, the maximum number of all dynamic IGMP (*, G) or (S, G) entries is the configured IGMP limit. Before setting **except**, configure the associated ACL. The interface then uses the ACL to filter the received IGMP Report messages. The number of entries corresponding to the multicast groups that match the ACL is not limited.

The **igmp limit** command must be used with ACL configuration commands. When configuring ACL rules, note that:

- In the basic ACL view, specify the **source** parameter in the **rule** command to set the range of multicast groups whose IGMP entries are not limited.

- In the advanced ACL view, specify the **source** parameter in the **rule** command to set the range of sources that send multicast data to the multicast groups. Specify the **destination** parameter to set the range of multicast groups whose IGMP entries are not limited.

Example

Set the maximum number of IGMP entries that can be created on the VLANIF100 to 220.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp limit 220
```

Set the maximum number of IGMP entries that can be created on the GE0/0/1 to 220.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp limit 220
```

8.1.22 igmp max-response-time

Function

The **igmp max-response-time** command sets the maximum response time for IGMP General Query messages on an interface.

The **undo igmp max-response-time** command restores the default maximum response time for General IGMP Query messages.

By default, the maximum response time for IGMP General Query messages is 10s on an interface.

Format

igmp max-response-time *interval*

undo igmp max-response-time

Parameters

Parameter	Description	Value
interval	Specifies the maximum response time for IGMP General Query messages.	The value is an integer that ranges from 1 to 25, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If hosts send IGMP Report messages immediately after they receive IGMP General Query messages, the querier on a shared network segment may receive a large number of Report messages sent from many hosts at the same time. This may cause congestion on the network.

To avoid such situations, IGMPv2 and IGMPv3 messages specify the maximum response time for IGMP General Query messages. When a host running IGMPv2 or IGMPv3 receives an IGMP General Query message, it starts a timer for the group it wants to join. The timer length is a random value between 0 and the maximum response time. When the timer times out, the host sends a Report message.

The maximum response time specifies the deadline for the host to send a Report message. An appropriate maximum response time allows hosts to respond to Query messages quickly and prevents hosts from sending Report messages at the same time.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- This command is valid only for IGMPv2 and IGMPv3.
- A shorter response time allows a multicast device to obtain multicast group member information more quickly, but consumes more bandwidth and system resources.
- The **igmp max-response-time** command has the same function as the **max-response-time** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

Set the maximum response time for IGMP General Query messages to 8 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp max-response-time 8
```

Set the maximum response time for IGMP General Query messages to 8 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp max-response-time 8
```

8.1.23 igmp on-demand

Function

The **igmp on-demand** command enables the IGMP on-demand function. This function enables a querier to maintain group memberships according to requirements of group members, without sending Query messages. After IGMP on-demand is enabled on an interface, dynamic IGMP entries on the interface will never age out.

The **undo igmp on-demand** command restores the default configuration.

By default, a querier does not maintain group memberships according to requirements of group members, and dynamic entries are aged out when the aging time expires.

Format

igmp on-demand

undo igmp on-demand

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a standard IGMP working process, a querier sends General Query messages periodically and collects group membership information based on received Report and Leave messages. Multicast group members respond to every Query message they receive. After IGMP on-demand is configured on the querier, the querier does not send Query messages, reducing IGMP packets exchanged between the querier and member hosts.

The IGMP on-demand function enables a querier to maintain group memberships based on requirements of members, without sending Query messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- IGMP on-demand applies only to IGMPv2 and IGMPv3.
- This command cannot be configured on a VLANIF interface if IGMP snooping is enabled in the VLAN corresponding to the VLANIF interface.
- If dynamic IGMP entries have been generated on the querier, run the **reset igmp group** command to clear these dynamic IGMP entries before running the **igmp on-demand** command.
- After the **igmp on-demand** command is executed on an interface (IGMP querier):
  - The interface does not send IGMP Query messages
  - IGMP group entries are generated after the interface receives IGMP Report messages and will never age out.
  - When the interface receives an IGMP Leave message, it deletes the corresponding IGMP entry.

Example

Enable the IGMP on-demand function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp on-demand
```

Enable the IGMP on-demand function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp on-demand
```

8.1.24 igmp prompt-leave

Function

The **igmp prompt-leave** command enables the fast leave function on an interface. This function enables an IGMP querier to delete IGMP entries immediately after receiving Leave messages from group members, without sending Group-Specific Query messages.

The **undo igmp prompt-leave** command disables fast leave on an interface.

By default, an IGMP querier sends a Group-Specific Query message after receiving a Leave message for a specific multicast group.

Format

igmp prompt-leave [**group-policy** *acl-number*]

undo igmp prompt-leave

Parameters

Parameter	Description	Value
group-policy	Specifies an IGMP group policy. If this parameter is specified, the fast leave function takes effect only for multicast groups specified in the policy. When specifying this parameter, ensure that the referenced ACL has been configured. The device filters Leave messages on the interface based on the ACL. ● If a host leaves a multicast group in the range permitted by the ACL, the device immediately deletes the multicast group entry without sending a Group-Specific Query message. ● If a host leaves a multicast group out of the range permitted by the ACL, the device sends a Group-Specific Query message. If this parameter is not specified, the fast leave function takes effect for all multicast groups.	-
acl-number	Specifies the number of a basic ACL or an advanced ACL. This ACL defines a range of multicast groups. The specified ACL is configured using the **acl** command.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some scenarios, a querier interface connects to only one receiver host. If the host frequently switches between multiple multicast groups, you can configure the fast leave function on the interface so that the interface can quickly respond to Leave messages sent from the host. After the fast leave function is configured, the querier does not send a Group-Specific Query message after receiving a Leave message. Instead, the querier directly notifies the upstream multicast device that the host has left the multicast group. The fast leave function reduces delay in response to Leave messages and saves network bandwidth.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- IGMP fast leave applies only to IGMPv2 and IGMPv3.
- When an interface has more than one receiver connected, enabling the fast leave function interrupts multicast traffic of the other receivers in the multicast group. It is recommended that you enable this function only on interfaces with one receiver.
- This command functions in the same way as the **prompt-leave** command used in the IGMP view, except that the configuration in the IGMP view is globally valid, whereas the configuration in the interface view is valid only for the specific interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when the configuration in the interface view is not done.

Example

Create ACL 2005 and configure a rule that allows hosts to fast leave multicast groups in the range of 225.1.0.0/16. Configure fast leave on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] acl number 2005
[HUAWEI-acl-basic-2005] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2005] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp prompt-leave group-policy 2005
```

Create ACL 2005 and configure a rule that allows hosts to fast leave multicast groups in the range of 225.1.0.0/16. Configure fast leave on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2005
[HUAWEI-acl-basic-2005] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2005] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp prompt-leave group-policy 2005
```

8.1.25 igmp proxy

Function

The **igmp proxy** command enables IGMP proxy on an interface.

The **undo igmp proxy** command disables IGMP proxy on an interface.

By default, IGMP proxy is disabled on an interface.

Format

igmp proxy [**track nqa** *admin-name test-name*]

undo igmp proxy

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
track nqa *admin-name test-name*	Specifies the administrator name and test name of an NQA test instance.	The value of either *admin-name* or *test-name* is a string of 1 to 32 case-sensitive characters, and spaces are not supported. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a simple tree topology, multicast switches directly connected to user network segments do not need to run any complicated multicast routing protocol (such as PIM). However, the upstream access devices have to manage many users because the multicast switches transparently transmit all IGMP messages from hosts. To reduce the load on the upstream device, configure IGMP proxy on the multicast switches. The multicast switches then collect and summarize Report/Leave messages received from downstream hosts before sending them to the upstream device. The multicast switches also maintain group memberships and forward multicast packets based on the group memberships. The upstream device considers the multicast switches as hosts.

IGMP proxy lacks a fault detection mechanism to trigger link switchover quickly. Therefore, multicast services will be interrupted for a long time when a link failure occurs. You can solve this problem by associating IGMP proxy with a network quality analysis (NQA) test instance. If you specify **track nqa** *admin-name test-name* in the command, IGMP proxy will be associated with the specified NQA test instance for end-to-end link status monitoring. When the NQA test instance detects a link failure on the active IGMP proxy interface, the switch with the IGMP proxy interface protection mode configured can trigger a switchover between the active/standby or active/active links quickly to minimize the communication interruption time.

- If an NQA test instance detects a primary link Down event, the IGMP proxy-capable device switches traffic from the primary link to the backup link or to the other primary link.
- If an NQA test instance detects a primary link Up event or if the NQA test instance is ineffective or deleted, the IGMP proxy-capable device switches traffic back from the backup link to the primary link or balances traffic between the primary links based on the computing result of the group hash algorithm.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

Only one active IGMP proxy interface and one backup IGMP proxy interface or two active IGMP proxy interfaces can be configured. Only the primary IGMP proxy interface can be associated with an NQA

IGMP proxy conflicts with the following features:

- PIM: If the **pim sm** or **pim dm** command has been configured on an interface, the **igmp proxy** command cannot be used on the interface. If the **igmp proxy** command is configured first, the **pim sm** or **pim dm** command cannot be used on the interface.
- IGMP: If the **igmp enable** command has been configured on an interface, the **igmp proxy** command cannot be used on the interface. If the **igmp proxy** command is configured first, the **igmp enable** command cannot be used on the interface.
- Static group: After a static group is configured on an interface, the **igmp proxy** command cannot be used on the interface. If the **igmp proxy** command has been configured, no static group can be configured on the interface.
- If two or more IGMP proxy interfaces have been configured on a device, the device's other interfaces cannot be configured as backup IGMP proxy interfaces.

Example

Enable IGMP proxy on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp proxy
```

Enable IGMP proxy on VLANIF100, and associate VLANIF100 with an NQA test instance named user test.

```
<HUAWEI> system-view
[HUAWEI] nqa test-instance user test
[HUAWEI-nqa-user-test] test-type icmp
[HUAWEI-nqa-user-test] destination-address ipv4 1.1.1.1
[HUAWEI-nqa-user-test] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp proxy track nqa user test
```

8.1.26 igmp proxy backup

Function

The **igmp proxy backup** command configures a backup IGMP proxy interface.

The **undo igmp proxy backup** command cancels the configuration.

By default, no backup IGMP proxy interface is configured.

Format

igmp proxy backup

undo igmp proxy backup

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, the IGMP proxy function becomes unavailable if the upstream interface with IGMP proxy configured fails. To enhance reliability of the IGMP service, configure a backup IGMP proxy interface after configuring IGMP proxy on the upstream interface. If the upstream interface fails, the backup interface takes over the IGMP proxy service to resume multicast services.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

An instance allows only one IGMP proxy interface and one backup IGMP proxy interface. Only one backup IGMP proxy interface can be configured on a device.

IGMP proxy conflicts with the following features:

- PIM: If the **pim sm** or **pim dm** command has been configured on an interface, the **igmp proxy backup** command cannot be used on the interface. If the **igmp proxy backup** command is configured first, the **pim sm** or **pim dm** command cannot be used on the interface.
- IGMP: If the **igmp enable** command has been configured on an interface, the **igmp proxy backup** command cannot be used on the interface. If the **igmp proxy backup** command is configured first, the **igmp enable** command cannot be used on the interface.
- Static group: After a static group is configured on an interface, the **igmp proxy backup** command cannot be used on the interface. If the **igmp proxy backup** command has been configured, no static group can be configured on the interface.
- If two or more IGMP proxy interfaces have been configured on a device, the device's other interfaces cannot be configured as backup IGMP proxy interfaces.

Example

Configure VLANIF100 as a backup IGMP proxy interface.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp proxy backup
```

8.1.27 igmp proxy interface reroute

Function

The **igmp proxy interface reroute** command deletes switchback delay configurations of IGMP proxy interfaces, so that the interfaces enter the switchback state immediately after the switchback trigger conditions are met.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

igmp proxy [**vpn-instance** *vpn-instance* | **all-instance**] **interface** [*interface-type interface-number*] **reroute**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance*	Specifies a VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all VPN instances.	-
interface [*interface-type interface-number*]	Specifies an IGMP proxy interface. If *interface-type interface-number* is not specified, the command deletes switchback delay configuration of all interfaces.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

To delete switchback delay configurations of IGMP proxy interfaces, run the **igmp proxy interface reroute** command, after which the IGMP proxy interfaces enter the switchback state immediately after the switchback trigger conditions are met.

If neither **vpn-instance** *vpn-instance* nor **all-instance** is specified, the command deletes switchback delay configurations of IGMP proxy interfaces in the public network instance only.

Example

Delete switchback delay configurations of IGMP proxy interfaces in the public network instance.

```
<HUAWEI> igmp proxy interface reroute
Warning: This operation will lead to reroute IGMP proxy in the instance to which the interface belongs.
Continue? [Y/N]:Y
```

8.1.28 igmp proxy reroute delay

Function

The **igmp proxy reroute delay** command sets a switchback delay for an IGMP proxy interface.

The **undo igmp proxy reroute delay** command restores the default configuration.

By default, an IGMP proxy interface never enters the switchback state.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

igmp proxy reroute delay { *delay-time* | **never** }

undo igmp proxy reroute delay [*delay-time* | **never**]

Parameters

Parameter	Description	Value
delay-time	Sets a switchback delay for an IGMP proxy interface.	The value is an integer ranging from 10 to 86400, in seconds.
never	Indicates that an IGMP proxy interface never enters the switchback state.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

After a primary IGMP proxy interface recovers, multicast routing entries are updated. If the primary IGMP proxy interface fails again during an entry update, multicast traffic may be lost. To resolve such issues in primary IGMP proxy interface flapping scenarios, run the **igmp proxy reroute delay** command to set a switchback delay for the IGMP proxy interface. The multicast routing entry update process then starts only after the specified switchback delay expires.

Example

Set the switchback delay to 100s for an IGMP proxy interface.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp proxy reroute delay 100
```

8.1.29 igmp query ip-source-policy

Function

The **igmp query ip-source-policy** command configures IGMP Query message filtering based on source addresses.

The **undo igmp query ip-source-policy** command restores the default configuration.

By default, no source address-based IGMP Query message filtering is configured.

Format

igmp query ip-source-policy *basic-acl-number*

undo igmp query ip-source-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of a basic ACL, which defines the range of source addresses.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker sends forged IGMP Query messages with an IP address smaller than the querier IP address, the querier will be replaced by the attacker. As a result, the real querier cannot respond to Report messages from group members and bandwidth is wasted. Source address-based IGMP Query message filtering can protect the querier from such attacks. After this function is configured on a switch, the switch accepts only the IGMP Query messages with source addresses permitted by the specified ACL. This function controls querier election.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

IGMP Query messages are encapsulated into IP messages. This command configures a policy to filter IGMP Query messages based on source addresses in IP headers, allowing only the source addresses that are in the ACL referenced in the policy.

The **igmp query ip-source-policy** command works with the **acl** command. For a numbered ACL, you can configure the source address of IGMP Query messages by specifying the **source** parameter in the **rule** command in the basic ACL view.

Example

Configure VLANIF100 to accept only the IGMP Query messages with the source address 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.10.1.1 0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp query ip-source-policy 2001
```

Configure GE0/0/1 to accept only the IGMP Query messages with the source address 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.10.1.1 0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp query ip-source-policy 2001
```

8.1.30 igmp require-router-alert

Function

The **igmp require-router-alert** command configures an interface to discard IGMP messages without the Router-Alert Option.

The **undo igmp require-router-alert** command disables an interface from checking for the Router-Alert Option in IGMP messages.

By default, the device does not check for the Router-Alert Option in IGMP messages and processes all the IGMP messages received on an interface.

Format

igmp require-router-alert

undo igmp require-router-alert

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a network device sends a packet to the corresponding protocol module for processing only when the destination address of the packet is a local interface address. Destination addresses of IGMP packets are multicast addresses but not interface addresses of multicast devices. Therefore, multicast devices do not send IGMP packets to the IGMP module, and the IGMP module cannot maintain group memberships.

The Router-Alert option in the IP header of an IGMP message solves this problem. If an IGMP message contains the Router-Alert option, the device sends the message to the routing protocol module.

You can configure the device to accept only IGMP messages with the Router-Alert option to improve IGMP security.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command has the same function as the **require-router-alert** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

Configure VLANIF100 to discard IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp require-router-alert
```

Configure GE0/0/1 to discard IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp require-router-alert
```

8.1.31 igmp robust-count

Function

The **igmp robust-count** command sets an IGMP querier robustness variable on an interface.

The **undo igmp robust-count** command restores the default IGMP querier robustness variable on an interface.

By default, the IGMP querier robustness variable is 2.

Format

igmp robust-count *robust-value*

undo igmp robust-count

Parameters

Parameter	Description	Value
robust-value	Specifies the IGMP querier robustness variable.	The value is an integer that ranges from 2 to 5.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The IGMP querier robustness variable specifies the retransmission count of IGMP packets to minimize the impact of packet loss on the network.

On a shared network segment, a querier maintains IGMP-attached group memberships. The robustness variable affects the timeout interval of group memberships. The timeout interval of group memberships is calculated using the formula:

Timeout interval of group memberships = Interval for sending IGMP General Query messages x Robustness variable + Maximum response time

The robustness variable determines the following values:

- Number of times the querier sends General Query messages when the querier starts

  When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The message sending interval during this process is 1/4 of the query interval configured using the **igmp timer query** or **timer query** command.

- Number of times the querier sends IGMPv2 Group-Specific Query messages or IGMPv3 Source-and-Group-Specific Query messages when the querier receives a Leave message

  When receiving an IGMP Leave message of a multicast group, the querier sends Group-Specific Query messages certain times specified by the robustness variable to check whether the group has members. When the querier receives a Report message indicating that source-group mapping changes, the querier sends Source-and-Group-Specific Query messages a certain number of times specified by the robustness variable. The interval for sending Group-Specific Query messages and Source-and-Group-Specific Query messages can set using the **igmp lastmember-queryinterval** or **lastmember-queryinterval** command.

- Number of times for a querier to send IGMPv3 group/source-specific query messages after receiving the Report message about the change of the relationship between the multicast group and its source list.

  When receiving a Report message, the querier sends group/source-specific query messages for the "robustness variable" times. The interval for sending group/source-specific query messages can be set using the **igmp lastmember-queryinterval** command or the **lastmember-queryinterval** command.

A larger robustness variable makes an IGMP querier more robust, but increases the timeout interval of group memberships.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **igmp robust-count** command has the same function as the **robust-count** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

Set the querier robustness variable on VLANIF100 to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp robust-count 3
```

Set the querier robustness variable on GE0/0/1 to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp robust-count 3
```

8.1.32 igmp send-router-alert

Function

The **igmp send-router-alert** command configures an interface to send IGMP messages containing the Router-Alert option in IP headers.

The **undo igmp send-router-alert** command disables an interface from sending IGMP messages containing the Router-Alert option in IP headers.

By default, the IP headers of IGMP messages sent by an interface contain the Router-Alert option.

Format

igmp send-router-alert

undo igmp send-router-alert

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch sends IGMP messages that contain the Router-Alert option in IP headers. If the switch needs to communicate with a device that does not support the Router-Alert option, run the **undo igmp send-router-alert** command to configure the switch to send IGMP messages without the Router-Alert option. The **igmp send-router-alert** command is usually used together with the **igmp require-router-alert** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **igmp send-router-alert** command has the same function as the **send-router-alert** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

Configure VLANIF100 to send IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo igmp send-router-alert
```

Configure GE0/0/1 to send IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] undo igmp send-router-alert
```

8.1.33 igmp ssm-mapping enable

Function

The **igmp ssm-mapping enable** command enables SSM mapping on an interface.

The **undo igmp ssm-mapping enable** command disables SSM mapping on an interface.

By default, SSM mapping is disabled on an interface.

Format

igmp ssm-mapping enable

undo igmp ssm-mapping enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SSM model allows only IGMPv3 hosts to specify the multicast sources which they want to receive data from. However, some hosts can only run IGMPv1 or IGMPv2. To enable these hosts to use the SSM service, configure IGMP SSM mapping on the switch. IGMP SSM mapping is implemented based on static SSM mapping entries on the switch. The switch converts (*, G) information in IGMPv1 and IGMPv2 Report messages to (S, G) information according to static SSM mapping entries to provide the SSM service for IGMPv1 and IGMPv2 hosts.

The **igmp ssm-mapping enable** command enables SSM mapping on an interface. The mappings between multicast source addresses and group addresses take effect only when SSM mapping is enabled on an interface. SSM mappings are configured using the **ssm-mapping** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The SSM mapping function takes effect on an interface only when the interface runs IGMPv3.

Example

Enable SSM mapping on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp ssm-mapping enable
```

Enable SSM mapping on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp ssm-mapping enable
```

8.1.34 igmp static-group

Function

The **igmp static-group** command configures a static multicast group on an interface.

The **undo igmp static-group** command deletes a static multicast group from an interface.

By default, no static multicast group is configured on an interface.

Format

igmp static-group *group-address* [**inc-step-mask** { *group-mask* | *group-mask-length* } **number** *group-number*] [**source** *source-address*]

undo igmp static-group { **all** | *group-address* [**inc-step-mask** { *group-mask* | *group-mask-length* } **number** *group-number*] [**source** *source-address*] }

igmp static-group *group-address* [**inc-step-mask** { *group-mask* | *group-mask-length* } **number** *group-number*] [**source** *source-address*] { **qinq pe-vid** *pe-vid* **ce-vid** *low-ce-vid* [**to** *high-ce-vid*] | **dot1q vid** *low-pe-vid* [**to** *high-pe-vid*] } (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo igmp static-group *group-address* [**inc-step-mask** { *group-mask* | *group-mask-length* } **number** *group-number*] [**source** *source-address*] { **qinq pe-vid** *pe-vid* **ce-vid** *low-ce-vid* [**to** *high-ce-vid*] | **dot1q vid** *low-pe-vid* [**to** *high-pe-vid*] } (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
group-address	Specifies a multicast group address. In batch configuration mode, this parameter specifies the start address of the multicast group range.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
inc-step-mask	Sets the step mask of group addresses in batch configuration mode.	-

Parameter	Description	Value
group-mask	Specifies the step mask of a group address in batch configuration mode, that is, the gap between two consecutive group addresses.	The value is a wildcard mask format that ranges from 0.0.0.1 to 15.255.255.255, in dotted decimal notation.
group-mask-length	Specifies the step mask length in batch configuration mode.	The value is an integer that ranges from 4 to 32. If *group-mask-length* is used to configure the step mask and the **display current-configuration** command is used to display related configurations, the step mask of group addresses is displayed in *group-mask* format.
number *group-number*	Specifies the number of group addresses in batch configuration mode.	The value is an integer that ranges from 2 to 512.
source *source-address*	Specifies a multicast source address. If the specified static group address is an SSM group address, you must specify a multicast source address for the group.	The address is in dotted decimal notation.
all	Indicates all multicast groups that an interface statically joins.	-
qinq	Statically adds a sub-interface for QinQ Virtual Local Area Network (VLAN) tag termination to a multicast group.	-
pe-vid *pe-vid*	Specifies the ID of the outer VLAN tag.	The value is a decimal integer that ranges from 1 to 4094.
ce-vid	Indicates the ID of the inner VLAN tag.	-
low-ce-vid	Specifies the lower limit of the CE-VLAN ID (inner VLAN tag).	The value is a decimal integer that ranges from 1 to 4094.

Parameter	Description	Value
to	Indicates a value range.	-
high-ce-vid	Specifies the upper limit of the CE-VLAN ID (inner VLAN tag).	The value is a decimal integer that ranges from 1 to 4094. The value of *high-ce-vid* cannot be smaller than that of *low-ce-vid*. By default, the values of *high-ce-vid* and *low-ce-vid* are the same.
dot1q	Statically adds a sub-interface for dot1q VLAN tag termination to a multicast group.	-
vid	Indicates the VLAN ID.	-
low-pe-vid	Specifies the lower limit of PE-VLAN ID (outer VLAN tag).	The value is a decimal integer that ranges from 1 to 4094.
high-pe-vid	Specifies the upper limit of PE-VLAN ID (outer VLAN tag).	The value is a decimal integer that ranges from 1 to 4094. The value of *high-pe-vid* cannot be smaller than that of *low-pe-vid*. By default, the values of *high-pe-vid* and *low-pe-vid* are the same.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following are two scenarios in which you can configure static multicast groups on user-side interfaces of the switch:

- There are long-term group members on a shared network segment, and the switch needs to forward multicast data to these group members quickly and steadily.
- A network segment has no group member or hosts on the network segment cannot send Report messages, but multicast data needs to be sent to this network segment.

After a static multicast group is configured on an interface, the switch considers that the multicast group always has members on the network segment of the interface. Therefore, the switch always forwards multicast data of the multicast group.

The **igmp static-group** command is used on an interface connected to user hosts. The command can configure a single group or source-group binding on an interface or configure multiple groups or source-group bindings in a batch.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Follow-up Procedure

If a user host no longer needs to receive multicast data of a static group, delete the static group configuration.

Precautions

- The IGMP entries of static groups configured on an interface never time out. The switch considers that this interface is always connected to group members, and keeps forwarding multicast packets of the specified multicast groups to the network segment of the interface.
- After you run the **igmp static-group** command without specifying the **qinq** or **dot1q** keyword to configure batch multicast static groups for the first time and when you run this command again, the new configuration overwrites the previous one if only the value of **group-number** is changed but the values of *group-address* and *group-mask* | *group-mask-length* are the same.

  After you run the **igmp static-group** command with specifying the **qinq** or **dot1q** keyword to configure batch multicast static groups for the first time and when you run this command again, the new configuration overwrites the previous one if only the value of **group-number** is changed but the values of *group-address* and *group-mask* | *group-mask-length* and the values of tag parameters the same. If the values of tag parameters are different, the device considers that the later command is different from the first one and the new configuration does not overwrite the previous configuration.
- You can specify the **qinq** keyword for only the sub-interface for QinQ VLAN tag termination and **dot1q** keyword for only the sub-interface for dot1q VLAN tag termination. The static group with tag parameters can be configured only on the sub-interface for QinQ VLAN tag termination or the sub-interface for dot1q VLAN tag termination.
- When the interface is configured with multiple VLAN tags, you must specify the **qinq** or **dot1q** keyword. The multicast source address cannot be specified in such a case. That is, source address and the **qinq** or **dot1q** keyword cannot be specified at the same time.

- The specified range of VLAN IDs must be consistent with that specified in the **dot1q termination vid** command or the **qinq termination pe-vid ce-vid** command. If they are inconsistent, only the intersected tag values take effect.
- When the interface that connects a multicast device to the user network segment joins a multicast group in both dynamic and static modes, the interface preferentially joins the multicast group in static mode if a conflict occurs.
- You can configure overlapping multicast group addresses in different batch configurations. When you configure multiple static multicast groups in a batch on an interface, do not delete any static group configuration before the system completes the batch static group configuration.
- Do not statically add an interface to multicast groups if the interface is in the PIM NDR or assert loser state, because such an interface will not be added to the PIM outbound interface list.

Example

Configure static multicast group 224.1.1.1 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp static-group 224.1.1.1
```

Configure the switch to forward multicast packets from multicast source 192.168.11.1 to multicast group 232.1.1.1 through VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp static-group 232.1.1.1 source 192.168.11.1
```

Configure 10 static multicast groups on VLANIF100 in a batch. Set the start multicast group address to 225.1.1.1 and the step mask length to 32.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp static-group 225.1.1.1 inc-step-mask 32 number 10
```

Configure 10 source-group bindings on VLANIF100 in a batch. Set the start multicast group address to 232.1.1.1, the source address to 192.168.11.1, and the step mask length to 32.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp static-group 232.1.1.1 inc-step-mask 32 number 10 source 192.168.11.1
```

Configure static multicast group 224.1.1.1 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp static-group 224.1.1.1
```

Configure the sub-interface for QinQ VLAN tag termination GE 0/0/1.1 to statically join multicast groups in batches, with the start group address of 225.0.0.0, the incremental mask length of 32, and the number of group addresses of 2. The outer VLAN tag is 1 and the inner VLAN tag ranges from 1 to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] vcmp role silent
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface gigabitethernet0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] igmp static-group 225.0.0.0 inc-step-mask 32 number 2 qinq pe-vid 1
ce-vid 1 to 3
```

8.1.35 igmp timer other-querier-present

Function

The **igmp timer other-querier-present** command sets the other querier present timer on an interface.

The **undo igmp timer other-querier-present** command restores the default value of the other querier present timer on an interface.

The formula used to calculate the other querier present timer value is:

Other querier present timer = Robustness variable x Interval for sending IGMP General Query messages + 1/2 x Maximum response time for IGMP query messages

If the default values of the robustness variable, the interval for sending IGMP General Query messages, and the maximum response time for IGMP query messages are used, the other querier present timer value is 125s.

Format

igmp timer other-querier-present *interval*

undo igmp timer other-querier-present

Parameters

Parameter	Description	Value
interval	Specifies the other querier present timer.	The value is an integer that ranges from 60 to 300, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user network segment connects to multiple Layer 3 multicast devices, only one Layer 3 multicast device is elected as the IGMP querier to send Query messages to hosts on the network segment. If the querier fails to send Query messages, group memberships cannot be created or maintained. Non-queriers running IGMPv2 or IGMPv3 start the other querier present timer after they fail in the querier election. If the non-queriers do not receive Query messages from the querier before the timer times out, they consider the querier failed and start a new querier election.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The **igmp timer other-querier-present** command applies only to IGMPv2 and IGMPv3.
- The **igmp timer other-querier-present** command has the same function as the **timer other-querier-present** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

NOTICE

If the other querier present timer value is shorter than the interval for sending IGMP General Query messages, the querier election is triggered frequently.

Example

On VLANIF100, set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp timer other-querier-present 200
```

On GE0/0/1, set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp timer other-querier-present 200
```

8.1.36 igmp timer query

Function

The **igmp timer query** command sets the interval at which an interface sends IGMP General Query messages.

The **undo igmp timer query** command restores the default interval at which an interface sends IGMP General Query messages.

By default, an interface sends IGMP General Query messages at an interval of 60s.

Format

igmp timer query *interval*

undo igmp timer query

Parameters

Parameter	Description	Value
interval	Specifies the interval at which an interface sends IGMP General Query messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IGMP querier checks whether a local network segment has group members by sending IGMP General Query messages at an interval, known as the general query interval. You can set the general query interval based on the needs of your network. The general query interval affects the following processes:

- When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The message sending interval during this process is 1/4 of the general query interval. The robustness variable can be set using the **igmp robust-count** command or the **robust-count** command.

- After the startup process is complete, the querier sends General Query messages at intervals to maintain the group memberships on the interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The querier is more sensitive when it sends General Query messages at a shorter interval, but more bandwidth and resources are consumed.
- The function of the **igmp timer query** command is the same as that of the **timer query** command used in the IGMP view. The configuration in the IGMP view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

NOTE

The default *interval* value in this command is 60 seconds, which is different than the default value 125 seconds defined by the RFC standard. A Huawei querier and a non-Huawei querier must send IGMP general query messages at the same interval.

Example

Set the interval at which VLANIF100 sends General Query messages to 50 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp timer query 50
```

Set the interval at which GE0/0/1 sends General Query messages to 50 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp timer query 50
```

8.1.37 igmp ttl-check

Function

The **igmp ttl-check** command enables the device to check the TTL values in received IGMP Report, Leave, and Query messages on a specific interface.

The **undo igmp ttl-check** command restores the default configuration.

By default, the device does not check the TTL values in received IGMP Report, Leave, and Query messages on an interface.

Format

igmp ttl-check

undo igmp ttl-check

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command enables TTL check for IGMP Report, Leave, and Query messages on an interface. This function protects the system against attacking IGMP messages by dropping the messages of which the TTL value is not 1. By default, TTL values of IGMP messages are not checked on an interface.

You can also configure TTL check for IGMP Report, Leave, and Query messages by using the **ttl-check** command in the IGMP view. This command takes effect for all IGMP-enabled interfaces.

Precautions

If both the **igmp ttl-check** and **ttl-check** commands are run, the **igmp ttl-check** configuration in the interface view takes precedence over the **ttl-check** configuration in the IGMP view.

Example

Enable TTL check for IGMP Report, Leave, and Query messages on a physical interface.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp ttl-check
```

Enable TTL check for IGMP Report, Leave, and Query messages on a VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] quit
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] igmp ttl-check
```

8.1.38 igmp version

Function

The **igmp version** command specifies an IGMP version on an interface.

The **undo igmp version** command restores the default IGMP version on an interface.

By default, an interface runs IGMPv2.

Format

igmp version *version*

undo igmp version

Parameters

Parameter	Description	Value
version	Specifies the IGMP version running on the interface.	The value is integer that ranges from 1 to 3.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch can only identify IGMP messages of a version earlier than its own IGMP version. To ensure normal IGMP operation, set on the switch an IGMP version the same as or alter than that running on member hosts.

If multiple switches exist on a shared network segment, configure the same IGMP version on all switch interfaces connected to hosts. Otherwise, errors may occur in IGMP operation because interfaces running different IGMP versions send packets with different formats.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command functions in the same way as the **version** command used in the IGMP view, except that the configuration in the IGMP view is globally valid, whereas the configuration in the interface view is valid only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when the configuration in the interface view is not done.

Example

Configure IGMPv1 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] igmp version 1
```

Configure IGMPv1 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] igmp version 1
```

8.1.39 lastmember-queryinterval (IGMP)

Function

The **lastmember-queryinterval** command configures interval at which an IGMP querier sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages after receiving IGMP Leave messages from hosts.

The **undo lastmember-queryinterval** command restores the default value.

By default, the interval at which an IGMP querier sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages is 1 second.

Format

lastmember-queryinterval *interval*

undo lastmember-queryinterval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages.	The value is an integer that ranges from 1 to 5, in seconds.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the querier receives a Leave message that a host sends to leave a multicast group, the querier periodically sends IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages to check for other members in the multicast group. The **lastmember-queryinterval** command sets the interval at which the querier sends Last Member Query messages. The querier stops forwarding multicast data to the group if it receives no Report message from the group within the period specified by *interval* x *robust-value*. Here, *robust-value* is the robustness variable configured using the **igmp robust-count** or **robust-count** command.

If the querier does not receive any Report message within the specified period, it considers that the last member has left the group and no longer maintains the membership of this group.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The **igmp lastmember-queryinterval** command is valid only when the IGMP querier runs IGMPv2 or IGMPv3.
- This command has the same function as the **igmp lastmember-queryinterval** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, set the interval for sending IGMP Group-Specific Query messages or IGMP Group-and-Source-Specific Query messages to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] lastmember-queryinterval 3
```

8.1.40 limit (IGMP)

Function

The **limit** command sets the maximum number of IGMP entries that can be created globally or in an instance.

The **undo limit** command restores the maximum number of IGMP entries that can be created globally or in an instance to the default value.

The following lists the maximum number of IGMP entries that can be created globally or in an instance on each model by default:

- S5720-LI, S5720S-LI: 1022
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5735S-H, S5736-S, S6720S-S: 1536
- S6730-S, S6730S-S: 4096
- S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H: 8192

Format

limit *number*

undo limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of IGMP entries that can be created globally or in the current instance.	The value is an integer that ranges from 1 to *The maximum number of IGMP entries that can be created globally or in an instance by default*. **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command sets the maximum number of IGMP entries supported globally or in an instance.

When the number of IGMP entries reaches the limit, the system does not create any IGMP entries. To enable the switch to create more IGMP entries, delete useless entries or increase the limit. Alternatively, create static IGMP entries.

The number of IGMP entries is counted as follows:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.
- Each (*, G) entry established with SSM mapping is counted as one entry.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can also run the **igmp global limit** *number* command in the system view to set the maximum number of global IGMP group memberships. If both the **limit** and **igmp global limit** *number* commands are executed, the smaller value takes effect.

Example

Set the maximum number of IGMP entries that can be created globally to 248.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] limit 248
```

8.1.41 max-response-time (IGMP)

Function

The **max-response-time** command sets a global maximum response time for IGMP General Query messages.

The **undo max-response-time** command restores the global maximum response time for IGMP General Query messages to the default value.

By default, the global maximum response time for IGMP General Query messages is 10 seconds.

Format

max-response-time *interval*

undo max-response-time

Parameters

Parameter	Description	Value
interval	Specifies the maximum response time for IGMP General Query messages.	The value is an integer that ranges from 1 to 25, in seconds.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If hosts send IGMP Report messages immediately after they receive IGMP General Query messages, the querier on a shared network segment may receive a large number of Report messages sent from many hosts at the same time. This may cause congestion on the network.

To avoid such situations, IGMPv2 and IGMPv3 messages specify the maximum response time for IGMP General Query messages. When a host running IGMPv2 or IGMPv3 receives an IGMP General Query message, it starts a timer for the group it wants to join. The timer length is a random value between 0 and the maximum response time. When the timer times out, the host sends a Report message.

The maximum response time specifies the deadline for the host to send a Report message. An appropriate maximum response time allows hosts to respond to Query messages quickly and prevents hosts from sending Report messages at the same time.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- This command applies only to IGMPv2 and IGMPv3.
- A smaller response time allows the switch to learn multicast memberships more quickly but occupies more bandwidth and system resources.
- This command has the same function as the **igmp max-response-time** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, set the maximum response time for IGMP General Query messages to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] max-response-time 8
```

8.1.42 prompt-leave (IGMP)

Function

The **prompt-leave** command enables the fast leave function globally. After receiving a Leave message for a group, the device immediately deletes the group entry, without sending an IGMP Group-Specific Query message or IGMP Group-and-Source-Specific Query message.

The **undo prompt-leave** command restores the default configuration.

By default, a multicast device sends an IGMP Group-Specific Query message or IGMP Group-and-Source-Specific Query message after receiving a Leave message from a host.

Format

prompt-leave [**group-policy** *acl-number*]

undo prompt-leave

Parameters

Parameter	Description	Value
group-policy	Specifies a group policy that controls the range of groups to which the fast leave takes effect.	-
acl-number	Specifies the number of a basic or advanced ACL. This list specifies the range of multicast groups.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.

Views

IGMP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In most cases, after receiving a Leave message of a group or source-specific group, a multicast device sends an IGMP Group-Specific Query message or IGMP Group-and-Source-Specific Query message to check whether this group has other members. To minimize the response delay and save network bandwidth, configure fast leave on multicast devices. This function enables a multicast device to delete a group or source/group entry immediately after receiving a Leave message, without sending an IGMP Group-Specific Query message or IGMP Group-and-Source-Specific Query message.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

IGMP fast leave applies only to IGMPv2 and IGMPv3.

This command functions in the same way as the **igmp prompt-leave** command used in the interface view, except that the configuration in the IGMP view is globally valid, whereas the configuration in the interface view is valid only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when the configuration in the interface view is not done.

Example

Enable IGMP fast leave in the IGMP view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] prompt-leave
```

In the IGMP view, create ACL 2000, configure an ACL rule that permits group 225.1.0.0/16, and enable IGMP fast leave for the group.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp
[HUAWEI-igmp] prompt-leave group-policy 2000
```

8.1.43 proxy reroute delay

Function

The **proxy reroute delay** command sets a switchback delay for IGMP proxy interfaces in the IGMP view.

The **undo proxy reroute delay** command restores the default configuration.

By default, IGMP proxy interfaces never enter the switchback state.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

proxy reroute delay { *delay-time* | **never** }

undo proxy reroute delay [*delay-time* | **never**]

Parameters

Parameter	Description	Value
delay-time	Sets a switchback delay for IGMP proxy interfaces.	The value is an integer ranging from 10 to 86400, in seconds.
never	Indicates that IGMP proxy interfaces never enter the switchback state.	-

Views

IGMP view of the public network instance or IGMP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

After a primary IGMP proxy interface recovers, multicast routing entries are updated. If the primary IGMP proxy interface fails again during an entry update, multicast traffic may be lost. To resolve such issues in primary IGMP proxy interface flapping scenarios, run the **proxy reroute delay** command to set a switchback delay for IGMP proxy interfaces in the IGMP view. The multicast routing entry update process then starts only after the specified switchback delay expires.

The **proxy reroute delay** command configuration applies to all IGMP proxy interfaces in the public network instance or a VPN instance. If the **igmp proxy reroute delay** command is also run for a specific IGMP proxy interface, the **igmp proxy reroute delay** command takes precedence over the **proxy reroute delay** command configuration.

Example

Set the switchback delay to 100s for IGMP proxy interfaces in the public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] igmp
[HUAWEI-igmp] proxy reroute delay 100
```

8.1.44 proxy source-lifetime

Function

The **proxy source-lifetime** command sets the timeout period for an (S, G) entry that an IGMP proxy-capable switch generates.

The **undo proxy source-lifetime** command restores the default configuration.

By default, the timeout period of an (S, G) entry that an IGMP proxy-capable switch generates is 210 seconds.

Format

proxy source-lifetime *interval*

undo proxy source-lifetime

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of an (S, G) entry.	The value is an integer that ranges from 60 to 65535, in seconds. The default value is recommended for general use.

Views

IGMP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IGMP proxy-capable switch starts a timer for each (S, G) entry and records the time when a multicast source S sends multicast packets. The **proxy source-lifetime** command sets the timeout period for (S, G) entries on an IGMP proxy-capable switch. An IGMP proxy interface starts a timer when it receives the first multicast packet from a multicast source and resets the timer every time it receives a multicast packet from the multicast source. If the interface does not receive any multicast packet from the multicast source within the timeout period, it considers the (S, G) entry invalid.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Example

#Set the timeout period for (S, G) entries to 200s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] proxy source-lifetime 200
```

In VPN instance mvpn, set the timeout period for (S, G) entries to 200s.

8.1.45 proxy source-policy

Function

The **proxy source-policy** command configures an IGMP proxy-capable router to filter received multicast data packets based on source addresses or source and group addresses.

The **undo proxy source-policy** command restores the default configuration.

By default, an IGMP proxy-capable router does not filter received multicast data packets.

Format

proxy source-policy *acl-number*

undo proxy source-policy

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL or an advanced ACL. The ACL defines a multicast group range.	The number of a basic ACL is an integer in the range 2000 to 2999. The number of an advanced ACL is an integer in the range 3000 to 3999.

Views

IGMP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an IGMP proxy-capable device needs to restrict multicast data packets sent from some multicast sources, run the **proxy source-policy** command to configure the device to filter multicast data packets based on source addresses or source and group addresses. This command can also be used to filter the multicast data encapsulated in Register messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **proxy source-policy** command takes effect only when IGMP proxy is enabled.

To reference a numbered ACL to a proxy source policy, run the **proxy source-policy** and **acl** commands together.

- In the basic ACL view, specify the **source** parameter in the **rule** command to set a multicast group range.
- In the advanced ACL view, specify **source** in the **rule** command to set a source address range and specify **destination** to set a group address range.

Named ACLs are classified into basic and advanced ACLs. The configuration rules of a named ACL are the same as that of a numbered ACL.

Example

Configure an IGMP proxy-capable router to accept the multicast data packets from multicast source 10.10.1.2 and to discard the multicast data packets from the multicast source 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.10.1.2 0
[HUAWEI-acl-basic-2001] rule deny source 10.10.1.1 0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] igmp
[HUAWEI-igmp] proxy source-policy 2001
```

Configure an IGMP proxy-capable router to accept the multicast data packets sent from multicast source 10.10.1.2 to multicast group 232.1.0.0.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl name myacl
[HUAWEI-acl-adv-myacl] rule permit ip source 10.10.1.2 0 destination 232.1.0.0 0.0.255.255
[HUAWEI-acl-adv-myacl] quit
[HUAWEI] igmp
[HUAWEI-igmp] proxy source-policy acl-name myacl
```

8.1.46 proxy ssm-policy

Function

The **proxy ssm-policy** command configures an SSM group address range for IGMP proxy.

The **undo proxy ssm-policy** command restores the default configuration.

The default SSM group address range for IGMP proxy is 232.0.0.0/8.

Format

proxy ssm-policy *basic-acl-number*

undo proxy ssm-policy

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of a basic ACL. This ACL defines a range of multicast groups.	The sequence number is an integer that ranges from 2000 to 2999.

Views

IGMP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The default SSM group address range is 232.0.0.0 to 232.255.255.255. Generally, an IGMP proxy device provides the SSM service for hosts only when it receives Report messages with a group address in this range. If the SSM group address range needs to be narrowed to ensure security of a multicast network or be expanded to increase the number of SSM group addresses, configure a new SSM group address range on the IGMP proxy device. Ensure that all the multicast devices on the network are configured with the same SSM group address range.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The SSM model can be used in the following situations:

- Multicast group addresses are in an SSM address range, IGMPv3 is running on the user network segment, and multicast source addresses are specified in Report messages.

- Multicast group addresses are in an SSM address range, IGMPv1 or IGMPv2 is running on the user network segment, and SSM mapping is configured.

The **proxy ssm-policy** command works with the **acl** command. If a basic ACL is configured, you can specify **source** in the **rule** command to configure an SSM address range.

Example

Set the SSM group address range for IGMP proxy to 232.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 232.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp
[HUAWEI-igmp] proxy ssm-policy 2000
```

8.1.47 require-router-alert (IGMP)

Function

The **require-router-alert** command configures the switch to discard IGMP messages without the Router-Alert option.

The **undo require-router-alert** command disables the switch from checking for the Router-Alert option in IGMP messages.

By default, the switch does not check whether the received IGMP messages contain the Router-Alert option in IP headers, and it accepts all the received IGMP messages.

Format

require-router-alert

undo require-router-alert

Parameters

None

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a network device sends a packet to the corresponding protocol module for processing only when the destination address of the packet is a local interface address. Destination addresses of IGMP packets are multicast addresses but not interface addresses of multicast devices. Therefore, multicast devices do not send IGMP packets to the IGMP module, and the IGMP module cannot maintain group memberships.

The Router-Alert option in IP packet headers solves this problem. This option indicates that a packet needs to be sent to the protocol module.

You can configure the switch to accept only IGMP messages with the Router-Alert option. This configuration improves security of the IGMP service.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command has the same function as the **igmp require-router-alert** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, configure the switch to discard IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] require-router-alert
```

8.1.48 reset igmp control-message counters

Function

The **reset igmp control-message counters** command clears statistics about IGMP messages.

Format

reset igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters** [**interface** *interface-type interface-number*] [**message-type** { **query** | **report** }]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears IGMP message statistics in a specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
all-instance	Clears IGMP message statistics in all instances.	-
interface *interface-type interface-number*	Clears IGMP message statistics on a specified interface. If this parameter is not specified, the command clears IGMP statistics on all interfaces.	-
message-type	Clears statistics about IGMP messages of a specified type. If this parameter is not specified, the command clears statistics about all IGMP messages.	-
query	Clears statistics about Query messages received by an interface.	-
report	Clears statistics about Report messages received by an interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

IGMP still operates normally after IGMP message statistics are deleted.

Example

Clear statistics about IGMP messages on all interfaces.

```
<HUAWEI> reset igmp control-message counters
```

Clear statistics about IGMP messages on VLANIF100.

```
<HUAWEI> reset igmp control-message counters interface vlanif 100
```

8.1.49 reset igmp explicit-tracking

Function

The **reset igmp explicit-tracking** command deletes information about the hosts with dynamic group memberships established through IGMP on an interface.

Format

reset igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **explicit-tracking** { **all** | **interface** *interface-type interface-number* [**host** *host-address* [**group** *group-address* [**source** *source-address*]]] }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Deletes information about the hosts with IGMP-attached group memberships on interfaces in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Deletes information about the hosts with IGMP-attached group memberships on interfaces in all instances.	-
all	Deletes information about all the hosts.	-
interface *interface-type interface-number*	Deletes information about the hosts with IGMP-attached group memberships on a specified interface. If this parameter is not specified, the command deletes information about the hosts with IGMP-attached group memberships on all interfaces.	-
host *host-address*	Specifies the IP address of a host.	The address is in dotted decimal notation.
group *group-address*	Specifies the address of a multicast group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
source *source-address*	Specifies the address of a multicast source.	The address is in dotted decimal notation.

3: Management level

Usage Guidelines

You can use this command to delete information about the hosts with dynamic group memberships established on interfaces using IGMP.

Example

Delete information about IGMP host 192.168.0.12 in group 232.1.1.1 on VLANIF10.

```
<HUAWEI> reset igmp explicit-tracking interface vlanif 10 host 192.168.0.12 group 232.1.1.1
```

Delete information about IGMP host 192.168.0.12 in (10.12.12.12, 232.1.1.1) on VLANIF10.

```
<HUAWEI> reset igmp explicit-tracking interface vlanif 10 host 192.168.0.12 group 232.1.1.1 source
10.12.12.12
```

8.1.50 reset igmp group

Function

The **reset igmp group** command deletes dynamic IGMP entries on interfaces.

Format

reset igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group** { **all** | **interface** *interface-type interface-number* { **all** | *group-address* [**mask** { *group-mask* | *group-mask-length* }] [*source-address* [**mask** { *source-mask* | *source-mask-length* }]] } }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Deletes dynamic IGMP entries in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Deletes dynamic IGMP entries in all instances.	-
all	The first **all** deletes dynamic IGMP entries on all interfaces. The second **all** deletes all dynamic IGMP entries on a specified interface.	-
interface *interface-type interface-number*	Deletes dynamic IGMP entries on a specified interface.	-
group-address	Deletes dynamic IGMP entries of a specified group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
mask	Sets the mask of a multicast source address or group address.	-
group-mask	Specifies the mask of a multicast group address.	The mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies a multicast source address.	The address is in dotted decimal notation.

Parameter	Description	Value
source-mask	Specifies the mask of a multicast source address.	The mask is in dotted decimal notation.
source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 32.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command does not delete static group memberships configured on interfaces.

Deleting IGMP entries on an interface does not prevent the interface from joining the involved groups again.

NOTICE

After IGMP group memberships are deleted, group members may fail to receive multicast data. Therefore, exercise caution when using this command.

Example

Delete dynamic IGMP entries on all interfaces.

```
<HUAWEI> reset igmp group all
```

Delete all dynamic IGMP entries on VLANIF100.

```
<HUAWEI> reset igmp group interface vlanif 100 all
```

Delete the IGMP entries of group 225.0.0.1 on VLANIF100.

```
<HUAWEI> reset igmp group interface vlanif 100 225.0.0.1
```

Delete IGMP entries of groups 225.1.1.0 to 225.1.1.255 on VLANIF100.

```
<HUAWEI> reset igmp group interface vlanif 100 225.1.1.0 mask 255.255.255.0
```

8.1.51 reset igmp group ssm-mapping

Function

The **reset igmp group ssm-mapping** command deletes group memberships established with SSM mapping.

Format

reset igmp [**vpn-instance** *vpn-instance-name* | **all-instance**] **group ssm-mapping** { **all** | **interface** *interface-type interface-number* { **all** | *group-address* [**mask** { *group-mask* | *group-mask-length* }] } }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Deletes group memberships established with SSM mapping in a specified VPN instance.	The value must be an existing VPN instance name.
all-instance	Deletes group memberships established with SSM mapping in all instances.	-
all	First **all**: deletes group memberships established with SSM mapping on all interfaces. Second **all**: deletes all group membership established with SSM mapping on the specified interface.	-
interface *interface-type interface-number*	Deletes group memberships established with SSM mapping on a specified interface.	-
group-address	Deletes the group membership established with SSM mapping for a specified group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Sets the mask of a multicast group address.	-
group-mask	Specifies the mask of a multicast group address.	The mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.

Views

User view

Default Level

3: Management level

Usage Guidelines

You can use this command to delete group memberships established with SSM mapping.

NOTICE

After IGMP group memberships are cleared, group members may fail to receive multicast data. Therefore, confirm your operation before clearing IGMP group information.

Example

Delete group memberships established with SSM mapping on all the interfaces.

```
<HUAWEI> reset igmp group ssm-mapping all
```

8.1.52 robust-count (IGMP)

Function

The **robust-count** command sets a global robustness variable for an IGMP querier.

The **undo robust-count** command restores the default robustness variable.

By default, the robustness variable of an IGMP querier is 2.

Format

robust-count *robust-value*

undo robust-count

Parameters

Parameter	Description	Value
robust-value	Specifies the robustness variable of an IGMP querier.	The value is an integer that ranges from 2 to 5.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The IGMP querier robustness variable specifies the retransmission count of IGMP packets to minimize the impact of packet loss on the network.

On a shared network, a querier maintains IGMP-attached group memberships on an interface. The robustness variable determines the timeout interval of group memberships. The timeout interval of group memberships is calculated using the following formula:

Timeout interval of group memberships = Interval for sending IGMP General Query messages x Robustness variable + Maximum response time

The robustness variable determines the following values:

- Number of times the querier sends General Query messages at startup

  When the querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query members of multicast groups. The interval for sending General Query messages during this process is 1/4 of the interval configured using the **igmp timer query** or **timer query** command.
- In IGMPv2 and IGMPv3, the robustness variable determines the number of times the querier sends Group-Specific Query or Source-and-Group-Specific Query messages.

  When receiving an IGMP Leave message of a multicast group, the querier sends Group-Specific Query messages a certain number of times specified by the robustness variable to check whether the group has members. When the querier receives a Report message indicating that source-group mapping changes, the querier sends Source-and-Group-Specific Query messages a certain number of times specified by the robustness variable. The interval for sending Group-Specific Query messages and Source-and-Group-Specific Query messages can be set using the **igmp lastmember-queryinterval** or **lastmember-queryinterval** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- A larger robustness variable makes an IGMP querier more robust, but increases the timeout interval of group memberships.
- This command has the same function as the **igmp robust-count** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view is valid only for the current interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, set the robustness variable of an IGMP querier to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] robust-count 3
```

8.1.53 send-router-alert (IGMP)

Function

The **send-router-alert** command configures the switch to send IGMP messages with the Router-Alert option in IP headers.

The **undo send-router-alert** command configures the switch to send IGMP messages without the Router-Alert option.

By default, IGMP messages sent by the switch contain the Router-Alert option.

Format

send-router-alert

undo send-router-alert

Parameters

None

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, IGMP messages sent by the switch contain the Router-Alert option in their IP headers. If the switch needs to communicate with a device that does not support the Router-Alert option, run the **undo send-router-alert** command to configure the switch to send IGMP messages without the Router-Alert option. The **send-router-alert** command is usually used together with the **require-router-alert** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command has the same function as the **igmp send-router-alert** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, configure the switch to send IGMP messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] undo send-router-alert
```

8.1.54 ssm-mapping (IGMP)

Function

The **ssm-mapping** command configures an SSM mapping rule to map a multicast source to a group address.

The **undo ssm-mapping** command deletes an SSM mapping rule.

By default, no SSM mapping rule is configured.

Format

ssm-mapping *group-address* { *group-mask* | *group-mask-length* } *source-address*

undo ssm-mapping { *group-address* { *group-mask* | *group-mask-length* } [*source-address*] | **static all** }

Parameters

Parameter	Description	Value
group-address	Specifies a multicast group address.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
group-mask	Specifies the mask of a multicast group address.	The mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies a multicast source address.	The address is in dotted decimal notation.
static all	Deletes all the configured static SSM mapping entries.	-

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hosts that support only IGMPv1 and IGMPv2 cannot join SSM groups. To enable multicast devices to provide the SSM service for these hosts, configure SSM mapping on the multicast devices. An SSM mapping entry maps a multicast source to a multicast group. After SSM mapping entries are configured on a multicast device, the device can convert (*, G) information in Report messages of IGMPv1 and IGMPv2 to (S, G) information.

The default range of SSM group addresses is 232.0.0.0 to 232.255.255.255. You can use the **ssm-policy** command to change the address range. All multicast groups out of this range are ASM groups.

The configured SSM mapping entries take effect only after the **igmp ssm-mapping enable** command is run on the interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- You can configure multiple static SSM mapping entries by running this command several times.
- To delete an SSM mapping entry, run the **undo ssm-mapping** *group-address* { *group-mask* | *group-mask-length* } *source-address* command. The **undo ssm-mapping static all** command deletes all the SSM mapping entries. Do not use this command unless necessary.

Example

In the public network instance, configure an SSM mapping entry to map multicast source address 10.8.8.8 to group address 225.5.5.5/32.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] ssm-mapping 225.5.5.5 32 10.8.8.8
```

8.1.55 timer other-querier-present (IGMP)

Function

The **timer other-querier-present** command sets the other querier present timer.

The **undo timer other-querier-present** command restores the default value of the other querier present timer.

The formula used to calculate the other querier present timer value is:

Other querier present timer = Robustness variable x Interval for sending IGMP General Query messages + 1/2 x Maximum response time for IGMP query messages

If the robustness variable, the interval for sending IGMP General Query messages, and the maximum response time for IGMP Query messages all use default values, the other querier present timer value is 125 seconds.

Format

timer other-querier-present *interval*

undo timer other-querier-present

Parameters

Parameter	Description	Value
interval	Specifies the other querier present timer value.	The value is an integer that ranges from 60 to 300, in seconds.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user network segment connects to multiple Layer 3 multicast devices, only one Layer 3 multicast device is elected as the IGMP querier to send Query messages to hosts on the network segment. If the querier fails to send Query messages, group memberships cannot be created or maintained. Non-queriers running IGMPv2 or IGMPv3 start the other querier present timer after they fail in the querier election. If the non-queriers do not receive Query messages from the querier before the timer times out, they consider the querier failed and start a new querier election.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- This command applies only to IGMPv2 and IGMPv3.
- This command has the same function as the **igmp timer other-querier-present** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when the configuration in the interface view is not done.

NOTICE

If the other querier present timer value is shorter than the interval for sending IGMP General Query messages, the querier election is triggered frequently.

Example

In the IGMP view, set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] timer other-querier-present 200
```

8.1.56 timer query (IGMP)

Function

The **timer query** command sets a global interval for sending IGMP General Query messages.

The **undo timer query** command restores the default interval for sending IGMP General Query messages.

By default, the interval for sending IGMP General Query messages is 60 seconds.

Format

timer query *interval*

undo timer query

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending IGMP General Query messages	The value is an integer that ranges from 1 to 18000, in seconds.

Views

IGMP view of the public network instance, IGMP view of a VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IGMP querier checks whether a local network segment has group members by sending IGMP General Query messages at an interval, known as the general query interval. You can set the general query interval based on needs of your network. The general query interval affects the following processes:

- When the querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query members of multicast groups. The message sending interval during this process is 1/4 of the interval for sending General Query messages. The robustness variable is configured using the **igmp robust-count** or **robust-count** command.
- After the startup process is complete, the querier sends General Query messages at intervals to maintain the group memberships on the interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The querier is more sensitive when it sends General Query messages at a shorter interval. However, more bandwidth and switch resources are consumed in this case.
- This command has the same function as the **igmp timer query** command used in the interface view. The configuration in the IGMP view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when no configuration is performed in the interface view.

Example

In the IGMP view, set the global interval for sending IGMP General Query messages to 125 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] timer query 125
```

8.1.57 ttl-check (IGMP)

Function

The **ttl-check** command enables the device to check the TTL values in received IGMP Report, Leave, and Query messages on all interfaces.

The **undo ttl-check** command restores the default configuration.

By default, the device does not check the TTL values in received IGMP Report, Leave, and Query messages.

Format

ttl-check

undo ttl-check

Parameters

None

Views

IGMP view of the public network instance or IGMP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

To protect a device against IGMP message attacks, run the **ttl-check** command to enable the device to check the TTL values in received IGMP Report, Leave, and Query messages on all interfaces and discard such a message if its TTL value is not 1.

Example

Enable TTL check for IGMP Report, Leave, and Query messages in the IGMP view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] ttl-check
```

8.1.58 version (IGMP)

Function

The **version** command configures a global IGMP version.

The **undo version** command restores the default configuration.

By default, the IGMP version is IGMPv2.

Format

version *version*

undo version

Parameters

Parameter	Description	Value
version	Specifies the IGMP version running on the interface.	The value is integer that ranges from 1 to 3.

Views

IGMP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch can identify IGMP messages of a version earlier than its own IGMP version. To ensure normal IGMP operation, set on the switch an IGMP version the same as or later than that running on user hosts.

If multiple switches exist on a shared network segment, configure the same IGMP version on all switch interfaces connected to hosts. Otherwise, errors may occur in IGMP operation because interfaces running different IGMP versions send packets with different formats.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command functions in the same way as the **igmp version** command used in the interface view, except that the configuration in the IGMP view is globally valid, whereas the configuration in the interface view is valid only for the specified interface. The configuration in the interface view takes precedence over the configuration in the IGMP view. The configuration in the IGMP view is used only when the configuration in the interface view is not done.

Example

Set the IGMP version to IGMPv3 globally.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] igmp
[HUAWEI-igmp] version 3
```

8.2 MLD Configuration Commands

8.2.1 MLD Configuration Commands

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.

Product	Support
S6700	Supported.

8.2.2 display default-parameter mld

Function

The **display default-parameter mld** command displays default MLD configurations.

Format

display default-parameter mld

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check default MLD parameter settings even after MLD parameters are modified. This command helps you determine which MLD parameters have been modified.

Example

Display default MLD configurations.

```
<HUAWEI> display default-parameter mld
 MLD View Default Configurations:
 --------------------------------
 Lastmember-queryinterval: 1 s
 Lastmember-query time: 2 s
 Max-response-time: 10 s
 Require-router-alert: disabled
 Robust-count: 2
 Send-router-alert: enabled
 Ssm-mapping: disabled
 Timer query: 125 s

 Interface View Default Configurations:
 -------------------------------------
 Group-policy: disabled
 Last listener query time: 2 s
 Lastlistener-query-interval: 1 s
 Max-response-time: 10 s
```

```
Other-querier-present-timer-expiry: off
Prompt-leave: disabled
Require-router-alert: disabled
Robust-count: 2
Send-router-alert: enabled
Ssm-mapping: disabled
Startup-query-timer-expiry: off
Static-group:  disabled
Timer query: 125 s
Version: 2
Ipsec sa: disabled
```

Table 8-19 Description of the **display default-parameter mld** command output

Item	Description
MLD View Default Configurations	Default configurations in the MLD view.
Lastmember-queryinterval	Interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages. This parameter is configured using the **lastlistener-queryinterval (MLD view)** command in the MLD view or the **mld lastlistener-queryinterval** command in the interface view.
Lastmember-query time	Last listener query time, equaling Lastmember-query-interval x Robust-count.
Max-response-time	Maximum response time for MLD Query messages. This parameter is configured using the **max-response-time (MLD view)** command in the MLD view or the **mld max-response-time** command in the interface view.
Require-router-alert	Whether the switch checks the Router-Alert option in received MLD messages. This function is configured using the **require-router-alert (MLD view)** command in the MLD view or the **mld require-router-alert** command in the interface view.
Robust-count	Robustness variable of the MLD querier. This parameter is configured using the **robust-count (MLD view)** command in the MLD view or the **mld robust-count** command in the interface view.
Send-router-alert	Whether the MLD messages sent from the switch carry the Router-Alert option. This function is configured using the **send-router-alert (MLD view)** command in the MLD view or the **mld send-router-alert** command in the interface view.

Item	Description
Ssm-mapping	Status of the MLD SSM mapping function. The value can be: ● enabled: This function is enabled. ● disabled: This function is disabled. This function is configured using the **mld ssm-mapping enable** command in the interface view.
Timer query	Interval for sending MLD General Query messages. This parameter is configured using the **timer query (MLD view)** command in the MLD view or the **mld timer query** command in the interface view.
Interface View Default Configurations	Default configurations in the interface view.
Group-policy	Whether a multicast group policy is configured. ● enabled: A multicast group policy is configured. ● disabled: No multicast group policy is configured. A multicast group policy is configured using the **mld group-policy** command.
Last listener query time	Last listener query time, equaling Lastlistener-query-interval x Robust-count.
Lastlistener-query-interval	Interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages.
Other-querier-present-timer-expiry	Status of the other querier present timer. ● off: The interface considers itself a querier and no other queriers exist. ● on: The interface no longer considers itself a querier and another querier exists.
Prompt-leave	Whether the fast leave function is configured. This function is configured using the **mld prompt-leave** command.
Startup-query-timer-expiry	Status of the query timer on the interface that functions as the querier. ● off: The interface has sent Query messages. ● on: The interface has not finished sending Query messages.

Item	Description
Static-group	Whether static multicast groups are configured. ● enabled: Static multicast groups are configured. ● disabled: No static multicast groups are configured. A static multicast group is configured on an interface using the **mld static-group** command.
Version	MLD version number. MLD has two versions: MLDv1 and MLDv2. This parameter is configured using the **mld version** command.
Ipsec sa	Whether IPSec is enabled on the interface. The switch does not support this function.

8.2.3 display mld control-message counters

Function

The **display mld control-message counters** command displays statistics about MLD control messages.

Format

display mld control-message counters [**interface** *interface-type interface-number*] [**message-type** { **query** \| **report** }]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about MLD messages on a specified interface. If this parameter is not specified, the command displays statistics about MLD messages on all interfaces.	-
message-type	Displays statistics about MLD messages of a specified type. If this parameter is not specified, the command displays statistics about all types of MLD messages.	-
query	Displays statistics about Query messages received by the interface. Query messages are sent from a querier.	-
report	Displays statistics about Report messages received by the interface. Report messages are sent by hosts to join a multicast group.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the number of MLD control messages sent and received on an interface.

Example

Display statistics about the MLD messages sent and received by VLANIF100.

```
<HUAWEI> display mld control-message counters interface vlanif 100
Interface message counter information
 Vlanif100(FE80::219:74FF:FE59:3302):
 Message Type                 Sent        Valid       Invalid     Ignore

 ALLOW Report                 0           0           0           0
 BLOCK Report                0           0           0           0
 Source Records Total         0           0           0           0
 -----------------------------------------------------------------
 Others                     -           -           0           0
 -----------------------------------------------------------------
```

Table 8-20 Description of the **display mld control-message counters interface vlanif 100** command output

Item	Description
Interface message counter information	Statistics about MLD messages on an interface.
Vlanif100(FE80::219:74FF:FE59:3302)	Interface type and interface number (IPv6 link-local address).
Message Type	Type of the MLD messages.
Sent	Number of MLD messages sent from the interface.

Item	Description
Valid	Number of valid MLD messages received by the interface.
Invalid	Number of invalid MLD messages received by the interface.
Ignore	Number of received MLD messages ignored by the interface.
General Query	Number of MLD General Query messages.
Group Query	Number of MLD Multicast Address Specific Query messages.
Source Group Query	Number of MLD Multicast Address and Source Specific Query messages.
Report ASM	Number of MLDv1 Multicast Listener Report messages with multicast group addresses in the ASM group address range.
Report SSM	Number of MLDv1 Multicast Listener Report messages with multicast group addresses in the SSM group address range.
DONE ASM	Number of MLDv1 Multicast Listener Done messages with multicast group addresses in the ASM group address range.
DONE SSM	Number of MLDv1 Multicast Listener Done messages with multicast group addresses in the SSM group address range.
ISIN Report	Number of MLDv2 Multicast Listener ISIN Report messages.
ISEX Report	Number of MLDv2 Multicast Listener ISEX Report messages.
TOIN Report	Number of MLDv2 Multicast Listener TOIN Report messages.
TOEX Report	Number of MLDv2 Multicast Listener TOEX Report messages.
ALLOW Report	Number of MLDv2 Multicast Listener ALLOW Report messages.
BLOCK Report	Number of MLDv2 Multicast Listener BLOCK Report messages.
Source Records Total	Number of multicast sources carried in MLDv2 messages.

Item	Description
Others	Total number of ignored MLD messages and invalid MLD messages whose types cannot be identified.

8.2.4 display mld explicit-tracking

Function

The **display mld explicit-tracking** command displays information about the MLDv2 hosts that have joined the specific source/group in Include mode.

Format

display mld explicit-tracking [**interface** *interface-type interface-number* [**host-address** *ipv6-host-address* | **group** *ipv6-group-address* **source** *ipv6-source-address*]]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about MLDv2 hosts that join a specified multicast source in Include mode on a specified interface. If this parameter is not specified, the command displays information about MLDv2 hosts that join a specified multicast source in Include mode on all interfaces.	-
host-address *ipv6-host-address*	Specifies the link-local address of a host.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FE80:: to FE80:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
group *ipv6-group-address*	Specifies the IPv6 address of a multicast group.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.

Parameter	Description	Value
source *ipv6-source-address*	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to view information about MLDv2 hosts that have dynamically joined specified sources/groups in Include mode.

Example

Display information about the MLDv2 hosts that have joined the specific source/group in Include mode.

```
<HUAWEI> display mld explicit-tracking
Explicit-tracking information
 Total 2 hosts, 4 entries

 Vlanif100(FE80::2:4)
  0001.Host: FE80::224
       Uptime: 00:02:47
       Expires: 00:01:33
       (S, G) List:
         Group: FF44::1
             Source: FC00:0:0:1::1
               Uptime: 00:02:47
               Time since last refresh: 00:02:47
             Source: FC00:0:0:2222::3
               Uptime: 00:02:47
               Time since last refresh: 00:02:47
  0002.Host: FE80::225
       Uptime: 00:01:59
       Expires: 00:02:21
       (S, G) List:
         Group: FF44::1
             Source: FC00:0:0:1::1
               Uptime: 00:01:59
               Time since last refresh: 00:01:59
             Source: FC00:0:0:1::3
               Uptime: 00:01:59
               Time since last refresh: 00:01:59
```

Table 8-21 Description of the **display mld explicit-tracking** command output

Item	Description
Explicit-tracking information	Host information.

Item	Description
Total 2 hosts, 4 entries	Two hosts and four (S, G) entries in total.
Vlanif100(FE80::2:4)	Interface type and interface number (IPv6 link-local address).
Host	IPv6 host address.
Uptime	Running time after a host joins a multicast group. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Predicted timeout period of a host. After the host times out, the host is deleted from the MLD member list. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
(S, G) List	List of (S, G) entries.
Group	IPv6 multicast group address.
Source	IPv6 unicast address of a multicast source.
Time since last refresh	Time since the host joins a multicast group last time. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.

8.2.5 display mld group

Function

The **display mld group** command displays information about MLD groups that hosts have dynamically joined by sending Report messages.

Format

display mld group [*ipv6-group-address* | **interface** *interface-type interface-number*]* [**verbose**]

display mld group [**interface** *interface-type interface-number*] **entry-number**

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies an IPv6 multicast group address.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
interface *interface-type interface-number*	Specifies the type and number of an interface. If this parameter is not specified, the command displays MLD group membership information on all interfaces.	-
verbose	Displays detailed information about a multicast group. If this parameter is not specified, the command displays only the summary of the MLD group.	-
entry-number	Displays statistics about MLD multicast groups that hosts dynamically join.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check information about multicast groups that have established memberships.

Example

Display detailed information about all multicast groups that the interface dynamically joins.

```
<HUAWEI> display mld group verbose
Total entry on this router: 1
Interface group report information of VPN-Instance: public net
 Limited entry of this VPN-Instance: -
 Vlanif100(FE80::2E0:49FF:FE29:1103):
  Total entry on this interface: 1
  Limited entry on this interface: -
  Total 1 MLD Group reported
   Group: FF05::2
     Uptime: 00:01:07
     Expires: 00:03:45
     Last reporter: FE80::215:E9FF:FEAC:7666
     Last-listener-query-counter: 0
     Last-listener-query-timer-expiry: off
     Group mode: exclude
     Version1-host-present-timer-expiry: 00:03:45
```

Display statistics about MLD multicast groups that hosts dynamically join.

```
<HUAWEI> display mld group entry-number
Interface group report information of VPN-Instance: public net
  Total 100 MLD Groups reported
 Vlanif100(FE80:2300::4):
  Total 100 MLD Groups reported
```

Table 8-22 Description of the **display mld group** command output

Item	Description
Interface group report information of VPN-Instance	VPN instance to which MLD groups on an interface belong. **public net** indicates the public network instance.
Total entry on this router	Total number of dynamic MLD multicast groups on the switch.
Limited entry of this VPN-Instance	Maximum number of MLD entries that can be created for this instance.
Vlanif100(FE80::2E0:49FF:FE29:1103)	Interface type and interface number (IPv6 link-local address).
Total entry on this interface	Total number of dynamic MLD multicast groups on the interface.

Item	Description
Limited entry on this interface	Maximum number of MLD entries that the current interface can create.
Total 1 MLD Group reported	One MLD Report message is received on the interface.
Group	IPv6 address of an IPv6 multicast group.
Uptime	Time since a multicast group is discovered. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Time left before a group will be deleted from the MLD group table. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days. "off" indicates that the group will never be aged out.
Last reporter	Link-local address of the last host that sends a Multicast Listener Report message.

Item	Description
Last-listener-query-counter	Number of Multicast Address and Source Specific Query messages sent by the querier. After the querier receives an MLD done message sent from a host leaving a group, it sends the specified number of Multicast Address and Source Specific Query messages to check whether this group has other members on the network segment. The Last-listener-query-counter value reduces by 1 every time the querier sends a Multicast Address and Source Specific Query message. The number of times is configured using the **mld robust-count** command.
Last-listener-query-timer-expiry	The timeout time of the Multicast Address and Source Specific Query timer. The timer starts when the querier receives an MLD done message sent from a host leaving a group. The timer value is configured using the **mld lastlistener-queryinterval** command.
Group mode	Filter mode of multicast groups, that is, exclude or include.
Version1-host-present-timer-expiry	Timeout time of MLDv1 hosts. The timer value is calculated using the following formula: Timer value = General query interval x Robustness variable + Maximum response time for Query messages. The three parameters used in the formula are configured using the **mld timer query**, **mld robust-count**, and **mld max-response-time** commands respectively.

8.2.6 display mld group ssm-mapping

Function

The **display mld group ssm-mapping** command displays information about multicast group entries established with MLD SSM mapping.

Format

display mld group [*ipv6-group-address* | **interface** *interface-type interface-number*]* **ssm-mapping** [**verbose**]

display mld group ssm-mapping [**interface** *interface-type interface-number*] **entry-number**

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies an IPv6 multicast group address. If this parameter is not specified, the command displays information about all multicast group entries established with SSM mapping.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
interface *interface-type interface-number*	Displays information about the multicast group entries established with SSM mapping on a specified interface. If this parameter is not specified, the command displays information about multicast group entries established with SSM mapping on all interfaces.	-
verbose	Displays detailed information about multicast group entries established with SSM mapping. If this parameter is not specified, the command displays only the summary of multicast groups mapped by SSM mapping.	-
entry-number	Displays statistics about MLD multicast groups established with SSM mapping.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display mld group ssm-mapping** command to view information about multicast group entries that are established with SSM mapping. SSM mapping entries can be configured using the **ssm-mapping (MLD view)** command.

Example

Display detailed information about all multicast group entries established with SSM mapping.

```
<HUAWEI> display mld group ssm-mapping verbose
Total entry on this router: 1
Interface group report information of VPN-Instance: public net
 Limited entry of this VPN-Instance: -
 Vlanif100(FE80::DD:84):
  Total entry on this interface: 1
  Limited entry on this interface: -
  Total 1 MLD SSM-Mapping Group reported
   Group: FF36::1
     Uptime: 00:00:13
     Expires: 00:04:07
     Last reporter: FE80::10
     Last-listener-query-counter: 0
     Last-listener-query-timer-expiry: off
     Group mode: exclude
     Version1-host-present-timer-expiry: 00:04:07
```

Display detailed information about MLD multicast groups established with SSM mapping.

```
<HUAWEI> display mld group ssm-mapping entry-number
Interface group report information of VPN-Instance: public net
  Total 100 MLD SSM-Mapping Groups reported
 Vlanif100(FE80:2300::4):
  Total 100 MLD SSM-Mapping Groups reported
```

Table 8-23 Description of the **display mld group ssm-mapping** command output

Item	Description
Interface group report information of VPN-Instance	VPN instance to which MLD groups on an interface belong. **public net** indicates the public network instance.
Total entry on this router	Number of multicast group entries established with SSM mapping on the switch.
Limited entry of this VPN-Instance	Maximum number of multicast group entries that can be generated in the VPN instance.
Vlanif100(FE80::DD:84)	Interface type and interface number (IPv6 link-local address).

Item	Description
Total entry on this interface	Number of multicast group entries established with SSM mapping on the interface.
Limited entry on this interface	Maximum number of multicast group entries that can be generated on the interface.
Total 1 MLD SSM-Mapping Group reported	Total number of SSM mapping groups is 1.
Group	Multicast group address.
Uptime	Time since a multicast group is discovered. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Timeout period of a group. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Last reporter	Link-local address of the last host that sends a Multicast Listener Report message.
Last-listener-query-counter	Number of times for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages.
Last-listener-query-timer-expiry	Interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages.
Group mode	Filter mode of the multicast group, that is, include or exclude.
Version1-host-present-timer-expiry	Timeout period of an MLDv1 host.

8.2.7 display mld group static

Function

The **display mld group static** command displays information about static MLD multicast groups on interfaces.

Format

display mld group [*ipv6-group-address*] **static** [**up** | **down**] [**verbose**]

display mld group [*ipv6-group-address*] **static interface-number**

display mld group [*ipv6-group-address* | **interface** *interface-type interface-number*]* **static** [**verbose**]

display mld group static interface *interface-type interface-number* **entry-number**

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies an IPv6 multicast group address. If this parameter is not specified, the command displays information about all multicast groups with memberships.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
up | **down**	Displays information about an Up or Down interface. If this parameter is not specified, the command displays information about all interfaces.	-
verbose	Displays detailed information about the interfaces that statically join MLD multicast groups or source-specific multicast groups. If this parameter is not specified, the command displays only the summary of the MLD group.	-

Parameter	Description	Value
interface-number	Displays the number of the interfaces that statically join MLD multicast groups.	-
interface *interface-type interface-number*	Displays information about the MLD multicast groups that the specified interface statically joins.	-
entry-number	Displays the number of the MLD multicast groups that the interface statically joins.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mld group static** command to view information about the multicast groups and the interfaces that statically join MLD multicast groups or source-specific multicast groups. To configure a static multicast group on an interface, run the **mld static-group** command.

Example

Display information about statically joined MLD groups.

```
<HUAWEI> display mld group static
Static join group information
 Total 2 entries, Total 2 active entries
  (*, FF25::1)
  Interface:Vlanif10
  State:UP
  Expires:Never

  (*, FF25:100::1)
  Interface:Vlanif10
  State:UP
  Expires:Never
```

Table 8-24 Description of the **display mld group static** command output

Item	Description
Static join group information	Information about the MLD multicast groups that a switch statically joins.
Total 2 entries, Total 2 active entries	Total number of static multicast groups and active entries set on the switch.
(*, FF25::1)	(*, G) entry.
Interface:Vlanif10	Interface where the multicast group exists.
State	Status of an entry.
Expires	Timeout period of a multicast group.

Display detailed information about all static MLD multicast groups on an interface.

```
<HUAWEI> display mld group static verbose
Static join group information
 Total 1 entry
  00001.(*, FF25::1)
      Total List of 2 joined interfaces
      1.Vlanif10
          State:              UP
          Reference Count:    1
          Multicast Boundary:YES
          Outgoing Interface:YES
      2.Vlanif20
          State:              UP
          Reference Count:    1
          Multicast Boundary:YES
          Outgoing Interface:YES
```

Table 8-25 Description of the **display mld group static verbose** command output

Item	Description
Static join group information	Information about the multicast groups that an interface statically joins.
Total 1 entry	Number of static MLD group memberships on the device.
00001.(*, FF25::1)	(*, G) entry.
Total List of 2 joined interfaces	List of the interfaces that statically join multicast groups.
1.Vlanif10	Type and number of the interface.

Item	Description
State	Status of an interface, including: - UP: The interface is working properly. - DOWN: An error occurs on the physical link of the interface.
Reference Count	Number of times when a multicast group on the current interface is referenced.
Multicast Boundary	Whether the multicast forwarding boundary is configured. - YES - NO This function is configured using the **multicast boundary** *ipv6-group-address ipv6-group-mask-length* command.
Outgoing Interface	Whether downstream interfaces are available. - YES - NO

Display information about all the interfaces that statically join multicast groups and are in Up state.

```
<HUAWEI> display mld group static up
Static join group information
 Total 4 entries
  00001.(*,FF25::1)
      Total List of 2 joined interfaces
      Total Matched 2 interfaces
      1.Vlanif10
      2.Vlanif20
  00002.(FC00:0:0:1::1,FF25::1)
      Total List of 2 joined interfaces
      Total Matched 2 interfaces
      1.Vlanif10
      2.Vlanif20
```

Table 8-26 Description of the **display mld group static up** command output

Item	Description
Total List of 2 joined interfaces	Number of the interfaces that statically join multicast groups.
Total Matched 2 interfaces	List of the interfaces that statically join multicast groups and are in Up state.

Display the number of interfaces that statically join all multicast groups.

```
<HUAWEI> display mld group static interface-number
Static join group information
 Total 2 entries
  (*, FF25::1)
  Interface-Number:24

  (*, FF25::2)
  Interface-Number:24
```

Table 8-27 Description of the **display mld group static interface-number** command output

Item	Description
Interface-Number	Number of the interfaces that statically join multicast groups.

8.2.8 display mld interface

Function

The **display mld interface** command displays MLD information on an interface.

Format

display mld interface [*interface-type interface-number* | **up** | **down**] [**verbose**]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays MLD information on a specified interface. If this parameter is not specified, the command displays MLD information on all interfaces.	-
up	Indicates that the status of the IPv6 protocol on the MLD interface is Up, that is, MLD is in Active state.	-
down	Indicates that the status of the IPv6 protocol on the MLD interface is Down, that is, MLD is in Inactive state.	-
verbose	Displays detailed information about MLD interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the MLD configuration and running status on an interface, run the **display mld interface** command. This command displays MLD information only when MLD-enabled interfaces exist on the device.

Example

Display the MLD configuration and running status on VLANIF100.

```
<HUAWEI> display mld interface vlanif 100 verbose
Interface information
 Vlanif100(FE80::2E0:B4FF:FE35:FF01):
   MLD is enabled
   Current MLD version is 2
   MLD state: up
   MLD group policy: none
   MLD limit: -
   Value of query interval for MLD (negotiated): 125 s
   Value of query interval for MLD (configured): 125 s
   Value of other querier timeout for MLD: 0 s
   Value of maximum query response time for MLD: 10 s
   Value of last listener query time: 2 s
   Value of last listener query interval: 1 s
   Value of startup query interval: 31 s
   Value of startup query count: 2
   General query timer expiry (hours:minutes:seconds): 00:00:28
   Querier for MLD: FE80::2E0:B4FF:FE35:FF01 (this router)
   MLD activity: 2 joins, 0 dones
   Robustness (negotiated): 2
   Robustness (configured): 2
   Require-router-alert: disabled
   Send-router-alert: enabled
   Ip-source-policy: disabled
   Query Ip-source-policy: disabled
   Prompt-leave: disabled
   SSM-Mapping: enabled
   Startup-query-timer-expiry: off
   Other-querier-present-timer-expiry: off
    TTL-check: disabled
  Total 2 MLD Groups reported
```

Table 8-28 Description of the **display mld interface** command output

Item	Description
Vlanif100(FE80::2E0:B4FF:FE35:FF01)	Interface type and interface number (IPv6 link-local address).
MLD is enabled	MLD is enabled. To enable MLD, run the **mld enable** command.
Current MLD version is 2	MLD version is set to 2 on the interface. To set the MLD version, run the **mld version** command.
MLD state	Status of the MLD interface, that is, up or down.

Item	Description
MLD group policy	ACL6 number of the MLD group policy. To set ACL6 number of the MLD group policy, run the **mld group-policy** command.
MLD limit	Maximum number of MLD group members that the current interface can maintain. To set the maximum number of MLD group members that the current interface can maintain, run the **mld limit** command.
Value of query interval for MLD (negotiated)	Actual interval for sending MLD Query messages after negotiation, in seconds.
Value of query interval for MLD (configured)	Configured interval for sending MLD Query messages, in seconds. To set the interval for sending MLD Query messages, run the **mld timer query** command.
Value of other querier timeout for MLD	Timeout period of other MLD queriers, in seconds. To set the timeout period of an MLD querier, run the **mld timer other-querier-present** command.
Value of maximum query response time for MLD	Maximum response time for MLD Query messages, in seconds. To set the maximum response time for MLD Query messages, run the **mld max-response-time** command.
Value of last listener query time	Last listener query time, in seconds. The last listener query time is calculated by multiplying the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages by the robustness variable.
Value of last listener query interval	Interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages (Last listener query), in seconds. To set the interval for sending Last listener query, run the **mld lastlistener-queryinterval** command.

Item	Description
Value of startup query interval	Interval for sending Query messages when a querier starts, in seconds. The interval is 1/4 the query interval configured using the **mld timer query** command.
Value of startup query count	Number of times the querier sends Query messages when a querier starts. To set the number of times for sending Query messages when the querier starts, run the **mld robust-count** command.
General query timer expiry (hours:minutes:seconds)	Timeout period of the general query timer.
Querier for MLD	Link-local address of the MLD querier.
MLD activity	Statistics about MLD activities (join or leave).
Robustness (negotiated)	Robustness variable after negotiation by the non-querier device.
Robustness (configured)	Robustness variable set on the interface. To set the robustness variable on an interface, run the **mld robust-count** command.
Require-router-alert	Whether the switch discards MLD packets that do not contain the Router-Alert option in IP packet headers. ● enable: The switch discards MLD packets that do not contain the Router-Alert option in IP packet headers. ● disable: The switch does not discard MLD packets that do not contain the Router-Alert option in IP packet headers. This function is configured using the **mld require-router-alert** command.

Item	Description
Send-router-alert	Whether the sent MLD packet carries the Router-Alert option. To configure whether the sent MLD packet carries the Router-Alert option, run the **mld send-router-alert** command.
Ip-source-policy	Whether to filter Multicast Listener Report/Done messages based on host addresses. ● enabled: The switch filters MLD Report/Leave messages based on host addresses. ● disabled: The switch does not filter MLD Report/Leave messages based on host addresses. This function is configured using the **mld ip-source-policy** command.
Query Ip-source-policy	Whether to filter MLD Query messages based on host addresses. To configure whether to filter MLD Query messages based on host addresses, run the **mld query ip-source-policy** command.
Prompt-leave	Whether fast leave is enabled. ● enabled: Fast leave is enabled. ● disabled: Fast leave is disabled. This function is configured using the **mld prompt-leave** command.
SSM-Mapping	Whether SSM mapping is enabled. ● enabled: SSM mapping is enabled. ● disabled: SSM mapping is disabled. This function is configured using the **mld ssm-mapping enable** command.

Item	Description
Startup-query-timer-expiry	Status of the timer for the interface functioning as the querier after startup to send Query messages. ● off: The interface sends Query messages immediately after startup. ● on: The interface delays sending Query messages after startup.
Other-querier-present-timer-expiry	Status of the timer identifying whether another querier is present. ● off: The interface considers itself a querier and no other queriers exist. ● on: The interface no longer considers itself a querier and another querier exists.
TTL-check	Whether the function to check the TTL values in received MLD Report, Leave, and Query messages is enabled: ● enabled ● disabled
Total 2 MLD Groups reported	Two Multicast Listener Report messages are received on the interface.

8.2.9 display mld invalid-packet

Function

The **display mld invalid-packet** command displays statistics and details about invalid MLD packets received by a device.

Format

display mld invalid-packet [**interface** *interface-type interface-number* | **message-type** { **done** | **query** | **report** }]*

display mld invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about invalid MLD messages received by a specified interface. If this parameter is not specified, the command displays statistics about invalid MLD messages on all interfaces.	-
message-type	Displays statistics about invalid MLD messages of a specified type.	-
done	Displays statistics about invalid Multicast Listener Done messages.	-
query	Displays statistics about invalid Query messages.	-
report	Displays statistics about invalid Multicast Listener Report messages.	-
packet-number	Displays details of a specified number of invalid MLD messages recently received.	The value is an integer that ranges from 1 to 100.
verbose	Displays details of invalid MLD messages.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mld invalid-packet** command to view statistics and details of invalid MLD messages for fault location and rectification.

If MLD entries fail to be generated on a multicast network, you can run the **display mld invalid-packet** command first to check whether devices have received invalid MLD messages. If the command output contains statistics about invalid MLD messages, you need to run the **display mld invalid-packet** [*packet-number*] **verbose** command to view details of invalid MLD messages to locate the fault.

You can run the following related commands to view information about specific invalid MLD messages:

- Run the **display mld invalid-packet** command to view statistics about invalid MLD messages received by a device.
- Run the **display mld invalid-packet interface** *interface-type interface-number* command to view statistics about invalid MLD messages received by a specified interface.

- Run the **display mld invalid-packet** *packet-number* **verbose** command to view details of invalid MLD messages recently received. Currently, details of a maximum of 100 invalid MLD messages can be displayed.

Example

Display statistics about invalid MLD messages received by the device.

```
<HUAWEI> display mld invalid-packet
        Statistics of invalid packets for public net:
-------------------------------------------------------------------
MLD Query invalid packet:
Unwanted Source List    : 1000        Zero Max Resp Code      : 0
Fault Length            : 1000        Invalid Multicast Group : 0
Bad Checksum            : 0

MLD Report invalid packet:
Fault Length            : 0           Invalid Multicast Group : 0
Invalid Multicast Source: 0           Bad Checksum            : 0
Illegal Report Type     : 0

MLD Done invalid packet:
Invalid Multicast Group : 0           Bad Checksum            : 0
-------------------------------------------------------------------
```

Table 8-29 Description of the **display mld invalid-packet** command output

Item	Description
Statistics of invalid packets for public net	Invalid packets received in the public net.
MLD Query invalid packet	Invalid MLD Query messages.
Unwanted Source List	Messages with unwanted source lists.
Zero Max Resp Code	Messages with the Max Resp Code fields being 0.
Fault Length	Messages with invalid lengths.
Invalid Multicast Group	Messages with invalid multicast group addresses.
Bad Checksum	Messages with checksum errors.
MLD Report invalid packet	Invalid MLD Report messages.
Invalid Multicast Source	Messages with invalid multicast source addresses.
Illegal Report Type	Messages with the illegal Report message type.
MLD Done invalid packet	Invalid Multicast Listener Done messages.

Display details of one invalid MLD message recently received by the device.

```
<HUAWEI> display mld invalid-packet 1 verbose
      Detailed information of invalid packets
```

```
-----------------------------------------------------
Packet information (Index 1):
-----------------------------------------------------
Interface           :  Vlanif100
Time                :  2012-06-09 11:03:51 UTC-08:00
Message Length      :  24
Invalid Type        :  Invalid Multicast Group
0000: 84 00 4c d7 00 00 00 00 11 17 00 00 00 00 00 00
0010: 00 00 00 00 00 01 00 01
-----------------------------------------------------
```

Table 8-30 Description of the **display mld invalid-packet 1 verbose** command output

Item	Description
Detailed information of invalid packets	Details of the invalid MLD message.
Packet information (Index 1)	Sequence number of the invalid MLD message (numbered in the opposite order that the message is received).
Interface	Interface receiving the invalid MLD message.
Time	Time when the invalid MLD message is received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is configured using the **clock timezone** command; DST indicates that the daylight saving time is configured using **clock daylight-saving-time** command.
Message Length	Length of the invalid MLD message.
Invalid Type	Type of the invalid MLD message: ● Unwanted Source List ● Zero Max Resp Code ● Fault Length ● Invalid Multicast Group ● Bad Checksum ● Invalid Multicast Source ● Illegal Report Type
0000: 84 00 4c d7 00 00 00 00 11 17 00 00 00 00 00 00 0010: 00 00 00 00 00 01 00 01	Contents of the invalid MLD message.

8.2.10 display mld routing-table

Function

The **display mld routing-table** command displays information about the MLD routing table.

Format

display mld routing-table [*ipv6-source-address* [*ipv6-source-mask-length*] | *ipv6-group-address* [*ipv6-group-mask-length*]] * [**static**] [**outgoing-interface-number** [*number*]]

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
ipv6-source-mask-length	Specifies the mask length of the IPv6 address of a multicast source.	The value is an integer that ranges from 0 to 128.
ipv6-group-address	Specifies an IPv6 multicast group address.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
ipv6-group-mask-length	Specifies the mask length of the IPv6 multicast group address.	The value is an integer that ranges from 8 to 128.
static	Displays the MLD routing table of the static multicast group.	-
outgoing-interface-number	Displays the number of the outbound interfaces in MLD routing entries.	-

Parameter	Description	Value
number	Specifies the number of outbound interfaces. After this parameter is specified, the command displays information about the specified number of outbound interfaces.	The value is an integer that ranges from 1 to 2048.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view MLD routing entries, run the **display mld routing-table** command. You can specify parameters to view specified routing information, which facilitates fault location.

NOTE

This command provides output information only when PIM (IPv6) is not enabled on the MLD-capable interface.

Example

Display the MLD routing entry of the specified multicast group.

```
<HUAWEI> display mld routing-table
Routing table
 Total 2 entries

 00001. (FC00:0:0:1::3, FF44::)
       List of 1 downstream interface in include mode
        Vlanif100 (FE80::EE:53),
                    Protocol: STATIC

 00002. (*, FF55::)
       List of 1 downstream interface
        Vlanif100 (FE80::EE:53),
                    Protocol: MLD
```

Table 8-31 Description of the **display mld routing-table** command output

Item	Description
Routing table	MLD routing table.
Total 2 entries	Total number of MLD routing entries.
00001. (FC00:0:0:1::3, FF44::)	Entry 00001. (S, G) indicates that data is transmitted from S to G. (*, G) indicates that data is transmitted from any source to G.
List of 1 downstream interface in include mode	List of the downstream interfaces that join the multicast group in INCLUDE mode.
Vlanif100(FE80::EE:53)	Interface type and interface number (IPv6 link-local address).
Protocol	Protocol type. ● SSM-MAP: Entries are generated using MLD SSM mapping. ● MLD: Entries are generated using MLD. ● STATIC: Entries are generated by the MLD static multicast group.
List of 1 downstream interface	Downstream interface list.

8.2.11 display mld ssm-mapping

Function

The **display mld ssm-mapping** command displays the configuration of MLD SSM mapping.

Format

display mld ssm-mapping { **group** [*ipv6-group-address*] | **interface** [*interface-type interface-number*] }

Parameters

Parameter	Description	Value
group *ipv6-group-address*	Specifies the source IPv6 address of a specified multicast group.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.

Parameter	Description	Value
interface *interface-type interface-number*	Displays whether a specified interface is enabled with SSM mapping. If this parameter is not specified, the command displays information about all Up interfaces enabled with SSM mapping.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view multicast sources mapped to a multicast group. SSM mapping entries can be configured using the **ssm-mapping (MLD view)** command. The **display mld ssm-mapping** command also allows you to view the SSM mapping status on an interface, which can be configured using the **mld ssm-mapping enable** command.

Example

Display information about the interface configured with SSM mapping.

```
<HUAWEI> display mld ssm-mapping interface
Interface information
Vlanif100(FE80::1)
```

Table 8-32 Description of the **display mld ssm-mapping interface** command output

Item	Description
Vlanif100(FE80::1)	Interface type and interface number (IPv6 address).

Display information about SSM mapping of all multicast sources and groups.

```
<HUAWEI> display mld ssm-mapping group
MLD SSM-Mapping conversion table
 Group: FF3E::/64
  Number of Source(s): 3
     FC00:0:0:1::1
```

```
    FC00:0:0:1::2
    FC00:0:0:1::3
```

Table 8-33 Description of the **display mld ssm-mapping group** command output

Item	Description
MLD SSM-Mapping conversion table	MLD SSM mapping entries.
Group	Address of a multicast group.
Number of Source(s)	Number of multicast sources configured with SSM mapping.
FC00:0:0:1::1	Multicast source address.

Check whether MLD SSM mapping is enabled on VLANIF100.

```
<HUAWEI> display mld ssm-mapping interface Vlanif 100
MLD SSM-Mapping is enabled
```

Table 8-34 Description of the **display mld ssm-mapping interface Vlanif 100** command output

Item	Description
MLD SSM-Mapping is enabled	SSM mapping is enabled on the interface.

8.2.12 display mld ssm-mapping interface

Function

The **display mld ssm-mapping interface** command displays information about interfaces enabled with SSM mapping.

Format

display mld ssm-mapping interface [*interface-type interface-number* [**group** *ipv6-group-address*]]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies an interface.	-

Parameter	Description	Value
group *ipv6-group-address*	Displays the source address list associated with a specified group.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display mld ssm-mapping interface** command to view information about an interface enabled with SSM mapping.

Example

Display information about the interface configured with SSM mapping.

```
<HUAWEI> display mld ssm-mapping interface
Interface information
 Vlanif100(FE80::1)
```

Table 8-35 Description of the **display mld ssm-mapping interface** command output

Item	Description
Vlanif100(FE80::1)	Interface type and interface number (IPv6 link-local address).

8.2.13 lastlistener-queryinterval (MLD view)

Function

The **lastlistener-queryinterval** command globally sets the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages after the MLD querier receives an MLD Done message from a host.

The **undo lastlistener-queryinterval** command restores the default value.

By default, the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages is 1 second.

Format

lastlistener-queryinterval *interval*

undo lastlistener-queryinterval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages after the MLD querier receives a Multicast Listener Done message.	The value is an integer that ranges from 1 to 5, in seconds.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the MLD querier receives a Multicast Listener Done message of a multicast group, the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages continuously to check for other members in the multicast group. The **lastlistener-queryinterval** command sets the interval at which the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages. If the querier receives no Multicast Listener Report message for a specified period, the querier stops forwarding data to the multicast group. The period is calculated by multiplying *interval* by *robust-value*. To set *robust-value*, run the **mld robust-count** or **robust-count (MLD view)** command.

If the querier receives a Multicast Listener Report message from a host within the maximum response time, the querier maintains the membership of the multicast group. Otherwise, the querier considers that the last member has left the group and does not maintain the membership of the multicast group.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of this command is the same as that of the **mld lastlistener-queryinterval** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

In the MLD view, set the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] lastlistener-queryinterval 3
```

8.2.14 limit (MLD view)

Function

The **limit** command sets the maximum number of MLD entries that can be created globally.

The **undo limit** command restores the maximum number of MLD entries that can be created globally to the default value.

The following lists the maximum number of MLD entries allowed on each model by default:

- S5720-LI, S5720S-LI: 496
- S5735S-H, S5736-S, S6720S-S: 512
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S: 4096

Format

limit *number*

undo limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of MLD entries that can be created globally.	The value is an integer that ranges from 1 to *The maximum number of MLD entries allowed by default*. **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command sets the maximum number of MLD entries globally.

When the number of MLD entries reaches the limit, the system no longer creates MLD entries. To enable the switch to allow new join requests, you can either delete useless entries or increase the limit. Alternatively, configure static multicast groups or source-group bindings on interfaces.

The number of MLD entries can be counted in the following methods:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.
- Each (*, G) entry for SSM mapping is counted as one entry.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **mld global limit** *number* command in the system view to set the maximum number of global MLD group memberships. If both the **limit** and **mld global limit** *number* commands are run, the smaller value takes effect.

Example

Set the maximum number of MLD entries to 1000 globally.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] limit 1000
```

8.2.15 max-response-time (MLD view)

Function

The **max-response-time** command sets a global maximum response time for MLD General Query messages.

The **undo max-response-time** command restores the default global maximum response time for MLD General Query messages.

By default, the global maximum response time for MLD General Query messages is 10 seconds.

Format

max-response-time *interval*

undo max-response-time

Parameters

Parameter	Description	Value
interval	Specifies the maximum response time for MLD General Query messages.	The value is an integer that ranges from 1 to 25, in seconds.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If hosts send Multicast Listener Report messages immediately after receiving MLD General Query messages, the querier on the local network segment may receive a large number of Multicast Listener Report messages from the hosts at the same time. This may cause congestion on the network.

To avoid such situations, MLD messages specify the maximum response time for MLD General Query messages. When a host receives an MLD Query message, the host starts a timer for the multicast group that it joins. The timer length is a random value between 0 and the maximum response time. When the timer times out, the host sends a Multicast Listener Report message to the querier.

The maximum response time specifies the deadline for the host to send a Multicast Listener Report message. A proper maximum response time allows hosts to respond to MLD Query messages and prevents hosts from sending Report messages at the same time.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- A shorter response time allows a multicast device to obtain multicast group member information more quickly, but consumes more bandwidth and system resources.
- The function of this command is the same as that of the **mld max-response-time** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

In the MLD view, set the maximum response time for MLD General Query messages to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] max-response-time 8
```

8.2.16 mld

Function

The **mld** command displays the MLD view.

The **undo mld** command clears all configurations in the MLD view.

Format

mld

undo mld

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Global MLD parameters must be configured in the MLD view.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

In using the **undo mld** command, you need to enter Y or N to confirm the action. This command will clear global MLD configurations. So, use this command with caution.

Example

Enter the MLD view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld]
```

8.2.17 mld enable

Function

The **mld enable** command enables MLD on an interface.

The **undo mld enable** command disables MLD on an interface.

By default, MLD is disabled on an interface.

Format

mld enable

undo mld enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a shared IPv6 network segment, hosts and multicast devices must run MLD. A multicast device can process MLD messages sent from hosts only after MLD is enabled on the interfaces connected to user network segments.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- If MLD parameters are configured on an interface, the parameter settings take effect only after MLD is enabled.
- If PIM (IPv6) and MLD need to be enabled on the same interface, enable PIM (IPv6) and MLD in sequence.
- Running the **mld enable** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.
- When Layer 2 and Layer 3 multicast are both deployed, pay attention to the following points:
  - If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable MLD on the corresponding VLANIF interface first, and then enable MLD snooping in the VLAN. If MLD snooping is enabled in the VLAN first, MLD cannot be enabled on the VLANIF interface.
  - If Layer 2 and Layer 3 multicast are both configured in a VLAN, you must delete the Layer 2 multicast configuration before you can modify or delete the Layer 3 multicast configuration. This means that you must disable MLD snooping in the VLAN first, then modify or disable the MLD and PIM (IPv6) configuration in the VLANIF interface view, and finally enable MLD snooping in the VLAN. Otherwise, the Layer 3 multicast configuration cannot be modified or deleted on the corresponding VLANIF interface.
  - If a VLANIF interface is shut down in the VLANIF interface view, Layer 2 multicast in the corresponding VLAN becomes ineffective accordingly. To make Layer 2 multicast effective, you must disable MLD snooping in the VLAN first, then disable MLD and PIM (IPv6) in the VLANIF interface view, and finally enable MLD snooping in the VLAN.
  - When both Layer 2 and Layer 3 multicast services are configured, traffic is forwarded based on Layer 3 multicast forwarding entries instead of Layer 2 multicast forwarding entries. This means that Layer 2 multicast provides physical outbound interfaces for Layer 3 multicast, implementing accurate forwarding of multicast data. In addition, the maximum number of Layer 3 multicast forwarding entries depends on the maximum number of Layer 2 multicast forwarding entries.
  - The default MLD version of the switch is MLDv2 (configured using the **mld version** *version* command); the default MLD snooping version of the

switch is MLDv1 (configured using the **mld-snooping version** *version* command). When Layer 2 and Layer 3 multicast services are both configured, MLD and MLD snooping must have the same version number.

Example

Enable MLD on VLANIF100 connected to a user network segment.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld enable
```

Enable MLD on GE0/0/1 connected to a user network segment.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld enable
```

8.2.18 mld global limit

Function

The **mld global limit** command sets the maximum number of MLD entries that can be created on the entire switch.

The **undo mld global limit** command deletes the configured maximum number of MLD entries.

The following lists the maximum number of MLD entries allowed on each model by default:

- S5720-LI, S5720S-LI: 496
- S5735S-H, S5736-S, S6720S-S: 512
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S: 4096

Format

mld global limit *number*

undo mld global limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of MLD entries that can be created on the entire switch.	The value is an integer that ranges from 1 to *The maximum number of MLD entries allowed by default*. **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of MLD entries reaches the limit, the system no longer creates MLD entries. To enable the switch to allow new join requests, you can either delete useless entries or modify the limit. Alternatively, you can enable static addition on a multicast group or source group.

The number of MLD entries can be counted in the following methods:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.
- Each (*, G) entry for SSM mapping is counted as one entry.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **limit (MLD view)** command in the MLD view to set the maximum number of global MLD group entries. If both the **mld global limit** and **limit (MLD view)** commands are run, the smaller value takes effect.

Example

Set the maximum number of MLD entries that can be created on the switch to 500.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld global limit 500
```

8.2.19 mld group-policy

Function

The **mld group-policy** command configures an MLD group policy on an interface to limit the range of multicast groups that the hosts can join.

The **undo mld group-policy** command deletes the MLD group policy.

By default, no MLD group policy is configured on an interface, and the hosts can join any multicast groups.

Format

mld group-policy *acl6-number* [**1** | **2**]

undo mld group-policy

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic or advanced IPv6 ACL6. This ACL6 defines the range of multicast groups.	The number of a basic ACL6 is an integer that ranges from 2000 to 2999. The number of an advanced ACL6 is an integer that ranges from 3000 to 3999.
1	Limits the range of multicast groups that MLDv1 hosts can join.	-
2	Limits the range of multicast groups that MLDv2 hosts can join.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To control the range of multicast groups that hosts on the network attached to an interface can join, specify an ACL6 in the **mld group-policy** command. This configuration improves security of the MLD application. You can also run this command to prevent the switch from receiving Multicast Listener Report messages for specified groups.

If the MLD version is not specified, ACL6 rule is applicable to the two versions by default.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

An ACL6 defining the range of multicast groups has been created.

The **mld group-policy** command is used with the **acl ipv6** command. To use a numbered ACL6 in the MLD group policy:

- In the basic ACL6 view, set **source** in the **rule (basic ACL6 view)** command to the range of multicast groups that an interface can join.
- In the advanced ACL6 view, set **source** in the **rule (advanced ACL6 view)** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that an interface can join.

The configurations of the Named ACL6 and the advanced ACL6 are the same, and can implement filtering of both source addresses and multicast group addresses. The Named ACL6 can also be configured with the **time-range** parameter.

After the **mld group-policy** command is executed on an interface:

- The interface filters the received Report messages based on the ACL6 and maintains memberships only for the multicast groups permitted by the ACL6.
- The interface discards the Report messages that are denied by the ACL6. If the entries of the multicast groups denied by the ACL6 exist on the switch, the switch deletes these entries when the aging time of the entries expires.

Example

Create ACL6 2005, and configure a rule that allows hosts to receive data of multicast group FF13::101. Configure an MLD group policy on VLANIF100 and reference ACL6 2005 to allow hosts connected to the interface to join only multicast group FF13::101.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2005
[HUAWEI-acl6-basic-2005] rule permit source ff13::101 128
[HUAWEI-acl6-basic-2005] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld group-policy 2005
```

Create ACL6 2005, and configure a rule that allows hosts to receive data of multicast group FF13::101. Configure an MLD group policy on GE0/0/1 and reference ACL6 2005 to allow hosts connected to the interface to join only multicast group FF13::101.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2005
[HUAWEI-acl6-basic-2005] rule permit source ff13::101 128
[HUAWEI-acl6-basic-2005] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld group-policy 2005
```

8.2.20 mld ip-source-policy

Function

The **mld ip-source-policy** command enables filtering of Multicast Listener Report/ Done messages based on source addresses.

The **undo mld ip-source-policy** command disables filtering of MLD messages based on source addresses.

By default, a multicast device does not filter MLD messages based on source addresses.

Format

mld ip-source-policy *basic-acl6-number*

undo mld ip-source-policy

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the number of a basic ACL6, which defines the range of source addresses.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MLD runs on receiver hosts and their directly connected multicast devices. A multicast device processes all received Multicast Listener Report/Done messages. For security purposes, you can configure the multicast device to filter Multicast Listener Report/Done messages received on an interface.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

For a numbered ACL, the **mld ip-source-policy** command works with the **acl ipv6** command. You can configure the source address of MLD messages by specifying the **source** parameter in the **rule** command in the basic ACL view.

Example

Configure VLANIF100 to accept only the Multicast Listener Report/Done messages with the source address FC00::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld ip-source-policy 2001
```

Configure GE0/0/1 to accept only the Multicast Listener Report/Done messages with the source address FC00::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld ip-source-policy 2001
```

8.2.21 mld lastlistener-queryinterval

Function

The **mld lastlistener-queryinterval** command sets the interval at which the MLD querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages after receiving Multicast Listener Done messages from a host.

The **undo mld lastlistener-queryinterval** command restores the default value.

By default, the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages is 1 second.

Format

mld lastlistener-queryinterval *interval*

undo mld lastlistener-queryinterval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages.	The value is an integer that ranges from 1 to 5, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the MLD querier receives a Multicast Listener Done message of a multicast group, the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages continuously to check for other members in the multicast group. The **mld lastlistener-queryinterval** command sets the interval at which the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages. If the querier receives no Multicast Listener Report message for a specified period, the querier stops forwarding data to the multicast group. The period is calculated by multiplying *interval* by *robust-value*. To set *robust-value*, run the **mld robust-count** or **robust-count (MLD view)** command.

If the querier receives a Multicast Listener Report message from a host within the maximum response time, the querier maintains the membership of the multicast group. Otherwise, the querier considers that the last member has left the group and does not maintain the membership of the multicast group.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of the **mld lastlistener-queryinterval** command is the same as that of the **lastlistener-queryinterval** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Set the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query message to 3 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld lastlistener-queryinterval 3
```

Set the interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query message to 3 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld lastlistener-queryinterval 3
```

8.2.22 mld limit

Function

The **mld limit** command sets the maximum number of MLD group memberships that the current interface can maintain.

The **undo mld limit** command restores the maximum number of MLD group memberships that the current interface can maintain to the default value.

The following lists the maximum number of MLD group memberships that can be maintained on the current interface of each model by default:

- S5720-LI, S5720S-LI: 496
- S5735S-H, S5736-S, S6720S-S 512
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5731-H, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S: 2048
- S6720S-EI, S6735-S, S6720-EI: 4096

Format

mld limit *number* [**except** *acl6-number*]

undo mld limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of MLD group memberships that can be maintained on the current interface.	The value is an integer that ranges from 1 to *The maximum number of MLD group memberships that can be maintained on the current interface by default*. **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.
except	Specifies the range of multicast groups that are not limited by the specified maximum number.	-
acl6-number	Specifies the basic or advanced ACL6.	The value is an integer. The number of the basic ACL6 ranges from 2000 to 2999. The basic ACL6 filters group addresses only, without distinguishing (*, G) entries and (S, G) entries. The number of the advanced ACL6 ranges from 3000 to 3999. The advanced ACL6 filters (S, G) entries of the interface only.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of MLD entries reaches the limit, the system does not create any MLD entries. To allow more new join requests, delete unnecessary entries or increase the limit. Alternatively, configure static multicast groups or source-group bindings on interfaces.

The number of MLD entries can be counted in the following methods:

- Each (*, G) entry is counted as one entry.
- Each (S, G) entry is counted as one entry.
- Each (*, G) entry for SSM mapping is counted as one entry.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If **except** is not set in the command, the maximum number of MLD entries corresponding to all the groups or source/groups is limited.

Before setting **except**, configure the associated ACL6. The interface then filters the received MLD Join messages according to the ACL6. The maximum number of entries corresponding to the multicast groups that match the ACL6 is not limited.

The **mld limit** command must be used with ACL6 configuration commands. When configuring ACL6 rules, note that:

- In the basic ACL6 view, specify the **source** parameter in the **rule (basic ACL6 view)** command for setting the range of multicast groups whose MLD entries do not need to be limited.
- In the advanced ACL6 view, specify the **source** parameter in the **rule (advanced ACL6 view)** command for setting the range of sources that are allowed to send multicast data to the multicast groups. Specify the **destination** parameter in the **rule (advanced ACL6 view)** command for setting the range of multicast groups whose MLD entries do not need to be limited.

The Named ACL and the advanced ACL can be configured based on the same rules, and can implement filtering of both source addresses and multicast group addresses. The **time-range** parameter takes effect in the **rule** command only for the Named ACL.

Example

Set the maximum number of MLD entries that can be created on the VLANIF100 to 500.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld limit 500
```

Create the advanced ACL6 with the number being 3100; set the maximum number of MLD entries that can be created on VLANIF100 to 500; allow the hosts to receive messages from the specific-source multicast group (FC00:0:0:2001::1, FF3E::1). That is, the specific-source multicast group (FC00:0:0:2001::1, FF3E::1) is not limited by the maximum number of MLD entries.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] acl ipv6 3100
[HUAWEI-acl6-adv-3100] rule permit ipv6 source fc00:0:0:2001::1 64 destination ff3e::1 64
[HUAWEI-acl6-adv-3100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld limit 500 except 3100
```

Set the maximum number of MLD entries that can be created on the GE0/0/1 to 500.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld limit 500
```

8.2.23 mld max-response-time

Function

The **mld max-response-time** command sets the maximum response time for MLD General Query messages on an interface.

The **undo mld max-response-time** command restores the default maximum response time for General MLD Query messages.

By default, the maximum response time for MLD General Query messages is 10s on an interface.

Format

mld max-response-time *interval*

undo mld max-response-time

Parameters

Parameter	Description	Value
interval	Specifies the maximum response time for MLD General Query messages.	The value is an integer that ranges from 1 to 25, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If hosts send Multicast Listener Report messages immediately after receiving MLD General Query messages, the querier on the local network segment may receive a large number of Multicast Listener Report messages from the hosts at the same time. This may cause congestion on the network.

To avoid such situations, MLD messages specify the maximum response time for MLD General Query messages. When a host receives an MLD Query message, the host starts a timer for the multicast group that it joins. The timer length is a random value between 0 and the maximum response time. When the timer times out, the host sends a Multicast Listener Report message to the querier.

The maximum response time specifies the deadline for the host to send a Multicast Listener Report message. A proper maximum response time allows hosts to respond to MLD Query messages and prevents hosts from sending Report messages at the same time.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- A shorter response time allows a multicast device to obtain multicast group member information more quickly, but consumes more bandwidth and system resources.
- The function of the **mld max-response-time** command is the same as that of the **max-response-time (MLD view)** command used in the MLD view. The configuration in the MLD view takes effect for all interfaces, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Set the maximum response time for MLD General Query messages to 8 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld max-response-time 8
```

Set the maximum response time for MLD General Query messages to 8 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld max-response-time 8
```

8.2.24 mld on-demand

Function

The **mld on-demand** command enables the MLD on-demand function. This function enables a querier to maintain group memberships according to requirements of group members, without sending Query messages. After MLD on-demand is enabled on an interface, dynamic MLD entries on the interface will never age out.

The **undo mld on-demand** command restores the default configuration.

By default, a querier does not maintain group memberships according to requirements of group members, and dynamic entries are aged out when the aging time expires.

Format

mld on-demand

undo mld on-demand

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a standard MLD working process, a querier sends General Query messages periodically and collects group membership information based on received Multicast Listener Report and Done messages. Group members respond to every Query message they receive. The querier stops sending Query messages after MLD on-demand is configured, reducing MLD packets exchanged between the querier and receiver hosts.

The MLD on-demand function enables a querier to maintain group memberships based on Report messages sent from hosts, reducing traffic transmitted between the querier and receiver hosts.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- The **mld on-demand** command can be used on the querier only.
- If dynamic MLD entries have been generated on the querier, run the **reset mld group** command to clear these dynamic MLD entries before running the **mld on-demand** command.
- After the **mld on-demand** command is executed on an interface:
  - The interface no longer sends MLD Query messages.

  - MLD group entries are generated after the interface receives Multicast Listener Report messages and will never age out.
  - When the interface receives a Multicast Listener Done message, it deletes the corresponding MLD group entry.
- The **mld on-demand** configuration of the VLANIF interface and the **mld-snooping enable** command in a VLAN are mutually exclusive.

Example

Enable the MLD on-demand function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld on-demand
```

Enable the MLD on-demand function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld on-demand
```

8.2.25 mld prompt-leave

Function

The **mld prompt-leave** command enables the fast leave function on an interface. This function enables an MLD querier to delete MLD entries immediately after receiving Multicast Listener Done messages from group members, without sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages.

The **undo mld prompt-leave** command disables fast leave on an interface.

By default, an MLD querier sends a Multicast Address Specific Query message or Multicast Address and Source Specific Query message after receiving a Multicast Listener Done message for a specific multicast group.

Format

mld prompt-leave [**group-policy** *acl6-number*]

undo mld prompt-leave

Parameters

Parameter	Description	Value
group-policy	Specifies an MLD multicast group policy. If this parameter is specified, the fast leave function takes effect only for multicast groups specified in the policy. When specifying this parameter, ensure that the referenced ACL6 has been configured. The interface filters Multicast Listener Done messages on the interface based on the ACL6. ● If a host leaves a multicast group in the range permitted by the ACL6, the device immediately deletes the multicast group entry without sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages. ● If a host leaves a multicast group out of the range permitted by the ACL6, the device sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages. If this parameter is not specified, the fast leave function takes effect for all multicast groups.	-
acl6-number	Specifies the number of a basic ACL6 or an advanced ACL6. This ACL6 defines the range of multicast groups.	The number of a basic ACL6 is an integer that ranges from 2000 to 2999. The number of an advanced ACL6 is an integer that ranges from 3000 to 3999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some scenarios, an interface on the MLD querier connects to only one receiver host. If the host frequently switches between multiple multicast groups, you can configure fast leave on the interface of the querier so that the interface can quickly respond to Multicast Listener Done messages sent from the host. After fast leave is configured, the querier does not send a Multicast Address Specific Query message or Multicast Address and Source Specific Query message after receiving a Multicast Listener Done message. Instead, the querier directly notifies the upstream multicast device that the host has left the multicast group. The fast leave function reduces delay in response to Multicast Listener Done messages and saves network bandwidth.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- When an interface has more than one receiver connected, enabling fast leave interrupts multicast traffic of the other receivers in the multicast group. You are advised to enable this function on interfaces with only one receiver.
- When configuring an ACL6 to specify the range of multicast groups, pay attention to the following points:
  - When you run the **rule** command in the view of a basic ACL6, set **source** to the address range of multicast groups that hosts can fast leave.
  - When you run the **rule** command in the view of an advanced ACL6, set **source** to the multicast source address and **destination** to the range of multicast groups that hosts can fast leave.

Example

Configure fast leave on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld prompt-leave
```

Configure fast leave on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld prompt-leave
```

8.2.26 mld query ip-source-policy

Function

The **mld query ip-source-policy** command configures MLD Query message filtering based on source addresses.

The **undo mld query ip-source-policy** command restores the default configuration.

By default, no source address-based MLD Query message filtering is configured.

Format

mld query ip-source-policy *basic-acl6-number*

undo mld query ip-source-policy

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the number of a basic ACL6, which defines the range of source addresses.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker sends forged MLD Query messages with an IPv6 address smaller than the querier IPv6 address, the querier is replaced by the attacker. As a result, the real querier cannot respond to Multicast Listener Report messages from group members and bandwidth is wasted. Source address-based MLD Query message filtering can protect the querier from such attacks. With this function configured, the switch accepts only the MLD Query messages with source addresses permitted by the specified ACL6. This function controls querier election.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- MLD Query messages are encapsulated into IPv6 messages. This command is used to filter the source addresses in IPv6 headers.
- After you configure source address-based MLD Query message filtering on an interface, the interface filters out the MLD Query messages whose source addresses do not match a specified ACL6 rule.

Example

Configure VLANIF100 to receive the MLD Query messages with the source address FC00::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld query ip-source-policy 2001
```

Configure GE0/0/1 to receive the MLD Query messages with the source address FC00::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld query ip-source-policy 2001
```

8.2.27 mld require-router-alert

Function

The **mld require-router-alert** command configures an interface to discard MLD messages without the Router-Alert option.

The **undo mld require-router-alert** command disables an interface from checking for the Router-Alert option in MLD messages.

By default, all received MLD messages are processed, including the MLD messages without the Router-Alert option.

Format

mld require-router-alert

undo mld require-router-alert

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a network device sends a message to the routing protocol module for processing only when the destination address of the message is a local interface address. Destination addresses of MLD messages are multicast addresses but not addresses of interfaces on multicast devices. Therefore, multicast devices do not send MLD messages to the MLD module for processing, and the MLD module cannot maintain group memberships.

The Router-Alert option in the IPv6 header of an MLD message solves this problem. If an MLD message contains the Router-Alert option, the device sends the message to the MLD module.

You can configure the device to accept only MLD messages with the Router-Alert option to improve MLD security.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of the **mld require-router-alert** command is the same as that of the **require-router-alert (MLD view)** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The system prefers the configuration in the interface view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Configure VLANIF100 to discard MLD messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld require-router-alert
```

Configure GE0/0/1 to discard MLD messages without the Router-Alert option.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld require-router-alert
```

8.2.28 mld robust-count

Function

The **mld robust-count** command sets a robustness variable of an MLD querier on an interface.

The **undo mld robust-count** command restores the default robustness variable of an MLD querier.

By default, the robustness variable of an MLD querier is 2.

Format

mld robust-count *robust-value*

undo mld robust-count

Parameters

Parameter	Description	Value
robust-value	Specifies the robustness variable of an MLD querier.	The value is an integer that ranges from 2 to 5.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The MLD querier robustness variable specifies the retransmission count of MLD packets to minimize the impact of packet loss on the network.

On a shared network segment, a querier maintains MLD group memberships. The robustness variable affects the timeout period of group memberships. The timeout period of the group membership is calculated using the formula:

Timeout period of the group memberships = Interval for sending MLD General Query messages x Robustness variable + Maximum response time

The robustness variable determines the following values:

- Number of times the querier sends General Query messages when the querier starts

  When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The interval for sending General Query messages is configured using the **mld timer query** or **timer query (MLD view)** command.
- Number of times the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages

  When receiving a Multicast Listener Done message of a multicast group, the querier sends Multicast Address Specific Query messages a certain number of times specified by the robustness variable to check whether the group has members. When the querier receives a Multicast Listener Report message indicating that source-group mapping changes, the querier sends Multicast

Address and Source Specific Query messages a certain number of times specified by the robustness variable. The interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages is set using the **mld lastlistener-queryinterval** or **lastlistener-queryinterval (MLD view)** command.

A larger robustness variable makes an MLD querier more robust but increases the timeout period of group memberships.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of the **mld robust-count** command is the same as that of the **robust-count (MLD view)** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Set the robustness variable of the querier on VLANIF100 to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld robust-count 3
```

Set the robustness variable of the querier on GE0/0/1 to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld robust-count 3
```

8.2.29 mld send-router-alert

Function

The **mld send-router-alert** command configures an interface to send MLD messages containing the Router-Alert option in IPv6 headers.

The **undo mld send-router-alert** command disables an interface from sending MLD messages containing the Router-Alert option in IPv6 headers.

By default, the IPv6 headers of MLD messages sent by an interface contain the Router-Alert option.

Format

mld send-router-alert

undo mld send-router-alert

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch sends MLD messages that contain the Router-Alert option in IPv6 headers. If the switch needs to communicate with a device that does not support the Router-Alert option, run the **undo mld send-router-alert** command to configure the switch to send MLD messages without the Router-Alert option. The **mld send-router-alert** command is usually used together with the **mld require-router-alert** command.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of the **mld send-router-alert** command is the same as that of the **send-router-alert (MLD view)** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Configure VLANIF100 to send MLD messages with the Router-Alert option in their IPv6 headers.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld send-router-alert
```

Configure GE0/0/1 to send MLD messages with the Router-Alert option in their IPv6 headers.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld send-router-alert
```

8.2.30 mld ssm-mapping enable

Function

The **mld ssm-mapping enable** command enables MLD SSM mapping on an interface.

The **undo mld ssm-mapping enable** command disables MLD SSM mapping on an interface.

By default, MLD SSM mapping is disabled on an interface.

Format

mld ssm-mapping enable

undo mld ssm-mapping enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SSM model allows MLDv2 hosts to specify the multicast sources from which they want to receive data. However, some hosts can only run MLDv1. To allow these hosts to use SSM, configure MLD SSM mapping on the switch. MLD SSM mapping is implemented based on static SSM mapping entries on the switch. The switch converts (*, G) information in MLDv1 Multicast Listener Report messages to (S, G) information according to static SSM mapping entries to provide the SSM service for MLDv1 hosts.

The **mld ssm-mapping enable** command enables MLD SSM mapping on an interface. The mappings between SSM sources and multicast group addresses take effect only when MLD SSM mapping is enabled on an interface. SSM mapping entries are configured using the **ssm-mapping (MLD view)** command.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

SSM mapping enabled on an interface is irrelevant to the version number of MLD.

Example

Enable MLD SSM mapping on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld ssm-mapping enable
```

Enable MLD SSM mapping on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld ssm-mapping enable
```

8.2.31 mld static-group

Function

The **mld static-group** command configures a static multicast group on an interface.

The **undo mld static-group** command deletes a static multicast group from an interface.

By default, no static multicast group is configured on an interface.

Format

mld static-group *ipv6-group-address* [**inc-step-mask** *ipv6-group-mask-length* **number** *group-number*] [**source** *ipv6-source-address*]

undo mld static-group { **all** | *ipv6-group-address* [**inc-step-mask** *ipv6-group-mask-length* **number** *group-number*] [**source** *ipv6-source-address*] }

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies the IPv6 address of the multicast group that an interface statically joins. In batch configuration mode, this parameter specifies the initial address of the multicast group addresses.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.

Parameter	Description	Value
inc-step-mask *ipv6-group-mask-length*	Specifies the incremental length of the step mask in batch configuration mode.	The value is an integer that ranges from 8 to 128.
number *group-number*	Specifies the number of group addresses in batch configuration mode.	The value is an integer that ranges from 2 to 512.
source *ipv6-source-address*	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
all	Specifies all the multicast groups that the interface statically joins.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following are two scenarios in which you can configure static multicast groups on user-side interfaces of the switch:

- There are long-term group members on a shared network segment, and the switch needs to forward multicast data to these group members quickly and steadily.
- A network segment has no group member or hosts on the network segment cannot send Report messages, but multicast data needs to be sent to this network segment.

After a static multicast group is configured on an interface, the switch considers that the multicast group always has members on the network segment of the interface. Therefore, the switch always forwards multicast data of the multicast group.

The **mld static-group** command is used on an interface connected to user hosts. The command can configure a single group or source-group binding on an interface or configure multiple groups or source-group bindings in a batch.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- After multicast groups are configured in batches for the first time, if you only modify the value of *group-number* but not the value of *ipv6-group-address* or *ipv6-group-mask-length* to configure multicast groups in batches again, the new configurations overwrite the corresponding original configurations.
- After you run the **mld static-group** command on an interface connected to user hosts, the entries matching the MLD groups that the interface statically joins never time out. The switch considers that this interface is always connected to group members, and keeps forwarding multicast packets of the specified multicast groups to the network segment where the interface resides.
- You can configure overlapping multicast group addresses in different batch configurations. When you configure multiple static multicast groups in a batch on an interface, do not delete any static group configuration before the system completes the batch static group configuration.
- If a user host no longer needs to receive multicast data of a static group, delete the static group configuration.
- When the interface that connects a multicast device to the user network segment joins a multicast group in both dynamic and static modes, the interface preferentially joins the multicast group in static mode if a conflict occurs.
- Running the **mld static-group** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

Example

Configure static multicast group FF13::101 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld static-group ff13::101
```

Configure the switch to forward multicast packets from multicast source FC00::101 to multicast group FF14::202 through VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld static-group ff14::202 source fc00::101
```

Add VLANIF100 statically to two multicast groups in a batch. Set the start multicast group address to FF25::1 and the step mask length to 24.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld static-group ff25::1 inc-step-mask 24 number 2
```

Add VLANIF100 statically to two multicast source/groups in a batch. Set the start multicast group address to FF33::1, the source address to FC00::101, and the step mask length to 24.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld static-group ff33::1 inc-step-mask 24 number 2 source fc00::101
```

Configure static multicast group FF13::101 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld static-group ff13::101
```

8.2.32 mld timer other-querier-present

Function

The **mld timer other-querier-present** command sets the other querier present timer on an interface.

The **undo mld timer other-querier-present** command restores the default value of the other querier present timer on an interface.

By default, the Keepalive period of the other queriers is calculated as follows:

Other querier present timer = Robustness variable x Interval for sending MLD General Query messages + 1/2 x Maximum response time

If the default values of the robustness variable, interval for sending MLD General Query messages, and maximum response time are used, the other querier present timer value is 255 seconds.

Format

mld timer other-querier-present *interval*

undo mld timer other-querier-present

Parameters

Parameter	Description	Value
interval	Specifies the other querier present timer.	The value is an integer that ranges from 60 to 300, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user network segment connects to multiple Layer 3 multicast devices, only one Layer 3 multicast device is elected as the MLD querier to send Query messages to hosts on the network segment. To create and maintain normal group memberships, non-queriers running MLD start the other querier present timer after they fail in the querier election. If the non-queriers do not receive Query messages from the querier before the timer times out, they consider the querier failed and start a new querier election.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of the **mld timer other-querier-present** command is the same as that of the **timer other-querier-present (MLD view)** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

NOTICE

If the other querier present timer is shorter than the interval for sending General Query messages, the querier election is triggered frequently.

Example

On VLANIF100, set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld timer other-querier-present 200
```

On GE0/0/1, set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld timer other-querier-present 200
```

8.2.33 mld timer query

Function

The **mld timer query** command sets the interval at which an interface sends MLD General Query messages.

The **undo mld timer query** command restores the default interval at which an interface sends MLD General Query messages.

By default, an interface sends MLD General Query messages at an interval of 125s.

Format

mld timer query *interval*

undo mld timer query

Parameters

Parameter	Description	Value
interval	Specifies the interval at which an interface sends MLD General Query messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An MLD querier checks whether a local network segment has multicast group members by sending MLD General Query messages at an interval, known as the general query interval. You can set the general query interval based on needs of your network. The general query interval affects the following processes:

- When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The message sending interval during this process is 1/4 of the interval for sending General Query messages.

The robustness variable can be set using the **mld robust-count** or **robust-count (MLD view)** command.

- After the startup process is complete, the querier sends General Query messages at intervals to maintain the group memberships on the interface.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- The querier is more sensitive when it sends General Query messages at a smaller interval. However, more bandwidth and switch resources are consumed in this case.
- The function of the **MLD timer query** command is the same as that of the **timer query (MLD view)** command used in the MLD view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The system prefers the configuration in the interface view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Set the interval at which VLANIF100 sends General Query messages to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld timer query 200
```

Set the interval at which GE0/0/1 sends General Query messages to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld timer query 200
```

8.2.34 mld ttl-check

Function

The **mld ttl-check** command enables the device to check the TTL values in received MLD Report, Done, and Query messages on a specific interface.

The **undo mld ttl-check** command restores the default configuration.

By default, the device does not check the TTL values in received MLD Report, Done, and Query messages on an interface.

Format

mld ttl-check

undo mld ttl-check

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command enables TTL check for MLD Report, Leave, and Query messages on an interface. This function protects the system against attacking MLD messages by dropping the messages of which the TTL value is not 1. By default, TTL values of MLD messages are not checked on an interface.

You can also configure TTL check for MLD Report, Leave, and Query messages by using the **ttl-check** command in the MLD view. This command takes effect for all MLD-enabled interfaces.

Precautions

If both the **mld ttl-check** and **ttl-check** commands are run, the **mld ttl-check** configuration in the interface view takes precedence over the **ttl-check** configuration in the MLD view.

Example

Enable TTL check for MLD Report, Leave, and Query messages on a physical interface.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mld ttl-check
```

Enable TTL check for MLD Report, Leave, and Query messages on a VLANIF interface.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] quit
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] mld ttl-check
```

8.2.35 mld version

Function

The **mld version** command specifies an MLD version on an interface.

The **undo mld version** command restores the default MLD version on an interface.

By default, an interface runs MLDv2.

Format

mld version *version*

undo mld version

Parameters

Parameter	Description	Value
version	Specifies the MLD version running on the interface.	The value is integer that ranges from 1 to 2.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast switch can only identify MLD messages of a version earlier than its own MLD version. To ensure normal MLD operation, set on the switch an MLD version the same as or later than that running on user hosts.

If many switches exist on a shared network segment, configure the same MLD version on all switch interfaces connected to hosts. If multicast devices run MLD of different versions, errors may occur in MLD operation because interfaces running different MLD versions send messages in different formats.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Example

Configure MLDv2 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] mld version 2
```

Configure MLDv2 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] mld version 2
```

8.2.36 require-router-alert (MLD view)

Function

The **require-router-alert** command configures the switch to discard MLD messages without the Router-Alert option.

The **undo require-router-alert** command disables the switch from checking the Router-Alert option in MLD messages.

By default, the switch does not check whether the received MLD messages contain Router-Alert options in IPv6 headers, and it accepts all the received MLD messages.

Format

require-router-alert

undo require-router-alert

Parameters

None

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a network device sends a message to the routing protocol module for processing only when the destination address of the message is a local interface address. Destination addresses of MLD messages are multicast addresses but not addresses of interfaces on multicast devices. Therefore, multicast devices do not send MLD messages to the MLD module for processing, and the MLD module cannot maintain group memberships.

The Router-Alert option in the IPv6 header of an MLD message solves this problem. If an MLD message contains the Router-Alert option, the device sends the message to the MLD module.

You can configure the device to accept only MLD messages with the Router-Alert option to improve MLD security.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of this command is the same as that of the **mld require-router-alert** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

In the MLD view, configure the switch to discard the MLD messages that do not contain Router-Alert options in IPv6 headers.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] require-router-alert
```

8.2.37 reset mld control-message counters

Function

The **reset mld control-message counters** command deletes statistics of MLD messages.

Format

reset mld control-message counters [**interface** *interface-type interface-number*] [**message-type** { **query** | **report** }]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears MLD packet statistics on a specified interface. If this parameter is not specified, MLD packets on all interfaces are deleted.	-

Parameter	Description	Value
message-type	Clears statistics about MLD messages of a specified type. If this parameter is not specified, the command clears statistics about MLD messages of all types.	-
query	Clears the number of received Query messages.	-
report	Clears the number of received Multicast Listener Report messages.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

After statistics about MLD messages are deleted, MLD still operates properly.

Example

Delete statistics about MLD messages from all interfaces.

```
<HUAWEI> reset mld control-message counters
```

Delete statistics about MLD messages from VLANIF100.

```
<HUAWEI> reset mld control-message counters interface vlanif 100
```

8.2.38 reset mld explicit-tracking

Function

The **reset mld explicit-tracking** command deletes hosts that dynamically join a multicast group using MLD from an interface.

Format

reset mld explicit-tracking { **all** | **interface** *interface-type interface-number* [**host** *ipv6-host-address* [**group** *ipv6-group-address* [**source** *ipv6-source-address*]]] }

Parameters

Parameter	Description	Value
all	Indicates information about all MLD hosts.	-
interface *interface-type interface-number*	Specifies the type and number of an interface. If this parameter is not specified, the command deletes hosts that dynamically join the host group using MLD from all interfaces.	-
host *ipv6-host-address*	Specifies the link-local address of a host.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FE80:: to FE80:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
group *ipv6-group-address*	Specifies an IPv6 multicast group address.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
source *ipv6-source-address*	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.

Views

User view

Default Level

3: Management level

Usage Guidelines

You can use this command to delete hosts that dynamically join a multicast group using MLD from an interface. A host can rejoin the multicast group after being deleted from this group.

Example

Delete the host FE80::101 that joins multicast group FF23::101 through MLD on VLANIF100.

```
<HUAWEI> reset mld explicit-tracking interface vlanif 100 host fe80::101 group ff23::101
```

Delete the host FE80::101 that joins the (FC00:0:0:1::12, FF23::101) forwarding entry from VLANIF100.

```
<HUAWEI> reset mld explicit-tracking interface vlanif 100 host fe80::101 group ff23::101 source
fc00:0:0:1::12
```

8.2.39 reset mld group

Function

The **reset mld group** command deletes dynamic MLD entries on interfaces.

Format

reset mld group all

reset mld group interface *interface-type interface-number* { **all** | *ipv6-group-address* [*ipv6-group-mask-length*] [*ipv6-source-address* [*ipv6-source-mask-length*]] }

Parameters

Parameter	Description	Value
all	The first **all** deletes dynamic MLD entries on all interfaces. The second **all** deletes all MLD entries on a specified interface.	-
interface *interface-type interface-number*	Deletes dynamic MLD entries on a specified interface.	-
ipv6-group-address	Deletes dynamic MLD entries of a specified multicast group.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
ipv6-group-mask-length	Specifies the mask length of the multicast group address.	The value is an integer that ranges from 8 to 128.

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
ipv6-source-mask-length	Specifies the mask length of the multicast source address.	The value is an integer that ranges from 0 to 128.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command deletes all the dynamic MLD group memberships on an interface, including common group memberships and group memberships established with SSM mapping. This command cannot delete statically configured MLD group memberships.

A host can rejoin the multicast group after being deleted from this group.

NOTICE

After dynamic MLD entries on an interface are deleted, the interface cannot receive multicast data. Exercise caution before running this command.

Example

Delete dynamic MLD entries within the range of FF03::101:0 to FF03::101:FFFF on VLANIF100.

```
<HUAWEI> reset mld group interface vlanif 100 ff03::101:0 112
```

8.2.40 reset mld group ssm-mapping

Function

The **reset mld group ssm-mapping** command deletes multicast group entries established with MLD SSM mapping.

Format

reset mld group ssm-mapping all

reset mld group ssm-mapping interface *interface-type interface-number* { **all** | *ipv6-group-address* [*ipv6-group-mask-length*] }

Parameters

Parameter	Description	Value
all	The first **all** deletes multicast group entries established with MLD SSM mapping on all interfaces. The second **all** deletes all multicast group entries established with MLD SSM mapping on a specified interface.	-
interface *interface-type interface-number*	Deletes the multicast group entries established with MLD SSM mapping on a specified interface.	-
ipv6-group-address	Specifies an IPv6 multicast group address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
ipv6-group-mask-length	Specifies the mask length of the multicast group address.	The value is an integer that ranges from 8 to 128.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command is valid only on the multicast groups that an interface has dynamically joined, and deletes only the MLDv1 multicast group entries within the range of SSM group addresses.

SSM mapping can be re-configured after being deleted.

NOTICE

After the multicast group entries established with MLD SSM mapping on an interface are deleted, the interface cannot receive multicast data. Exercise caution before running this command.

Example

Delete multicast group entries established with MLD SSM mapping within the range of FF13::101:0 to FF13::101:FFFF on VLANIF100.

```
<HUAWEI> reset mld group ssm-mapping interface vlanif 100 ff13::101:0 112
```

8.2.41 robust-count (MLD view)

Function

The **robust-count** command sets a global robustness variable for an MLD querier.

The **undo robust-count** command restores the default robustness variable.

By default, the robustness variable of an MLD querier is 2.

Format

robust-count *robust-value*

undo robust-count

Parameters

Parameter	Description	Value
robust-value	Specifies the robustness variable of an MLD querier.	The value is an integer that ranges from 2 to 5.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The MLD querier robustness variable specifies the retransmission count of MLD packets to minimize the impact of packet loss on the network.

On a shared network segment, a querier maintains MLD group memberships. The robustness variable affects the timeout period of group memberships. The timeout period of the group membership is calculated using the formula:

Timeout period of the group memberships = Interval for sending MLD General Query messages x Robustness variable + Maximum response time

The robustness variable determines the following values:

- Number of times the querier sends General Query messages when the querier starts

  When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The interval for sending General Query messages is configured using the **mld timer query** or **timer query (MLD view)** command.

- Number of times the querier sends Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages

  When receiving a Multicast Listener Done message of a multicast group, the querier sends Multicast Address Specific Query messages a certain number of times specified by the robustness variable to check whether the group has members. When the querier receives a Multicast Listener Report message indicating that source-group mapping changes, the querier sends Multicast Address and Source Specific Query messages a certain number of times specified by the robustness variable. The interval for sending Multicast Address Specific Query messages or Multicast Address and Source Specific Query messages is set using the **mld lastlistener-queryinterval** or **lastlistener-queryinterval (MLD view)** command.

A larger robustness variable makes an MLD querier more robust but increases the timeout period of group memberships.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of this command is the same as that of the **mld robust-count** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the current interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

Set the robustness variable of an MLD querier to 3 in the MLD view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] robust-count 3
```

8.2.42 send-router-alert (MLD view)

Function

The **send-router-alert** command configures the switch to send MLD messages containing the Router-Alert option in IPv6 headers.

The **undo send-router-alert** command disables the switch from sending MLD messages containing the Router-Alert option in IPv6 headers.

By default, the MLD messages sent by the switch contain the Router-Alert option.

Format

send-router-alert

undo send-router-alert

Parameters

None

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the MLD messages sent by the switch contain the Router-Alert option in their IPv6 headers. If the switch needs to communicate with a device that does not support the Router-Alert option, run the **undo send-router-alert** command to configure the switch to send MLD messages without the Router-Alert option. The **send-router-alert** command is usually used together with the **require-router-alert (MLD view)** command.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of this command is the same as that of the **mld send-router-alert** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

In the MLD view, configure the switch to send MLD packets with the Router-Alert option in IPv6 headers.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] send-router-alert
```

8.2.43 ssm-mapping (MLD view)

Function

The **ssm-mapping** command configures an SSM mapping entry to map a multicast source to a group address.

The **undo ssm-mapping** command deletes an SSM mapping entry.

By default, no SSM mapping entry is configured.

Format

ssm-mapping *ipv6-group-address ipv6-group-mask-length ipv6-source-address*

undo ssm-mapping { **all** | *ipv6-group-address ipv6-group-mask-length* [*ipv6-source-address*] }

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies the IPv6 address of a multicast group configured with SSM mapping.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF.
ipv6-group-mask-length	Specifies the mask length of the IPv6 multicast group address.	The value is an integer, which can be 16, 32, 64, or 128.
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
all	Deletes all the configured static SSM mapping entries.	-

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hosts that support only MLDv1 cannot join SSM groups. To enable multicast devices to provide the SSM service for these hosts, configure SSM mapping on the multicast devices. An SSM mapping entry maps a multicast source to a multicast group. After SSM mapping entries are configured on a multicast device, the device can convert (*, G) information in Report messages of MLDv1 to (S, G) information.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- You can configure multiple static SSM mapping entries by running the **ssm-mapping** command several times.
- To delete an SSM mapping entry, run the **undo ssm-mapping** *ipv6-group-address ipv6-group-mask-length* [*ipv6-source-address*] command. The **undo ssm-mapping all** command deletes all the SSM mapping entries. Exercise caution before running this command.

Example

Configure an SSM mapping entry mapping the source address FC00::1 to group address FF35::1/128.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] ssm-mapping ff35::1 128 fc00::1
```

8.2.44 timer other-querier-present (MLD view)

Function

The **timer other-querier-present** command sets a global other querier present timer.

The **undo timer other-querier-present** command restores the default value of the other querier present timer.

By default, the Keepalive period of the other queriers is calculated as follows:

Other querier present timer = Robustness variable x Interval for sending MLD General Query messages + 1/2 x Maximum response time

If the default values of the robustness variable, interval for sending MLD General Query messages, and maximum response time are used, the other querier present timer value is 255 seconds.

Format

timer other-querier-present *interval*

undo timer other-querier-present

Parameters

Parameter	Description	Value
interval	Specifies the other querier present timer.	The value is an integer that ranges from 60 to 300, in seconds.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user network segment connects to multiple Layer 3 multicast devices, only one Layer 3 multicast device is elected as the MLD querier to send Query messages to hosts on the network segment. To create and maintain normal group memberships, non-queriers running MLD start the other querier present timer after they fail in the querier election. If the non-queriers do not receive Query messages from the querier before the timer times out, they consider the querier failed and start a new querier election.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The function of this command is the same as that of the **mld timer other-querier-present** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

NOTICE

If the other querier present timer is shorter than the interval for sending General Query messages, the querier election is triggered frequently.

Example

Set the other querier present timer to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] timer other-querier-present 200
```

8.2.45 timer query (MLD view)

Function

The **timer query** command sets a global interval for sending MLD General Query messages.

The **undo timer query** command restores the default interval for sending MLD General Query messages.

By default, the interval for sending MLD General Query messages is 125 seconds.

Format

timer query *interval*

undo timer query

Parameters

Parameter	Description	Value
interval	Interval for sending MLD General Query messages	The value is an integer that ranges from 1 to 18000, in seconds.

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An MLD querier checks whether a local network segment has multicast group members by sending MLD General Query messages at an interval, known as the general query interval. You can set the general query interval based on needs of your network. The general query interval affects the following processes:

- When a querier starts, it sends General Query messages a certain number of times specified by the robustness variable to query the multicast groups that have members on the shared network segment. The message sending interval during this process is 1/4 of the interval for sending General Query messages. The robustness variable can be set using the **mld robust-count** or **robust-count (MLD view)** command.
- After the startup process is complete, the querier sends General Query messages at intervals to maintain the group memberships on the interface.

Prerequisites

Layer 3 IPv6 multicast has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

- The querier is more sensitive when it sends General Query messages at a smaller interval. However, more bandwidth and switch resources are consumed in this case.
- The function of this command is the same as that of the **mld timer query** command used in the interface view. The configuration in the MLD view is globally valid, whereas the configuration in the interface view takes effect only for the specified interface. The configuration in the interface view takes precedence over the configuration in the MLD view. The configuration in the MLD view is used only when no configuration is performed in the interface view.

Example

In the MLD view, set the interval for sending MLD General Query messages to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] timer query 200
```

8.2.46 ttl-check (MLD view)

Function

The **ttl-check** command enables the device to check the TTL values in received MLD Report, Done, and Query messages on all interfaces.

The **undo ttl-check** command restores the default configuration.

By default, the device does not check the TTL values in received MLD Report, Done, and Query messages.

Format

ttl-check

undo ttl-check

Parameters

None

Views

MLD view

Default Level

2: Configuration level

Usage Guidelines

To protect a device against MLD message attacks, run the **ttl-check** command to enable the device to check the TTL values in received MLD Report, Done, and Query messages on all interfaces and discard such a message if its TTL value is not 1.

Example

Enable the device to check the TTL values in received MLD Report, Done, and Query messages on all interfaces.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] mld
[HUAWEI-mld] ttl-check
```

8.3 IPv4 PIM Configuration Commands

8.3.1 Command Support

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.
S6700	Supported.

NOTE

Only S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the PIM multi-instance feature.

8.3.2 bsm semantic fragmentation (IPv4)

Function

The **bsm semantic fragmentation** command enables BSR message fragmentation.

The **undo bsm semantic fragmentation** command disables BSR message fragmentation.

By default, BSR message fragmentation is not enabled.

Format

bsm semantic fragmentation

undo bsm semantic fragmentation

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A BSR message carries information about all C-RPs on the network. Therefore, if there is a large number of C-RPs on the network, the length of a BSR message exceeds the MTU of the outgoing interface. As a result, the BSR message cannot be processed and RP election fails. Consequently, multicast services cannot be transmitted normally. In this case, you can enable BSR message fragmentation to ensure that the devices on the network can learn consistent RP information and MDTs can be successfully established.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

You can also configure IP fragmentation to solve the preceding problem. The difference between IP fragmentation and BSR message fragmentation is as follows:

- If IP fragmentation is enabled, the protocol layer transmits the entire BSR message up to the IP layer regardless of the length of the BSR message. The BSR message is then fragmented at the IP layer. During the transmission of BSR message fragments to the destination, if one fragment is lost, the destination cannot parse the entire BSR message. As a result, the destination cannot learn RP information and MDTs cannot be established, which causes a multicast data forwarding failure.
- If BSR message fragmentation is enabled, the protocol layer directly fragments a long BSR message. During the transmission of BSR message fragments to the destination, if one fragment is lost, only the information carried in this fragment is lost. As a result, only MDTs corresponding to the information carried in the lost fragments cannot be established. Since the other BSR message fragments can still reach the destination, the corresponding MDTs can be correctly established.

BSR message fragmentation is recommended because IP fragmentation causes all fragments to become unavailable when fragment information is lost.

Precautions

Enable BSR message fragmentation on all devices on the network. If BSR message fragmentation is not enabled on some devices, RP information on these devices is inconsistent with that on other devices and MDTs cannot be established on these devices.

Example

Enable BSR message fragmentation in the public network instance PIM view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] bsm semantic fragmentation
```

8.3.3 bsr-policy (IPv4)

Function

The **bsr-policy** command specifies the range of valid bootstrap router (BSR) addresses. Then the switch drops the BSR messages sent from the addresses out of this range to defend against BSR spoofing.

The **undo bsr-policy** command restores the default configuration.

By default, the range of BSR addresses is not limited, and all BSR packets are considered valid.

Format

bsr-policy *basic-acl-number*

undo bsr-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the basic ACL number. The ACL defines the filtering policy for the range of source addresses of BSR packets. This parameter corresponds to *basic-acl-number* in the **acl** command.	The value is an integer that ranges from 2000 to 2999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM-SM network that applies the BSR mechanism, you can configure any switch as a C-BSR to take part in BSR election. Once a switch is elected as the BSR, the switch is responsible for advertising RP information in the network. To prevent the valid BSR from being maliciously replaced, take the following measures:

- Certain hosts try changing the RP mapping to spoof the switch by forging BSR packets.

  Solution: The attack often occurs on edge switches because the BSR packet is a multicast packet with the TTL value of 1. As the BSR is inside the network and hosts are outside the network, the switches can perform neighbor checks and RPF checks on the received BSR packets to prevent the attack.
- Certain attackers control the switch on the network, or the switch accesses the network. The attackers configure the switch as a C-BSR, and help the switch win the BSR election. The attackers obtain the right of advertising RP information in the network.

  Solution: After the switch is configured as a C-BSR, the switch spreads multicast BSR packets in the network. The BSR packets have a TTL value of 1 and are forwarded hop by hop. As long as the neighboring switch cannot receive the packets, the packets are not spread in the entire network. The solution is to use the **bsr-policy** command on every switch in the network to limit the valid BSR range. For example, only switches 10.1.1.1/32 and 10.1.1.2/32 are elected as BSRs; therefore, the switches do not receive or forward other BSR packets.

The two countermeasures mentioned above can partially protect BSRs in the network. However, if attackers control a valid BSR, problems can still be caused on the network.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

After the **bsr-policy** command is run, the switch accepts only BSR messages matching the configured policy.

Precautions

The **bsr-policy** command and the **acl** command are used together. In the ACL view, you can set the source address range for BSR packets by specifying the **source** parameter in the **rule** command.

Example

In the public network instance PIM view, configure address 10.1.1.0/24 as the valid BSR address range.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.1.1.0 0.0.0.255
[HUAWEI-acl-basic-2001] quit
```

```
[HUAWEI] pim
[HUAWEI-pim] bsr-policy 2001
```

8.3.4 c-bsr (IPv4)

Function

The **c-bsr** command configures a C-BSR.

The **undo c-bsr** command restores the default configuration.

By default, the C-BSR is not configured.

Format

c-bsr *interface-type interface-number* [*hash-length* [*priority*]]

undo c-bsr

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of an interface. C-BSR is configured on this interface. PIM-SM must be enabled on this interface to make the configuration effective. **NOTE** To avoid frequent protocol changes caused by interface flapping, using loopback interfaces is recommended.	-
hash-length	Specifies the hash mask length of the C-BSR. The mask is used in a hash function to calculate the RP.	The value is an integer that ranges from 0 to 32. By default, the value is 30.
priority	Specifies a priority of the C-BSR. The greater the value, the higher the priority of the C-BSR.	The value is an integer ranging from 0 to 255. By default, the value is 0.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

One or more C-BSRs need to be configured in a PIM-SM domain. A BSR is elected from C-BSRs and is responsible for collecting C-RP information and summarizing C-RP information into an RP-set. The RP-set is then encapsulated in a BootStrap message and advertised to all the devices in the PIM domain.

The process of BSR election is as follows:

1. Each C-BSR considers itself as the BSR of the local PIM-SM domain and uses IP address of this interface as the address of the BSR to send Bootstrap messages.
2. When a C-BSR receives a Bootstrap message from other devices, it compares the BSR in the received Bootstrap message with the current BSR. The BSR with the highest priority is preferred. If BSRs have the same priority, the BSR with a larger IP address is preferred. If the BSR carried in the received Bootstrap message is superior to the current BSR, the C-BSR replaces its BSR address with the address of the BSR carried in the received Bootstrap message.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Before configuring an interface as a C-BSR, enable PIM-SM on the interface.

For the multicast BSR messages learned through the GRE tunnel, you need to configure a static multicast route to ensure that the next hop to the BSR is a GRE interface. You need to configure static multicast routes properly to avoid routing loops.

Example

In the PIM view of public network instance, configure a C-BSR on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim sm
[HUAWEI-Vlanif100] quit
[HUAWEI] pim
[HUAWEI-pim] c-bsr vlanif 100
```

In the PIM view, configure a C-BSR on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim sm
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] pim
[HUAWEI-pim] c-bsr gigabitethernet 0/0/1
```

8.3.5 c-bsr admin-scope

Function

The **c-bsr admin-scope** command configures a BSR administrative scope in a PIM-SM domain.

The **undo c-bsr admin-scope** command restores the default configuration.

By default, no BSR administrative scope is configured.

Format

c-bsr admin-scope

undo c-bsr admin-scope

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, each PIM-SM domain has only one BSR that serves all the devices in the entire PIM-SM domain. To achieve more effective management, you can divide a PIM-SM domain into multiple BSR administrative domains and a global domain. This can reduce the workload of a single BSR and designate a private-network group address for users in a specific domain.

Each BSR administrative domain maintains one BSR that serves multicast groups on network segment 239.0.0.0/8. Multicast packets for groups on this network segment cannot pass through the border of the BSR administrative domain. Multicast groups that do not belong to any BSR administrative domain belong to a global domain. The global domain maintains a BSR that serves all the remaining multicast groups, namely, multicast groups beyond the range 239.0.0.0/8.

A BSR administrative domain is similar to a VPN in unicast, and multicast address segment 239.0.0.0/8 is equivalent to unicast address segment 10.0.0.0/8. Other multicast group addresses can be used on the public network and address conflicts need be avoided. If a PIM-SM domain is divided into different BSR administrative domains, each BSR administrative domain is equivalent to a VPN, serving the multicast groups on the network segment 239.0.0.0/8. You can use the same multicast group address in different BSR administration domains. If you configure the BSR in a BSR administration domain to serve multicast groups beyond 239.0.0.0/8, a message indicating a configuration error will be displayed.

The **c-bsr admin-scope** command configures a BSR administrative scope on the switch.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

After the **undo pim** command or the **undo multicast routing-enable** command is run in the system view, the BSR administrative domain is automatically disabled.

Precautions

The **c-bsr admin-scope** command needs to be run on all the devices in a PIM-SM domain.

Example

In the public network instance PIM view, configure a BSR administrative scope in a PIM-SM domain.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr admin-scope
```

8.3.6 c-bsr global

Function

The **c-bsr global** command configures the switch as a C-BSR in the global domain.

The **undo c-bsr global** command restores the default configuration.

By default, no C-BSR is configured in the global domain.

Format

c-bsr global [**hash-length** *hash-length* | **priority** *priority*] *

undo c-bsr global

Parameters

Parameter	Description	Value
hash-length *hash-length*	Specifies the hash mask length of a C-BSR in the global domain.	The value is an integer that ranging from 0 to 32. By default, the value is 30.
priority *priority*	Specifies the priority of the C-BSR in the global domain. The greater the value, the higher the priority of the C-BSR.	The value is an integer ranging from 0 to 255. By default, it is 0.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, each PIM-SM domain has only one BootStrap router (BSR) and the BSR serves all the devices in the entire PIM-SM domain. To achieve more effective management, you can divide a PIM-SM domain into multiple BSR administrative domains and a global domain.

Each BSR administrative domain maintains one BSR that serves the multicast groups in a specific group address range. Multicast packets for groups in the range cannot pass through the border of the BSR administrative domain. Addresses of multicast groups that BSRs in different BSR administrative domains serve can overlap. Overlapped multicast groups, however, similar to private group addresses, take effect only in local BSR administrative domains. Multicast groups that do not belong to any BSR administrative domain belong to a global domain. A global domain maintains a BSR that serves all the remained multicast groups.

The **c-bsr global** command configures the switch as a C-BSR in the global domain. The BSR in the global domain is generated through election.

C-BSRs compare the priorities and IP addresses to elect the BSR in the global area. The conditions for the election are as follows:

- The C-BSR with the highest priority is elected as the BSR.
- In the case of the same priority, the C-BSR with the largest IP address is elected as the BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If the **c-bsr global** command is run several times, the latest configuration overrides the previous one.

After the **undo pim** command or the **undo multicast routing-enable** command is run in the system view, the C-BSRs in the global domain are automatically disabled.

Precautions

The **c-bsr global** command takes effect only in a BSR administrative domain and can enable a device in a BSR administrative domain to receive multicast data of groups beyond 239.0.0.0/8.

The **c-bsr global** command needs to be used together with the **c-bsr admin-scope** command.

Example

In the public network instance PIM view, configure the switch as a C-BSR in the global domain, and then set the priority of the C-BSR to 1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr global priority 1
```

8.3.7 c-bsr group

Function

The **c-bsr group** command specifies the range of multicast groups that an administrative domain can serve on a C-BSR.

The **undo c-bsr group** command restores the default configuration.

By default, range of multicast groups that an administrative domain can serve is not configured.

Format

c-bsr group *group-address* { *mask* | *mask-length* } [**hash-length** *hash-length* | **priority** *priority*] *

undo c-bsr group *group-address*

Parameters

Parameter	Description	Value
group-address	Specifies a multicast group address.	The address is in dotted decimal notation. The value ranges from 239.0.0.0 to 239.255.255.255.
mask	Specifies the mask of a multicast group address.	The address is in dotted decimal notation.
mask-length	Indicates the mask length of a multicast address.	The value is an integer ranging from 8 to 32.
hash-length *hash-length*	Specifies the hash mask length for the C-BSR in a BSR administrative domain.	The value is an integer ranging from 0 to 32. By default, it is 30.
priority *priority*	Specifies the priority of the C-BSR in the BSR administrative domain. A larger value indicates a higher priority.	The value is an integer ranging from 0 to 255. By default, it is 0.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a PIM-SM domain is divided into different BSR administrative domains, configure a multicast group address for each BSR administrative domain on the C-BSR. The group addresses must be in the range of 239.0.0.0/8. The group address ranges served by different BSR administrative domains can overlap. The address of a multicast group that a BSR administrative domain serves is used as a private group address.

By running this command on the C-BSR of each administrative domain, you can specify the group address of the administrative domain served by each C-BSR and the priority of each C-BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Configuration Impact

If the **c-bsr group** command is run several times, the latest configuration overrides the previous one.

After the **undo pim** command or the **undo multicast routing-enable** command is run in the system view or the VPN instance view, the C-BSRs in the BSR administrative domain are automatically disabled.

Example

In the public network instance PIM view, configure a C-BSR in the BSR administrative domain to serve groups 239.0.0.0/8, and set the priority of the C-BSR to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr group 239.0.0.0 255.0.0.0 priority 10
```

8.3.8 c-bsr hash-length (IPv4)

Function

The **c-bsr hash-length** command configures the global hash mask length of a C-BSR.

The **undo c-bsr hash-length** command restores the default configuration.

By default, the global hash mask length of a C-BSR is 30.

Format

c-bsr hash-length *hash-length*

undo c-bsr hash-length

Parameters

Parameter	Description	Value
hash-length	Specifies the global hash mask length of a C-BSR.	The value is an integer that ranges from 0 to 32.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During dynamic RP election, if C-RPs have the same interface address mask and priority for a specified multicast group, a hash function needs to be executed to select the RP for the multicast group. The switch performs hash calculation for the group address of G, C-RP address, and hash mask length of the C-RPs with the same priority and compares the hash values. The C-RP with the greatest hash value acts as the RP for G.

The hash mask length is used to adjust the hash calculation result.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can run the **c-bsr** *interface-type interface-number hash-length* command in the PIM view to configure the C-BSR interface and specify the hash mask length. The **c-bsr hash-length** *hash-length* command specifies the global hash mask length. If both **c-bsr** *interface-type interface-number hash-length* and **c-bsr hash-length** *hash-length* are used, the **c-bsr** *interface-type interface-number hash-length* command takes effect.

Example

In the public network instance PIM view, set the global hash mask length of a C-BSR to 16.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr hash-length 16
```

8.3.9 c-bsr holdtime (IPv4)

Function

The **c-bsr holdtime** command configures the timeout period during which the C-BSR waits to receive Bootstrap messages sent by the BSR.

The **undo c-bsr holdtime** command restores the default configuration.

By default, the timeout period during which the C-BSR waits to receive Bootstrap messages sent by the BSR is 130s.

Format

c-bsr holdtime *interval*

undo c-bsr holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout time during which C-BSR waits for the Bootstrap message to be sent by BSR.	The value is an integer that ranges from 1 to 214748364, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a C-BSR is elected as the BSR, it periodically sends Bootstrap messages carrying its own IP address and the RP-set information. The interval for sending Bootstrap messages is BS_interval, which can be configured using the **c-bsr interval** command.

Other C-BSRs that fail in the election are suppressed from sending Bootstrap messages and start the timer to monitor the elected BSR. The timeout period of a timer is holdtime, which can be configured using the **c-bsr holdtime** command.

- If the C-BSR receives the Bootstrap messages sent by the BSR, the C-BSR refreshes the timer. The C-BSRs that fail in the election also refresh the timeout period of the BSR according to the holdtime. After the BSR times out, the C-BSRs receive new BSR messages.
- If the timer times out, the elected BSR is considered faulty. The C-BSRs that failed in the election triggers a new BSR election, preventing service interruption.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

In actual applications, all C-BSRs in the same PIM domain must use the same BS_interval and holdtime; otherwise, the BSR will become unstable. This may result in multicast faults. Note the following points:

- If BS_interval and holdtime are configured at the same time, ensure that BS_interval is less than holdtime.
- If BS_interval or holdtime is configured, use the following formula to calculate the other one: holdtime = 2 x BS_interval + 10. The following determines which value is used:
  - If holdtime is configured and the calculated BS_interval is less than the minimum value of BS_interval, the minimum value is used.
  - If BS_interval is configured and the calculated holdtime is more than the maximum value of holdtime, the maximum value is used.
- If neither BS_interval nor holdtime is configured, the default values are used. The default BS_interval is 60s and the default holdtime is 130s.

Example

In the PIM view of public network instance, set the timeout interval during which the C-BSR waits for the Bootstrap message to be sent by BSR to 150 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr holdtime 150
```

8.3.10 c-bsr interval (IPv4)

Function

The **c-bsr interval** command configures the interval for the BSR to continuously send Bootstrap messages.

The **undo c-bsr interval** command restores the default configuration.

By default, the interval for the BSR to continuously send Bootstrap messages is 60s.

Format

c-bsr interval *interval*

undo c-bsr interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for the BSR to continuously send the Bootstrap messages.	The value is an integer that ranges from 1 to 107374177, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a C-BSR is elected as the BSR, it periodically sends Bootstrap messages carrying its own IP address and the RP-set information to the network.

Other C-BSRs that fail in the election are suppressed from sending Bootstrap messages and start the timer to monitor the BSR. The timeout period of a timer is holdtime, which can be configured using the **c-bsr holdtime** command. The following applies to the timer:

- If the C-BSR receives the Bootstrap messages sent by the BSR, the C-BSR refreshes the timer.
- If the timer times out, the BSR is considered to be faulty. The C-BSRs that failed in the election triggers a new BSR election, preventing service interruption.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

In actual applications, all C-BSRs in the same PIM domain must use the same BS_interval and holdtime values; otherwise, the BSR will become unstable. This may result in a multicast fault. Note the following points:

- If BS_interval and holdtime are configured at the same time, ensure that BS_interval is less than holdtime.
- If only one of the BS_interval and holdtime is configured, use the following formula to calculate the other parameter: holdtime = 2 x BS_interval + 10. The following determines which value is used:
  - If holdtime is configured and the calculated BS_interval is less than the minimum value of BS_interval, the minimum value is used.
  - If BS_interval is configured and the calculated holdtime is more than the maximum value of holdtime, the maximum value is used.

- If neither the BS_interval nor the holdtime is configured, default values are used. The default value of BS_interval is 60s, and the default value of holdtime is 130s.

Example

In the PIM view of public network instance, set the interval for the C-BSR to continuously send Bootstrap messages to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr interval 30
```

8.3.11 c-bsr priority (IPv4)

Function

The **c-bsr priority** command configures the global priority for a C-BSR.

The **undo c-bsr priority** command restores the default configuration.

By default, the global priority of the C-BSR is 0.

Format

c-bsr priority *priority*

undo c-bsr priority

Parameters

Parameter	Description	Value
priority	Specifies the global priority of the C-BSR. The greater the value, the higher the priority of the C-BSR.	The value is an integer that ranges from 0 to 255.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple C-BSRs take part in the BSR election in the PIM-SM domain, the following situations occur:

- The switch with the highest priority wins in the BSR election.

- If they have the same priority, the switch with the largest IP address wins in the BSR election.

To enable a C-BSR to function as the BSR, you can run the **c-bsr priority** command to increase the priority value of the C-BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can run the **c-bsr** *interface-type interface-number priority* command in the PIM view to configure the C-BSR interface and specify the C-BSR priority. The **c-bsr priority** *priority* command specifies the global C-BSR priority. If both **c-bsr** *interface-type interface-number priority* and **c-bsr priority** *priority* are used, the **c-bsr** *interface-type interface-number priority* command takes effect.

Example

In the PIM view of public network instance, configure the global priority of the C-BSR to 5.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-bsr priority 5
```

8.3.12 c-rp (IPv4)

Function

The **c-rp** command configures the switch to advertise itself as a C-RP to the BSR.

The **undo c-rp** command restores the default configuration.

By default, no C-RP is configured.

Format

c-rp *interface-type interface-number* [**group-policy** *basic-acl-number* | **priority** *priority* | **holdtime** *hold-interval* | **advertisement-interval** *adv-interval*] *

undo c-rp *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of an interface. The IP address of the specified interface is advertised as a C-RP address. **NOTE** To avoid frequent protocol changes caused by interface flapping, using loopback interfaces is recommended.	-
group-policy *basic-acl-number*	Specifies the range of the multicast groups served by a C-RP. The range is restricted to the multicast group range permitted by the specified ACL. The *basic-acl-number* parameter specifies the number of the basic ACL to identify the service range of the advertised RP.	The value is an integer ranging from 2000 to 2999.
priority *priority*	Specifies the priority of a C-RP. The greater the value, the lower the priority.	The value is an integer ranging from 0 to 255. The default value is 0.
holdtime *hold-interval*	Specifies the timeout period during which the BSR waits to receive an Advertisement message from a C-RP.	The value is an integer ranging from 1 to 65535, in seconds. The default value is 150.
advertisement-interval *adv-interval*	Specifies the interval for a C-RP to send Advertisement messages.	The value is an integer ranging from 1 to 65535, in seconds. The default value is 60.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RP is the core of a PIM-SM domain, and therefore a C-RP must be able to communicate with the other devices in the PIM-SM domain. You are advised to configure a C-RP on the core switch and reserve enough bandwidth between the switch and each of the other devices in the PIM-SM domain.

An RP is elected from multiple C-RPs following these rules, in descending order of precedence:

1. The C-RP with the longest mask length of the served group address range matching the multicast group that users have joined wins.
2. The C-RP with highest priority wins.
3. The C-RP with the largest hash value wins.
4. The C-RP with the largest address wins.

Prerequisites

- IP multicast routing has been enabled using the **multicast routing-enable** command.
- PIM-SM has been enabled on the interface that acts as the C-RP.

Configuration Impact

An interface is specified in the command; therefore, the settings of **group-policy** *basic-acl-number*, **priority** *priority*, **holdtime** *hold-interval* and **advertisement-interval** *adv-interval* configured using this command override the global parameter settings that the interface obtains from the PIM view. If you run this command multiple times and specify the same interface, only the latest configuration takes effect.

NOTE

If IP address unnumbered is configured, it is not recommended to configure C-RP on the interfaces that use the same addresses. If the interfaces have different priorities, the BSR considers that the C-RP configuration has been repeatedly modified.

Precautions

- *basic-acl-number* specifies a group range. All permitted group ranges will be advertised as the ranges of groups that the RP serves. If no group range is specified, the C-RP serves all multicast groups.
- To enable a C-RP to serve multiple PIM-SM domains, configure multiple **rule**s in the ACL to specify multicast group ranges for the domains.
- The **c-rp** command needs to be used together with the **acl** command. In the ACL view, **source** can be specified in the **rule** command to specify the range of groups that a C-RP serves.

Example

In the PIM view of public network instance, use basic ACL 2069 to specify Loopback 0 as the C-RP for PIM-SM domains 225.1.0.0/16 and 226.2.0.0/16, and set the C-RP priority to 10.

```
<HUAWEI> system-view
[HUAWEI] acl number 2069
[HUAWEI-acl-basic-2069] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2069] rule permit source 226.2.0.0 0.0.255.255
[HUAWEI-acl-basic-2069] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface loopback 0
```

```
[HUAWEI-LoopBack0] pim sm
[HUAWEI-LoopBack0] quit
[HUAWEI] pim
[HUAWEI-pim] c-rp loopback 0 group-policy 2069 priority 10
```

8.3.13 c-rp advertisement-interval (IPv4)

Function

The **c-rp advertisement-interval** command sets the interval at which a C-RP sends Advertisement messages.

The **undo c-rp advertisement-interval** command restores the default interval.

By default, a C-RP sends Advertisement messages at an interval of 60 seconds.

Format

c-rp advertisement-interval *interval*

undo c-rp advertisement-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which a C-RP sends Advertisement messages.	The value ranges from 1 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

All C-RPs in a PIM-SM domain periodically send Advertisement messages to the same BSR. The BSR can collect the integrated RP-Set.

The **c-rp advertisement-interval** command sets the interval at which a C-RP sends Advertisement messages to the BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can also set the advertisement interval when you run the **c-rp** *interface-type interface-number* **advertisement-interval** *adv-interval* command in the PIM view to configure the C-RP interface. The **c-rp advertisement-interval** *interval* command specifies the global advertisement interval. If both the commands are configured, the interval configured by the **c-rp** *interface-type interface-number* **advertisement-interval** *adv-interval* command takes effect.

Example

In the PIM view of public network instance, set the interval at which a C-RP sends Advertisement messages to 30s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-rp advertisement-interval 30
```

8.3.14 c-rp holdtime (IPv4)

Function

The **c-rp holdtime** command configures the holdtime for a received Advertisement message on a BSR.

The **undo c-rp holdtime** command restores the default holdtime.

By default, the holdtime for a received Advertisement message is 150 seconds.

Format

c-rp holdtime *interval*

undo c-rp holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout period for a BSR to wait the Advertisement message from a C-RP.	The value ranges from 1 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When *interval* is set on a C-RP, the C-RP encapsulates *interval* in an Advertisement message and sends it to the BSR. The BSR obtains this *interval* from the message and starts the timer. If the BSR receives no Advertisement message from the C-RP within the timeout period, the BSR regards the C-RP invalid or unreachable.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can also set the holdtime for a received Advertisement message when you run the **c-rp** *interface-type interface-number* **holdtime** *hold-interval* in the PIM view to configure a C-PR interface. The **c-rp holdtime** *hold-interval* configures the global holdtime for Advertisement messages. If both the two commands are configured, the holdtime configured by the **c-rp** *interface-type interface-number* **holdtime** *hold-interval* command takes effect.

Example

In the PIM view of public network instance, set the holdtime for a received Advertisement message to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-rp holdtime 100
```

8.3.15 c-rp priority (IPv4)

Function

The **c-rp priority** command configures the global priority of a C-RP.

The **undo c-rp priority** command restores the default configuration.

By default, the global priority of a C-RP is 0.

Format

c-rp priority *priority*

undo c-rp priority

Parameters

Parameter	Description	Value
priority	Specifies the global priority of a C-RP. The greater the value, the lower the priority.	The value is an integer that ranges from 0 to 255.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following rules are used to elect an RP from multiple C-RPs, in descending order of precedence:

- The C-RP with the interface address that has the longest mask wins.
- The C-RP with highest priority wins.
- The C-RP with the largest hash value wins.
- The C-RP with the largest address wins.

To enable a C-RP to function as an RP, you can run the **c-rp priority** command to increase the priority of the C-RP.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

You can run the **c-rp** *interface-type interface-number* **priority** *priority* command in the PIM view to configure the C-RP interface and specify the C-RP priority. The **c-rp priority** *priority* command specifies the global C-RP priority. If both **c-rp** *interface-type interface-number* **priority** *priority* and **c-rp priority** *priority* are used, the **c-rp** *interface-type interface-number* **priority** *priority* command takes effect.

Example

In the PIM view of public network instance, set the global priority of a C-RP to 5.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] c-rp priority 5
```

8.3.16 crp-policy (IPv4)

Function

The **crp-policy** limits the range of valid C-RP addresses and the range of the multicast addresses served by a C-RP. The BSR drops the C-RP messages with addresses out of the specified range to protect valid C-RPs.

The **undo crp-policy** command restores the default configuration.

By default, the BSR does not limit the range of valid C-RP addresses and the range of the multicast groups served by a C-RP. The BSR considers all the received C-RP messages valid.

Format

crp-policy *advanced-acl-number*

undo crp-policy

Parameters

Parameter	Description	Value
advanced-acl-number	Specifies the number of an advanced ACL. The ACL defines the range of the C-RP addresses and the range of the group addresses served by a C-RP.	The value is an integer that ranges from 3000 to 3999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM SM network that uses the BSR mechanism, any switch can be configured as a C-RP to serve the multicast groups in a specified range. Each C-RP sends its information to the BSR in unicast mode. The BSR summarizes all received C-RP information into am RP-set and floods it on the entire network using BSR messages. The local switch then works out the RP serving a specific multicast group address range according to the RP-set.

To protect valid C-RPs from spoofing, configure **crp-policy** on BSR switches to limit the range of valid C-RP addresses and the range of multicast group addresses served by a C-RP. Configure the same filtering rule on each C-BSR because any C-BSR can become the BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If an ACL rule is specified but no C-RP address range is set, all C-RP messages are denied.

Precautions

The **crp-policy** command and the **acl** command are used together. In the ACL view, you can set the valid source address range for the C-RP by specifying the **source** parameter in the **rule** command. You can set the address range of multicast groups that are served by specifying the **destination** parameter in the **rule** command.

A received C-RP message matches the configured filtering policy only when the C-RP address carried by the message matches **source** and the group address range carried by the message is a subset of the group address range defined in the ACL.

Example

Configure a C-RP policy on the C-BSR, which allows only the C-RP with the address 10.1.1.1/32 and allows the C-RP to serve only the multicast groups 225.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 3100
[HUAWEI-acl-adv-3100] rule permit ip source 10.1.1.1 0 destination 225.1.0.0 0.0.255.255
[HUAWEI-acl-adv-3100] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] crp-policy 3100
```

8.3.17 display default-parameter pim-dm

Function

The **display default-parameter pim-dm** command displays default configurations about PIM-DM.

Usage Guidelines

The **display default-parameter pim-dm** command displays default configurations about PIM-DM. Even if PIM-DM parameters are modified, the **display default-parameter pim-dm** command still displays default parameter settings. Therefore, you can use this command to check which parameters on the device have been modified.

Example

Display default configurations about PIM-DM.

```
<HUAWEI> display default-parameter pim-dm
 PIM View Default Configurations:
 --------------------------------
 Hello-option dr-priority: 1
 Hello-option holdtime: 105 s
 Hello-option lan-delay: 500 ms
 Hello-option neighbor-tracking: disabled
 Hello-option override-interval: 2500 ms
```

```
Holdtime assert: 180 s
Holdtime join-prune: 210 s
Source-lifetime: 210 s
State-refresh-interval: 60 s
State-refresh-rate-limit: 30 s
State-refresh-ttl: 255
Hello periodic interval: 30 s
Join-prune periodic interval: 60 s

Interface View Default Configurations:
-------------------------------------
Pim bfd: disabled
Pim hello-option dr-priority: 1
Pim hello-option holdtime: 105 s
Pim hello-option lan-delay: 500 ms
Pim hello-option neighbor-tracking: disabled
Pim hello-option override-interval: 2500 ms
Pim holdtime assert: 180 s
Pim holdtime join-prune: 210 s
Pim require-genid: disabled
Pim silent: disabled
Pim state-refresh-capable: enabled
Pim timer dr-switch-delay: disabled
Pim timer graft-retry: 3 s
Pim hello periodic interval: 30 s
Pim join-prune periodic interval: 60 s
Pim triggered-hello-delay: 5 s
Pim version: 2
Pim ipsec sa: disabled
Pim neighbor-policy: disabled
```

Table 8-36 Description of the **display default-parameter pim-dm** command output

Item	Description
PIM View Default Configurations	Default configurations in the PIM view.
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv4)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state. This parameter is configured by the **hello-option holdtime (IPv4)** command.
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment. This parameter is configured by the **hello-option lan-delay (IPv4)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. ● enabled: Neighbor tracking is enabled. ● disabled: Neighbor tracking is disabled This function is configured using the **hello-option neighbor-tracking (IPv4)** command.

Item	Description
Hello-option override-interval	Interval for sending Prune Override messages. This parameter is configured by the **hello-option override-interval (IPv4)** command.
Holdtime assert	Time period for holding the Assert state. This parameter is configured by the **holdtime assert (IPv4)** command.
Holdtime join-prune	Time period for holding the Join or Prune state. This parameter is configured by the **holdtime join-prune (IPv4)** command.
Source-lifetime	Timeout period of an (S, G) entry. This parameter is configured by the **source-lifetime (IPv4)** command.
State-refresh-interval	Interval for sending State-Refresh messages. This parameter is configured by the **state-refresh-interval (IPv4)** command.
State-refresh-rate-limit	Minimum interval from when the last State-Refresh message is received to when the next State-Refresh message is received. This parameter is configured by the **state-refresh-rate-limit (IPv4)** command.
State-refresh-ttl	TTL value of the State-Refresh message. This parameter is configured by the **state-refresh-ttl (IPv4)** command.
Hello periodic interval	Interval for sending Hello messages. This parameter is configured by the **timer hello (IPv4)** command.
Join-prune periodic interval	Interval for sending Join/Prune messages. This parameter is configured by the **timer join-prune (IPv4)** command.
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether PIM BFD is enabled on the interface. This parameter is configured by the **pim bfd enable** command.
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim hello-option dr-priority** command.

Item	Description
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state. This parameter is configured by the **pim hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at the shared network segment where the interface resides. This parameter is configured by the **pim hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. - enabled: Neighbor tracking is enabled. - disabled: Neighbor tracking is disabled This function is configured using the **pim hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages. This parameter is configured by the **pim hello-option override-interval** command.
Pim holdtime assert	Time period for the interface to hold the Assert state. This parameter is configured by the **pim holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state. This parameter is configured by the **pim holdtime join-prune** command.
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. - enabled: The received Hello message is required to carry the Generation ID. - disabled: The received Hello message is not required to carry the Generation ID. This parameter is configured using the **pim require-genid** command.

Item	Description
Pim silent	Whether the interface is set to PIM silent state. ● enabled: The interface is in PIM silent state. ● disabled: The interface is not in PIM silent state. This function is configured using the **pim silent** command.
Pim state-refresh-capable	Whether State-Refresh is enabled on the interface. ● enabled: State-Refresh is enabled on the interface. ● disabled: State-Refresh is disabled on the interface. This function is configured using the **pim state-refresh-capable** command.
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. ● enabled: The DR switch delay is set on the interface. ● disabled: The DR switch delay is not set on the interface. This parameter is configured by the **pim timer dr-switch-delay** command.
Pim timer graft-retry	Interval for the interface to retransmit Graft messages. This parameter is configured by the **pim timer graft-retry** command.
Pim hello periodic interval	Interval for the interface to send Hello messages. This parameter is configured by the **pim timer hello** command.
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages. This parameter is configured by the **pim timer join-prune** command.
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages. This parameter is configured by the **pim triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.

Item	Description
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. This parameter is configured by the **pim ipsec sa** command.
Pim neighbor-policy	Whether a neighbor policy is configured on the interface. - enabled: A neighbor policy is configured on the interface. - disabled: No neighbor policy is configured on the interface. This parameter is configured by the **pim neighbor-policy** command.

```

Table 8-37 Description of the **display default-parameter pim-sm** command output

Item	Description
PIM View Default Configurations	Default configurations in the PIM view.

Item	Description
Auto-rp listening enable	Whether the auto-RP listening function is enabled. The switch does not support this function.
Bsr-policy	Whether the valid address range of the BSR is set. This parameter is configured by the **bsr-policy (IPv4)** command.
C-bsr admin-scope	Whether the BSR administrative domain is configured. This parameter is configured by the **c-bsr admin-scope** command.
C-bsr global	Whether the C-BSR in the global domain is configured. This parameter is configured by the **c-bsr global** command.
C-bsr group	Whether the C-BSR in the BSR administrative domain is configured. This parameter is configured by the **c-bsr group** command.
C-bsr hash-length	Global hash mask length of the C-BSR. This parameter is configured by the **c-bsr hash-length (IPv4)** command.
C-bsr holdtime	Waiting time for the BSR to receive the Bootstrap message. This parameter is configured by the **c-bsr holdtime (IPv4)** command.
C-bsr interval	Interval for the BSR to send Bootstrap messages. This parameter is configured by the **c-bsr interval (IPv4)** command.
C-bsr priority	Global priority of the C-BSR. This parameter is configured by the **c-bsr priority (IPv4)** command.
C-rp advertisement-interval	Interval for the C-RP to send Advertisement messages. This parameter is configured by the **c-rp advertisement-interval (IPv4)** command.
C-rp holdtime	Waiting time for the BSR to receive the Advertisement message. This parameter is configured by the **c-rp holdtime (IPv4)** command.
C-rp priority	Global priority of the C-RP. This parameter is configured by the **c-rp priority (IPv4)** command.

Item	Description
Crp-policy	Whether the valid address range of the C-RP and the range of multicast groups that the C-RP serves are set. This parameter is configured by the **crp-policy (IPv4)** command.
Bsm semantic fragmentation	Whether the BSR fragmentation is enabled. This parameter is configured by the **bsm semantic fragmentation (IPv4)** command.
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv4)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state, in seconds. This parameter is configured by the **hello-option holdtime (IPv4)** command.
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment, in milliseconds. This parameter is configured by the **hello-option lan-delay (IPv4)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. This parameter is configured by the **hello-option neighbor-tracking (IPv4)** command.
Hello-option override-interval	Interval for sending Prune Override messages, in milliseconds. This parameter is configured by the **hello-option override-interval (IPv4)** command.
Holdtime assert	Time period for holding the Assert state, in seconds. This parameter is configured by the **holdtime assert (IPv4)** command.
Holdtime join-prune	Time period for holding the Join or Prune state, in seconds. This parameter is configured by the **holdtime join-prune (IPv4)** command.
Probe-interval	Interval for sending Probe messages (empty Register messages) to the RP, in seconds. This parameter is configured by the **probe-interval (IPv4)** command.
Register-header-checksum	Whether calculating the checksum based on information in Register message header is required. This parameter is configured by the **register-header-checksum** command.

Item	Description
Register-policy	Whether the rule for filtering Register messages is configured. This parameter is configured by the **register-policy (IPv4)** command.
Register-suppression-timeout	Time period for holding the register-suppression state, in seconds. This parameter is configured by the **register-suppression-timeout (IPv4)** command.
Source-lifetime	Timeout period of an (S, G) entry, in seconds. This parameter is configured by the **source-lifetime (IPv4)** command.
Source-policy	Whether the rule for filtering multicast sources is configured. This parameter is configured by the **source-policy (IPv4)** command.
Spt-switch-threshold	Whether the threshold of the multicast packet rate that triggers the switch from the RPT to the SPT is configured. This parameter is configured by the **spt-switch-threshold (IPv4)** command.
Ssm-policy	Whether the SSM group address range is set. This parameter is configured by the **ssm-policy (IPv4)** command.
Static-rp	Whether the static RP is configured. This parameter is configured by the **static-rp (IPv4)** command.
Hello periodic interval	Interval for sending Hello messages, in seconds. This parameter is configured by the **timer hello (IPv4)** command.
Join-prune periodic interval	Interval for sending Join/Prune messages, in seconds. This parameter is configured by the **timer join-prune (IPv4)** command.
Timer spt-switch	Whether the interval for checking whether the multicast packet rate exceeds the threshold before the switchover from RPT to SPT is configured, in seconds. This parameter is configured by the **timer spt-switch (IPv4)** command.
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether PIM BFD is enabled on the interface. This parameter is configured by the **pim bfd enable** command.

Item	Description
Pim bsr-boundary	Whether the PIM boundary is configured on the interface. This parameter is configured by the **pim bsr-boundary** command.
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim hello-option dr-priority** command.
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state, in seconds. This parameter is configured by the **pim hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment on the interface, in milliseconds. This parameter is configured by the **pim hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. This parameter is configured by the **pim hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages, in milliseconds. This parameter is configured by the **pim hello-option override-interval** command.
Pim holdtime assert	Time period for the interface to hold the Assert state, in seconds. This parameter is configured by the **pim holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state, in seconds. This parameter is configured by the **pim holdtime join-prune** command.
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. This parameter is configured by the **pim require-genid** command.
Pim silent	Whether PIM Silent is enabled on the interface. This parameter is configured by the **pim silent** command.
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. This parameter is configured by the **pim timer dr-switch-delay** command.

Item	Description
Pim hello periodic interval	Interval for the interface to send Hello messages, in seconds. This parameter is configured by the **pim timer hello** command.
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages, in seconds. This parameter is configured by the **pim timer join-prune** command.
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages, in seconds. This parameter is configured by the **pim triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. This parameter is configured by the **pim ipsec sa** command.
Pim join-policy	Whether the join-policy is configured on the interface. This parameter is configured by the **pim join-policy** command.
Pim neighbor-policy	Whether the neighbor-policy is configured on the interface. This parameter is configured by the **pim neighbor-policy** command.

8.3.19 display default-parameter pim-ssm

Function

The **display default-parameter pim-ssm** command displays default configurations of PIM-SM for SSM.

Format

display default-parameter pim-ssm

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display default-parameter pim-ssm** command displays default configuration of PIM-SM for SSM. Even if the configuration of PIM-SM for SSM is modified, the **display default-parameter pim-ssm** command still displays default parameter settings. Therefore, you can use this command to check which parameters on the device have been modified.

Example

Display default configuration of PIM-SM for SSM.

```
<HUAWEI> display default-parameter pim-ssm
 PIM View Default Configurations:
 ---------------------------------
 Hello-option dr-priority: 1
 Hello-option holdtime: 105 s
 Hello-option lan-delay: 500 ms
 Hello-option neighbor-tracking: disabled
 Hello-option override-interval: 2500 ms
 Holdtime assert: 180 s
 Holdtime join-prune: 210 s
 Probe-interval: 5 s
 Register-header-checksum: disabled
 Register-policy: disabled
 Register-suppression-timeout: 60 s
 Source-lifetime: 210 s
 Source-policy: disabled
 Ssm-policy: disabled
 Hello periodic interval: 30 s
 Join-prune periodic interval: 60 s

 Interface View Default Configurations:
 --------------------------------------
 Pim bfd: disabled
 Pim hello-option dr-priority: 1
 Pim hello-option holdtime: 105 s
 Pim hello-option lan-delay: 500 ms
 Pim hello-option neighbor-tracking: disabled
 Pim hello-option override-interval: 2500 ms
 Pim holdtime assert: 180 s
 Pim holdtime join-prune: 210 s
 Pim require-genid: disabled
 Pim silent: disabled
 Pim timer dr-switch-delay: disabled
 Pim hello periodic interval: 30 s
 Pim join-prune periodic interval: 60 s
 Pim triggered-hello-delay: 5 s
 Pim version: 2
 Pim ipsec sa: disabled
 Pim join-policy: disabled
 Pim neighbor-policy: disabled
```

Table 8-38 Description of the **display default-parameter pim-ssm** command output

Item	Description
PIM View Default Configurations	Default configurations in the PIM view.

Item	Description
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv4)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state, in seconds. This parameter is configured by the **hello-option holdtime (IPv4)** command.
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment, in milliseconds. This parameter is configured by the **hello-option lan-delay (IPv4)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. This parameter is configured by the **hello-option neighbor-tracking (IPv4)** command.
Hello-option override-interval	Interval for sending Prune Override messages, in milliseconds. This parameter is configured by the **hello-option override-interval (IPv4)** command.
Holdtime assert	Time period for holding the Assert state, in seconds. This parameter is configured by the **holdtime assert (IPv4)** command.
Holdtime join-prune	Time period for holding the Join or Prune state, in seconds. This parameter is configured by the **holdtime join-prune (IPv4)** command.
Probe-interval	Interval for sending Probe messages (empty Register messages) to the RP, in seconds. This parameter is configured by the **probe-interval (IPv4)** command.
Register-header-checksum	Whether calculating the checksum based on information in Register message header is required. This parameter is configured by the **register-header-checksum** command.
Register-policy	Whether the rule for filtering Register messages is configured. This parameter is configured by the **register-policy (IPv4)** command.
Register-suppression-timeout	Time period for holding the register-suppression state, in seconds. This parameter is configured by the **register-suppression-timeout (IPv4)** command.

Item	Description
Source-lifetime	Timeout period of an (S, G) entry, in seconds. This parameter is configured by the **source-lifetime (IPv4)** command.
Source-policy	Whether the rule for filtering multicast sources is configured. This parameter is configured by the **source-policy (IPv4)** command.
Ssm-policy	Whether the SSM group address range is set. This parameter is configured by the **ssm-policy (IPv4)** command.
Hello periodic interval	Interval for sending Hello messages, in seconds. This parameter is configured by the **timer hello (IPv4)** command.
Join-prune periodic interval	Interval for sending Join/Prune messages, in seconds. This parameter is configured by the **timer join-prune (IPv4)** command.
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether PIM BFD is enabled on the interface. This parameter is configured by the **pim bfd enable** command.
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim hello-option dr-priority** command.
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state, in seconds. This parameter is configured by the **pim hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment on the interface, in milliseconds. This parameter is configured by the **pim hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. This parameter is configured by the **pim hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages, in milliseconds. This parameter is configured by the **pim hello-option override-interval** command.

Item	Description
Pim holdtime assert	Time period for the interface to hold the Assert state, in seconds. This parameter is configured by the **pim holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state, in seconds. This parameter is configured by the **pim holdtime join-prune** command.
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. This parameter is configured by the **pim require-genid** command.
Pim silent	Whether PIM Silent is enabled on the interface. This parameter is configured by the **pim silent** command.
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. This parameter is configured by the **pim timer dr-switch-delay** command.
Pim hello periodic interval	Interval for the interface to send Hello messages, in seconds. This parameter is configured by the **pim timer hello** command.
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages, in seconds. This parameter is configured by the **pim timer join-prune** command.
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages, in seconds. This parameter is configured by the **pim triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. This parameter is configured by the **pim ipsec sa** command.
Pim join-policy	Whether the join-policy is configured on the interface. This parameter is configured by the **pim join-policy** command.
Pim neighbor-policy	Whether the neighbor-policy is configured on the interface. This parameter is configured by the **pim neighbor-policy** command.

8.3.20 display pim bfd session

Function

The **display pim bfd session** command displays the information about PIM BFD sessions.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **bfd session statistics**

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **bfd session** [**interface** *interface-type interface-number* | **neighbor** *neighbor-address*] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. The *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
statistics	Displays PIM BFD statistics.	-
interface *interface-type interface-number*	Specifies an interface to be displayed. *interface-type interface-number* specifies the type and number of the interface.	-
neighbor *neighbor-address*	Specifies the IP address of a PIM neighbor to be displayed.	The address is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pim bfd session** command output helps you locate communication faults between neighbors.

Example

Display PIM BFD sessions on VLANIF 10.

```
<HUAWEI> display pim bfd session interface vlanif 10
 VPN-Instance: public net

 Vlanif10 (10.1.2.2): Total 2 BFD sessions Created

 Neighbor     ActTx(ms)     ActRx(ms)     ActMulti     Local/Remote     State
 10.1.2.3     20            20            5            8756/8652        Up
 10.1.2.4     30            10            3            8754/8423        Up
```

Display PIM BFD sessions on VLANIF 10 when the switch is not enabled with global BFD.

```
<HUAWEI> display pim bfd session interface vlanif 10
 VPN-Instance: public net

 Vlanif10 (10.1.2.2): Total 1 BFD session Created

 Neighbor    ActTx(ms)    ActRx(ms)    ActMulti    Local/Remote          State
 10.1.2.1    --           --           --          0/0                   BFD global disable
```

Display the statistics of a PIM BFD session.

```
<HUAWEI> display pim bfd session statistics
 VPN-Instance: public net
  Total 1 PIM BFD session in this instance.

   Total 1 PIM BFD session up.
   Total 0 PIM BFD session down.
```

Display information about PIM BFD sessions of the neighbor 10.1.2.3.

```
<HUAWEI> display pim bfd session neighbor 10.1.2.3
VPN-Instance: public net
  Vlanif10 (10.1.2.2)
 Neighbor     ActTx(ms)     ActRx(ms)     ActMulti     Local/Remote     State
 10.1.2.3     20            20            5            8756/8652        Up
```

Table 8-39 Description of the **display pim bfd session** command output

Item	Description
Vlanif10 (10.1.2.2)	PIM interface name (the IP address).
Neighbor	IP address of a PIM neighbor.
ActTx (ms)	Actual minimum transmission interval, in milliseconds.
ActRx (ms)	Actual minimum receiving interval, in milliseconds.
ActMulti	Actual local detection multiple.
Local/Remote	Local and remote discriminators.

Item	Description
State	Status of the PIM BFD session. ● Up: indicates that the BFD session is set up successfully and detection packets are periodically exchanged. ● Init: indicates that the local end can communicate with the remote end and wants the session status to be Up. ● BFD global disable: indicates that BFD is globally disabled. ● Detect down: indicates that no BFD packets are not received when the detection time expires. ● Neighbour down: indicates that the packets with the State field being Down are received from neighbors.
Total 1 PIM BFD session in this instance	Total number of PIM BFD sessions in a public network instance or a VPN instance.
Total 1 PIM BFD session up	Number of PIM BFD sessions in the Up state in a public network instance or a VPN instance.
Total 0 PIM BFD session down	Number of PIM BFD sessions in the Down state in a public network instance or a VPN instance, that is, all PIM BFD sessions except the PIM BFD sessions in the Up state.

8.3.21 display pim bsr-info

Function

The **display pim bsr-info** command displays the BSRs in a PIM-SM domain.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **bsr-info**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command applies to the PIM-SM domain where the RP is dynamically elected among BSRs. You can run this command on any switch in the domain to view the BSR information.

- If the current switch is configured with the C-BSR, the command output includes information about the elected BSR and locally configured C-BSR.
- If the current switch is not configured with the C-BSR, the command output includes information about the elected BSR only.

Precautions

When the **display pim bsr-info** command is used, only information about the public network instance is displayed if the **vpn-instance** or **all-instance** is not specified.

This command has output only after C-BSRs have been configured in a PIM-SM domain.

Example

Display information about the BSR in the PIM-SM domain. If the switch is not configured with C-BSR, only information about the elected BSR is displayed.

```
<HUAWEI> display pim bsr-info
 VPN-Instance: public net
 Elected AdminScoped BSR Count: 0
 Elected BSR Address: 10.1.2.2
     Priority: 0
     Hash mask length: 30
     State: Accept Preferred
     Scope: Not scoped
     Uptime: 00:01:46
     Expires: 00:02:02
     C-RP Count: 1
```

Display information about BSR in the current PIM-SM.

If the switch is configured with C-BSR, information about the elected BSR and C-BSR is displayed.

```
<HUAWEI> display pim bsr-info
 VPN-Instance: public net
 Elected AdminScoped BSR Count: 0
 Elected BSR Address: 10.1.2.2
     Priority: 0
     Hash mask length: 30
     State: Elected
     Scope: Not scoped
     Uptime: 00:10:42
     Next BSR message scheduled at: 00:00:31
     C-RP Count: 1
 Candidate AdminScoped BSR Count: 0
 Candidate BSR Address: 10.1.2.2
     Priority: 0
```

```
    Hash mask length: 30
    State: Elected
    Scope: Not scoped
    Wait to be BSR: 0
```

Table 8-40 Description of the **display pim bsr-info** command output

Item	Description
Elected AdminScoped BSR Count	Number of elected AdminScoped BSRs.
Elected BSR Address	Address of the elected BSR.
Priority	Priority of the BSR. By default, the value is 0.
Hash mask length	Mask length in the RP hash calculation.
State	Status of the BSR.
Scope	Range of multicast addresses in the administrative scope when the BSR is an AdminScoped BSR. Not scoped indicates that the BSR is not an AdminScoped BSR.
Uptime	Period during which the BSR exists. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
Expires	Remaining time of the BSR. The time format is as follows: ● If the time is shorter than or equal to 24 hours, the format is hours:minutes:seconds. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is days:hours. ● If the time is longer than one week, the format is weeks:days.
C-RP Count	Number of RPs learned through the BSR.
Next BSR message scheduled at	Period after which the next BSR message is sent. BSR messages are sent only when the timer maintained by the elected BSR times out.

Item	Description
Candidate AdminScoped BSR Count	Number of AdminScoped C-BSRs.
Candidate BSR Address	Address of the C-BSR.
Wait to be BSR	Whether the current C-BSR is valid. The values are as follows: ● 0: indicates that the current C-BSR is valid. The current C-BSR takes part in the BSR election. ● 1: indicates that the current C-BSR is invalid. The current C-BSR does not take part in the BSR election. When the number of C-BSRs configured on the switch exceeds the threshold, the value is 1.

8.3.22 display pim claimed-route

Function

The **display pim claimed-route** command displays the unicast routing information used by PIM.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **claimed-route** [*source-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
source-address	Specifies the multicast source address.	The address is in decimal notation.

Views

All views

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display pim claimed-route** command is used to view information about unicast routes used by PIM, including RPF neighbors, interfaces, route types, and route selection policies.

Configuration Impact

Differences between the **display pim claimed-route** and **display multicast rpf-info** commands are as follows:

- The **display multicast rpf-info** command is used to check information about RPF neighbors, RPF interfaces, or whether there is a route to a specified source address.
- The **display pim claimed-route** command is used to check information about unicast routes used by multicast routing and entries of these routes.

Example

Display the unicast routing information used by PIM.

```
<HUAWEI> display pim claimed-route
 VPN-Instance: public net
 multicast load-splitting rule: source-group
 RPF information about: 10.1.0.0 in PIM-SM routing table
     RPF interface: Vlanif10, RPF neighbor: 10.1.2.2
     Referenced route/mask: 10.1.0.0/24
     Referenced route type: igp
     RPF-route selecting rule: preference-preferred
     The (S, G) or (*, G) list dependent on this route entry
     (10.1.0.1, 225.0.0.1)
```

Table 8-41 Description of the **display pim claimed-route** command output

Item	Description
multicast load-splitting rule	How multi-cast loads are split. The following policies apply: • group: multicast group-based load splitting • source: multicast source-based load splitting • source-group: multicast source and group-based load splitting • stable-preferred: stable-preferred load splitting • balance-preferred: balance-preferred load splitting This parameter is configured by the **multicast load-splitting** command.

Item	Description
RPF information about: 10.1.0.0 in PIM-SM routing table	RPF routing information with the source address of 10.1.0.0 in the PIM-SM routing table
RPF interface	RPF interface on the switch.
RPF neighbor	RPF neighbor of the switch.
Referenced route/mask	Destination address/mask of the referenced route.
Referenced route type	Type of the route.
RPF-route selecting rule	Preferred rule for selecting the RPF-route.
The (S,G) or (*,G) list dependent on this route entry	List of multicast entries based on RPF routes.

8.3.23 display pim control-message counters

Function

The **display pim control-message counters** command displays the number of sent, received, and invalid PIM control messages.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters message-type** { **probe** | **register** | **register-stop** | **crp** }

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters** [**message-type** { **assert** | **graft** | **graft-ack** | **hello** | **join-prune** | **state-refresh** | **bsr** } | **interface** *interface-type interface-number*] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
message-type	Indicates a PIM control message type.	-
probe	Indicates the Probe message.	-
register	Indicates the Register message.	-

Parameter	Description	Value
register-stop	Indicates the Register-stop message.	-
crp	Indicates the C-RP message.	-
assert	Indicates the Assert message.	-
graft	Indicates the Graft message.	-
graft-ack	Indicates the Graft-ack message.	-
hello	Indicates the Hello message.	-
join-prune	Indicates the Join/Prune message.	-
state-refresh	Indicates the State-Refresh message.	-
bsr	Indicates the BSR message.	-
interface *interface-type interface-number*	Indicates the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When multicast data messages cannot be forwarded on a PIM network, run the **display pim control-message counters** command to view statistics on protocol messages. The command output helps you locate faults.

When you run the **display pim control-message counters** command:

- If you specify **interface** *interface-type interface-number*, you can view the number of various PIM control messages that were sent and received on the specified interface only.
- If you specify **message-type**, you can view the number of PIM control messages of this type sent and received on all interfaces of the switch.

Example

Display the statistics about sent, received, and invalid PIM control messages on the device.

```
<HUAWEI> display pim control-message counters
 VPN-Instance: public net
 PIM global control-message counters:
 Message Type      Received        Sent           Invalid          Filtered
 Register          51              0              0                0
 Register-Stop     0               48             0                0
 Probe             44              0              0                0
 C-RP              0               0              0                0

 PIM control-message counters for interface: Vlanif10
```

```
 Message Type     Received        Sent           Invalid         Filtered
 Assert          0              6              0              0
 Graft           0              0              0              0
 Graft-Ack       0              0              0              0
 Hello           34496          34495          0              0
 Join-prune      26171          90             0              0
 State-Refresh   0              0              0              0
 BSR             0              0              0              0

 PIM control-message counters for interface: Vlanif20
 Message Type     Received        Sent           Invalid         Filtered
 Assert          0              0              0              0
 Graft           0              0              0              0
 Graft-Ack       0              0              0              0
 Hello           34491          34495          0              0
 Join-prune      0              41             0              0
 State-Refresh   0              0              0              0
 BSR             0              0              0              0
```

Display the statistics about sent, received, invalid PIM control messages on VLANIF 10.

```
<HUAWEI> display pim control-message counters interface Vlanif 10
 VPN-Instance: public net
 PIM control-message counters for interface: Vlanif 10
 Message Type     Received        Sent           Invalid     Filtered
 Assert          0              0              0          0
 Graft           0              0              0              0
 Graft-Ack       0              0              0              0
 Hello           328            331            0          0
 Join-prune      2              0              0          0
 State-Refresh   0              0              0              0
 BSR             0              0              0          0
```

Table 8-42 Description of the **display pim control-message counters** command output

Item	Description
PIM global control-message counters	Number of PIM control messages in the public network.
PIM control-message counters for interface	Name of the interface where statistics about PIM control messages are collected.
Message Type	Type of the control messages.
Received	Number of control messages received by the interface.
Sent	Number of control messages sent by the interface.
Invalid	Number of invalid control messages.
Filtered	Number of control messages filtered out by the interface.
Register	Number of Register messages.
Register-Stop	Number of Register-Stop messages.
Probe	Number of Probe messages.

Item	Description
C-RP	Number of CRP messages.
Assert	Number of Assert messages.
Graft	Number of Graft messages.
Graft-Ack	Number of Graft-Ack messages.
Hello	Number of Hello messages.
Join-prune	Number of Join/Prune messages.
State-Refresh	Number of State-Refresh messages.
BSR	Number of Bootstrap messages.

8.3.24 display pim grafts

Function

The **display pim grafts** command displays the information about unacknowledged PIM-DM Graft messages.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **grafts**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In PIM-DM, after sending the Graft message, the switch needs to wait to receive the Graft-Ack message from the upstream device. You can run the **display pim grafts** command to view the information about the PIM-DM Graft messages sent but unacknowledged.

Example

Display the unacknowledged PIM-DM graft messages on the switch.

```
<HUAWEI> display pim grafts
VPN-Instance: public net
Source                  Group                 Expire   RetransmitIn
10.0.5.200               226.3.3.3             00:02:52 00:00:02
```

Table 8-43 Description of the **display pim grafts** command output

Item	Description
Source	Multicast source address.
Group	Multicast group address.
Expire	Timeout period of an (S, G) entry.
RetransmitIn	Amount of time before the next retransmission of the Graft message.

8.3.25 display pim interface

Function

The **display pim interface** command displays PIM information on an interface.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **interface** [*interface-type interface-number* | **up** | **down**] [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
interface-type interface-number	Specifies the type and number of an interface.	-
up	Displays PIM information on interfaces in Up state.	-
down	Displays PIM information on interfaces in Down state.	-

Parameter	Description	Value
verbose	Displays detailed information about a PIM interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An interface with PIM enabled is called a PIM interface. The **display pim interface** command is used to display information about PIM interfaces, including the PIM state, number of PIM neighbors, interval at which Hello messages are sent, DR priority, and DR address.

When the **display pim interface** command is used:

- If *interface-type interface-number* is specified, the command displays various PIM state parameters on the specified interface.
- If *interface-type interface-number* is not specified, the command displays state parameters of all the PIM interfaces.
- If **up** is specified in the command, the command displays parameters of the PIM interfaces in the Up stated.
- If **down** is specified in the command, the command displays parameters of the PIM interfaces in the Down state.

Example

Display information about all the PIM interfaces.

```
<HUAWEI> display pim interface
 VPN-Instance: public net
 Interface      State   NbrCnt   HelloInt   DR-Pri     DR-Address
 Loop0          up      0        30         1          10.1.0.2    (local)
 Vlanif10       up      1        30         1          10.1.1.2
 Vlanif20       up      0        30         1          10.1.2.2    (local)
 Vlanif30       up      1        30         1          10.1.3.2
```

Table 8-44 Description of the **display pim interface** command output

Item	Description
Interface	Name of the PIM interface.
State	Status of the PIM interface, Up or Down.
NbrCnt	Number of PIM neighbors on the interface.

Item	Description
HelloInt	Interval for sending Hello messages, in seconds.
DR-Pri	DR priority.
DR-Address	DR address.

Display detailed information about PIM on VLANIF10.

```
<HUAWEI> display pim interface vlanif 10 verbose
 VPN-Instance: public net
 Interface: Vlanif10, 10.1.1.1
     PIM version: 2
     PIM mode: Sparse
     PIM state: up
     PIM DR: 10.1.1.2
     PIM DR Priority (configured): 1
     PIM neighbor count: 1
     PIM hello interval: 30 s
     PIM LAN delay (negotiated): 500 ms
     PIM LAN delay (configured): 500 ms
     PIM hello override interval (negotiated): 2500 ms
     PIM hello override interval (configured): 2500 ms
     PIM Silent: disabled
     PIM neighbor tracking (negotiated): disabled
     PIM neighbor tracking (configured): disabled
     PIM generation ID: 0XF5712241
     PIM require-GenID: disabled
     PIM hello hold interval: 105 s
     PIM assert hold interval: 180 s
     PIM triggered hello delay: 5 s
     PIM J/P interval: 60 s
     PIM J/P hold interval: 210 s
     PIM BSR domain border: disabled
     PIM BFD: enabled
     PIM dr-switch-delay timer : 20 s
     Number of routers on link not using DR priority: 0
     Number of routers on link not using LAN delay: 0
     Number of routers on link not using neighbor tracking: 2
     ACL of PIM neighbor policy: myacl
     ACL of PIM ASM join policy: 2000
     ACL of PIM SSM join policy: -
     ACL of PIM join policy: -
     PIM ipsec: disabled
```

Table 8-45 Description of the **display pim interface verbose** command output

Item	Description
Interface	Name and IP address of the PIM interface.
PIM version	PIM version enabled on the interface.
PIM mode	PIM mode used on the interface.
PIM state	Status of the PIM interface, Up or Down.
PIM DR	DR address on the interface.

Item	Description
PIM DR Priority (configured)	DR priority configured on the interface.
PIM neighbor count	Number of PIM neighbors on the interface.
PIM hello interval	Interval for sending PIM Hello messages, in seconds.
PIM LAN delay (negotiated)	Negotiated delay for transmitting packets on the interface, in milliseconds.
PIM LAN delay (configured)	Configured delay for transmitting packets on the interface, in milliseconds.
PIM hello override interval (negotiated)	Negotiated override interval on the interface, in milliseconds.
PIM hello override interval (configured)	Configured override interval on the interface, in milliseconds.
PIM Silent	Whether the interface is set to PIM silent state. - enabled: The interface is in the PIM silent state. - disabled: The interface is not in the PIM silent state. This function is configured using the **pim silent** command.
PIM neighbor tracking (negotiated)	Whether PIM neighbor tracking is enabled on the interface after negotiation. - enabled: PIM neighbor tracking is enabled on the interface. - disabled: PIM neighbor tracking is disabled on the interface.
PIM neighbor tracking (configured)	Whether PIM neighbor tracking is configured on the interface. - enabled: PIM neighbor tracking is configured on the interface. - disabled: PIM neighbor tracking is not configured on the interface. This function is configured using the **pim hello-option neighbor-tracking** command.
PIM generation ID	Generation ID option on the interface.

Item	Description
PIM require-GenID	Whether the switch is enabled to reject Hello messages not carrying the Generation ID. - enabled: The switch is enabled to reject Hello messages not carrying the Generation ID. - disabled: The switch is disabled from rejecting Hello messages not carrying the Generation ID. This function is configured using the **pim require-genid** command.
PIM hello hold interval	Interval during which the receiver of the Hello message to keep its neighbor reachable, in seconds.
PIM assert hold interval	Interval for sending Assert messages, in seconds.
PIM triggered hello delay	Maximum random delay for triggering Hello messages, in seconds.
PIM J/P interval	Interval at which the interface sends Join/Prune messages, in seconds.
PIM J/P hold interval	Period for holding the Join/Prune status on the interface, in seconds.
PIM BSR domain border	Whether the BSR boundary is configured on the interface. - enabled: The BSR boundary is configured on the interface. - disabled: The BSR boundary is not configured on the interface. This function is configured using the **multicast boundary** command.
PIM BFD	Whether PIM BFD is enabled. - enabled: PIM BFD is enabled. - disabled: PIM BFD is disabled. This function is configured using the **pim bfd enable** command.
PIM BFD min-tx-interval	Minimum interval for sending PIM BFD packets. This parameter is configured using the **pim bfd min-tx-interval** *tx-value* command.

Item	Description
PIM BFD min-rx-interval	Minimum interval for receiving PIM BFD packets. This parameter is configured using the **pim bfd min-rx-interval** *rx-value* command.
PIM BFD detect-multiplier	PIM BFD detection multiplier. This parameter is configured using the **pim bfd detect-multiplier** *multiplier-value* command.
PIM dr-switch-delay timer	DR switching delay.
Number of routers on link not using DR priority	Number of switches that do not use DR priority in all the network segments connected to the interface.
Number of routers on link not using LAN delay	Number of switches that do not use LAN delay in all the network segments connected to the interface.
Number of routers on link not using neighbor tracking	Indicates the number of switches that are not enabled with the neighbor tracing function in the network segment where the interface resides.
ACL of PIM neighbor policy	Neighbor filtering policy configured on the interface.
ACL of PIM ASM join policy	ASM Join information filtering policy configured on the interface.
ACL of PIM SSM join policy	SSM Join information filtering policy configured on the interface.
ACL of PIM join policy	Join information filtering policy configured on the interface.

Item	Description
PIM ipsec	Whether PIM IPSec is configured in the PIM view or interface view, and the SA policy name if PIM IPSec is configured. The value can be: ● PIM ipsec: enabled(sa-name: sa1) Security association sa1 has been configured to authenticate all PIM protocol packets using the **ipsec sa (IPv4)** command in the PIM view or the **pim ipsec sa** command in the interface view. If the SA is configured in the interface view, the configuration on the interface is displayed. Otherwise, the configuration in the PIM view is displayed. ● PIM hello ipsec: enabled(sa-name: sa1) Security association sa1 has been configured to authenticate only PIM Hello packets using the **hello ipsec sa (IPv4)** command in the PIM view or the **pim hello ipsec sa** command in the interface view. If the SA is configured in the interface view, the configuration on the interface is displayed. Otherwise, the configuration in the PIM view is displayed. ● PIM ipsec: disabled PIM IPSec is not configured in the PIM view or interface view.

8.3.26 display pim invalid-packet

Function

The **display pim invalid-packet** command displays statistics about invalid PIM messages received by a device and details of these messages.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet** [**interface** *interface-type interface-number* | **message-type** { **assert** | **bsr** | **hello** | **join-prune** | **graft** | **graft-ack** | **state-refresh** }] *

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet message-type** { **crp** | **register** | **register-stop** }

display pim invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about invalid PIM messages received in a specified VPN instance. The *vpn-instance-name* parameter specifies the VPN instance name.	The value must be an existing VPN instance name.
all-instance	Displays statistics about invalid PIM messages received in all VPN instances.	-
interface *interface-type interface-number*	Specifies the type and number of an interface on the switch.	-
message-type	Displays statistics about invalid PIM messages of a specific type.	-
assert	Displays statistics about invalid Assert messages.	-
bsr	Displays statistics about invalid BSR messages.	-
hello	Displays statistics about invalid Hello messages.	-
join-prune	Displays statistics about invalid Join/Prune messages.	-
graft	Displays statistics about invalid Graft messages.	-
graft-ack	Displays statistics about invalid Graft-Ack messages.	-
state-refresh	Displays statistics about invalid State-Refresh messages.	-
crp	Displays statistics about invalid C-RP messages.	-
register	Displays statistics about invalid Register messages.	-

Parameter	Description	Value
register-stop	Displays statistics about invalid Register-Stop messages.	-
packet-number	Displays details about a specified number of invalid PIM messages recently received.	The value is an integer that ranges from 1 to 100. By default, details of all the invalid PIM messages currently stored are displayed.
verbose	Displays details of invalid PIM messages.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

If a switch fails to create PIM entries, you can run the **display pim invalid-packet** command first to check whether the switch has received invalid PIM messages. If the command output displays counters of invalid PIM messages, run the **display pim invalid-packet** [*packet-number*] **verbose** command to view details of invalid PIM messages for fault location.

You can run the following commands to view information about specific invalid PIM messages:

- Run the **display pim** [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet** command to view statistics about invalid PIM messages received in a specified VPN instance or in all VPN instances.
- Run the **display pim invalid-packet interface** *interface-type interface-number* command to view statistics about invalid PIM messages received by a specified interface.
- Run the **display pim invalid-packet** *packet-number* **verbose** command to view details of invalid PIM messages recently received. Currently, details of a maximum of 100 invalid PIM messages can be displayed.

Example

Display statistics about invalid PIM messages received on the switch.

```
<HUAWEI> display pim invalid-packet
          Statistics of invalid packets for public net:
```

```
-------------------------------------------------------------------
PIM General invalid packet:
Invalid PIM Version      : 0          Invalid PIM Type         : 0
Fault Length             : 0          Bad Checksum             : 0

PIM Register invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Dest Addr        : 0

PIM Register-Stop invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Dest Addr        : 0          IP Source not RP         : 0

PIM CRP invalid packet:
Invalid Dest Addr        : 0          Invalid CRP Addr         : 0
Fault Length             : 0          CRP Adv Fault Length     : 0
Invalid Multicast Group : 0

PIM Assert invalid packet:
Invalid Dest Addr        : 0          Invalid IP Source Addr  : 0
Invalid Multicast Source: 0           Invalid Multicast Group : 0

PIM BSR invalid packet:
Bad Payload              : 0          Fault Length             : 0
Bad Scope Mask           : 0          Invalid Multicast Group : 0
Not CBSR But BSR         : 0          Invalid BSR Addr         : 0
Fault Hash Length        : 0          Invalid IP Source Addr  : 0

PIM Hello invalid packet:
Invalid Addr List        : 0          Fault Length             : 0
Bad Holdtime Length      : 0          Bad LanPruneDelay Length: 0
Bad DrPriority Length    : 0          Bad GenID Length         : 0
Invalid Dest Addr        : 0          Invalid IP Source Addr  : 0

PIM Join/Prune invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Up Neighbor      : 0          Invalid IP Source Addr  : 0
Invalid Dest Addr        : 0          Fault Length             : 0

PIM Graft invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Up Neighbor      : 0          Invalid IP Source Addr  : 0
Fault Length             : 0

PIM Graft-Ack invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Up Neighbor      : 0          Invalid IP Source Addr  : 0
Fault Length             : 0

PIM State Refresh invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0
Invalid Originator Addr : 0           Fault Length             : 0
-------------------------------------------------------------------
```

Table 8-46 Description of the **display pim invalid-packet** command output

Item	Description
PIM General invalid packet	General invalid PIM messages.
Invalid PIM Version	Number of messages with invalid PIM versions.
Invalid PIM Type	Number of messages with invalid PIM message types.

Item	Description
Fault Length	Number of messages of invalid lengths.
Bad Checksum	Number of messages with invalid checksum.
PIM Register invalid packet	Number of invalid PIM Register messages.
Invalid Multicast Source	Number of messages with invalid multicast source addresses.
Invalid Multicast Group	Number of messages with invalid multicast group addresses.
Invalid Dest Addr	Number of messages with invalid destination addresses.
PIM Register-Stop invalid packet	Number of invalid PIM Register-Stop messages.
IP Source not RP	Number of messages whose source addresses are not the RP address.
PIM CRP invalid packet	Number of invalid PIM C-RP messages.
Invalid CRP Addr	Number of messages with invalid C-RP addresses.
CRP Adv Fault Length	Number of messages whose CRP Adv fields are of invalid lengths.
PIM Assert invalid packet	Number of invalid PIM Assert messages.
Invalid IP Source Addr	Number of messages with invalid multicast source addresses.
PIM BSR invalid packet	Number of invalid PIM BSR messages.
Bad Payload	Number of messages with invalid payloads.
Bad Scope Mask	Number of messages with invalid scope masks.
Not CBSR But BSR	Number of BSR messages received on interfaces that do not act as a C-BSR.
Invalid BSR Addr	Number of messages with invalid BSR addresses.
Fault Hash Length	Number of messages with hash mask fields of invalid lengths.
PIM Hello invalid packet	Number of invalid PIM Hello messages.
Invalid Addr List	Number of messages with invalid address lists.
Bad Holdtime Length	Number of messages with Holdtime fields of invalid lengths.

Item	Description
Bad LanPruneDelay Length	Number of messages with LanPruneDelay fields of invalid lengths.
Bad DrPriority Length	Number of messages with DrPriority fields of invalid lengths.
Bad GenID Length	Number of messages with Generation ID fields of invalid lengths.
PIM Join/Prune invalid packet	Number of invalid PIM Join/Prune messages.
Invalid Up Neighbor	Number of messages with invalid upstream neighbors.
PIM Graft invalid packet	Number of invalid PIM Graft messages.
PIM Graft-Ack invalid packet	Number of invalid PIM Graft-Ack messages.
PIM State Refresh invalid packet	Number of invalid PIM State-Refresh messages.
Invalid Originator Addr	Number of messages with invalid Originator address.

Display details of one invalid PIM message recently received on the switch.

```
<HUAWEI> display pim invalid-packet 1 verbose
      Detailed information of invalid packets
-----------------------------------------------------
Packet information (Index 1):
-----------------------------------------------------
Interface           :  Vlanif10
Time                :  2010-6-1 20:04:35 UTC-08:00
Message Length      :  26
Invalid Type        :  Invalid Multicast Source
0000: 25 00 96 77 01 00 00 20 e1 01 01 01 01 00 e0 00
0010: 00 00 80 00 00 64 00 00 00 00
-----------------------------------------------------
```

Table 8-47 Description of the **display pim invalid-packet 1 verbose** command output

Item	Description
Detailed information of invalid packets	Details of an invalid PIM message.
Packet information (Index 1)	Sequence number of the invalid PIM message (numbered in the opposite order the message is received. For example, the index of the last received message is 1, the index of the penultimate message is 2, and so on).
Interface	Interface that received the invalid PIM message.

Item	Description
Time	Time when the invalid SPT switch message was received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST The format UTC±HH:MM indicates that a time zone has been configured using the **clock timezone** command; DST indicates that the daylight saving time has been configured using **clock daylight-saving-time** command.
Message Length	Length of the invalid PIM message.
Invalid Type	Type of the invalid PIM message.
0000: 25 00 96 77 01 00 00 20 e1 01 01 01 01 00 e0 00 0010: 00 00 80 00 00 64 00 00 00 00	Contents of the invalid PIM message.

8.3.27 display pim neighbor

Function

The **display pim neighbor** command displays information about PIM neighbors.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **neighbor** [*neighbor-address* | **interface** *interface-type interface-number* | **verbose**] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Parameter	Description	Value
neighbor-address	Specifies the IP address of a PIM neighbor.	The address is in dotted decimal notation.
verbose	Displays detailed information about PIM neighbors.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pim neighbor** command displays information about PIM neighbors, including the number of neighbors, DR priority, and BFD session status. You can adjust PIM neighbor relationships based on the command output.

When you run the **display pim neighbor** command:

- If you specify **interface** *interface-type interface-number*, the command displays information about PIM neighbors connected to the specified interface.
- If you do not specify **interface** *interface-type interface-number*, the command displays information about all PIM neighbors attached to the switch.

Example

Display information about all PIM neighbors.

```
<HUAWEI> display pim neighbor
 VPN-Instance: public net
 Total Number of Neighbors = 2

 Neighbor        Interface     Uptime       Expires      Dr-Priority  BFD-Session
 10.1.1.2        Vlanif10      02:50:49     00:01:31     1            Y
 10.1.2.2        Vlanif20      02:49:39     00:01:42     1            Y
```

Table 8-48 Description of the **display pim neighbor** command output

Item	Description
Total Number of Neighbors	Total number of PIM neighbors on an interface.
Neighbor	IP Address of a PIM neighbor.
Interface	Interface connected to a PIM neighbor.
Uptime	Time elapsed since a PIM neighbor relationship is set up.

Item	Description
Expires	Amount of time left before a PIM relationship times out.
Dr-Priority	DR priority of a PIM neighbor.
BFD-Session	Whether the BFD session has been set up with a neighbor. ● Y: The BFD session has been set up. ● N: The BFD session has not been set up.

Display detailed information about the PIM neighbor with IP address 10.1.1.2 in the public network instance.

```
<HUAWEI> display pim neighbor 10.1.1.2 verbose
 VPN-Instance: public net
 Neighbor: 10.1.1.2
     Interface: Vlanif 10
     Uptime: 02:53:50
     Expiry time: 00:01:30
     DR Priority: 1
     Generation ID: 0X90B0360B
     Holdtime: 105 s
     LAN delay: 500 ms
     Override interval: 2500 ms
     Neighbor tracking: Disabled
     PIM BFD-Session: Y
     PIM BFD-Session min-tx-interval: 1000 ms
     PIM BFD-Session min-rx-interval: 1000 ms
     PIM BFD-Session detect-multiplier: 3
```

Table 8-49 Description of the **display pim neighbor verbose** command output

Item	Description
Expiry time	Amount of time left before a PIM relationship times out.
Generation ID	PIM neighbor status random value.
Holdtime	Keepalive period of the PIM neighbor.
LAN delay	Delay in transmitting Prune messages.
Override interval	Override interval for a prune action.
State refresh interval	Interval at which State-Refresh messages are sent.
Neighbor tracking	Whether the neighbor tracking function is enabled. ● enabled: Neighbor tracking is enabled. ● disabled: Neighbor tracking is disabled.

Item	Description
PIM BFD-Session	Whether the BFD session is set up. ● Y: The BFD session has been set up. ● N: The BFD session has not been set up.
PIM BFD-Session min-tx-interval	Minimum interval at which PIM BFD packets are sent.
PIM BFD-Session min-rx-interval	Minimum interval at which PIM BFD packets are received.
PIM BFD-Session detect-multiplier	PIM BFD detection multiplier.

8.3.28 display pim routing-table

Function

The **display pim routing-table** command displays the PIM routing table.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table brief** [*group-address* [**mask** { *group-mask-length* | *group-mask* }] | *source-address* [**mask** { *source-mask-length* | *source-mask* }] | **incoming-interface** { *interface-type interface-number* | **register** }] *

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table** [*group-address* [**mask** { *group-mask-length* | *group-mask* }] | *source-address* [**mask** { *source-mask-length* | *source-mask* }] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **register** | **none** } | **mode** { **dm** | **sm** | **ssm** } | **flags** *flag-value* | **fsm**] * [**outgoing-interface-number** [*number*]]

display pim routing-table [*group-address* [**mask** { *group-mask-length* | *group-mask* }] | *source-address* [**mask** { *source-mask-length* | *source-mask* }] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **vpn-instance** *vpn-instance-name* | **register** | **none** } | **mode** { **dm** | **sm** | **ssm** } | **flags** *flag-value* | **fsm**] * [**outgoing-interface-number** [*number*]]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays PIM routing entries in a specified VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
all-instance	Displays PIM routing entries in all the instances.	-
group-address	Displays the PIM routing entry of a specified group.	The address is in dotted decimal notation. The value ranges from 224.0.1.0 to 239.255.255.255.
mask	Specifies the mask of a multicast source address or group address.	-
group-mask	Specifies the group address mask.	The address is in dotted decimal notation.
group-mask-length	Specifies the length of the group address mask.	The value is an integer that ranges from 4 to 32.
source-address	Displays the PIM routing entry of a specified multicast source.	The source address is in dotted decimal notation.
source-mask	Specifies the multicast source IP address mask.	The address mask is in dotted decimal notation.
source-mask-length	Specifies the length of the source address mask.	The value is an integer that ranges from 0 to 32.
incoming-interface	Displays the PIM routing entries with a specified interface as the upstream interface.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Indicates the register interface.	-
outgoing-interface	Displays the PIM routing entries with a specified interface as the downstream interface.	-
include	Displays the PIM routing entries with the downstream interface list containing a specified interface.	-

Parameter	Description	Value
exclude	Displays the PIM routing entries with the downstream interface list not containing a specified interface.	-
match	Displays the PIM routing entries with the downstream interface list containing only the specified interface.	-
none	Displays the PIM routing entries with an empty downstream interface list.	-
mode	Specifies the PIM operation mode.	-
dm	Displays PIM-DM routing entries.	-
sm	Displays PIM-SM routing entries.	-
ssm	Displays PIM-SSM routing entries.	-
flags *flag-value*	Displays PIM-SSM routing entries with the specified flag. The *flag-value* parameter is the type flag of entries.	-
fsm	Displays the details of FSM states.	-
outgoing-interface-number	Displays the number of downstream interfaces of PIM routing entries.	-
number	Specifies the number of the downstream interfaces to be displayed.	The value is an integer that ranges from 0 to 2048.
brief	Displays only the upstream interface names and the number of downstream interfaces in PIM routing entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to:

- Check whether PIM has been configured successfully on the network.
- Check the inbound interfaces, outbound interfaces, flags, and other information in the routing entries to identify failure points when forwarding errors occur on the PIM network.

The PIM routing table includes both (*, G) and (S, G) entries. (*, G) entries are used to set up a rendezvous point tree (RPT), and (S, G) entries are used to set up a shortest path tree (SPT).

Table 8-50 lists the values of the **flags** *flag-value* parameter.

Table 8-50 Values of the flag-value parameter

Item	Description
2msdp	The RP received a Register message recently and learned the (S, G) entry. The RP will notify MSDP of the (S, G) entry in the next SA message.
act	Multicast routing entries that have matched received data.
del	Multicast routing entries to be deleted.
exprune	Multicast routing entries pruned from the RPT, with no receiver interested in the data from the source.
ext	Multicast routing entries that contain downstream interfaces provided by other multicast routing protocols.
loc	Multicast routing entries on the switch directly connected to the network segment of the multicast source.
msdp	Multicast routing entries learned from recently received MSDP SA messages.
niif	Multicast routing entries with unknown upstream interfaces.
nonbr	Multicast routing entries in which the upstream neighbor address (link-local address) towards the RP or the source is not found.
none	Multicast routing entries without any flag.
rpt	Multicast routing entries that are on the RPT but do not use the RPT data.
sg_rcvr	The switch has receivers of the source specified in the (S, G) entry, and PIM is the owner of the downstream interfaces.
sgjoin	The switch has receivers of the source specified in the (S, G) entry, but PIM is not the owner of the downstream interfaces.

Item	Description
spt	Multicast routing entries on the shortest path tree (SPT).
swt	Multicast routing entries during the SPT switchover.
upchg	A route change has occurred. The current entry is using the original upstream interface to forward data and is waiting for data received from a new interface.
wc	(*, G) entry.

Example

Display the PIM routing table of the switch.

```
<HUAWEI> display pim routing-table
 VPN-Instance: public net
 Total 0 (*, G) entry; 1 (S, G) entry

 (172.16.0.12, 227.0.0.1)
     RP: 10.2.2.2
     Protocol: pim-sm, Flag: SPT LOC ACT
     UpTime: 02:54:43
     Upstream interface: Vlanif10
         Upstream neighbor: NULL
         RPF prime neighbor: NULL
     Downstream interface(s) information:
     Total number of downstreams: 1
         1: Vlanif20
             Protocol: pim-sm, UpTime: 02:54:43, Expires: 00:02:47
```

Table 8-51 Description of the **display pim routing-table** command output

Item	Description
Total 0 (*, G) entry; 1 (S, G) entry	Total number of (S, G) and (*, G) entries in the PIM routing table.
(172.16.0.12, 227.0.0.1)	(S, G) entry in the PIM routing table.
RP	RP address.
Protocol	PIM protocol type, which can be PIM-DM, PIM-SM or PIM-SSM.
Flag	Flag of PIM (S, G) or (*, G) entry. Refer to the table of *Values of the flag-value parameter*.
UpTime	Amount of time an interface has been Up.
Upstream interface	Upstream interface in an (S, G) entry or (*, G) entry.
Upstream neighbor	Upstream neighbor of an (S, G) or (*, G) entry.

Item	Description
RPF prime neighbor	RPF neighbor of an (S, G) or (*, G) entry. ● For a (*, G) entry, when the local device is an RP, the RPF neighbor in the (*, G) entry is null. ● For an (S, G) entry, when the local device is directly connected to the source, the RPF neighbor in the (S, G) entry is null.
Downstream interface(s) information	Information about the downstream interface, including the following: ● Total number of downstream interfaces ● Name of each downstream interface ● PIM protocol type configured for the downstream interface ● Keepalive period and timeout period of the downstream interface
Total number of downstreams	Number of downstream interfaces.
Expires	Timeout period of an interface.

Display the number of the downstream interfaces of PIM routing entries on the switch.

```
<HUAWEI> display pim routing-table outgoing-interface-number
 VPN-Instance: public net
 Total 2 (*, G) entries; 0 (S, G) entry

 (*, 226.1.1.1)
     RP: 10.2.2.2 (local)
     Protocol: pim-sm, Flag: WC EXT
     UpTime: 21:37:28
     Upstream interface: Register
         Upstream neighbor: NULL
         RPF prime neighbor: NULL
     Downstream interface(s) information:
     Total number of downstreams: 50

 (*, 226.1.2.1)
     RP: 10.2.2.2 (local)
     Protocol: pim-sm, Flag: WC EXT
     UpTime: 21:37:28
     Upstream interface: Register
         Upstream neighbor: NULL
         RPF prime neighbor: NULL
     Downstream interface(s) information:
     Total number of downstreams: 50
```

Table 8-52 Description of the **display pim routing-table outgoing-interface-number** command output

Item	Description
Total 2 (*, G) entries; 0 (S, G) entry	Total number of the (S, G) entries and (*, G) entries in the PIM routing table.
Total number of downstreams	Total number of the downstream interfaces of the (*, G) entries or (S, G) entries.

8.3.29 display pim rp-info

Function

The **display pim rp-info** command displays information about the RP for a multicast group.

Format

display pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **rp-info** [*group-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
group-address	Displays the information about the RP for a specified multicast group.	The address is in dotted decimal notation. The value ranges from 224.0.1.0 to 239.255.255.255.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use this command to view information about the RP for a multicast group.

Configuration Impact

The command output includes information about the RP discovered through the BSR mechanism and static RP.

If *group-address* is not specified, the command displays RP information for all the multicast groups.

Example

Display RP information for all the multicast groups in the public network instance.

```
<HUAWEI> display pim rp-info
 VPN-Instance: public net
 PIM-SM BSR RP Number:1
 Group/MaskLen: 224.0.0.0/4
     RP: 10.2.2.2 (local)
     Priority: 0
     Uptime: 03:01:36
     Expires: 00:02:29
 PIM SM static RP Number:1
     Static RP: 10.1.1.1
```

Table 8-53 Description of the **display pim rp-info** command output

Item	Description
PIM-SM BSR RP Number	Number of PIM-SM RPs elected dynamically using the BSR mechanism.
Group/MaskLen	Multicast group address and mask length.
RP	RP address.
Priority	Priority of the RP.
Uptime	Time elapsed since presence of the RP.
Expires	Amount of time left before the RP times out.
PIM SM static RP Number	Number of static RPs.
Static RP	IP address of a static RP.

8.3.30 graceful-restart (IPv4)

Function

The **graceful-restart** command enables PIM GR.

The **undo graceful-restart** command disables PIM GR.

By default, PIM GR is not enabled.

Format

graceful-restart

undo graceful-restart

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a stack is used on the PIM-SM network, after an active/standby switchover occurs in the stack system, multicast data transmission is interrupted because the new master device does not have PIM forwarding entries.

PIM GR enables the system to back up join and prune information in PIM routing entries to the new master device when an active/standby switchover is performed in the system. This ensures normal multicast data forwarding during restoration of the multicast distribution tree. For details about stack configuration, see Stack Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Device Management*.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

At least one switch interface must have PIM-SM enabled for the **graceful-restart** command to take effect.

Example

Enable PIM GR in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] graceful-restart
```

8.3.31 graceful-restart period (IPv4)

Function

The **graceful-restart period** command configures the minimum PIM GR period.

The **undo graceful-restart period** command restores the default minimum PIM GR period.

By default, the minimum PIM GR period is 120 seconds.

Format

graceful-restart period *period*

undo graceful-restart period

Parameters

Parameter	Description	Value
period	Specifies the minimum PIM GR period.	The value is an integer that ranges from 90 to 3600 in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **graceful-restart period** command ensures the minimum time for maintaining forwarding entries.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If you run the **graceful-restart period** command multiple times, only the latest configuration takes effect.

Precautions

Unicast protocol GR form the basis of PIM GR; therefore, the minimum PIM GR period must be longer than the unicast protocol GR period.

The PIM GR period also depends on the complexity of the network topology and increases with the expansion of unicast route capacity and multicast route capacity.

Example

Set the minimum PIM GR period in the PIM view of public network instance to 150 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
```

```
[HUAWEI-pim] graceful-restart
[HUAWEI-pim] graceful-restart period 150
```

8.3.32 hello ipsec sa (IPv4)

Function

The **hello ipsec sa** command specifies an IPSec SA globally used for encrypting and authenticating PIM Hello (IPv4) messages sent and received by the device.

The **undo hello ipsec sa** command deletes the IPSec SA globally used for encrypting and authenticating PIM Hello (IPv4) messages sent and received by the device.

By default, no IPSec SA is specified for encrypting and authenticating PIM Hello (IPv4) messages.

Format

hello ipsec sa *sa-name*

undo hello ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of the globally used SA.	The value is an existing SA name.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Huawei device connects to a non-Huawei device that can only encrypt and authenticate PIM Hello messages, run this command to configure the Huawei device to encrypt and authenticate only PIM Hello messages, so that the devices can interwork.

Prerequisites

- IP multicast routing has been enabled using the **multicast routing-enable** command.
- Basic IPSec functions have been configured.

Precautions

If you run both this command and the **ipsec sa (IPv4)** command in the PIM view, the last configured one takes effect.

This command has the same function as the **pim hello ipsec sa** command used in the interface view except for the effective scope. The configuration in the interface view takes precedence over the configuration in the PIM view. If SAs are specified in both the interface view and PIM view, the specified interface uses the SA configured in the interface view. If no SA is specified on an interface, the interface uses the SA specified in the PIM view.

Example

Configure the device to encrypt and authenticate PIM Hello messages using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello ipsec sa sa1
```

8.3.33 hello-option dr-priority (IPv4)

Function

The **hello-option dr-priority** command configures the priority of the switch that candidates for the Designated Router (DR).

The **undo hello-option dr-priority** command restores the default priority.

By default, the priority of the switch that candidates for the DR is 1.

Format

hello-option dr-priority *priority*

undo hello-option dr-priority

Parameters

Parameter	Description	Value
priority	Specifies the priority of the switch that candidates for the DR. The greater the value, the higher the priority.	The value is an integer ranging from 0 to 4294967295.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM network, switches on a shared network segment are candidates for the DR. The DR is responsible for registration of local multicast sources and the joining of receivers.

The DR is elected based on the priority and the IP address. Candidates send Hello messages with their priorities, and the switch with the highest priority becomes the DR. If multiple switches have the same priority, the switch with the largest IP address becomes the DR.

If at least one switch in the network does not support Hello packets that contain the priority, the switch with the largest IP address becomes the DR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **hello-option dr-priority** command has the same function as the **pim hello-option dr-priority** command in the interface view. By default, if the **pim hello-option dr-priority** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM view of public network instance, configure the DR priority of a switch to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello-option dr-priority 3
```

8.3.34 hello-option holdtime (IPv4)

Function

The **hello-option holdtime** command sets the timeout period for a switch to wait to receive Hello messages from its PIM neighbor.

The **undo hello-option holdtime** command restores the default configuration.

By default, the timeout period for a switch to wait to receive Hello messages from its PIM neighbor is 105 seconds.

Format

hello-option holdtime *interval*

undo hello-option holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout time during which a switch waits to receive a Hello message from its PIM neighbor.	The value is an integer ranging from 1 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM network, after the switch receives a Hello message from its PIM neighbor, it starts a timer. The timer length is the value of Holdtime in the Hello message. If the switch does not receive any Hello message from its PIM neighbor when the timer expires, it considers the neighbor invalid or unreachable.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- The **hello-option holdtime** command is valid for PIM-SM and PIM-DM.
- The timeout period must be greater than the interval for sending Hello messages. You can run the **timer hello** command to set the interval for sending Hello messages.
- The **hello-option holdtime** command has the same function as the **pim hello-option holdtime** command in the interface view. By default, if the **pim hello-option holdtime** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM view of public network instance, set the timeout interval to 120 seconds. The timeout interval is the period during which a switch waits to receive the Hello message from its PIM neighbor.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello-option holdtime 120
```

8.3.35 hello-option lan-delay (IPv4)

Function

The **hello-option lan-delay** command sets the delay in transmitting Prune message on the shared network segment.

The **undo hello-option lan-delay** command restores the default delay.

By default, the delay in transmitting Prune message on the shared network segment is 500 milliseconds.

Format

hello-option lan-delay *interval*

undo hello-option lan-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay in transmitting Prune message on the shared network segment.	The value is an integer that ranges from 1 to 32767, in milliseconds (ms).

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** values. The **lan-delay** parameter indicates the delay in transmitting messages in the LAN. If switches on the same link have different **lan-delay** values, the maximum value is used.

When a switch sends a Prune message to the upstream device in the same network segment, other switches that still request multicast data need to send a Join message to the upstream device within the override-interval period.

The value of the Prune-Pending Timer (PPT) is the sum of the **lan-delay** and **override-interval** values, and refers to the delay from the switch receiving a Prune message from the downstream interface to performing the prune action. If the switch receives a Join message from the downstream interface in PPT, the switch cancels the prune action.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

If the delay in transmitting Prune message is too short, the upstream switch will stop forwarding multicast packets before the downstream switch determines whether to override the Prune action or not. Exercise caution when you run the **hello-option lan-delay** command.

The **hello-option lan-delay** command has the same function as the **pim hello-option lan-delay** command in the interface view. By default, if the **pim hello-option lan-delay** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the delay in transmitting Prune message on the shared network segment to 200 ms in PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello-option lan-delay 200
```

8.3.36 hello-option neighbor-tracking (IPv4)

Function

The **hello-option neighbor-tracking** command enables the neighbor tracking function.

The **undo hello-option neighbor-tracking** command restores the default configuration.

By default, the neighbor tracking function is not enabled.

Format

hello-option neighbor-tracking

undo hello-option neighbor-tracking

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When sending a Hello message, the switch generates a Generation ID and encapsulates it into the message. The Generation ID changes only when the status of the switch changes. In this case, the neighboring device detects the Generation ID change after receiving the Hello message and immediately sends a Join message to the switch to update the neighbor relationship. If multiple devices on the shared network segment prepare to send Join messages to the same upstream PIM neighbor, only one device is allowed to send the Join message. After other devices detect the Join message, they do not send Join messages to the upstream neighbor. This means that the upstream neighbor cannot update neighbor relationships with downstream devices after a Generation ID change.

After the neighbor tracking function is enabled, when the device detects Join messages from other devices, the device still sends the Join messages to the same upstream PIM neighbor.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

Neighbor tracking can be implemented only when this function is enabled on all devices on the shared network segment.

The **hello-option neighbor-tracking** command has the same function as the **pim hello-option neighbor-tracking** command in the interface view. By default, if neighbor tracking is not used on an interface, the neighbor tracking configuration in the PIM view takes effect.

Example

In the PIM view of public network instance, enable the downstream neighbor tracking function.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello-option neighbor-tracking
```

8.3.37 hello-option override-interval (IPv4)

Function

The **hello-option override-interval** command sets the interval for overriding the prune action in a Hello message.

The **undo hello-option override-interval** command restores the default interval.

By default, the interval for overriding the prune action in a Hello message is 2500 ms.

Format

hello-option override-interval *interval*

undo hello-option override-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for overriding the prune action in a Hello message.	The value is an integer that ranges from 1 to 65535, in milliseconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** parameters. The **override-interval** parameter indicates the period during which a downstream switch can override the prune action.

When a switch sends a Prune message to the upstream device in the same network segment, other switches that still request multicast data need to send a Join message to the upstream device within the override-interval period.

When a device has only one PIM neighbor on a link and receives a Prune message from the neighbor, the device immediately deletes the downstream interface of the multicast routing entry. If a device has two or more PIM neighbors on a link and the **override-interval** values in the messages sent from the two neighbors are different, the largest **override-interval** value takes effect.

The value of Prune-Pending Timer (PPT) is the sum of **lan-delay** and **override-interval** values. When receiving a Prune message from a downstream interface, the switch does not perform the prune action until the PPT times out. If the switch receives a Join message from the downstream interface in PPT, the interface cancels the Prune action.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

The **hello-option override-interval** command has the same function as the **pim hello-option override-interval** command in the interface view. By default, if the **pim hello-option override-interval** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM view of public network instance, set the interval for denying the prune action in a Hello message to 2000 ms.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] hello-option override-interval 2000
```

8.3.38 holdtime assert (IPv4)

Function

The **holdtime assert** command sets the timeout period for all PIM interfaces to keep the Assert state on the local switch.

The **undo holdtime assert** command restores the default timeout.

By default, the timeout period for all PIM interfaces to keep the Assert state on the local switch is 180 seconds.

Format

holdtime assert *interval*

undo holdtime assert

Parameters

Parameter	Description	Value
interval	Specifies the time during which the PIM interface keeps the Assert state.	The value is an integer that ranges from 7 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the shared network segment connected to multiple PIM devices, if the same multicast packets reach these PIM devices and pass the RPF check, multiple copies of the same multicast packets are forwarded to this network segment. In this situation, these PIM devices need to initiate the assert mechanism. The device that wins assert election is responsible for multicast forwarding on the shared network segment. Other devices suppress multicast data forwarding and retain the Assert state for a period of time. After the timer for a PIM interface in the Assert state expires, the device that fails to be elected triggers a new round of election.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **holdtime assert** command is valid for PIM-SM and PIM-DM.

The **holdtime assert** command has the same function as the **pim holdtime assert** command in the interface view. By default, if the timeout period is not used on an interface, the timeout period configured in the PIM view is used.

Example

In the PIM view of public network instance, set the interval during which a switch keeps the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] holdtime assert 100
```

8.3.39 holdtime join-prune (IPv4)

Function

The **holdtime join-prune** command sets the holdtime value in Join/Prune messages sent by all PIM interfaces. The devices that receive Join/Prune messages set the time during which the downstream interface keeps the Join or Prune state according to holdtime.

The **undo holdtime join-prune** command restores the default value.

By default, the holdtime value in Join/Prune messages sent by all PIM interfaces is 210 seconds.

Format

holdtime join-prune *interval*

undo holdtime join-prune

Parameters

Parameter	Description	Value
interval	Specifies the value of holdtime carried in Join/Prune messages sent by the local switch.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Join/Prune message from the downstream device, the switch starts the hold timer. If this message carries group-join information and the switch does not receive subsequent Join/Prune messages from the downstream device when the timer expires, it suppresses multicast data forwarding to downstream interfaces of the specified group. If Join/Prune message carries group-prune information, the switch resumes multicast data forwarding to downstream interfaces when the hold timer expires.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

The holdtime of Join/Prune messages must be larger than the interval for sending Join/Prune messages and is generally 3.5 times the interval for sending Join/Prune messages.

The **holdtime join-prune** command has the same function as the **pim holdtime join-prune** command in the interface view. By default, if the holdtime value is not used on an interface, the holdtime value configured in the PIM view is used.

Example

In the PIM view of public network instance, set the time during which the downstream interface of a switch keeps the Join or Prune state to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] holdtime join-prune 280
```

8.3.40 ipsec sa (IPv4)

Function

The **ipsec sa** command specifies an IPSec SA globally used for encrypting and authenticating PIM messages sent and received by the device.

The **undo ipsec sa** command deletes the IPSec SA globally used for encrypting and authenticating PIM messages sent and received by the device.

By default, no IPSec SA is specified for encrypting and authenticating PIM messages.

Format

ipsec [**unicast-message**] **sa** *sa-name*

undo ipsec [**unicast-message**] **sa**

Parameters

Parameter	Description	Value
unicast-message	Authenticates only PIM unicast messages. If you do not specify this keyword, the device authenticates only PIM multicast messages.	-
sa-name	Specifies the name of the globally used SA.	The value is an existing SA name.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IPv4 multicast network, if multicast devices are attacked by forged PIM messages, multicast data forwarding between multicast devices will be interrupted. To protect multicast devices against such attacks, configure PIM IPSec on the multicast devices to authenticate PIM messages they send and receive.

Prerequisites

- IP multicast routing has been enabled using the **multicast routing-enable** command.

- Basic IPSec functions have been configured.

Precautions

If you run both the **ipsec sa** *sa-name* command and the **hello ipsec sa (IPv4)** command in the PIM view, the last configured one takes effect.

This command has the same function as the **pim ipsec sa** command used in the interface view, except for the effective scope. The configuration in the interface view takes precedence over the configuration in the PIM view. If SAs are specified in both the interface view and PIM view, the specified interface uses the SA configured in the interface view. If no SA is specified on an interface, the interface uses the SA specified in the PIM view.

Example

Configure the device to encrypt and authenticate PIM multicast messages using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] ipsec sa sa1
```

8.3.41 join-prune max-packet-length (IPv4)

Function

The **join-prune max-packet-length** command sets the maximum size of each PIM-SM Join/Prune message to be sent.

The **undo join-prune max-packet-length** command restores the default maximum size of each PIM-SM Join/Prune message to be sent.

By default, the maximum length of Join/Prune message sent by PIM-SM is 8100 bytes.

Format

join-prune max-packet-length *packet-length*

undo join-prune max-packet-length

Parameters

Parameter	Description	Value
packet-length	Specifies the maximum size of each PIM-SM Join/Prune message to be sent.	The value is an integer ranging from 100 to 8100, in bytes.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the peer device has low performance and takes a long time to process a large Join/Prune message carrying a lot of (S, G) entries, the maximum size of each Join/Prune message can be reduced to relieve the burden on the peer device.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

If the maximum size specified in the **join-prune max-packet-length** command is greater than the interface MTU, the maximum size of each message to be sent is equal to the interface MTU.

Example

Set the maximum size of each Join/Prune message to be sent to 2100 bytes.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] join-prune max-packet-length 2100
```

8.3.42 join-prune periodic-messages queue-size (IPv4)

Function

The **join-prune periodic-messages queue-size** command sets the maximum number of (S, G) entries carried in a PIM-SM Join/Prune message that is sent every second.

The **undo join-prune periodic-messages queue-size** command restores the default maximum number of (S, G) entries carried in a PIM-SM Join/Prune message that is sent every second.

By default, a PIM-SM Join/Prune message that is sent every second contains 1020 entries.

Format

join-prune periodic-messages queue-size *queue-size*

undo join-prune periodic-messages queue-size

Parameters

Parameter	Description	Value
queue-size	Specifies the maximum number of (S, G) entries carried in a PIM-SM Join/Prune message that is sent every second.	The value is an integer ranging from 16 to 4096.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the peer device has a low throughput, reduce the length of a queue for periodically sending messages to control the number of (S, G) entries. This setting allows the local device to send Join/Prune messages with a small number of (S, G) entries multiple times, preventing packet loss or route flapping.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

Example

Allow each PIM-SM Join/Prune message that is sent every second to carry a maximum of 2000 (S, G) entries.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] join-prune periodic-messages queue-size 2000
```

8.3.43 join-prune triggered-message-cache disable (IPv4)

Function

The **join-prune triggered-message-cache disable** command disables the Join/Prune message package function.

The **undo join-prune triggered-message-cache disable** command enables the Join/Prune message package function.

By default, the Join/Prune message package function is enabled.

Format

join-prune triggered-message-cache disable

undo join-prune triggered-message-cache disable

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The system performs more efficiently when sending package of PIM Join/Prune messages than when sending a large number of individual PIM Join/Prune messages. A switch sends PIM Join/Prune messages in packages. To disable the package function, run the **join-prune triggered-message-cache disable** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

Example

Disable the Join/Prune message package function.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] join-prune triggered-message-cache disable
```

8.3.44 neighbor-check (IPv4)

Function

The **neighbor-check** command enables the PIM neighbor check function.

The **undo neighbor-check** command restores the default setting.

By default, the PIM neighbor check function is not enabled.

Format

neighbor-check { **receive** | **send** }

undo neighbor-check { **receive** | **send** }

Parameters

Parameter	Description	Value
receive	Checks whether the Join/Prune and Assert messages are received from a PIM neighbor. If not, these messages are discarded.	-
send	Checks whether the Join/Prune and Assert messages are sent to a PIM neighbor. If not, these messages are not sent.	-

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM devices send Join/Prune messages to the upstream PIM neighbor to perform join, and prune actions and PIM neighbors often exchange Assert messages. To save system resources and protect security of Join/Prune messages and Assert messages, run the **neighbor-check** command to enable the PIM neighbor check function.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

You can specify both **receive** and **send** to enable the PIM neighbor check function for the received and sent Join/Prune and Assert messages.

Precautions

This command is valid only for PIM-SM.

Example

In the PIM view of public network instance, enable the PIM neighbor check function for the received Join/Prune and Assert messages.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] neighbor-check receive
```

8.3.45 pim

Function

The **pim** command displays the PIM view.

The **undo pim** command clears the configuration in the PIM view.

Format

pim [**vpn-instance** *vpn-instance-name*]

undo pim [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before performing PIM configurations, run the **pim** command to enter the PIM view.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

NOTE

Running the **undo pim** command in the system view may interrupt IPv4 PIM services and deletes all global IPv4 PIM configurations of the public network instance. To restore the IPv4 PIM services, you have to re-run the deleted commands.

Example

Enter the PIM view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] pim
[HUAWEI-pim]
```

8.3.46 pim bfd

Function

The **pim bfd** command adjusts the PIM BFD parameters on an interface.

The **undo pim bfd** command restores the default values of PIM BFD parameters.

By default, the minimum interval for transmitting BFD packets and minimum interval for receiving BFD packets are 1000 ms, and the BFD detection multiplier is 3.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

pim bfd { **min-tx-interval** *tx-value* | **min-rx-interval** *rx-value* | **detect-multiplier** *multiplier-value* } *

undo pim bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo pim bfd { **min-tx-interval** *tx-value* | **min-rx-interval** *rx-value* | **detect-multiplier** *multiplier-value* } *

Parameters

Parameter	Description	Value
min-tx-interval *tx-value*	Specifies the minimum interval for transmitting BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Parameter	Description	Value
min-rx-interval *rx-value*	Specifies the minimum interval for receiving BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Specifies the BFD detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.

Usage Guidelines

Usage Scenario

After PIM BFD is enabled, you may need to run the **pim bfd** command to adjust PIM BFD parameters to adapt to the state of the link. This command can set the minimum interval for sending BFD packets, minimum interval for receiving PIM BFD packets, and local detection multiplier.

In application, you can continuously configure one or more parameters. If some parameters are configured, other parameters that are not configured reserve the existing configurations.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid only for PIM-SM.

Before setting PIM BFD parameters, run the **pim bfd enable** command to enable PIM BFD. Otherwise, the configured parameters do not take effect.

The minimum values of *tx-value* and *rx-value* vary with products.

Example

Adjust the minimum interval for transmitting BFD packets on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] pim sm
[HUAWEI-Vlanif10] pim bfd enable
[HUAWEI-Vlanif10] pim bfd min-tx-interval 100
```

Adjust the minimum interval for transmitting BFD packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim sm
[HUAWEI-GigabitEthernet0/0/1] pim bfd enable
[HUAWEI-GigabitEthernet0/0/1] pim bfd min-tx-interval 100
```

8.3.47 pim bfd enable

Function

The **pim bfd enable** command enables PIM BFD on an interface.

The **undo pim bfd enable** command disables PIM BFD on an interface.

By default, PIM BFD is not enabled on an interface.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

pim bfd enable

undo pim bfd enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, Eth-Trunk interface view, 100GE interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command enables PIM BFD on an interface to quickly detect link failures on the interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Run the **pim sm** command on the interface to enable PIM-SM. You can run the **undo pim sm** command to disable PIM BFD on the interface.

Precautions

This command is valid for only PIM-SM.

PIM BFD depends on the BFD protocol. If global BFD is not enabled using the **bfd** command, PIM BFD sessions can still be set up but the session state is **BFD global disable**.

Example

Enable PIM BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim sm
[HUAWEI-Vlanif100] pim bfd enable
```

Enable PIM BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim sm
[HUAWEI-GigabitEthernet0/0/1] pim bfd enable
```

8.3.48 pim bsr-boundary

Function

The **pim bsr-boundary** command configures the BSR boundary of a PIM-SM domain on an interface.

The **undo pim bsr-boundary** command restores the default configuration.

By default, the BSR boundary of a PIM-SM domain is not set.

Format

pim bsr-boundary

undo pim bsr-boundary

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As the management core of the PIM-SM network, the BSR is responsible for sending collected RP-set information to PIM neighbors through Bootstrap messages.

You can divide a large PIM-SM network into multiple PIM-SM domains by configuring the bsr boundary on an interface. Each BSR then serves the local PIM-SM domain.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

The Bootstrap messages cannot traverse the BSR boundary but other multicast packets can.

Example

Configure the BSR boundary of a PIM-SM domain on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim bsr-boundary
```

Configure the BSR boundary of a PIM-SM domain on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim bsr-boundary
```

8.3.49 pim dm

Function

The **pim dm** command enables PIM-DM on an interface.

The **undo pim dm** command restores the default configuration.

By default, PIM-DM is disabled on an interface.

Format

pim dm

undo pim dm

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM-DM network, after PIM-DM is enabled on an interface, the switch can set up the PIM neighbor relationship with the neighboring device. The switch can then process protocol packets received from the PIM neighbor.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

- PIM-DM and PIM-SM cannot be enabled simultaneously on interfaces bound to the same VPN instance or public network instance.
- If PIM-DM and IGMP need to be enabled on the same interface, enable PIM-DM, and then enable IGMP.

- If Layer 2 multicast querier or Layer 2 multicast packet suppression is enabled in a VLAN, running the **pim dm** command on the corresponding VLANIF interface will fail.
- If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable IPv4 PIM on the corresponding VLANIF interface first, and then enable IGMP snooping in the VLAN. If IGMP snooping is enabled in the VLAN first, IPv4 PIM cannot be enabled on the corresponding VLANIF interface.
- PIM-DM cannot be deployed on the public network of the MVPN.
- Since V200R010, the S5720-HI, S5730-HI, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-HI, S6730-H, S6730S-H, S6730-S, and S6730S-S support IPv4 PIM configuration on dot1q and QinQ termination sub-interfaces only when the VLAN tag to be terminated (or both inner and outer VLAN tags on the QinQ termination sub-interface) is a single VLAN ID, but not a range of VLAN IDs. Sub-interfaces running PIM can only be used as inbound interfaces of multicast streams and cannot be used as outbound interfaces. The S5720-EI, S6720-EI, S6735-S, and S6720S-EI also support IPv4 PIM command configuration on dot1q and QinQ termination sub-interfaces, but they do not support multicast traffic forwarding on these sub-interfaces.
- PIM-DM and PIM-SM cannot be configured simultaneously in a VPN instance or the public network instance. IPv4 PIM can be configured in a VPN instance, but the VPN instance cannot be bound to a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command. Only the following products and versions support the IPv4 PIM multi-instance feature:
  - S5730-HI, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-HI, S6730-H, S6730S-H, S6730-S, and S6730S-S: all versions
  - S6700-EI and S5700-HI: V200R005C01
  - S6700-EI, S5700-HI, and S5710-HI: V200R005C02
  - S5710-HI: V200R005C03
  - S5720-EI, S5720-HI, S6720-EI, S6735-S, and S6720S-EI: V200R010 and later versions
- Secondary IP addresses does not support PIM, and the direct routes generated based on secondary IP addresses are not involved during multicast RPF check. Therefore, if the source IP address of multicast packets is on the same network segment as the secondary IP address of a Layer 3 interface, these multicast packets received on the Layer 3 interface cannot pass the RPF check.

Example

Enable PIM-DM on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim dm
```

Enable PIM-DM on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim dm
```

8.3.50 pim dr-election dr-priority

Function

The **pim dr-election dr-priority** command configures an IP address and a priority for PIM DR election.

The **undo dr-election dr-priority** command restores the default IP address and priority for PIM DR election.

By default, no IP address or priority is configured for PIM DR election.

NOTE

This command is supported only on the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, and S5731-H.

Format

pim dr-election *ip-address* **dr-priority** *priority-value*

undo pim dr-election *ip-address* **dr-priority** *priority-value*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address used for PIM DR election.	The value is in dotted decimal notation.
dr-priority *priority-value*	Specifies the DR priority of a PIM interface. A larger value indicates a higher priority.	The value is an integer in the range from 0 to 4294967295.

Views

VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a VXLAN multi-border distributed gateway scenario, the same primary IP address is configured for VBDIF interfaces on multiple border nodes. These VBDIF interfaces use the primary IP address to send PIM protocol packets. During PIM negotiation, the local device considers itself as a PIM DR and forwards multicast traffic. As a result, excessive multicast traffic instead of only one copy of multicast traffic is forwarded. In this case, you can run this command to specify the IP address used to send PIM protocol packets.

During PIM DR election, the IP address and DR priority configured using the **pim dr-election dr-priority** command take precedence over the interface IP address and the DR priority configured using the **pim hello-option dr-priority** command.

During PIM Assert election, the IP address configured using the **pim dr-election dr-priority** command takes precedence over the interface IP address.

Precautions

- PIM can be configured on a VBDIF interface, which supports only DR election.
- In the multi-border distributed gateway scenario, to solve the problem of multiple copies of multicast traffic on the network segment where the VBDIF interface resides, configure different IP addresses for PIM DR election.
- If a fault occurs in the multi-border scenario, PIM needs to be associated with BFD to implement fast route switchover. In this case, you need to configure a secondary IP address that is the same as the IP address for PIM DR election on the VBDIF interface to send BFD packets.
- After the **pim dr-election dr-priority** command is run on a VBDIF interface, the **pim hello-option dr-priority** command no longer takes effect.

Example

Set the IP address and priority for DR election on VBDIF 10 to 10.0.0.1 and 20 respectively.

```
<HUAWEI> system-view
[HUAWEI] bridge-domain 10
[HUAWEI-bd10] quit
[HUAWEI] interface vbdif 10
[HUAWEI-Vbdif10] pim dr-election 10.1.1.2 dr-priority 20
```

8.3.51 pim hello ipsec sa

Function

The **pim hello ipsec sa** command specifies an IPSec SA used for encrypting and authenticating PIM Hello messages sent and received on an interface.

The **undo pim hello ipsec sa** command deletes the IPSec SA used for encrypting and authenticating PIM Hello messages sent and received on an interface.

By default, no IPSec SA is specified for encrypting and authenticating PIM Hello messages on an interface.

Format

pim hello ipsec sa *sa-name*

undo pim hello ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of the SA used on an interface.	The value is an existing SA name.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Huawei device connects to a non-Huawei device that can only encrypt and authenticate PIM Hello messages, run this command to configure the Huawei device to encrypt and authenticate only PIM Hello messages.

Prerequisites

- IP multicast routing has been enabled using the **multicast routing-enable** command.
- Basic IPSec functions have been configured.

Precautions

If you run both this command and the **pim ipsec sa** command on an interface, the last configured one takes effect.

This command has the same function as the **hello ipsec sa (IPv4)** command used in the PIM view, except for the effective scope. The configuration in the interface view takes precedence over the configuration in the PIM view. If SAs are specified in both the interface view and PIM view, the specified interface uses the SA configured in the interface view. If no SA is specified on an interface, the interface uses the SA specified in the PIM view.

Example

Configure the device to encrypt and authenticate PIM Hello messages sent and received on VLANIF100 using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello ipsec sa sa1
```

Configure the device to encrypt and authenticate PIM Hello messages sent and received on GE0/0/1 using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello ipsec sa sa1
```

8.3.52 pim hello-option dr-priority

Function

The **pim hello-option dr-priority** command sets the priority for the PIM interface that is elected as DR.

The **undo pim hello-option dr-priority** command restores the default value of the priority.

By default, the priority for the PIM interface that is elected as DR is 1.

Format

pim hello-option dr-priority *priority*

undo pim hello-option dr-priority

Parameters

Parameter	Description	Value
priority	Specifies the priority of the PIM interface that is elected as DR. The greater the value, the higher the priority.	The value is an integer ranging from 0 to 4294967295.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM network, switches on a shared network segment are candidates for the DR. The DR is responsible for registration of local multicast sources and the joining of receivers.

The DR is elected based on the priority and the IP address. Candidates send Hello messages with their priorities, and the switch with the highest priority becomes the DR. If multiple switches have the same priority, the switch with the largest IP address becomes the DR.

If at least one switch in the network does not support Hello packets that contain the priority, the switch with the largest IP address becomes the DR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **pim hello-option dr-priority** command has the same function as the **hello-option dr-priority (IPv4)** command in the PIM view. By default, if the **pim hello-option dr-priority** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the priority of VLANIF100 that is elected as DR to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello-option dr-priority 3
```

Set the priority of GE0/0/1 that is elected as DR to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello-option dr-priority 3
```

8.3.53 pim hello-option holdtime

Function

The **pim hello-option holdtime** command sets the timeout period during which the PIM interface waits to receive the Hello message from its neighbor.

The **undo pim hello-option holdtime** command restores the default value of the timeout.

By default, the timeout period during which the PIM interface waits to receive the Hello message from its neighbor is 105 seconds.

Format

pim hello-option holdtime *interval*

undo pim hello-option holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which the PIM interface waits to receive Hello messages from its neighbor.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM network, after the switch receives a Hello message from its PIM neighbor, it starts a timer. The timer length is the value of Holdtime in the Hello message. If the switch does not receive any Hello message from its PIM neighbor when the timer expires, it considers the neighbor invalid or unreachable.

The **pim hello-option holdtime** command sets the timeout period during which the PIM interface waits to receive the Hello message from its neighbor.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The timeout period must be greater than the interval for sending Hello messages, which is set using the **pim timer hello** command.

The **pim hello-option holdtime** command has the same function as the **hello-option holdtime (IPv4)** command in the PIM view. By default, if the **pim hello-option holdtime** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the timeout period during which VLANIF100 waits to receive Hello messages from its neighbor to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello-option holdtime 120
```

Set the timeout period during which GE0/0/1 waits to receive Hello messages from its neighbor to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello-option holdtime 120
```

8.3.54 pim hello-option lan-delay

Function

The **pim hello-option lan-delay** command sets the delay in transmitting messages in a shared network in the interface view.

The **undo pim hello-option lan-delay** command restores the default value of the delay.

By default, the delay in transmitting messages in the shared network is 500 ms.

Format

pim hello-option lan-delay *interval*

undo pim hello-option lan-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay in transmitting messages in the shared network.	The value is an integer that ranges from 1 to 32767, in milliseconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** values. The **lan-delay** parameter indicates the delay in transmitting messages in the LAN. If switches on the same link have different **lan-delay** values, the maximum value is used.

When a switch sends a Prune message to the upstream device in the same network segment, other switches that still request multicast data need to send a Join message to the upstream device within the override-interval period.

The value of the Prune-Pending Timer (PPT) is the sum of the **lan-delay** and **override-interval** values, and refers to the delay from the switch receiving a Prune message from the downstream interface to performing the prune action. If the switch receives a Join message from the downstream interface in PPT, the switch cancels the prune action.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

If the prune delay is set too short, the upstream switch stops forwarding multicast packets before the downstream switch overrides Prune messages of neighbors. Exercise caution when you run this command.

The function of this command in the interface view is the same as that of the **hello-option lan-delay (IPv4)** command in the PIM view. By default, if the configuration on the interface is not performed, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the delay in transmitting messages to 200 ms in VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello-option lan-delay 200
```

Set the delay in transmitting messages to 200 ms in GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello-option lan-delay 200
```

8.3.55 pim hello-option neighbor-tracking

Function

The **pim hello-option neighbor-tracking** command enables the neighbor tracking function in the interface view.

The **undo pim hello-option neighbor-tracking** command restores the default configuration.

By default, the neighbor tracking function is not enabled.

Format

pim hello-option neighbor-tracking

undo pim hello-option neighbor-tracking

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When sending a Hello message, the switch generates a Generation ID and encapsulates it into the message. The Generation ID changes only when the status of the switch changes. In this case, the neighboring device detects the Generation ID change after receiving the Hello message and immediately sends a Join message to the switch to update the neighbor relationship. If multiple devices on the shared network segment prepare to send Join messages to the same upstream PIM neighbor, only one device is allowed to send the Join message. After other devices detect the Join message, they do not send Join messages to the upstream neighbor. This means that the upstream neighbor cannot update neighbor relationships with downstream devices after a Generation ID change.

After the neighbor tracking function is enabled, when the device detects Join messages from other devices, the device still sends the Join messages to the same upstream PIM neighbor.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

Neighbor tracking can be implemented only when all devices on the shared network segment have this function enabled.

The **pim hello-option neighbor-tracking** command has the same function as the **hello-option neighbor-tracking (IPv4)** command in the PIM view. By default, if the **pim hello-option neighbor-tracking** command is not used, the configuration in the PIM view takes effect; otherwise, the configuration in the interface view takes effect.

Example

Enable the neighbor tracking function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello-option neighbor-tracking
```

Enable the neighbor tracking function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello-option neighbor-tracking
```

8.3.56 pim hello-option override-interval

Function

The **pim hello-option override-interval** command sets the interval carried in Hello messages for overriding the prune action on the interface.

The **undo pim hello-option override-interval** command, restores the default configuration.

By default, the interval carried in Hello messages for overriding the prune action on the interface is 2500 milliseconds.

Format

pim hello-option override-interval *interval*

undo pim hello-option override-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval of overriding the prune action.	The value is an integer that ranges from 1 to 65535, in milliseconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** parameters. The **override-interval** parameter indicates the period during which a downstream switch can override the prune action.

When a switch sends a Prune message to the upstream device in the same network segment, other switches that still request multicast data need to send a Join message to the upstream device within the override-interval period.

When a device has only one PIM neighbor on a link and receives a Prune message from the neighbor, the device immediately deletes the downstream interface of the multicast routing entry. If a device has two or more PIM neighbors on a link and the **override-interval** values in the messages sent from the two neighbors are different, the largest **override-interval** value takes effect.

The value of Prune-Pending Timer (PPT) is the sum of **lan-delay** and **override-interval** values. When receiving a Prune message from a downstream interface, the switch does not perform the prune action until the PPT times out. If the switch receives a Join message from the downstream interface in PPT, the interface cancels the Prune action.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If you run the **pim hello-option override-interval** command multiple times, only the latest configuration takes effect.

Precautions

This command is valid for PIM-SM and PIM-DM.

The **pim hello-option override-interval** command has the same function as the **hello-option override-interval (IPv4)** command in the PIM view. By default, if the **pim hello-option override-interval** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval for overriding the prune action in Hello messages to 2000 ms in VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim hello-option override-interval 2000
```

Set the interval for overriding the prune action in Hello messages to 2000 ms in GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim hello-option override-interval 2000
```

8.3.57 pim holdtime assert

Function

The **pim holdtime assert** command sets the timeout period during which a PIM interface keeps the Assert state.

The **undo pim holdtime assert** command restores the default value of the timeout.

By default, the timeout period during which a PIM interface keeps the Assert state is 180 seconds.

Format

pim holdtime assert *interval*

undo pim holdtime assert

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which a PIM interface keeps the Assert state.	The value is an integer that ranges from 7 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the shared network segment connected to multiple PIM devices, if the same multicast packets reach these PIM devices and pass the RPF check, multiple copies of the same multicast packets are forwarded to this network segment. In this situation, these PIM devices need to initiate the assert mechanism. The device that wins assert election is responsible for multicast forwarding on the shared network segment. Other devices suppress multicast data forwarding and retain the Assert state for a period of time. After the timer for a PIM interface in the Assert state expires, devices that failed the previous election triggers a new round of election.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

The **pim holdtime assert** command has the same function as the **holdtime assert (IPv4)** command in the PIM view. By default, if the **pim holdtime assert** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the timeout period for the interface VLANIF100 to keep the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim holdtime assert 100
```

Set the timeout period for the interface GE0/0/1 to keep the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim holdtime assert 100
```

8.3.58 pim holdtime join-prune

Function

The **pim holdtime join-prune** command sets the holdtime in a Join/Prune message sent by the PIM interface.

The **undo pim holdtime join-prune** command restores the default value of the holdtime.

By default, the holdtime in a Join/Prune message sent by the PIM interface is 210 seconds.

Format

pim holdtime join-prune *interval*

undo pim holdtime join-prune

Parameters

Parameter	Description	Value
interval	Specifies the value of holdtime in a Join/Prune message sent by the PIM interface.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Join/Prune message from the downstream device, the switch starts the holdtime timer. If the switch does not receive subsequent Join/Prune messages from the downstream device within the holdtime interval, the switch suppresses forwarding of Join/Prune messages carrying group join information on the downstream interface in the group. If Join/Prune messages carry group prune information, the downstream interface is restored.

The **pim holdtime join-prune** command sets the holdtime interval for Join/Prune messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for PIM-SM and PIM-DM.

The holdtime of Join/Prune messages must be larger than the interval for sending Join/Prune messages and is generally 3.5 times the interval for sending Join/Prune messages.

The **pim holdtime join-prune** command has the same function as the **holdtime join-prune (IPv4)** command in the PIM view. By default, if the **pim holdtime join-prune** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the holdtime in a Join/Prune message sent by the interface VLANIF100 to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim holdtime join-prune 280
```

Set the holdtime in a Join/Prune message sent by the interface GE0/0/1 to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim holdtime join-prune 280
```

8.3.59 pim ipsec sa

Function

The **pim ipsec sa** command specifies an IPSec SA used for encrypting and authenticating PIM messages sent and received on an interface.

The **undo pim ipsec sa** command deletes the IPSec SA used for encrypting and authenticating PIM messages sent and received on an interface.

By default, no IPSec SA is specified for encrypting and authenticating PIM messages on an interface.

Format

pim ipsec sa *sa-name*

undo pim ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of the SA used on an interface.	The value is an existing SA name.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IPv4 multicast network, if multicast devices are attacked by forged PIM messages, multicast data forwarding between multicast devices will be interrupted. To protect multicast devices against such attacks, configure PIM IPSec on some interfaces to authenticate PIM messages sent and received on these interfaces.

Prerequisites

- IP multicast routing has been enabled using the **multicast routing-enable** command.
- Basic IPSec functions have been configured.

Precautions

If you run both this command and the **pim hello ipsec sa** command on an interface, the last configured one takes effect.

This command has the same function as the **ipsec sa (IPv4)** command used in the PIM view, except for the effective scope. The configuration in the interface view takes precedence over the configuration in the PIM view. If SAs are specified in both the interface view and PIM view, the specified interface uses the SA configured in the interface view. If no SA is specified on an interface, the interface uses the SA specified in the PIM view.

Example

Configure the device to encrypt and authenticate PIM messages sent and received on VLANIF100 using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim ipsec sa sa1
```

Configure the device to encrypt and authenticate PIM messages sent and received on GE0/0/1 using the PIM IPSec SA named **sa1**. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim ipsec sa sa1
```

8.3.60 pim join-policy

Function

The **pim join-policy** command enables the system to filter join information in Join/Prune messages.

The **undo pim join-policy** command restores the default setting.

By default, join information in Join/Prune message is not filtered.

Format

pim join-policy { **asm** { *basic-acl-number* } | **ssm** { *advanced-acl-number* } | *advanced-acl-number* }

undo pim join-policy [**asm** | **ssm**]

Parameters

Parameter	Description	Value
asm	Filters join information, with the group address in the ASM group address range.	-
basic-acl-number	Specifies the basic ACL number.	The value is an integer that ranges from 2000 to 2999.
ssm	Filters join messages, with the group addresses within the SSM group address range and specified source address.	-
advanced-acl-number	Specifies the advanced ACL number.	The value is an integer that ranges from 3000 to 3999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized users from joining multicast groups on a PIM-SM network by filtering join information in Join/Prune messages, run the **pim join-policy** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

The **pim join-policy** command is valid for only PIM-SM.

The **pim join-policy** command and the **acl** command are used together.

- If **asm** is specified, you can set the multicast group address range of join information in the basic ACL view by specifying the **source** parameter in the **rule** command.
- If **ssm** is specified, you can set the source address range and multicast group address range of join information in the advanced ACL view by specifying the **source** parameter and **destination** parameter in the **rule** command.

Example

Configure VLANIF100 to accept the join information with the group address in the range of 225.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim join-policy asm 2001
```

Configure GE0/0/1 to accept the join information with the group address in the range of 225.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim join-policy asm 2001
```

8.3.61 pim neighbor-policy

Function

The **pim neighbor-policy** command configures a policy for filtering PIM neighbors on an interface.

The **undo pim neighbor-policy** command restores the default setting.

By default, PIM neighbors on the interface are not filtered.

Format

pim neighbor-policy *basic-acl-number*

undo pim neighbor-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the basic ACL number.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized neighbors from being involved in the PIM protocol, run the **pim neighbor-policy** command to configure a policy for filtering PIM neighbors and set the address range of PIM neighbors. The switch sets up neighbor relationships with the addresses matching the filtering rules and deletes the neighbors that do not match the filtering rules.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

The **pim neighbor-policy** command and the **acl** command are used together. In the ACL view, set the address range of PIM neighbors by specifying **source** in the **rule** command.

Precautions

This command is valid for both PIM-DM and PIM-SM.

When configuring the neighbor filtering function on the interface, you must also configure the neighbor filtering function correspondingly on the PIM neighbor of the interface.

If a PIM device has established a neighbor relationship with the switch but its IP address is not in the configured range of valid neighbor addresses, the switch will no longer receive Hello messages from this PIM neighbor. When the holdtime of Hello messages expires, the neighbor relationship between the PIM device and the switch is terminated.

Example

Allow VLANIF100 to set up a PIM neighbor relationship with a PIM device at 10.4.4.4.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.4.4.4 0.0.0.0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim neighbor-policy 2001
```

Allow GE0/0/1 to set up a PIM neighbor relationship with a PIM device at 10.4.4.4.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.4.4.4 0.0.0.0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim neighbor-policy 2001
```

8.3.62 pim require-genid

Function

The **pim require-genid** command configures a PIM interface to reject the Hello messages without the Generation ID.

The **undo pim require-genid** command restores the default configuration.

By default, a PIM interface receives the Hello messages without the Generation ID.

Format

pim require-genid

undo pim require-genid

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an interface on the switch is enabled with PIM, the switch generates a random number as the Generation ID of the Hello message. If the status of the switch is updated, the switch generates a new Generation ID. When the switch finds that the Hello message received from a PIM neighbor contains a different Generation ID, it considers that the status of the PIM neighbor has changed.

To ensure that PIM neighbors work properly, run the **pim require-genid** command to configure a PIM interface to reject the Hello messages without the Generation ID.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for both PIM-DM and PIM-SM.

Example

Configure VLANIF100 to reject the Hello messages without the Generation ID.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim require-genid
```

Configure GE0/0/1 to reject the Hello messages without the Generation ID.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim require-genid
```

8.3.63 pim silent

Function

The **pim silent** command enables the PIM silent function on an interface.

The **undo pim silent** command cancels the PIM silent function on an interface.

By default, the PIM silent function is disabled on an interface.

Format

pim silent

undo pim silent

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To protect the switch against pseudo PIM Hello messages sent from malicious hosts, configure the **pim silent** command on the interface directly connected to the host network segment to set the interface to PIM silent mode. Then the interface cannot receive or forward any PIM packet, and all PIM neighbors and PIM state machines on this interface are deleted. This interface becomes the DR, but the IGMP function on the interface is not affected.

The PIM silent function applies only to the interface directly connected to a host network segment, and only one PIM switch can be connected to this network segment.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

Running the **pim silent** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

If PIM BFD function is enabled on the interface, this command cannot be configured.

This command and **pim timer dr-switch-delay** command are mutually exclusive.

NOTICE

After you run this command on an interface, the interface no longer receives or sends any PIM packets and other PIM functions on the interface become invalid. Confirm your action before using this command.

If a host network segment is connected to multiple switches and PIM silent is enabled on multiple interfaces, all these interfaces become static DRs. This causes multicast forwarding failures.

Example

Configure the PIM silent function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim silent
```

Configure the PIM silent function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim silent
```

8.3.64 pim sm

Function

The **pim sm** command enables PIM-SM on an interface.

The **undo pim sm** command restores the default configuration.

By default, PIM-SM is disabled on an interface.

Format

pim sm

undo pim sm

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With PIM-SM enabled on interfaces, switches can set up PIM neighbor relationships and process protocol packets received from PIM neighbors.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

- PIM-DM and PIM-SM cannot be enabled simultaneously on interfaces bound to the same VPN instance or public network instance.
- If PIM-SM and IGMP need to be enabled on the same interface, enable PIM-SM, and then enable IGMP.
- Running the **pim sm** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.
- If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable PIM on the corresponding VLANIF interface first, and then enable IGMP snooping in the VLAN. If IGMP snooping is enabled in the VLAN first, PIM cannot be enabled on the VLANIF interface.
- In versions earlier than V200R022C10, VBDIF interfaces cannot be configured as inbound or outbound interfaces of multicast entries. In V200R022C10, VBDIF interfaces can only be configured as outbound interfaces of multicast entries, and cannot be configured as inbound interfaces. In V200R023C00 and later versions, VBDIF interfaces can be configured as both inbound and outbound interfaces of multicast entries.
- After super VXLAN resource mode is configured using the **set vxlan resource super-mode** command, a maximum of 12,288 VBDIF interfaces can be configured as inbound interfaces of multicast entries. If the number of VBDIF interfaces to be configured as inbound interfaces exceeds the upper limit, the configuration takes effect only for the first 12,288 VBDIF interfaces.
- PIM can be configured on VBDIF interfaces. A VBDIF interface that has PIM configured can only connect the multicast source and receives, and it cannot function as a PIM interconnection interface.
- Since V200R010, the S5720-HI, S5730-HI, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-HI, S6730-H, S6730S-H, S6730-S, and S6730S-S support IPv4 PIM configuration on dot1q and QinQ termination sub-interfaces only when the VLAN tag to be terminated (or both inner and outer VLAN tags on the QinQ termination sub-interface) is a single VLAN ID, but not a range of VLAN IDs. Sub-interfaces running PIM can only be used as inbound interfaces of multicast streams and cannot be used as outbound interfaces. The S5720-EI, S6720-EI, S6735-S, and S6720S-EI also support IPv4 PIM command configuration on dot1q and QinQ termination sub-interfaces, but they do not support multicast traffic forwarding on these sub-interfaces.
- PIM-DM and PIM-SM cannot be configured simultaneously in a VPN instance or the public network instance. IPv4 PIM can be configured in a VPN instance, but the VPN instance cannot be bound to a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command. Only the following products and versions support the IPv4 PIM multi-instance feature:
  - S5730-HI, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-HI, S6730-H, S6730S-H, S6730-S, and S6730S-S: all versions
  - S6700-EI and S5700-HI: V200R005C01
  - S6700-EI, S5700-HI, and S5710-HI: V200R005C02
  - S5710-HI: V200R005C03
  - S5720-EI, S5720-HI, S6720-EI, S6735-S, and S6720S-EI: V200R010 and later versions
- Secondary IP addresses does not support PIM, and the direct routes generated based on secondary IP addresses are not involved during multicast RPF check. Therefore, if the source IP address of multicast packets is on the same

network segment as the secondary IP address of a Layer 3 interface, these multicast packets received on the Layer 3 interface cannot pass the RPF check.

Example

Enable PIM-SM on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim sm
```

Enable PIM-SM on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim sm
```

8.3.65 pim state-refresh-capable

Function

The **pim state-refresh-capable** command enables PIM-DM state refresh on an interface.

The **undo pim state-refresh-capable** command disables PIM-DM state refresh.

By default, PIM-DM state refresh is enabled.

Format

pim state-refresh-capable

undo pim state-refresh-capable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM-DM state refresh is implemented by periodically sending State-Refresh messages in the network. After receiving a State-Refresh message, the switch in the pruned state resets the prune-status timer, preventing the downstream interface from forwarding packets.

After PIM-DM state refresh is disabled on an interface, the interface starts to forward multicast data when the prune timer expires. The downstream routers that do not want to receive the data send Prune messages. The process repeats, wasting a lot of network resources. Enabling PIM-DM state refresh can reduce traffic on the network.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

This command is valid for only PIM-DM.

Example

Disable PIM-DM state refresh on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo pim state-refresh-capable
```

Disable PIM-DM state refresh on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] undo pim state-refresh-capable
```

8.3.66 pim timer dr-switch-delay

Function

The **pim timer dr-switch-delay** command enables PIM DR switching delay and configures the delay on an interface. When the interface changed from a DR to a non-DR, the interface continues to forward data before the delay expires.

The **undo pim timer dr-switch-delay** command disables PIM DR switching delay on the interface.

By default, when the interface changes from a DR to a non-DR, the interface stops forwarding data immediately.

Format

pim timer dr-switch-delay *interval*

undo pim timer dr-switch-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay.	The value is an integer that ranges from 10 to 3600, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the DR on a shared network segment becomes the non-DR, original multicast forwarding entries will be deleted immediately, causing multicast data interruption in a short time. To solve the problem, set the DR switching delay. Original multicast forwarding entries still take effect until the delay is reached.

After a new PIM neighbor joins, the outbound interface may not function as a DR any more; however, within the switching delay or before the new DR takes effect to forward multicast traffic, the original outbound interface still has the DR function and continues to forward multicast data. In this manner, non-stop multicast traffic forwarding is ensured during DR switchover.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

This command and **pim silent** command are mutually exclusive.

Example

Enable PIM DR switching delay on VLANIF100 and set the delay to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim timer dr-switch-delay 20
```

Enable PIM DR switching delay on GE0/0/1 and set the delay to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim timer dr-switch-delay 20
```

8.3.67 pim timer graft-retry

Function

The **pim timer graft-retry** command sets the interval for retransmitting Graft messages on an interface.

The **undo pim timer graft-retry** command restores the default value of the interval.

By default, the interval for retransmitting Graft messages on an interface is 3 seconds.

Format

pim timer graft-retry *interval*

undo pim timer graft-retry

Parameters

Parameter	Description	Value
interval	Specifies the interval of retransmitting Graft messages.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In PIM-DM mode, when a member joins a pruned group, the switch sends a Graft message and waits to receive an ACK message from the upstream switch. If the downstream switch does not receive the ACK message in the period configured through the command, the switch resends the Graft message until the switch receives the ACK message from the upstream switch.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

This command is valid for only PIM-DM.

Example

Set the interval for retransmitting Graft messages to 80s on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim timer graft-retry 80
```

Set the interval for retransmitting Graft messages to 80s on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim timer graft-retry 80
```

8.3.68 pim timer hello

Function

The **pim timer hello** command sets the interval for sending Hello messages on an interface.

The **undo pim timer hello** command restores the default value of the interval.

By default, the interval for sending Hello messages on an interface is 30 seconds.

Format

pim timer hello *interval*

undo pim timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Hello messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM devices periodically send Hello messages to maintain PIM neighbor relationships. You can run the **pim timer hello** command to set the interval for sending Hello messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for both PIM-DM and PIM-SM.

The interval for sending Hello messages must be shorter than the timeout period of PIM neighbors, which is set using the **hello-option holdtime (IPv4)** command.

The configuration is the same as the **timer hello (IPv4)** command in the PIM view but takes precedence over the command used in the PIM view. The value configured in the PIM view is used if no value is configured on the interface.

Example

Set the interval for sending Hello messages to 40 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim timer hello 40
```

Set the interval for sending Hello messages to 40 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim timer hello 40
```

8.3.69 pim timer join-prune

Function

The **pim timer join-prune** command sets the interval for periodically sending Join/Prune messages to the upstream device.

The **undo pim timer join-prune** command restores the default interval.

By default, the interval for periodically sending Join/Prune messages to the upstream device is 60 seconds.

Format

pim timer join-prune *interval*

undo pim timer join-prune

Parameters

Parameter	Description	Value
interval	Specifies the interval at which Join/Prune messages are sent.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device sends join information to the upstream device, requesting the upstream device to forward multicast data. The device sends prune information to the upstream device, requesting the upstream device to stop forwarding multicast data. Join information and prune information are encapsulated in Join/Prune messages. The device periodically sends Join/Prune messages to the upstream device to update the forwarding status.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid only for PIM-SM.

The interval configured through this command must be shorter than the interval configured through the **pim holdtime join-prune** command. The interval at which Join or Prune messages are sent must be shorter than the holdtime carried in Join/Prune messages.

The configuration is the same as that of the **timer join-prune (IPv4)** command in the PIM view. The system prefers the configuration in the interface view. The value configured in the PIM view is used if no value is configured on the interface.

Example

Set the interval for sending Join or Prune messages to 80 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim timer join-prune 80
```

Set the interval for sending Join or Prune messages to 80 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim timer join-prune 80
```

8.3.70 pim triggered-hello-delay

Function

The **pim triggered-hello-delay** command sets the maximum delay for triggering Hello messages.

The **undo pim triggered-hello-delay** command restores the default maximum delay.

By default, the maximum delay for triggering Hello messages is 5 seconds.

Format

pim triggered-hello-delay *interval*

undo pim triggered-hello-delay

Parameters

Parameter	Description	Value
interval	Specifies the maximum delay for triggering Hello messages.	The value is an integer that ranges from 1 to 5, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Conflicts will occur if multiple PIM devices send Hello message at the same time. To avoid such conflicts, when a PIM device detects Hello messages on the network, it waits for a random delay that is smaller than the value configured using this command before sending a Hello message.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Example

Set the maximum delay for triggering the Hello message to 3 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] pim triggered-hello-delay 3
```

Set the maximum delay for triggering the Hello message to 3 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] pim triggered-hello-delay 3
```

8.3.71 probe-interval (IPv4)

Function

The **probe-interval** command sets the interval for a switch to send Probe messages (null Register message) to the RP.

The **undo probe-interval** command restores the default value of the interval.

By default, the interval for a switch to send Probe messages to the RP is 5 seconds.

Format

probe-interval *interval*

undo probe-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Probe messages to RP.	The value is an integer that ranges from 1 to 1799, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When receiving a Register-Stop message sent by the RP, the DR at the source side stops sending Register messages and enters the register suppression state.

During the register suppression, the DR at the source side sends Probe messages to notify the RP that the multicast source is still in the Active state. After the register suppression times out, the DR at the source side starts to send Register messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

The interval set using the **probe-interval** command must be less than half the interval set using the **register-suppression-timeout (IPv4)** command.

Example

In the PIM view of public network instance, set the interval for sending Probe messages to RP to 6 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] probe-interval 6
```

8.3.72 register-header-checksum

Function

The **register-header-checksum** command configures devices to calculate the checksum based on the header of a Register message only.

The **undo register-header-checksum** command restores the default configuration.

By default, the checksum is calculated according to all the contents of a Register message.

Format

register-header-checksum

undo register-header-checksum

Parameters

None

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the source's DR calculates the checksum based on all fields in a Register message. After the **register-header-checksum** command is executed, the source's DR calculates the checksum based on the Register message header. This shortens the checksum calculation time and improves efficiency of encapsulating multicast data in Register messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

Example

Calculate the checksum based only on the header of a Register message PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] register-header-checksum
```

8.3.73 register-policy (IPv4)

Function

The **register-policy** command sets the rules used by an RP to filter Register messages.

The **undo register-policy** command restores the default setting.

By default, the rules for filtering Register messages are not configured.

Format

register-policy *advanced-acl-number*

undo register-policy

Parameters

Parameter	Description	Value
advanced-acl-number	Specifies the number of the advanced ACL that defines the rules for filtering packets based on source addresses or group addresses.	The value is an integer that ranges from 3000 to 3999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent the attack of invalid Register messages, you can configure devices to receive or deny Register messages according to the packet filtering rules.

If the (S, G) entry contained in a Register message does not pass the filtering of the ACL or the ACL does not filter the entry, RP discards the Register message. The multicast source cannot register with the RP.

If *advanced-acl-number* is set in the **register-policy** command but the corresponding ACL is not defined, the RP discards all Register messages. The RP cannot register with any multicast source.

The **register-policy** command and the **acl** command are used together. In the ACL view, you can set the multicast source address range by specifying the **source** parameter in the **rule** command, and set the multicast group address range by specifying the **destination** parameter in the **rule** command.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

NOTICE

When the **register-policy** command is used on the RP, only Register messages matching the rule of the ACL are received by the RP. If an undefined ACL is specified, the RP denies all Register messages.

This command is valid for only PIM-SM.

The **register-policy** command takes effect for only subsequently received Register messages. The multicast entries that have been registered successfully are not deleted and can still be used for multicast data forwarding.

Example

Configure the RP to receive Register packets sent by the source on network segment 10.10.0.0/16 to group 225.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 3000
[HUAWEI-acl-adv-3000] rule permit ip source 10.10.0.0 0.0.255.255 destination 225.1.0.0 0.0.255.255
[HUAWEI-acl-adv-3000] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] register-policy 3000
```

8.3.74 register-source

Function

The **register-source** command specifies the source address used by the source's DR to send Register messages.

The **undo register-source** command restores the default setting.

By default, the source address used by the source's DR to send Register messages is not specified.

Format

register-source *interface-type interface-number*

undo register-source

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the source's DR.	-

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the source IP address for sending Register messages is no longer the only IP address in the network for the RP router or the source IP address is filtered out, errors occur in the registration process and extra traffic occupies bandwidth on the network. In this case, use the **register-source** command to specify an appropriate interface as the source IP address for sending Register messages. Using the loopback address of the source's DR as the source IP address is recommended.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Before specifying the source IP address for sending Register messages, enable PIM-SM.

Precautions

The command is effective only when the specified interface is in Up state.

Example

In the PIM view of public network instance, specify the IP address of loopback 0 as the source IP address for source's DR to send Register messages.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] register-source loopback 0
```

8.3.75 register-suppression-timeout (IPv4)

Function

The **register-suppression-timeout** command sets the timeout period during which a switch keeps the register suppression state.

The **undo register-suppression-timeout** command restores the default timeout period.

By default, a switch keeps the register suppression state for 60 seconds.

Format

register-suppression-timeout *interval*

undo register-suppression-timeout

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which the switch keeps the register suppression state.	The value is an integer that ranges from 11 to 3600, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Register-Stop message from the RP, the switch immediately stops sending Register messages and enters the register suppression state.

The **register-suppression-timeout** command determines how long the switch keeps the register suppression state. When the timeout period expires, the switch (source DR) starts to send Register messages to the RP.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If the timeout period is too short, the RP receives burst multicast data more frequently. If the timeout period is too long, there will be a long delay for new receivers to join a group after an (S, G) entry on the RP times out.

You can use the **probe-interval (IPv4)** command to configure the switch to send null Register messages before the suppression timer times out. This configuration reduces burst Register messages and shortens the timeout period to reduce the delay for a new receiver to join a group.

Precautions

This command is valid only for PIM-SM.

The interval set by the **register-suppression-timeout** command must be larger than two times the interval set by the **probe-interval (IPv4)** command.

Example

In the PIM view of public network instance, set the timeout period during which the switch keeps the register suppression state to 70 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] register-suppression-timeout 70
```

8.3.76 reset pim control-message counters

Function

The **reset pim control-message counters** command resets the statistics about PIM Control messages.

Format

reset pim [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters** [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
interface *interface-type interface-number*	Specifies the name and the number of an interface. It is used to reset the statistics about PIM control messages on a specified interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a PIM-enabled interface on the switch has been forwarding multicast packets for a long period of time, the switch stores statistics on a large number of control messages. You can run this command to reset statistics on control messages.

Example

Reset the statistics about PIM control messages on all interfaces in the public network instance.

```
<HUAWEI> reset pim control-message counters
```

Reset the statistics about PIM control messages on VLANIF100 in the public network instance.

```
<HUAWEI> reset pim control-message counters interface vlanif 100
```

8.3.77 reset pim routing-table

Function

The **reset pim routing-table** command resets PIM status of a specified downstream interface in a specified PIM routing entry.

Format

reset pim [**vpn-instance** *vpn-instance-name*] **routing-table group** *group-address* **mask** { *group-mask-length* | *group-mask* } **source** *source-address* **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
group *group-address*	Specifies the multicast group address of a PIM routing entry.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
mask *group-mask-length*	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
mask *group-mask*	Specifies the mask of a multicast group address.	It is in dotted decimal notation.
source *source-address*	Specifies the source address of a PIM routing entry.	The value is in dotted decimal notation. If a (*, G) entry is specified, the source address is 0.0.0.0.
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset pim routing-table** command resets PIM status of a specified downstream interface in a specified PIM routing entry.

Configuration Impact

This command can reset the PIM status of the specified interface in a specified PIM routing entry. It cannot reset the IGMP state and static group memberships on a specified interface.

Precautions

This command is valid only for PIM-SM.

NOTICE

Resetting PIM status of downstream interfaces can trigger transmission of Join/Prune messages, which causes multicast service interruption.

Example

In the public network instance, reset PIM status of downstream interface VLANIF100 of (10.1.1.1, 225.0.0.1).

```
<HUAWEI> reset pim routing-table group 225.0.0.1 mask 255.255.255.0 source 10.1.1.1 interface vlanif 100
```

8.3.78 source-lifetime (IPv4)

Function

The **source-lifetime** command specifies the timeout period of (S, G) or (*, G) entries on the switch.

The **undo source-lifetime** command restores the default value of the timeout period.

By default, the timeout period is 210 seconds.

Format

source-lifetime { *interval* | **infinity** } [**group-policy** *acl-number*]

undo source-lifetime

undo source-lifetime { *interval* | **infinity** } [**group-policy** *acl-number*]

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of (S, G) or (*, G) entries on the switch.	The value is an integer that ranges from 60 to 65535, in seconds.
infinity	Indicates that (S, G) entries on the switch will never age out.	-
group-policy	Specifies a group policy to determine to which the configured timeout period takes effect.	-
acl-number	Specifies the number of a basic or advanced ACL.	The value is an integer that ranges from 2000 to 3999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch starts a timer for each (S, G) or (*, G) entry. The **source-lifetime** command sets the timer value. After receiving a multicast packet from S, the interface resets the timer. If the timer times out, the (S, G) or (*, G) entry is considered invalid.

- If you configure **source-lifetime** *interval*, the configured timeout period applies to all (S, G) entries.
- If you configure **source-lifetime** *interval* { **group-policy** *acl-number* }:
  - If you specify a basic ACL number in the command, the configured timeout period applies to the (S, G) entries in which the source addresses are permitted by the specified ACL.
  - If you specify an advanced ACL number in the command, the configured timeout period applies to the (S, G) entries in which the source and group addresses are permitted by the specified ACL.
  - If you specify an advanced ACL name in the command, the configured timeout period applies to the (S, G) entries in which the source and group addresses are permitted by the specified ACL.
- If you configure **source-lifetime infinity**, all (S, G) entries will never age out.
- If you configure **source-lifetime infinity** { **group-policy** *acl-number* }:
  - If you specify a basic ACL number in the command, the (S, G) entries in which the source addresses are permitted by the specified ACL will never age out.
  - If you specify an advanced ACL number in the command, the (S, G) entries in which the source and group addresses are permitted by the specified ACL will never age out.
  - If you specify an advanced ACL name in the command, the (S, G) entries in which the source and group addresses are permitted by the specified ACL will never age out.

If you run this command multiple times for the same range of multicast forwarding entries and specify *interval* and **infinity** respectively in the commands, **infinity** takes precedence over *interval*.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for both PIM-DM and PIM-SM.

Example

In the PIM view of public network instance, set the timeout period of an (S, G) or (*, G) entry of the switch to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] source-lifetime 200
```

8.3.79 source-policy (IPv4)

Function

The **source-policy** command configures a policy to filter received multicast data packets based on source addresses or source-group addresses.

The **undo source-policy** command deletes the configuration.

By default, a switch does not filter received multicast data packets based on source addresses or source-group addresses.

Format

source-policy *acl-number*

undo source-policy

Parameters

Parameter	Description	Value
acl-number	Specifies number of the basic or advanced ACL.	The value is an integer that ranges from 2000 to 3999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized source information from being advertised on the PIM network, run the **source-policy** command to configure the switch to filter received multicast data packets based on source addresses or source/group addresses.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If a basic ACL is referenced in the policy, multicast data packets that do not match the specified source addresses are discarded.

If an advanced AC is referenced in the policy, multicast data packets that do not match the specified group-source addresses are discarded.

Precautions

This command is valid for both PIM-DM and PIM-SM.

Example

In the PIM view of public network instance, configure the switch to receive multicast data packets with the source address of 10.10.1.2 and to discard those with the source address of 10.10.1.1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 10.10.1.2 0
[HUAWEI-acl-basic-2001] rule deny source 10.10.1.1 0
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] source-policy 2001
```

8.3.80 spt-switch-threshold (IPv4)

Function

The **spt-switch-threshold** command sets the rate threshold of the multicast packets when the DR at the member side joins the SPT.

The **undo spt-switch-threshold** command restores the default value.

By default, the system performs SPT switchover on receiving the first multicast data packet through the RPT.

Format

spt-switch-threshold { *traffic-rate* | **infinity** } [**group-policy** *basic-acl-number* [**order** *order-value*]]

undo spt-switch-threshold [*traffic-rate* | **infinity**] [**group-policy***basic-acl-number*]

Parameters

Parameter	Description	Value
traffic-rate	Specifies the threshold rate for the switchover from the RPT to the SPT. **NOTE** Setting this parameter may affect operation of multicast services. You are advised to use the default triggering condition. That is, an SPT switchover is triggered immediately after the first multicast data packet is received from the RPT. The default triggering condition can reduce the number of multicast packets forwarded on the RPT.	The value is an integer that ranges from 1 to 4194304, in kbit/s.
infinity	Indicates that the SPT switchover is never triggered.	-
basic-acl-number	Specifies an entry of the group-policy list. It works with the multicast group that matches **group-policy** *basic-acl-number* to enable the threshold. *basic-acl-number* specifies the number of the basic ACL that defines the range of multicast groups.	If the parameter is not set, the threshold is applied to all multicast groups. The value ranges from 2000 to 2999.
order *order-value*	Adjusts the order of the ACLs in the group-policy list.	If a group matches multiple ACLs, the threshold is selected in the order specified by *order-value*. *order-value* specifies the updated number. It is an integer. The value is any value other than original one in the current group-policy list. If the parameter is not set, the order of the ACLs in the group-policy list does not change.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The source's DR encapsulates multicast packets in a Register message, and then transmits the unicast Register message to the RP. Then, the RP decapsulates the Register message and forwards the multicast packets to the receivers along the RPT. By default, when the RP or receiver's DR receives the first multicast packet, it initiates an SPT switchover to the source.

After the **spt-switch-threshold** command is executed on the receiver's DR, the receiver's DR periodically checks the forwarding rate of multicast packets. When the forwarding rate exceeds the threshold, the receiver's DR sends a Join messages to the source, triggering the SPT switchover.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid to all devices that may function as the DR at the member side, but is invalid to RPs.

This command is valid for only PIM-SM.

If this command is used several times for the same group, the first matching command takes effect.

Example

In the PIM view of public network instance, set the traffic rate threshold to 4 kbit/s. If the transmission rate of packets from the source to the multicast group exceeds the threshold, the switch triggers an SPT switchover so that packets are forwarded along the SPT towards the source.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] spt-switch-threshold 4
```

In the public network instance, create a group-policy that uses ACL 2010, specify the **infinity** keyword in the command to ensure that an SPT switchover will never be triggered, and set the order of ACL 2010 in the group-policy to 1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2010
[HUAWEI-acl-basic-2010] rule permit source 225.1.1.1 0
[HUAWEI-acl-basic-2010] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] spt-switch-threshold infinity group-policy 2010 order 1
```

8.3.81 ssm-policy (IPv4)

Function

The **ssm-policy** command sets the range of SSM group addresses.

The **undo ssm-policy** command restores the default configuration.

By default, the range of SSM group addresses is 232.0.0.0/8.

Format

ssm-policy *basic-acl-number*

undo ssm-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of the basic ACL that defines the range of SSM group addresses.	The value is an integer that ranges from 2000 to 2999.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the address of an SSM group ranges from 232.0.0.0 to 232.255.255.255. You can run the **ssm-policy** command to specify the range of PIM SSM group addresses. All the PIM-SM interfaces consider that PIM SSM is enabled on all the multicast groups in the specified address range. The specified SSM group address range can be beyond 232.0.0.0/8.

You can enable SSM mode under the following conditions:

- The address of the multicast group is in the range of SSM group addresses, the network segment where the host resides runs IGMPv3, and the source address is specified in the Report message.
- The address of the multicast group is in the range of SSM group addresses, the network segment where the host resides runs IGMPv1 or IGMPv2, and the switch is configured with SSM mapping.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

The **ssm-policy** command and the **acl** command are used together.

- For the numbered ACL, in the ACL view, you can set the address range of SSM multicast groups by specifying the **source** parameter in the **rule** command.

- For the Named ACL, in the ACL view, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the multicast group address range specified by the **destination** parameter and the period specified by the **time-range** parameter.

Example

In the PIM view of public network instance, set the range of PIM SSM multicast addresses to 232.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 232.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2000] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] ssm-policy 2000
```

8.3.82 state-refresh-interval (IPv4)

Function

The **state-refresh-interval** command sets the interval for sending PIM State-Refresh messages.

The **undo state-refresh-interval** command restores the default value of the interval.

By default, the interval for sending PIM State-Refresh messages is 60 seconds.

Format

state-refresh-interval *interval*

undo state-refresh-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending PIM State-Refresh messages.	The value is an integer that ranges from 1 to 255, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the PIM-DM network, the device periodically sends State-Refresh messages to update the timeout interval of the prune timer on the downstream device. By doing this, the interface that has no multicast requirements retains in prune state. You can use the **state-refresh-interval** command to set the interval at which State-Refresh messages are sent.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

To prevent a pruned interface from forwarding packets when the Prune status times out, the interval for sending State-Refresh messages is shorter than the period for keeping the Prune status.

You can run the **holdtime join-prune (IPv4)** command to set the period during which the device keeps the Prune status.

This command is valid for only PIM-DM.

This command takes effect only on the switch directly connected to a source.

Example

Set the interval for sending PIM State-Refresh messages to 70s in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] state-refresh-interval 70
```

8.3.83 state-refresh-rate-limit (IPv4)

Function

The **state-refresh-rate-limit** command sets the minimum period to wait before receiving the next PIM State-Refresh message.

The **undo state-refresh-rate-limit** command restores the default value.

By default, the minimum period to wait to receive the next PIM State-Refresh message is 30 seconds.

Format

state-refresh-rate-limit *interval*

undo state-refresh-rate-limit

Parameters

Parameter	Description	Value
interval	Specifies the minimum period for waiting to receive the next PIM State-Refresh message.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch can receive multiple PIM State-Refresh messages in a short period. Some of the messages are the same. To avoid duplicate messages, you can run the **state-refresh-rate-limit** command to set the period to wait to receive the next State-Refresh message.

- Before the State-Refresh timer times out, the switch discards the received duplicate State-Refresh messages.
- After the State-Refresh timer times out, the switch can receive the next State-Refresh message.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

This command is valid for only PIM-DM.

Example

Set the minimum period to wait to receive the next PIM State-Refresh message to 45s in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] state-refresh-rate-limit 45
```

8.3.84 state-refresh-ttl (IPv4)

Function

The **state-refresh-ttl** command sets the TTL value for sending PIM State-Refresh messages.

The **undo state-refresh-ttl** command restores the default value of the TTL.

By default, the TTL value for sending PIM State-Refresh messages is 255.

Format

state-refresh-ttl *ttl-value*

undo state-refresh-ttl

Parameters

Parameter	Description	Value
ttl-value	Specifies the TTL value of the PIM State-Refresh message sent by an interface.	The value is an integer that ranges from 1 to 255.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a State-Refresh message, a switch decreases the TTL value in the message by 1, and then sends the message to the downstream device until the value of the TTL becomes 0. If the network is small, the message is delivered in a loop. You can use the **state-refresh-ttl** command to set an appropriate TTL value depending on the scale of your network.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command in the public network instance or VPN instance.

Precautions

This command is valid for only PIM-DM.

This command takes effect only on the switch directly connected to a source.

Example

Set the TTL value for sending PIM State-Refresh messages to 45 in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] state-refresh-ttl 45
```

8.3.85 static-rp (IPv4)

Function

The **static-rp** command configures a static RP.

The **undo static-rp** command restores the default configuration.

By default, no static RP is configured.

Format

static-rp *rp-address* [*basic-acl-number*] [**preferred**]

undo static-rp *rp-address*

Parameters

Parameter	Description	Value
rp-address	Specifies address of a static RP.	The address is in dotted decimal notation. It must be a valid unicast IP address and cannot be configured as an address of network segment 127.0.0.0/8.
basic-acl-number	Specifies the basic ACL that is used to control the range of multicast groups served by a static RP.	The value is an integer that ranges from 2000 to 2999.
preferred	Indicates that the static RP is preferred.	-

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When only one RP exists on a network, you can manually specify the static RP address and do not need to configure dynamic RP. This saves the bandwidth used for information exchange between the C-RPs and the BSR.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

If the static RP address is the address of an Up interface on the local device, the local device works as the static RP. PIM does not need to be enabled on the interface where the static RP address is located.

If no ACL is specified, the static RP serves all the multicast groups of 224.0.0.0/4. If an ACL is specified but no rule is configured in the ACL, the static RP serves all the groups of 224.0.0.0/4. If ACL rules are configured, the static RP serves only the multicast groups permitted by the ACL.

If the **static-rp** command does not contain **preferred**, devices apply the BSR mechanism to elect a dynamic RP. If dynamic RP is not configured or the dynamic RP is invalid, the static RP becomes valid. If the **static-rp** command contains **preferred**, the static RP is preferred over the dynamic RP.

If you run this command multiple times, multiple static RPs are configured. If multiple static RPs serve the same group, the RP with the largest IP address is selected to serve the group. If you specify the same RP address when running the **static-rp** command multiple times, the latest RP takes effect.

Precautions

NOTE

Up to 50 static RPs can be configured by using this command, but an ACL cannot be applied to multiple static RPs. If no ACL is referenced, only one static RP can be configured.

To ensure normal operating of a static RP, run the **static-rp** command to configure the same RP information on all devices in the PIM-SM domain.

The **static-rp** and **acl** commands are used together. In the ACL view, when the **rule** command is used to configure a filtering rule, you can set the address range of multicast groups that are served by the static RP by specifying the **source** parameter in the **rule** command. The filtering rule is effective only with the **source** parameter and the time period specified by the **time-range** parameter.

This command is valid only for PIM-SM.

Example

In the PIM view of public network instance, configure the switch with address 10.110.0.6 as a static RP serving the groups permitted by ACL 2001, and configure the static RP to be preferred.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 225.1.0.0 0.0.255.255
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] static-rp 10.110.0.6 2001 preferred
```

8.3.86 timer hello (IPv4)

Function

The **timer hello** command sets the interval at which the PIM switch sends Hello messages.

The **undo timer hello** command restores the default interval.

By default, the interval at which the PIM switch sends Hello messages is 30 seconds.

Format

timer hello *interval*

undo timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval at which Hello messages are sent.	The value is an integer ranging from 1 to 18000, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM routers periodically send Hello messages to maintain PIM neighbor relationships. You can run the **pim timer hello** command to set the interval for sending Hello messages.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Configuration Impact

This command is valid for both PIM-DM and PIM-SM.

The interval at which the PIM switch sends Hello messages should be less than the timeout period of the PIM neighbor. You can run the **hello-option holdtime (IPv4)** command to set the timeout period of PIM neighbors.

The **timer hello** command has the same function as the **pim timer hello** command in the interface view. By default, if the **pim timer hello** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval at which PIM Hello messages are sent to 40s in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] pim
[HUAWEI-pim] timer hello 40
```

8.3.87 timer join-prune (IPv4)

Function

The **timer join-prune** command configures the interval at which Join/Prune messages are sent to an upstream device.

The **undo timer join-prune** command restores the default interval.

By default, the interval at which Join/Prune messages are sent to an upstream device is 60 seconds.

Format

timer join-prune *interval*

undo timer join-prune

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Join/Prune messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch sends join information to the upstream device, requesting the upstream device to forward multicast data. The switch sends prune information to the upstream device, requesting the upstream device to stop forwarding multicast data. Join information and prune information are encapsulated in Join/Prune messages. The PIM router periodically sends Join/Prune messages to the upstream router to update the forwarding status.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid only for PIM-SM.

The interval configured using the **timer join-prune** command must be shorter than the interval configured using the **holdtime join-prune (IPv4)** command.

The **timer join-prune** command has the same function as the **pim timer join-prune** command in the interface view. By default, if the **pim timer join-prune** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval at which Join/Prune messages are sent to 80s in the PIM view of public network instance.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] timer join-prune 80
```

8.3.88 timer spt-switch (IPv4)

Function

The **timer spt-switch** command sets the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from the RPT to the SPT.

The **undo timer spt-switch** command restores the default value of the interval.

By default, the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from the RPT to the SPT is 15 seconds.

Format

timer spt-switch *interval*

undo timer spt-switch

Parameters

Parameter	Description	Value
interval	Specifies the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from RPT to SPT.	The value is an integer that ranges from 15 to 65535, in seconds.

Views

PIM view of public network instance or PIM view of VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **timer spt-switch** command to set the interval for checking whether the rate for transmitting multicast data exceeds the threshold.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is valid for only PIM-SM.

Before running this command, you must set the threshold for SPT switchover by using the **spt-switch-threshold (IPv4)** command; otherwise, the **timer spt-switch** command takes no effect.

Example

In the PIM view of public network instance, set the interval for checking the rate for transmitting the multicast data before the switchover from RPT to SPT to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] pim
[HUAWEI-pim] spt-switch-threshold 100
[HUAWEI-pim] timer spt-switch 30
```

8.4 IPv6 PIM Configuration Commands

8.4.1 Command Support

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.
S6700	Supported.

8.4.2 bsm semantic fragmentation (IPv6)

Function

The **bsm semantic fragmentation** command enables BSR message fragmentation.

The **undo bsm semantic fragmentation** command disables BSR message fragmentation.

By default, BSR message fragmentation is not enabled.

Format

bsm semantic fragmentation

undo bsm semantic fragmentation

Parameters

None

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A BSR message carries information about all C-RPs on the network. Therefore, if there is a large number of C-RPs on the network, the length of a BSR message exceeds the MTU of the outgoing interface. As a result, the BSR message cannot be processed and RP election fails. Consequently, multicast services cannot be transmitted normally. In this case, you can enable BSR message fragmentation to ensure that the devices on the network can learn consistent RP information and MDTs can be successfully established.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

You can also configure IP fragmentation to solve the preceding problem. The difference between IP fragmentation and BSR message fragmentation is as follows:

- If IP fragmentation is enabled, the protocol layer transmits the entire BSR message up to the IP layer regardless of the length of the BSR message. The BSR message is then fragmented at the IP layer. If one fragment is lost during transmission, the destination cannot parse the entire BSR message. As a result, the destination cannot learn RP information and MDTs cannot be established, which causes a multicast data forwarding failure.

- If BSR message fragmentation is enabled, the protocol layer directly fragments a long BSR message. If one fragment is lost during transmission, only the information carried in this fragment is lost. As a result, only MDTs corresponding to the information carried in the lost fragments cannot be established. Since the other BSR message fragments can still reach the destination, the corresponding MDTs can be correctly established.

BSR message fragmentation is recommended because IP fragmentation causes all fragments to become unavailable when fragment information is lost.

Precautions

Enable BSR message fragmentation on all devices on the network. If BSR message fragmentation is not enabled on some devices, RP information on these devices is inconsistent with that on other devices and an MDT cannot be established correctly.

Example

Enable BSR message fragmentation in the PIM-IPv6 view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] bsm semantic fragmentation
```

8.4.3 bsr-policy (IPv6)

Function

The **bsr-policy** command specifies the range of valid bootstrap router (BSR) addresses so that the device discards BSR messages sent from addresses out of this range. This prevents BSR spoofing.

The **undo bsr-policy** command restores the default configuration.

By default, the range of BSR addresses is not limited, and all BSR packets are considered valid.

Format

bsr-policy *basic-acl6-number*

undo bsr-policy

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the basic ACL number. The ACL defines the filtering policy for the range of source addresses of BSR packets.	The value is an integer that ranges from 2000 to 2999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM-SM network that applies the BSR mechanism, you can configure any switch as a C-BSR to take part in the BSR election. Once a switch is elected as the BSR, it is responsible for advertising RP information in the network. To prevent the valid BSR from being maliciously replaced, take the following measures:

- Attacking hosts change the RP mapping to spoof the switch by forging BSR packets.

  Solution: Such attacks often occur on edge devices because a BSR packet is a multicast packet with TTL value of 1. As the BSR is inside the network and hosts are outside the network, the switches can perform neighbor check and RPF check on the received BSR packets to prevent the attacks.
- A switch is controlled by an attacker or an authorized switch is connected to the network. The attacker configures the switch as a C-BSR and makes the switch win the BSR election, so as to obtain the right of advertising RP information in the network.

  Solution: After the switch is configured as a C-BSR, it spreads multicast BSR packets in the network. The BSR packets have a TTL value of 1 and are forwarded hop by hop. As long as the neighboring device does not accept the BSR packets, the packets will not spread in the entire network. The solution is to use the **bsr-policy** command on every device in the network to specify the valid BSR range. For example, you can configure a policy to allow only switches with addresses FC00:0:0:2001::1/62 and FC00:0:0:2001::2/64 to function as BSRs. Then switches will not accept or forward BSR packets with addresses out of this range.

The two countermeasures mentioned above can partially protect BSRs in the network. If attackers control a valid BSR, it also brings problems to the network.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

After the **bsr-policy** command is run, the switch accepts only BSR messages matching the configured policy.

Precautions

The **bsr-policy** command and the **acl ipv6 (system view)** command are used together. In the ACL view, you can set the source address range for BSR packets by specifying the **source** parameter in the **rule (basic ACL6 view)** command.

Example

In the PIM-IPv6 view, configure address FC00:0:0:2001::/64 as the valid BSR address range.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00:0:0:2001:: 64
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] bsr-policy 2001
```

8.4.4 c-bsr (IPv6)

Function

The **c-bsr** command configures a C-BSR.

The **undo c-bsr** command restores the default configuration.

By default, the C-BSR is not configured.

Format

c-bsr *ipv6-address* [*hash-length* [*priority*]]

undo c-bsr

Parameters

Parameter	Description	Value
ipv6-address	Specifies the global IPv6 unicast address of a C-BSR. **NOTE** To avoid frequent protocol changes caused by interface flapping, use the loopback interface address as the global IPv6 unicast address of the C-BSR.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
hash-length	Specifies the hash mask length of the C-BSR. The mask is used in a hash function to calculate the RP.	The value is an integer that ranges from 0 to 128. By default, the value is 126.

Parameter	Description	Value
priority	Specifies a priority of the C-BSR. A larger value indicates a higher priority.	The value is an integer ranging from 0 to 255. By default, the value is 0.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

One or more C-BSRs need to be configured in a PIM-SM domain. A BSR is elected from multiple C-BSRs and is responsible for collecting C-RP information and summarizing C-RP information into an RP-set. The RP-set is then encapsulated in a BootStrap message and advertised to all the devices in the PIM domain.

The process of BSR election is as follows:

- Each C-BSR considers itself as the BSR of the local PIM-SM domain and uses the IPv6 address of this interface as the address of the BSR to send Bootstrap messages.
- When a C-BSR receives a Bootstrap message from other devices, it compares the BSR in the received Bootstrap message with the current BSR. The BSR with the highest priority is preferred. If BSRs have the same priority, the BSR with a larger IPv6 address is preferred. If the BSR carried in the received Bootstrap message is superior to the current BSR, the C-BSR replaces its BSR address with the BSR address carried in the received Bootstrap message.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If PIM-SM (IPv6) is disabled on an interface, the interface can be configured as a C-BSR but the configuration does not take effect.

For the multicast BSR messages learned through the GRE tunnel, you need to configure a static multicast route to ensure that the next hop to the BSR is a GRE interface. You need to configure static multicast routes properly to avoid routing loops.

Example

In the PIM-IPv6 view, set the IPv6 address of the C-BSR to FC00:0:0:3001::1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
```

```
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr fc00:0:0:3001::1
```

8.4.5 c-bsr admin-scope (IPv6)

Function

The **c-bsr admin-scope** command configures a BSR administrative scope in a PIM-SM domain.

The **undo c-bsr admin-scope** command restores the default configuration.

By default, no BSR administrative scope is configured.

Format

c-bsr admin-scope

undo c-bsr admin-scope

Parameters

None

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, each PIM-SM domain has only one BSR that serves all the devices in the entire PIM-SM domain. To achieve more effective management, you can divide a PIM-SM domain into multiple BSR administrative scopes and a global domain. This can reduce the workload of a single BSR and designate a private-network group address for users in a specific domain.

Each BSR administrative scope maintains a BSR that serves the multicast groups in a specified range. The multicast packets for the groups in a BSR administrative domain cannot travel across the boundary of the domain. The global domain maintains a BSR that serves all multicast groups that do not belong to any BSR administrative domains.

The relationship between the BSR administrative domain and the global domain is described as follows from the aspects of the region, group address range, and multicast function.

- Region

  Though different BSR administrative domains may serve the same group, devices in each BSR administrative domain differ. One device cannot belong to multiple BSR administrative domains. Each BSR administrative domain is independent of and isolated from each other geographically. A BSR administrative domain manages the multicast groups in a specific group address range. The multicast packets for the group in the range can be transmitted only in this administrative domain and cannot pass through the border of the BSR administrative domain.

A global domain contains all the switches on the PIM-SM network. The multicast packet that does not belong to any BSR administrative domain can be transmitted on the entire PIM network.

- Group address range

  Each BSR administrative domain serves the multicast groups in a specific group address range. The multicast groups that different BSR administrative domains serve can overlap. The address of the multicast group that the BSR administrative domain serves is valid only in its BSR administrative domain. That is, the multicast address is used as a private group address.

  The multicast group that does not belong to any BSR administrative domain belongs to a global domain.

- Multicast function

  The global domain and each BSR administrative domain have their respective Candidate-Rendezvous Point (C-RP) and BSR devices. Functions enabled on these devices take effect only in the local domain. That is, the BSR mechanism and the RP election are independent of each other among administrative domains.

  Each BSR administrative domain has its border. Multicast information of this domain, such as the C-RP Advertisement message and BSR BootStrap message, can be transmitted only within the domain. Multicast information of a global domain can be transmitted in the entire global domain and traverse any BSR administrative domain.

NOTE

Each BSR administrative domain corresponds to a scope ID defining the range of multicast groups.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **c-bsr admin-scope** command needs to be run on all the devices in a PIM-SM domain.

Example

Configure a BSR administrative scope in a PIM-SM domain.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr admin-scope
```

8.4.6 c-bsr global (IPv6)

Function

The **c-bsr global** command configures the switch as a C-BSR in the global domain.

The **undo c-bsr global** command restores the default configuration.

By default, no C-BSR is configured in the global domain.

Format

c-bsr global [**hash-length** *hash-length* | **priority** *priority*] *

undo c-bsr global

Parameters

Parameter	Description	Value
hash-length *hash-length*	Specifies the hash mask length of a C-BSR in the global domain.	The value is an integer that ranging from 0 to 128. By default, the value is 126.
priority *priority*	Specifies the priority of the C-BSR in the global domain.	The value is an integer that ranges from 0 to 255. By default, it is 0. The greater the value, the higher the priority of the C-BSR.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A PIM-SM network is divided into multiple BSR administrative domains and a global domain. The global domain maintains a BSR that serves the remaining multicast groups.

The **c-bsr global** command configures the switch as a C-BSR in the global domain. The BSR in the global domain is generated through election.

The rules of electing a BSR from C-BSRs in the global domain are as follows:

1. The C-BSR with the highest priority is elected as the BSR.
2. In the case of the same priority, the C-BSR with the highest IP address is elected as the BSR.

NOTE

A global domain contains all the switches on the PIM-SM network. The multicast packet that does not belong to any BSR administrative domain can be transmitted on the entire PIM network.

The multicast group that does not belong to any BSR administrative domain belongs to a global domain.

Multicast information of a global domain can be transmitted in the entire global domain and traverse any BSR administrative domain.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **c-bsr global** command takes effect only in a BSR administrative domain and can enable a device in this BSR administrative domain to accept multicast data for groups beyond the address range of the administrative domain.

Example

In the PIM-IPv6 view, configure the switch as a C-BSR in the global domain, and then set the priority of the C-BSR to 1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr global priority 1
```

8.4.7 c-bsr hash-length (IPv6)

Function

The **c-bsr hash-length** command configures the global hash mask length of a C-BSR.

The **undo c-bsr hash-length** command restores the default configuration.

By default, the global hash mask length of a C-BSR is 126.

Format

c-bsr hash-length *hash-length*

undo c-bsr hash-length

Parameters

Parameter	Description	Value
hash-length	Specifies the global hash mask length of a C-BSR.	The value is an integer that ranges from 0 to 128.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During dynamic RP election, if C-RPs have the same interface address mask and priority for a specified multicast group, a hash function needs to be executed to select the RP for the multicast group. The switch performs hash calculation for the group address of G, C-RP address, and hash mask length of the C-RPs with the same priority and compares the hash values. The C-RP with the greatest hash value acts as the RP for G.

The hash mask length is used to adjust the hash calculation result.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **c-bsr** *ipv6-address hash-length* command in the PIM-IPv6 view configure the hash mask length while configuring a C-BSR address. The **c-bsr hash-length** *hash-length* command specifies the global hash mask length. If both the two commands are configured, the hash mask length configured by the **c-bsr** *ipv6-address hash-length* command takes effect.

Example

In the PIM-IPv6 view, set the global hash mask length of a C-BSR to 16.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr hash-length 16
```

8.4.8 c-bsr holdtime (IPv6)

Function

The **c-bsr holdtime** command configures the timeout period during which the C-BSR waits to receive Bootstrap messages sent by the BSR.

The **undo c-bsr holdtime** command restores the default configuration.

By default, the timeout period during which the C-BSR waits to receive Bootstrap messages sent by the BSR is 130s.

Format

c-bsr holdtime *interval*

undo c-bsr holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout time during which C-BSR waits for the Bootstrap message to be sent by BSR.	The value is an integer that ranges from 1 to 214748364, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a C-BSR is elected as the BSR, it periodically sends Bootstrap messages carrying its own IPv6 address and the RP-set information. The interval for sending Bootstrap messages is BS_interval, which can be configured using the **c-bsr interval** command.

Other C-BSRs that fail in the election are suppressed from sending Bootstrap messages and start the timer to monitor the elected BSR. The timeout period of a timer is holdtime, which can be configured using the **c-bsr holdtime** command.

- If the C-BSR receives the Bootstrap messages sent by the BSR, the C-BSR refreshes the timer. The C-BSRs that fail in the election also refresh the timeout period of the BSR according to the holdtime.
- If the timer times out, the elected BSR is considered faulty. The C-BSRs that fail the previous election elect a new BSR. Services are not interrupted.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

In actual applications, all C-BSRs in the same PIM domain must use the same BS_interval and holdtime. If the configured values are different, the BSR may become unstable. This may result in multicast faults. Note the following points:

- If BS_interval and holdtime are configured at the same time, ensure that BS_interval is less than holdtime.
- If BS_interval or holdtime is configured, use the following formula to calculate the other one: holdtime = 2 x BS_interval + 10. The following determines which value is used:
  - If holdtime is configured and the calculated BS_interval is less than the minimum value of BS_interval, the minimum value is used.

  - If BS_interval is configured and the calculated holdtime is more than the maximum value of holdtime, the maximum value is used.
- If neither BS_interval nor holdtime is configured, the default values are used. The default BS_interval is 60s and the default holdtime is 130s.

Example

In the PIM-IPv6 view, set the timeout interval during which the C-BSR waits for the Bootstrap message to be sent by BSR to 150 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr holdtime 150
```

8.4.9 c-bsr interval (IPv6)

Function

The **c-bsr interval** command configures the interval at which the BSR continuously sends Bootstrap messages.

The **undo c-bsr interval** command restores the default interval.

By default, the BSR sends Bootstrap messages at a 60-second interval.

Format

c-bsr interval *interval*

undo c-bsr interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which a BSR continuously sends Bootstrap messages.	The value is an integer that ranges from 1 to 107374177, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a C-BSR is elected as the BSR, it periodically sends Bootstrap messages carrying its own IPv6 address and the RP-set information.

The interval for sending Bootstrap messages is BS_interval, which can be configured using the **c-bsr interval** command.

Other C-BSRs that fail in the election are suppressed from sending Bootstrap messages and start the timer to monitor the BSR. The timeout period of a timer is holdtime, which can be configured using the **c-bsr holdtime** command. The following applies to the timer:

- If the C-BSR receives the Bootstrap messages sent by the BSR, the C-BSR refreshes the timer.
- If the timer times out, the BSR is considered to be faulty. The C-BSRs that failed in the election triggers a new BSR election to prevent service interruption.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

In actual applications, all C-BSRs in the same PIM domain must use the same BS_interval and holdtime values. If C-BSRs use different BS_interval or holdtime values, the BSR changes frequently, causing multicast forwarding errors. Note the following points:

- If BS_interval and holdtime are configured at the same time, ensure that BS_interval is less than holdtime.
- If only one of the BS_interval and holdtime is configured, use the following formula to calculate the other parameter: holdtime = 2 x BS_interval + 10. The following determines which value is used:
  - If holdtime is configured and the calculated BS_interval is less than the minimum value of BS_interval, the minimum value is used.
  - If BS_interval is configured and the calculated holdtime is more than the maximum value of holdtime, the maximum value is used.
- If neither the BS_interval nor the holdtime is configured, default values are used. The default value of BS_interval is 60s, and the default value of holdtime is 130s.

Example

In the PIM-IPv6 view, set the interval for the C-BSR to continuously send Bootstrap messages to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr interval 30
```

8.4.10 c-bsr priority (IPv6)

Function

The **c-bsr priority** command configures the global C-BSR priority.

The **undo c-bsr priority** command restores the default configuration.

By default, the global C-BSR priority is 0.

Format

c-bsr priority *priority*

undo c-bsr priority

Parameters

Parameter	Description	Value
priority	Specifies the global priority of the C-BSR.	The value is an integer that ranges from 0 to 255. A larger value indicates a higher priority.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple C-BSRs participate in the BSR election in the PIM-SM domain:

- The switch with the highest priority wins in the BSR election.
- If they have the same priority, the switch with the largest IPv6 address wins in the BSR election.

To enable a C-BSR to function as the BSR, you can run the **c-bsr priority** command to increase the priority value of the C-BSR.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **c-bsr** *ipv6-address hash-length priority* command in the PIM-IPv6 view to set the C-BSR priority while configuring a C-BSR. The **c-bsr priority** *priority* command sets the global priority. When both the two commands are configured, the priority configured by the **c-bsr** *ipv6-address hash-length priority* command takes effect.

Example

In the PIM-IPv6 view, set the global C-BSR priority to 5.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
```

```
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr priority 5
```

8.4.11 c-bsr scope

Function

The **c-bsr scope** command specifies the scope ID of the BSR administrative domain served by a C-BSR.

The **undo c-bsr scope** command restores the default configuration.

By default, no scope ID is specified for a C-BSR. That is, the C-BSR does not belong to any BSR administrative domain.

Format

c-bsr scope *scope-id* [**hash-length** *hash-length* | **priority** *priority*] *

undo c-bsr scope *scope-id*

Parameters

Parameter	Description	Value
scope-id	Specifies the scope ID of the administrative domain served by a C-BSR.	The value is an integer that ranges from 3 to 15.
hash-length *hash-length*	Specifies the hash mask length of a C-BSR in a BSR administrative domain.	The value is an integer that ranges from 0 to 128. The default value is 126.
priority *priority*	Specifies the priority of a C-BSR in a BSR administrative domain.	The value is an integer that ranges from 0 to 255. The default value is 0. The greater the value, the higher the priority.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Each BSR administrative domain is assigned a scope ID. To configure a C-BSR to serve a BSR administrative domain, use the **c-bsr scope** command to specify the scope ID of the BSR administrative domain. Packets forwarded by the C-BSR cannot travel across the boundary of the BSR administrative domain.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

A BSR administrative domain has been configured using the **c-bsr admin-scope (IPv6)** command in the PIM-IPv6 view.

Precautions

The multicast group that does not belong to any BSR administrative domain belongs to a global domain.

Example

In the PIM-IPv6 view, configure the switch as a C-BSR in the BSR administrative domain to serve groups of Scope 5, and set the priority of the C-BSR to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-bsr scope 5 priority 10
```

8.4.12 c-rp (IPv6)

Function

The **c-rp** command configures the switch to advertise itself as a C-RP to the BSR.

The **undo c-rp** command restores the default configuration.

By default, no C-RP is configured.

Format

c-rp *ipv6-address* [**advertisement-interval** *adv-interval* | [**group-policy** *basic-acl6-number* | **scope** *scope-id*] | **holdtime** *hold-interval* | **priority** *priority*] *

undo c-rp *ipv6-address* [**scope** *scope-id*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the global IPv6 unicast address of a C-RP. **NOTE** To avoid frequent protocol changes caused by interface flapping, use the loopback interface address as the global IPv6 unicast address of the C-RP.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Parameter	Description	Value
advertisement-interval *adv-interval*	Specifies the interval at which the C-RP sends Advertisement messages.	The value is an integer that ranges from 1 to 65535, in seconds. By default, the value is 60 seconds.
group-policy *basic-acl6-number*	Specifies the range of multicast groups that the C-RP serves. The range is limited through the ACL6. *basic-acl6-number* specifies the number of the basic ACL6 used to limit the range of multicast groups that the C-RP serves.	The value is an integer that ranges from 2000 to 2999.
scope *scope-id*	Specifies the scope ID of the BSR administrative domain that a C-RP serves.	The value is an integer that ranges from 3 to 15.
holdtime *hold-interval*	Specifies the holdtime period during which the C-RP sends Advertisement messages. *hold-interval* specifies the time remaining before the C-RP sends Advertisement messages.	The value is an integer that ranges from 1 to 65535, in seconds. By default, the value is 150 seconds.
priority *priority*	Specifies the priority of a C-RP. The value of *priority* indicates the priority of a C-RP.	The value is an integer that ranges from 0 to 255. By default, the value is 192. The greater the value is, the lower the priority is.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RP is the core of a PIM-SM (IPv6) domain, and therefore a C-RP must be able to communicate with the other devices in the PIM-SM (IPv6) domain. It is recommended that you configure a C-RP on the device that aggregates multicast traffic and reserve enough bandwidth between this device and each of the other devices in the PIM-SM (IPv6) domain.

The rules used to elect an RP from multiple C-RPs are as follows, in descending order of precedence:

1. The C-RP with the longest mask length of the served group address range matching the multicast group that users have joined wins.
2. The C-RP with highest priority wins.
3. The C-RP with the largest hash value wins.
4. The C-RP with the largest IPv6 address wins.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

The **group-policy** *basic-acl6-number*, **priority** *priority*, **holdtime** *hold-interval* and **advertisement-interval** *adv-interval* set by using the command take precedence over the values of the global parameters configured in the PIM-IPv6 view because this command specifies an interface address. If this command is run several times on the same interface, only the latest configuration is valid.

Precautions

- If PIM-SM (IPv6) is disabled on an interface, the interface can be configured as a C-RP but the configuration does not take effect.
- **group-policy** *basic-acl6-number* specifies a group range. All permitted group ranges will be advertised as the ranges of groups that the RP serves. If no group range is specified for a C-RP or a C-RP is configured to serve all addresses, the C-RP serves all multicast groups.

The **c-rp** command and the **acl** command are used together.

- For the IPv6 numbered ACL, in the ACL6 view, you can set the address range of multicast groups that are serviced by the candidate RP by specifying the **source** parameter in the **rule** command.
- For the IPv6 Named ACL, in the ACL6 view, you can set the address range of multicast groups that are serviced by the candidate RP by specifying the **destination** parameter in the **rule** command.

If you want the switch to function as C-RPs in multiple BSR administrative domains, you need to specify the scope ID of each BSR administrative domain. For each scope ID, the settings of **advertisement-interval** *interval*, **priority** *priority-value*, and **holdtime** *interval* will overwrite the global settings in the PIM view.

Example

In the PIM-IPv6 view, configure an interface with the IPv6 address FC00:0:0:2001::1 as a C-RP of the PIM-SM (IPv6) domain.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-rp fc00:0:0:2001::1
```

8.4.13 c-rp advertisement-interval (IPv6)

Function

The **c-rp advertisement-interval** command sets the interval at which a C-RP sends Advertisement messages.

The **undo c-rp advertisement-interval** command restores the default interval.

By default, a C-RP sends Advertisement messages at an interval of 60 seconds.

Format

c-rp advertisement-interval *interval*

undo c-rp advertisement-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which a C-RP sends Advertisement messages.	The value ranges from 1 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

All C-RPs in a PIM-SM domain periodically send Advertisement messages to the same BSR. The BSR can collect the integrated RP-Set.

The **c-rp advertisement-interval** command sets the interval at which a C-RP sends Advertisement messages to the BSR.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **c-rp** *ipv6-address* **advertisement-interval** *interval* command in the PIM-IPv6 view to configure the advertisement interval while configuring a C-RP. The **c-rp advertisement-interval** *interval* command specifies the global interval. If both the commands are configured, the interval configured by the **c-rp** *ipv6-address* **advertisement-interval** *interval* command takes effect.

Example

In the PIM-IPv6 view, set the interval at which a C-RP sends Advertisement messages to 30s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-rp advertisement-interval 30
```

8.4.14 c-rp holdtime (IPv6)

Function

The **c-rp holdtime** command configures the holdtime for a received Advertisement message on a BSR.

The **undo c-rp holdtime** command restores the default holdtime.

By default, the holdtime for a received Advertisement message is 150 seconds.

Format

c-rp holdtime *hold-interval*

undo c-rp holdtime

Parameters

Parameter	Description	Value
hold-interval	Specifies the timeout period for a BSR to wait the Advertisement message from a C-RP.	The value ranges from 1 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When *hold-interval* is set on a C-RP, the C-RP encapsulates *hold-interval* in an Advertisement message and sends it to the BSR. The BSR obtains this *hold-interval* from the message and starts the timer. If the BSR receives no Advertisement message from the C-RP within the timeout period, the BSR regards the C-RP invalid or unreachable.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **c-rp** *ipv6-address* **holdtime** *hold-interval* command in the PIM-IPv6 view to configure the advertisement message holdtime while configuring a C-RP. The **c-rp holdtime** *hold-interval* configures the global holdtime for Advertisement messages. If both the two commands are configured, the holdtime configured by the **c-rp** *ipv6-address* **holdtime** *hold-interval* command takes effect.

Example

In the PIM-IPv6 view, set the holdtime for a received Advertisement message to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-rp holdtime 100
```

8.4.15 c-rp priority (IPv6)

Function

The **c-rp priority** command configures the global C-RP priority.

The **undo c-rp priority** command restores the default configuration.

By default, the global C-RP priority is 192.

Format

c-rp priority *priority*

undo c-rp priority

Parameters

Parameter	Description	Value
priority	Specifies the global C-RP priority.	The value is an integer that ranges from 0 to 255. A larger value indicates a lower priority.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following rules are used to elect an RP from multiple C-RPs, in descending order of precedence:

- The C-RP with the interface address that has the longest mask wins.
- The C-RP with highest priority wins.
- The C-RP with the largest hash value wins.
- The C-RP with the largest IPv6 address wins.

To enable a C-RP to function as an RP, you can run the **c-rp priority** command to increase the priority of the C-RP.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can also run the **c-rp** *ipv6-address* **priority** *priority* command in the PIM-IPv6 view to configure the C-RP priority while configuring a C-RP. The **c-rp priority** *priority* command specifies the global C-RP priority. If both the two commands are configured, the priority configured by the **c-rp** *ipv6-address* **priority** *priority* command takes effect.

Example

In the PIM-IPv6 view, set the global C-RP priority to 5.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] c-rp priority 5
```

8.4.16 crp-policy (IPv6)

Function

The **crp-policy** command limits the range of valid C-RP addresses and the range of the multicast addresses served by a C-RP. The BSR drops the C-RP messages with addresses out of the specified range to protect valid C-RPs.

The **undo crp-policy** command restores the default configuration.

By default, the BSR does not limit the range of valid C-RP addresses and the range of the multicast groups served by a C-RP. The BSR considers all the received C-RP messages valid.

Format

crp-policy *advanced-acl6-number*

undo crp-policy

Parameters

Parameter	Description	Value
advanced-acl6-number	Specifies the number of an advanced ACL. The ACL defines the range of the C-RP addresses and the range of the group addresses served by a C-RP.	The value is an integer that ranges from 3000 to 3999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM SM network that uses the BSR mechanism, any switch can be configured as a C-RP to serve the multicast groups in a specified range. Each C-RP sends its information to the BSR in unicast mode. The BSR summarizes all received C-RP information into an RP-set, and floods it to the entire network using BSR messaged. The local switch then works out the RP serving a specific multicast group address range according to the RP-set.

To protect valid C-RPs from being spoofed, configure **crp-policy** on the BSR to limit the range of valid C-RP addresses and the range of multicast group addresses served by a C-RP. Configure the same filtering rule on each C-BSR because any C-BSR can become the BSR.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

The **crp-policy** command and the **acl ipv6 (system view)** command are used together. In the ACL6 view, you can set the valid source address range for the C-RP by specifying the **source** parameter in the **rule (advanced ACL6 view)** command. You can set the address range of multicast groups that are served by specifying the **destination** parameter in the **rule (advanced ACL6 view)** command.

If an ACL rule is specified but no C-RP address range is set, all C-RP messages are denied.

The **crp-policy** command and the **acl** command are used together. In the ACL6 view, you can set the valid source address range for the C-RP by specifying the **source** parameter in the **rule** command, and set the address range of multicast groups that are serviced by specifying the **destination** parameter in the **rule** command.

The matching of the received C-RP message succeeds only when the C-RP address carried in the message matches **source** and the address of the multicast groups carried in the message is a subset of the group address range in the ACL.

The configurations of the named ACL6 and the advanced ACL are the same, and can implement filtering of both source addresses and multicast group addresses. The named ACL can also be configured with the **time-range** parameter.

Example

Configure a C-RP policy on the C-BSR, which allows only the C-RP with the address FC00:0:0:2001::1/128 and allows the C-RP to serve only the multicast groups FF13::101/128.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 3100
[HUAWEI-acl6-adv-3100] rule permit ipv6 source fc00:0:0:2001::1 128 destination ff13::101 128
[HUAWEI-acl6-adv-3100] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] crp-policy 3100
```

8.4.17 display default-parameter pim-dm6

Function

The **display default-parameter pim-dm6** command displays default PIM-DM (IPv6) configurations.

Format

display default-parameter pim-dm6

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display default-parameter pim-dm6** command displays default PIM-DM (IPv6) configurations. Even if PIM-DM (IPv6) parameters are modified, the **display default-parameter pim-dm6** command still displays default parameter settings. Therefore, you can use this command to check which parameters have been modified.

Example

Display default configurations about PIM-DM (IPv6).

```
<HUAWEI> display default-parameter pim-dm6
 PIM6 View Default Configurations:
 --------------------------------
 Hello-option dr-priority: 1

Table 8-54 Description of the **display default-parameter pim-dm6** command output

Item	Description
PIM6 View Default Configurations	Default configurations in the PIM-IPv6 view.
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv6)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state. This parameter is configured by the **hello-option holdtime (IPv6)** command.

Item	Description
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment. This parameter is configured by the **hello-option lan-delay (IPv6)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. ● enabled: Neighbor tracking is enabled. ● disabled: Neighbor tracking is disabled This function is configured using the **hello-option neighbor-tracking (IPv6)** command.
Hello-option override-interval	Interval for sending Prune Override messages. This parameter is configured by the **hello-option override-interval (IPv6)** command.
Holdtime assert	Time period for holding the Assert state. This parameter is configured by the **holdtime assert (IPv6)** command.
Holdtime join-prune	Time period for holding the Join or Prune state. This parameter is configured by the **holdtime join-prune (IPv6)** command.
Source-lifetime	Timeout period of an (S, G) entry. This parameter is configured by the **source-lifetime (IPv6)** command.
State-refresh-interval	Interval for sending State-Refresh messages. This parameter is configured by the **state-refresh-interval (IPv6)** command.
State-refresh-rate-limit	Minimum interval from when the last State-Refresh message is received to when the next State-Refresh message is received. This parameter is configured by the **state-refresh-rate-limit (IPv6)** command.
State-refresh-ttl	TTL value of the State-Refresh message. This parameter is configured by the **state-refresh-ttl (IPv6)** command.
Hello periodic interval	Interval for sending Hello messages. This parameter is configured by the **timer hello (IPv6)** command.
Join-prune periodic interval	Interval for sending Join/Prune messages. This parameter is configured by the **timer join-prune (IPv6)** command.

Item	Description
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether the PIM BFD is enabled on the interface. This parameter is configured by the **pim ipv6 bfd enable** command.
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim ipv6 hello-option dr-priority** command.
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state. This parameter is configured by the **pim ipv6 hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at the shared network segment where the interface resides. This parameter is configured by the **pim ipv6 hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. ● enabled: Neighbor tracking is enabled. ● disabled: Neighbor tracking is disabled This function is configured using the **pim ipv6 hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages. This parameter is configured by the **pim ipv6 hello-option override-interval** command.
Pim holdtime assert	Time period for the interface to hold the Assert state. This parameter is configured by the **pim ipv6 holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state. This parameter is configured by the **pim ipv6 holdtime join-prune** command.

Item	Description
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. - enabled: The received Hello message is required to carry the Generation ID. - disabled: The received Hello message is not required to carry the Generation ID. This parameter is configured using the **pim ipv6 require-genid** command.
Pim silent	Whether the interface is in PIM silent state. - enabled: The interface is in PIM silent state. - disabled: The interface is not in PIM silent state. This parameter is configured using the **pim ipv6 silent** command.
Pim state-refresh-capable	Whether State-Refresh is enabled on the interface. - enabled: State-Refresh is enabled on the interface. - disabled: State-Refresh is disabled on the interface. This function is configured using the **pim ipv6 state-refresh-capable** command.
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. - enabled: The DR switch delay is set on the interface. - disabled: The DR switch delay is not set on the interface. This function is configured using the **pim ipv6 timer dr-switch-delay** command.
Pim timer graft-retry	Interval for the interface to retransmit Graft messages. This parameter is configured by the **pim ipv6 timer graft-retry** command.
Pim hello periodic interval	Interval for the interface to send Hello messages. This parameter is configured by the **pim ipv6 timer hello** command.

Item	Description
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages. This parameter is configured by the **pim ipv6 timer join-prune** command.
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages. This parameter is configured by the **pim ipv6 triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. The switch does not support this function.
Pim neighbor-policy	Whether the neighbor-policy is set on the interface. ● enabled: A neighbor policy is configured on the interface. ● disabled: No neighbor policy is configured on the interface. This function is configured using the **pim ipv6 neighbor-policy** command.

8.4.18 display default-parameter pim-sm6

Function

The **display default-parameter pim-sm6** command displays default PIM-SM (IPv6) configurations.

Format

display default-parameter pim-sm6

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display default-parameter pim-sm6** command displays default configurations about PIM-SM (IPv6) for both ASM and SSM. Even if PIM-SM (IPv6) parameters are modified, the **display default-parameter pim-sm6** command still displays default parameter settings. This command helps you determine which parameters have been modified.

Example

Display default PIM-SM (IPv6) configurations.

```
<HUAWEI> display default-parameter pim-sm6
 PIM6 View Default Configurations:
  ---------------------------------
  Bsr-policy: disabled
  C-bsr admin-scope: disabled
  C-bsr global: disabled
  C-bsr group: none
  C-bsr hash-length: 126
  C-bsr holdtime: 130 s
  C-bsr interval: 60 s
  C-bsr priority: 0
  C-rp advertisement-interval: 60 s
  C-rp holdtime: 150 s
  C-rp priority: 192
  Crp-policy: disabled
  Bsm semantic fragmentation: disabled
  Embedded-rp: enabled
  Hello-option dr-priority: 1
  Hello-option holdtime: 105 s
  Hello-option lan-delay: 500 ms
  Hello-option neighbor-tracking: disabled
  Hello-option override-interval: 2500 ms
  Holdtime assert: 180 s
  Holdtime join-prune: 210 s
  Probe-interval: 5 s
  Register-policy: disabled
  Register-suppression-timeout: 60 s
  Source-lifetime: 210 s
  Source-policy: disabled
  Spt-switch-threshold: disabled
  Ssm-policy: disabled
  Static-rp:  disabled
  Hello periodic interval: 30 s
  Join-prune periodic interval: 60 s
  Timer spt-switch: 15 s

  Interface View Default Configurations:
  --------------------------------------
  Pim bfd: disabled
  Pim bsr-boundary: disabled
  Pim hello-option dr-priority: 1
  Pim hello-option holdtime: 105 s

Table 8-55 Description of the **display default-parameter pim-sm6** command output

Item	Description
PIM6 View Default Configurations	Default configurations in the PIM-IPv6 view.
Bsr-policy	Whether the valid address range of the BSR is set. This parameter is configured by the **bsr-policy (IPv6)** command.
C-bsr admin-scope	Whether the BSR administrative domain is configured. This parameter is configured by the **c-bsr admin-scope (IPv6)** command.
C-bsr global	Whether the C-BSR in the global domain is configured. This parameter is configured by the **c-bsr global (IPv6)** command.
C-bsr group	Whether the C-BSR in the BSR administrative domain is configured. This parameter is configured by the **c-bsr scope** command.
C-bsr hash-length	Global hash mask length of the C-BSR. This parameter is configured by the **c-bsr hash-length (IPv6)** command.
C-bsr holdtime	Waiting time for the BSR to receive the Bootstrap message. This parameter is configured by the **c-bsr holdtime (IPv6)** command.
C-bsr interval	Interval for the BSR to send Bootstrap messages. This parameter is configured by the **c-bsr interval (IPv6)** command.
C-bsr priority	Global priority of the C-BSR. This parameter is configured by the **c-bsr priority (IPv6)** command.
C-rp advertisement-interval	Interval for the C-RP to send Advertisement messages. This parameter is configured by the **c-rp advertisement-interval (IPv6)** command.
C-rp holdtime	Waiting time for the BSR to receive the Advertisement message. This parameter is configured by the **c-rp holdtime (IPv6)** command.
C-rp priority	Global priority of the C-RP. This parameter is configured by the **c-rp priority (IPv6)** command.

Item	Description
Crp-policy	Whether the valid address range of the C-RP and the range of multicast groups that the C-RP serves are set. This parameter is configured by the **crp-policy (IPv6)** command.
Bsm semantic fragmentation	Whether the BSR fragmentation is enabled. This parameter is configured by the **bsm semantic fragmentation (IPv6)** command.
Embedded-rp	Whether the embedded RP is enabled. This parameter is configured by the **embedded-rp** command.
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv6)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state. This parameter is configured by the **hello-option holdtime (IPv6)** command.
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment. This parameter is configured by the **hello-option lan-delay (IPv6)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. This parameter is configured by the **hello-option neighbor-tracking (IPv6)** command.
Hello-option override-interval	Interval for sending Prune Override messages. This parameter is configured by the **hello-option override-interval (IPv6)** command.
Holdtime assert	Time period for holding the Assert state. This parameter is configured by the **holdtime assert (IPv6)** command.
Holdtime join-prune	Time period for holding the Join or Prune state. This parameter is configured by the **holdtime join-prune (IPv6)** command.
Probe-interval	Interval for sending Probe messages (empty Register messages) to the RP. This parameter is configured by the **probe-interval (IPv6)** command.
Register-policy	Whether the rule for filtering Register messages is configured. This parameter is configured by the **register-policy (IPv6)** command.

Item	Description
Register-suppression-timeout	Time period for holding the register-suppression state. This parameter is configured by the **register-suppression-timeout (IPv6)** command.
Source-lifetime	Timeout period of an (S, G) entry. This parameter is configured by the **source-lifetime (IPv6)** command.
Source-policy	Whether the rule for filtering multicast sources is configured. This parameter is configured by the **source-policy (IPv6)** command.
Spt-switch-threshold	Whether the threshold of the multicast packet rate that triggers the switch from the RPT to the SPT is configured. This parameter is configured by the **spt-switch-threshold (IPv6)** command.
Ssm-policy	Whether the SSM group address range is set. This parameter is configured by the **ssm-policy (IPv6)** command.
Static-rp	Whether the static RP is configured. This parameter is configured by the **static-rp (IPv6)** command.
Hello periodic interval	Interval for sending Hello messages. This parameter is configured by the **timer hello (IPv6)** command.
Join-prune periodic interval	Interval for sending Join/Prune messages. This parameter is configured by the **timer join-prune (IPv6)** command.
Timer spt-switch	Whether the interval for checking whether the multicast packet rate exceeds the threshold before the switchover from RPT to SPT is configured. This parameter is configured by the **timer spt-switch (IPv6)** command.
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether the PIM BFD is enabled on the interface. This parameter is configured by the **pim ipv6 bfd enable** command.
Pim bsr-boundary	Whether the PIM boundary is configured on the interface. This parameter is configured by the **pim ipv6 bsr-boundary** command.

Item	Description
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim ipv6 hello-option dr-priority** command.
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state. This parameter is configured by the **pim ipv6 hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment on the interface. This parameter is configured by the **pim ipv6 hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. This parameter is configured by the **pim ipv6 hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages. This parameter is configured by the **pim ipv6 hello-option override-interval** command.
Pim holdtime assert	Time period for the interface to hold the Assert state. This parameter is configured by the **pim ipv6 holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state. This parameter is configured by the **pim ipv6 holdtime join-prune** command.
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. This parameter is configured by the **pim ipv6 require-genid** command.
Pim silent	Whether PIM Silent is enabled on the interface. This parameter is configured by the **pim ipv6 silent** command.
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. This parameter is configured by the **pim ipv6 timer dr-switch-delay** command.
Pim hello periodic interval	Interval for the interface to send Hello messages. This parameter is configured by the **pim ipv6 timer hello** command.
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages. This parameter is configured by the **pim ipv6 timer join-prune** command.

Item	Description
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages. This parameter is configured by the **pim ipv6 triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. The switch does not support this function.
Pim join-policy	Whether the join-policy is configured on the interface. This parameter is configured by the **pim ipv6 join-policy** command.
Pim neighbor-policy	Whether the neighbor-policy is configured on the interface. This parameter is configured by the **pim ipv6 neighbor-policy** command.

8.4.19 display default-parameter pim-ssm6

Function

The **display default-parameter pim-ssm6** command displays default configurations of PIM-SM (IPv6) for SSM.

 Pim join-policy: disabled
 Pim neighbor-policy: disabled
```

Table 8-56 Description of the **display default-parameter pim-ssm6** command output

Item	Description
PIM6 View Default Configurations	Default configurations in the PIM-IPv6 view.
Hello-option dr-priority	Priority for DR election. This parameter is configured by the **hello-option dr-priority (IPv6)** command.
Hello-option holdtime	Time period for the neighbor to hold the reachable state. This parameter is configured by the **hello-option holdtime (IPv6)** command.

Item	Description
Hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment. This parameter is configured by the **hello-option lan-delay (IPv6)** command.
Hello-option neighbor-tracking	Whether neighbor tracking is enabled. This parameter is configured by the **hello-option neighbor-tracking (IPv6)** command.
Hello-option override-interval	Interval for sending Prune Override messages. This parameter is configured by the **hello-option override-interval (IPv6)** command.
Holdtime assert	Time period for holding the Assert state. This parameter is configured by the **holdtime assert (IPv6)** command.
Holdtime join-prune	Time period for holding the Join or Prune state. This parameter is configured by the **holdtime join-prune (IPv6)** command.
Probe-interval	Interval for sending Probe messages (empty Register messages) to the RP. This parameter is configured by the **probe-interval (IPv6)** command.
Register-policy	Whether the rule for filtering Register messages is configured. This parameter is configured by the **register-policy (IPv6)** command.
Register-suppression-timeout	Time period for holding the register-suppression state. This parameter is configured by the **register-suppression-timeout (IPv6)** command.
Source-lifetime	Timeout period of an (S, G) entry. This parameter is configured by the **source-lifetime (IPv6)** command.
Source-policy	Whether the rule for filtering multicast sources is configured. This parameter is configured by the **source-policy (IPv6)** command.
Ssm-policy	Whether the SSM group address range is set. This parameter is configured by the **ssm-policy (IPv6)** command.
Hello periodic interval	Interval for sending Hello messages. This parameter is configured by the **timer hello (IPv6)** command.

Item	Description
Join-prune periodic interval	Interval for sending Join/Prune messages. This parameter is configured by the **timer join-prune (IPv6)** command.
Interface View Default Configurations	Default configurations in the interface view.
Pim bfd	Whether the PIM BFD is enabled on the interface. This parameter is configured by the **pim ipv6 bfd enable** command.
Pim hello-option dr-priority	Priority for DR election on the interface. This parameter is configured by the **pim ipv6 hello-option dr-priority** command.
Pim hello-option holdtime	Time period for the neighbor on the interface to hold the reachable state. This parameter is configured by the **pim ipv6 hello-option holdtime** command.
Pim hello-option lan-delay	Delay in transmitting Prune messages at a shared network segment on the interface. This parameter is configured by the **pim ipv6 hello-option lan-delay** command.
Pim hello-option neighbor-tracking	Whether neighbor tracking is enabled on the interface. This parameter is configured by the **pim ipv6 hello-option neighbor-tracking** command.
Pim hello-option override-interval	Interval for the interface to send Prune Override messages. This parameter is configured by the **pim ipv6 hello-option override-interval** command.
Pim holdtime assert	Time period for the interface to hold the Assert state. This parameter is configured by the **pim ipv6 holdtime assert** command.
Pim holdtime join-prune	Time period for the interface to hold the Join or Prune state. This parameter is configured by the **pim ipv6 holdtime join-prune** command.
Pim require-genid	Whether the received Hello message is required to carry the Generation ID. This parameter is configured by the **pim ipv6 require-genid** command.
Pim silent	Whether PIM Silent is enabled on the interface. This parameter is configured by the **pim ipv6 silent** command.

Item	Description
Pim timer dr-switch-delay	Whether the DR switch delay is set on the interface. This parameter is configured by the **pim ipv6 timer dr-switch-delay** command.
Pim hello periodic interval	Interval for the interface to send Hello messages. This parameter is configured by the **pim ipv6 timer hello** command.
Pim join-prune periodic interval	Interval for the interface to send Join/Prune messages. This parameter is configured by the **pim ipv6 timer join-prune** command.
Pim triggered-hello-delay	Maximum delay for the interface to send Hello messages. This parameter is configured by the **pim ipv6 triggered-hello-delay** command.
Pim version	Version of PIM enabled on the interface.
Pim ipsec sa	Whether PIM IPSec is enabled on the interface. The switch does not support this function.
Pim join-policy	Whether the join-policy is configured on the interface. This parameter is configured by the **pim ipv6 join-policy** command.
Pim neighbor-policy	Whether the neighbor-policy is configured on the interface. This parameter is configured by the **pim ipv6 neighbor-policy** command.

8.4.20 display pim ipv6 bsr-info

Function

The **display pim ipv6 bsr-info** command displays the BSRs in a PIM-SM (IPv6) domain.

Format

display pim ipv6 bsr-info

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check BSR configuration on a PIM-SM (IPv6) network.

Example

Display information about BSR in the current PIM-SM (IPv6) domain. If the switch is configured with C-BSR, information about the elected BSR and C-BSR is displayed.

```
<HUAWEI> display pim ipv6 bsr-info
VPN-Instance: public net
 Elected AdminScoped BSR Count: 0
 Elected BSR Address: FC00:0:0:2004::2
     Priority: 0
     Hash mask length: 128
     State: Elected
     Scope: 5
     Uptime: 00:00:07
     Next BSR message scheduled at: 00:00:53
     C-RP Count: 0
 Candidate AdminScoped BSR Count: 0
 Candidate BSR Address: FC00:0:0:2004::2
     Priority: 0
     Hash mask length: 128
     State: Elected
     Scope: 5
     Wait to be BSR: 0
```

Table 8-57 Description of the **display pim ipv6 bsr-info** command output

Item	Description
Elected AdminScoped BSR Count	number of elected AdminScoped BSRs.
Elected BSR Address	IPv6 address of the elected BSR.
Priority	Priority of the BSR.
Hash mask length	Mask length in the RP hash calculation.

Item	Description
State	Status of the BSR. - Accept Preferred: No C-BSR is configured on the device and another device functions as a BSR and does not time out. - Accept Any: No C-BSR is configured on the device and the current BSR times out (applicable to the situation that a BSR administrative domain is set) - Candidate: A C-BSR is configured on a device and another device functions as a BSR. - Pending: The device changes from the non-BSR state to the BSR state or a C-BSR is configured on the device and the current BSR times out. - Elected: The device is elected as the BSR.
Scope	Scope ID of the BSR administrative domain served by a BSR. Not scoped indicates that the BSR is not an AdminScoped BSR.
Uptime	Period during which the BSR exists.
Next BSR message scheduled at	Period after which the next BSR message is sent. BSR messages are sent only when the timer maintained by the elected BSR times out.
C-RP Count	Number of RPs learned through the BSR.
Candidate AdminScoped BSR Count	Number of AdminScoped C-BSRs.
Candidate BSR Address	IPv6 Address of the C-BSR.
Wait to be BSR	Whether the current C-BSR is valid. The values are as follows: - 0: The current C-BSR is valid. The current C-BSR takes part in the BSR election. - 1: The current C-BSR is invalid. The current C-BSR does not take part in the BSR election. When the number of C-BSRs configured on the switch exceeds the threshold, the value is 1.

8.4.21 display pim ipv6 bfd session

Function

The **display pim ipv6 bfd session** command displays information about PIM IPv6 BFD sessions.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display pim ipv6 bfd session statistics

display pim ipv6 bfd session [**interface** *interface-type interface-number* | **neighbor** *ipv6-link-local-address*]*

Parameters

Parameter	Description	Value
statistics	Displays statistics about PIM IPv6 BFD sessions.	-
interface *interface-type interface-number*	Displays information about PIM IPv6 BFD sessions on a specified interface. *interface-type interface-number* specifies the type and number of an interface.	-
neighbor *ipv6-link-local-address*	Displays information about PIM IPv6 BFD sessions on a specified neighbor. *ipv6-link-local-address* specifies the link-local address of a PIM neighbor.	The value ranges from FE80:: to FE80:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF, in hexadecimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After PIM BFD (IPv6) is configured to detect the status of PIM neighbors, a PIM IPv6 BFD session needs to be established. The **display pim ipv6 bfd session** command can be used to view statistics about and configurations of PIM IPv6 BFD sessions.

Precautions

The two ends of a BFD session negotiate the actual interval at which PIM IPv6 BFD packets are sent, the interval at which PIM IPv6 BFD packets are received, and the detection period based on the following negotiation mechanisms:

- The formula used to calculate the interval for sending PIM IPv6 BFD packets and the formula used to calculate the interval for receiving PIM IPv6 BFD packets are as follows:
  - Interval for sending PIM IPv6 BFD packets = Max (Local **min-tx-interval**, Remote **min-rx-interval**)
  - Interval for receiving PIM IPv6 BFD packets = Max (Remote **min-tx-interval**, Local **min-rx-interval**)
- The formula used to calculate the detection period is as follows:
  - Detection period = Remote **detect-multiplier** x Max (Remote **min-tx-interval**, Local **min-rx-interval**)

Example

Display information about PIM IPv6 BFD sessions on all interfaces.

```
<HUAWEI> display pim ipv6 bfd session
 VPN-Instance: public net
 Total 1 BFD session Created

 Vlanif100 (FE80::7): Total 1 BFD session Created

 Neighbor        ActTx(ms) ActRx(ms) ActMulti Local/Remote State
 FE80::6         200       300       4        8211/8214    Up
```

Display information about the PIM IPv6 BFD session on VLANIF 100.

```
<HUAWEI> display pim ipv6 bfd session interface vlanif 100
 VPN-Instance: public net

 Vlanif100 (FE80::7): Total 1 BFD session Created

 Neighbor        ActTx(ms) ActRx(ms) ActMulti Local/Remote State
 FE80::6         200       300       4        8211/8214    Up
```

Table 8-58 Description of the **display pim ipv6 bfd session** command output

Item	Description
Total 1 BFD session Created	Total number of established PIM IPv6 BFD sessions.
Vlanif100 (FE80::7)	PIM interface name (Link-local address).
Neighbor	IPv6 link-local address of a PIM neighbor.
ActTx(ms)	Actual interval for sending PIM IPv6 BFD packets.
ActRx(ms)	Actual interval for receiving PIM IPv6 BFD packets.
ActMulti	Actual detection multiplier of PIM IPv6 BFD packets.
Local/Remote	Local/remote discriminator of a PIM IPv6 BFD session.
State	Status of a PIM IPv6 BFD session: ● Up: indicates that the BFD session is set up successfully and detection packets are periodically exchanged. ● Init: indicates that the local end can communicate with the remote end and wants the session status to be Up. ● Admin down: indicates that the session is in the administratively Down state (The **shutdown** command is run in the BFD session view). ● Down: indicates that the BFD session is down.

Display statistics about PIM IPv6 BFD sessions.

```
<HUAWEI> display pim ipv6 bfd session statistics
 VPN-Instance: public net
  Total 1 PIM BFD session in this instance.

   Total 1 PIM BFD session up.
   Total 0 PIM BFD session down.
```

Table 8-59 Description of the display pim ipv6 bfd session statistics command output

Item	Description
Total 1 PIM BFD session in this instance	Total number of PIM IPv6 BFD sessions.
Total 1 PIM BFD session up	Total number of PIM IPv6 BFD sessions in the Up state.

Item	Description
Total 0 PIM BFD session down	Total number of PIM IPv6 BFD sessions in the Down state, that is, the total number of PIM IPv6 BFD sessions minus the number of PIM IPv6 BFD sessions in the Up state.

8.4.22 display pim ipv6 claimed-route

Function

The **display pim ipv6 claimed-route** command displays the unicast routing information used by PIM (IPv6).

Format

display pim ipv6 claimed-route [*ipv6-source-address*]

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is in hexadecimal format.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pim ipv6 claimed-route** command displays the unicast routes used by PIM (IPv6), such as the RPF neighbors, detailed information about interfaces, route types, and route selection policy.

Example

Display the unicast route of multicast source FC00:0:0:2001::2.

```
<HUAWEI> display pim ipv6 claimed-route fc00:0:0:2001::2
VPN-Instance: public net
multicast load-splitting rule: source-group
RPF information about: FC00:0:0:2001::2 in PIM-SM routing table
    RPF interface: Vlanif100, RPF neighbor: FE80::A01:100:1
    Referenced route/mask: FC00:0:0:2001::/64
    Referenced route type: igp
    RPF-route selecting rule: preference-preferred
    The (S, G) or (*, G) list dependent on this route entry
    (FC00:0:0:2001::2, FF03::1)
```

Table 8-60 Description of the **display pim ipv6 claimed-route** command output

Item	Description
multicast load-splitting rule	Mode in which multi-cast loads are split. The following policies apply: ● group: multicast group-based load splitting ● source: multicast source-based load splitting ● source-group: multicast source and group-based load splitting ● stable-preferred: stable-preferred load splitting ● balance-preferred: balance-preferred load splitting
RPF information about: FC00:0:0:2001::2 in PIM-SM routing table	RPF routing information with the source address of FC00:0:0:2001::2 in the PIM-SM (IPv6) routing table
RPF interface	RPF interface in a routing entry.
RPF neighbor	RPF neighbor in a routing entry.
Referenced route/mask	Route/mask used by PIM.
Referenced route type	Type of a route.
RPF-route selecting rule	Preferred rule for selecting the RPF-route.
The (S, G) or (*, G) list dependent on this route entry	List of multicast entries based on RPF routes.

8.4.23 display pim ipv6 control-message counters

Function

The **display pim ipv6 control-message counters** command displays the number of sent and received PIM (IPv6) control messages.

Format

display pim ipv6 control-message counters message-type { **probe** | **register** | **register-stop** | **crp** }

display pim ipv6 control-message counters [**message-type** { **assert** | **graft** | **graft-ack** | **hello** | **join-prune** | **state-refresh** | **bsr** } | **interface** *interface-type interface-number*] *

Parameters

Parameter	Description	Value
message-type	Indicates the types of PIM control message.	-
probe	Indicates the Probe message.	-
register	Indicates the Register message.	-
register-stop	Indicates the Register-stop message.	-
crp	Indicates the C-RP message.	-
assert	Indicates the Assert message.	-
graft	Indicates the Graft message.	-
graft-ack	Indicates the Graft-ack message.	-
hello	Indicates the Hello message.	-
join-prune	Indicates the Join-prune message.	-
state-refresh	Indicates the State-Refresh message.	-
bsr	Indicates the BSR message.	-
interface *interface-type interface-number*	Indicates the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When multicast forwarding fails on a PIM (IPv6) network, run the **display pim control-message counters** command to view statistics about protocol packets. The command output helps you locate faults.

Example

Display the number of PIM (IPv6) control messages that were sent and received on VLANIF100.

```
<HUAWEI> display pim ipv6 control-message counters interface vlanif 100
VPN-Instance: public net
 PIM control-message counters for interface: Vlanif100
 Message Type     Received         Sent            Invalid      Filtered
 Assert           0                0               0            0
 Graft            0                0               0            0
 Graft-Ack        0                0               0            0
 Hello            328              331             0            0
 Join-prune       2                0               0            0
 State-Refresh    0                0               0            0
 BSR              9778             0               0            0
```

Table 8-61 Description of the **display pim ipv6 control-message counters** command output

Item	Description
PIM control-message counters for interface	Name of the interface for collecting statistics on PIM control messages
Message Type	Type of the control messages.
Received	Number of control messages received by the current interface.
Sent	Number of control messages sent by the current interface.
Invalid	Number of invalid control packets.
Filtered	Number of control messages filtered out by the current interface.
Assert	Number of Assert messages.
Graft	Number of Graft messages.
Graft-Ack	Number of Graft-Ack messages.
Hello	Number of Hello messages.
Join-prune	Number of Join/Prune messages.
State-Refresh	Number of State-Refresh messages.
BSR	Number of Bootstrap messages.

8.4.24 display pim ipv6 grafts

Function

The **display pim ipv6 grafts** command displays the information about unacknowledged PIM-DM (IPv6) Graft messages.

Format

display pim ipv6 grafts

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In PIM-DM (IPv6), after sending the Graft message, the switch needs to wait to receive the Graft-Ack message from the upstream device.

You can run the **display pim ipv6 grafts** command to view the information about the PIM-DM (IPv6) Graft messages sent but unacknowledged.

Example

Display the unacknowledged PIM-DM (IPv6) graft messages.

```
<HUAWEI> display pim ipv6 grafts
Source                   Group                  Expire    RetransmitIn
fc00:0:0:2001::2           ff03::101              00:02:52  00:00:02
```

Table 8-62 Description of the **display pim ipv6 grafts** command output

Item	Description
Source	Multicast source address.
Group	Multicast group address.
Expire	Timeout period of an (S, G) entry.
RetransmitIn	Amount of time before the next Graft message is transmitted.

8.4.25 display pim ipv6 interface

Function

The **display pim ipv6 interface** command displays information about PIM (IPv6) on an interface.

Format

display pim ipv6 interface [*interface-type interface-number* | **up** | **down**] [**verbose**]

Parameters

Parameter	Description	Value
interface-type interface-number	Indicates the type and number of an interface.	-

Parameter	Description	Value
up	Indicates that the IPv6 status is Up on the PIM interface.	-
down	Indicates that the IPv6 status is Down on the PIM interface.	-
verbose	Indicates detailed information about a PIM (IPv6) interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An interface enabled with PIM (IPv6) is called a PIM (IPv6) interface. The **display pim ipv6 interface** command is used to display information about PIM (IPv6) interfaces, including status of the PIM (IPv6) interface, the number of PIM (IPv6) neighbors, interval at which Hello messages are sent, DR priority, and DR address.

Example

Display PIM (IPv6) information on VLANIF100.

```
<HUAWEI> display pim ipv6 interface vlanif 100
 VPN-Instance: public net
 Interface           State NbrCnt HelloInt   DR-Pri     DR-Address
 Vlanif100             up    0      30         1          FE80::2E0:3FFF:FE27:AE01(local)
```

Table 8-63 Description of the display pim ipv6 interface command output

Item	Description
Interface	Name of the PIM (IPv6) interface.
State	Status of the PIM (IPv6) interface, up or down.
NbrCnt	Number of PIM (IPv6) neighbors on the interface.
HelloInt	Interval for sending Hello messages, in seconds.
DR-Pri	DR priority.
DR-Address	DR address.

Display detailed information about PIM (IPv6) on VLANIF100.

```
<HUAWEI> display pim ipv6 interface vlanif 100 verbose
 VPN-Instance: public net
 Interface: Vlanif100, FE80::2E0:3FFF:FE27:AE01
     PIM version: 2
     PIM mode: Sparse
     PIM state: up
     PIM DR: FE80::2E0:3FFF:FE27:AE01 (local)
     PIM DR Priority (configured): 1
     PIM neighbor count: 0
     PIM hello interval: 30 s
     PIM LAN delay (negotiated): 500 ms
     PIM LAN delay (configured): 500 ms
     PIM hello override interval (negotiated): 2500 ms
     PIM hello override interval (configured): 2500 ms
     PIM Silent: disabled
     PIM neighbor tracking (negotiated): disabled
     PIM neighbor tracking (configured): disabled
     PIM generation ID: 0x18FF94EC
     PIM require-GenID: disabled
     PIM hello hold interval: 105 s
     PIM assert hold interval: 180 s
     PIM triggered hello delay: 5 s
     PIM J/P interval: 60 s
     PIM J/P hold interval: 210 s
     PIM BSR domain border: disabled
     PIM BFD: disabled
     PIM dr-switch-delay timer : not configured
     Number of routers on link not using DR priority: 0
     Number of routers on link not using LAN delay: 0
     Number of routers on link not using neighbor tracking: 1
     ACL of PIM neighbor policy: myacl6
     ACL of PIM ASM join policy: 2000
     ACL of PIM SSM join policy: -
     ACL of PIM join policy: -
```

Table 8-64 Description of the **display pim ipv6 interface verbose** command output

Item	Description
PIM version	Version number of PIM (IPv6) enabled on the interface.
PIM mode	PIM mode.
PIM state	Status of the PIM (IPv6) interface, up or down.
PIM DR	DR address on the interface.
PIM DR Priority (configured)	Configured DR priority on the interface.
PIM neighbor count	Number of PIM (IPv6) neighbors on the interface.
PIM hello interval	Interval for sending Hello messages.
PIM LAN delay (negotiated)	Negotiated delay for transmitting packets on the interface.
PIM LAN delay (configured)	Configured delay for transmitting packets on the interface.

Item	Description
PIM hello override interval (negotiated)	Negotiated override interval on the interface.
PIM hello override interval (configured)	Configured override interval on the interface.
PIM Silent	Whether the PIM Silent (IPv6) function is enabled on the interface.
PIM neighbor tracking (negotiated)	Whether the PIM (IPv6) neighbor tracking function is enabled on the interface after negotiation.
PIM neighbor tracking (configured)	Whether the PIM (IPv6) neighbor tracking function is configured on the interface.
PIM generation ID	Generation ID option on the interface.
PIM require-GenID	Whether the function of rejecting the Hello messages without the Generation ID option is enabled.
PIM hello hold interval	Interval for the receiver of the Hello message to keep its neighbor reachable.
PIM assert hold interval	Interval for sending Assert messages.
PIM triggered hello delay	Maximum random delay for triggering Hello messages.
PIM J/P interval	Interval for the interface to send Join/Prune messages.
PIM J/P hold interval	Period for holding the Join/Prune status on the interface.
PIM BSR domain border	Whether the BSR domain boundary is configured on the interface.
PIM dr-switch-delay timer	DR switching delay.
Number of routers on link not using DR priority	Number of switches that do not use DR priority in all the network segments connected to the interface.
Number of routers on link not using LAN delay	Number of switches that do not use LAN delay in all the network segments connected to the interface.
Number of routers on link not using neighbor tracking	Number of switches that are not enabled with the neighbor tracing function in the network segment where the interface resides.
ACL of PIM neighbor policy	Neighbor filtering policy configured on the interface.

Item	Description
ACL of PIM ASM join policy	ASM Join information filtering policy configured on the interface.
ACL of PIM SSM join policy	SSM Join information filtering policy configured on the interface.
ACL of PIM join policy	Join information filtering policy configured on the interface.

8.4.26 display pim ipv6 invalid-packet

Function

The **display pim ipv6 invalid-packet** command displays statistics about invalid PIM (IPv6) messages received by a device and details of these messages.

Format

display pim ipv6 invalid-packet [**interface** *interface-type interface-number* | **message-type** { **assert** | **bsr** | **hello** | **join-prune** | **graft** | **graft-ack** | **state-refresh** }] *

display pim ipv6 invalid-packet message-type { **crp** | **register** | **register-stop** }

display pim ipv6 invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about invalid PIM (IPv6) messages received by a specified interface. *interface-type interface-number* specifies the interface type and interface number.	-
message-type	Displays statistics about invalid PIM (IPv6) messages of a specific type.	-
assert	Displays statistics about invalid Assert messages.	-
bsr	Displays statistics about invalid BSR messages.	-
hello	Displays statistics about invalid Hello messages.	-

Parameter	Description	Value
join-prune	Displays statistics about invalid Join/ Prune messages.	-
graft	Displays statistics about invalid Graft messages.	-
graft-ack	Displays statistics about invalid Graft-Ack messages.	-
state-refresh	Displays statistics about invalid State-Refresh messages.	-
crp	Displays statistics about invalid C-RP messages.	-
register	Displays statistics about invalid Register messages.	-
register-stop	Displays statistics about invalid Register-Stop messages.	-
packet-number	Displays details of a specified number of invalid PIM (IPv6) messages recently received.	The value is an integer that ranges from 1 to 100. By default, details of all the invalid PIM (IPv6) messages currently stored are displayed.
verbose	Displays details of invalid PIM (IPv6) messages.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

When a fault occurs on a PIM (IPv6) network, use the **display pim ipv6 invalid-packet** command to check statistics and details about invalid PIM (IPv6) packets. The command output can help you locate the fault.

If PIM (IPv6) entries fail to be generated on a multicast network, you can run the **display pim ipv6 invalid-packet** command first to check whether devices have received invalid PIM (IPv6) messages. If the command output contains statistics about invalid PIM (IPv6) messages, run the **display pim ipv6 invalid-packet** [*packet-number*] **verbose** command to view details of invalid PIM (IPv6) messages to locate the fault.

You can run the following related commands to view information about specific invalid IPv6 PIM messages:

- Run the **display pim ipv6 invalid-packet** command to view statistics about invalid IPv6 PIM messages received by a device in the public network instance.
- Run the **display pim ipv6 invalid-packet interface** *interface-type interface-number* command to view statistics about invalid IPv6 PIM messages received by a specified interface.
- Run the **display pim ipv6 invalid-packet** *packet-number* **verbose** command to view details of invalid IPv6 PIM messages recently received. Currently, details of a maximum of 100 invalid IPv6 PIM messages can be displayed.

Example

Display statistics about invalid PIM (IPv6) messages received by a device.

```
<HUAWEI> display pim ipv6 invalid-packet

          Statistics of invalid packets for public net:
-------------------------------------------------------------------
PIM General invalid packet: Invalid PIM Version     : 0          Invalid PIM Type        : 0 Fault Length            :
0          Bad Checksum           : 0
PIM Register invalid packet:
Invalid Multicast Source: 0          Invalid Multicast Group : 0
Invalid Dest Addr       : 0

PIM Register-Stop invalid packet:
Invalid Multicast Source: 0          Invalid Multicast Group : 0
Invalid Dest Addr       : 0          IP Source not RP        : 0

PIM CRP invalid packet:
Invalid Dest Addr       : 0          Invalid CRP Addr        : 0
Fault Length            : 0          CRP Adv Fault Length    : 0
Invalid Multicast Group : 0

PIM Assert invalid packet:
Invalid Dest Addr       : 0          Invalid IP Source Addr  : 0
Invalid Multicast Source: 0          Invalid Multicast Group : 0

PIM BSR invalid packet:
Bad Payload             : 0          Fault Length            : 0
Bad Scope Mask          : 0          Invalid Multicast Group : 0
Not CBSR But BSR        : 0          Invalid BSR Addr        : 0
Fault Hash Length       : 0          Invalid IP Source Addr  : 0

PIM Hello invalid packet:
Invalid Addr List       : 0          Fault Length            : 0
Bad Holdtime Length     : 0          Bad LanPruneDelay Length: 0
Bad DrPriority Length   : 0          Bad GenID Length        : 0
Invalid Dest Addr       : 0          Invalid IP Source Addr  : 0

PIM Join/Prune invalid packet:
Invalid Multicast Source: 0          Invalid Multicast Group : 0
Invalid Up Neighbor     : 0          Invalid IP Source Addr  : 0
Invalid Dest Addr       : 0          Fault Length            : 0
 PIM Graft invalid packet: Invalid Multicast Source: 0          Invalid Multicast Group : 0 Invalid Up
```

```
Neighbor     : 0           Invalid IP Source Addr  : 0 Fault Length            : 0  PIM Graft-Ack invalid packet:
Invalid Multicast Source: 0           Invalid Multicast Group : 0 Invalid Up Neighbor     : 0           Invalid IP
Source Addr  : 0 Fault Length            : 0  PIM State Refresh invalid packet: Invalid Multicast Source: 0
Invalid Multicast Group : 0 Invalid Originator Addr : 0           Fault Length            : 0
----------------------------------------------------------------------
```

Table 8-65 Description of the **display pim ipv6 invalid-packet** command output

Item	Description
PIM General invalid packet	Number of general invalid PIM (IPv6) messages.
Invalid PIM Version	Number of messages with invalid PIM (IPv6) version.
Invalid PIM Type	Number of messages with invalid PIM (IPv6) message type.
Fault Length	Number of messages with invalid lengths.
Bad Checksum	Number of messages with invalid checksum.
PIM Register invalid packet	Number of PIM Register messages.
Invalid Multicast Source	Number of messages with invalid multicast source addresses.
Invalid Multicast Group	Number of messages with invalid multicast group addresses.
Invalid Dest Addr	Number of messages with invalid destination addresses.
PIM Register-Stop invalid packet	Number of invalid Register-Stop messages.
IP Source not RP	Number of messages whose source addresses are not the RP address.
PIM CRP invalid packet	Number of invalid C-RP messages.
Invalid CRP Addr	Number of messages with invalid C-RP addresses.
CRP Adv Fault Length	Number of messages with CRP Adv fields of invalid lengths.
PIM Assert invalid packet	Number of invalid Assert messages.
Invalid IP Source Addr	Number of messages with invalid source addresses.
PIM BSR invalid packet	Number of invalid BSR messages.
Bad Payload	Number of messages with invalid payloads.
Bad Scope Mask	Number of messages with invalid scope masks.

Item	Description
Not CBSR But BSR	Number of messages received from non-C-BSRs.
Invalid BSR Addr	Number of messages with invalid BSR addresses.
Fault Hash Length	Number of messages whose hash mask fields of invalid lengths.
PIM Hello invalid packet	Number of invalid Hello messages.
Invalid Addr List	Number of messages with invalid address lists.
Bad Holdtime Length	Number of messages whose Holdtime fields are of invalid lengths.
Bad LanPruneDelay Length	Number of messages whose LanPruneDelay fields are of invalid lengths.
Bad DrPriority Length	Number of messages with DrPriority fields of invalid lengths.
Bad GenID Length	Number of messages with GenerationID fields of invalid lengths.
PIM Join/Prune invalid packet	Number of invalid Join/Prune messages.
Invalid Up Neighbor	Number of messages with invalid upstream neighbors.
PIM Graft invalid packet	Number of invalid Graft messages.
PIM Graft-Ack invalid packet	Number of invalid Graft-Ack messages.
PIM State Refresh invalid packet	Number of invalid State-Refresh messages.
Invalid Originator Addr	Number of messages with invalid Originator address.

Display details of one invalid PIM (IPv6) message recently received lately.

```
<HUAWEI> display pim ipv6 invalid-packet 1 verbose
      Detailed information of invalid packets
-------------------------------------------------------
Packet information (Index 1):
-------------------------------------------------------
Interface           :  Vlanif100
Time                :  2012-06-01 20:04:35 UTC-08:00
Message Length      :  26
Invalid Type        :  Invalid Multicast Source

-------------------------------------------------------
```

Table 8-66 Description of the display pim ipv6 invalid-packet 1 verbose command output

Item	Description
Detailed information of invalid packets	Details about invalid PIM (IPv6) messages.
Packet information (Index 1)	Sequence number of an invalid PIM (IPv6) message (numbered in the opposite order).
Interface	Number of interfaces that receive the invalid PIM (IPv6) message.
Time	Time when the invalid SPT switch message was received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST The format UTC±HH:MM indicates that a time zone was configured with the **clock timezone** command; DST indicates that the daylight saving time is configured through **clock daylight-saving-time** command.
Message Length	Length of the invalid PIM (IPv6) message.
Invalid Type	Type of the invalid PIM (IPv6) message.
0000: 25 00 96 77 01 00 00 20 e1 01 01 01 01 00 e0 00 0010: 00 00 80 00 00 64 00 00 00 00	Contents of the invalid PIM (IPv6) message.

8.4.27 display pim ipv6 neighbor

Function

The **display pim ipv6 neighbor** command displays information about PIM (IPv6) neighbors.

Format

display pim ipv6 neighbor [*ipv6-link-local-address* | **interface** *interface-type interface-number* | **verbose**] *

Parameters

Parameter	Description	Value
ipv6-link-local-address	Specifies the IPv6 link-local address of a neighbor.	The value ranges from FE80:: to FE80:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF, in hexadecimal notation.
interface *interface-type interface-number*	Specifies the type and number of an interface.	-
verbose	Indicates the details of PIM neighbors.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pim ipv6 neighbor** command displays PIM (IPv6) neighbor information, including the number of PIM (IPv6) neighbors and DR priorities of neighbors. You can adjust PIM (IPv6) neighbor relationships according to the command output.

Example

Display detailed information about PIM (IPv6) neighbors on VLANIF100.

```
<HUAWEI> display pim ipv6 neighbor interface vlanif 100 verbose
 VPN-Instance: public net

 Total Number of Neighbors on this interface  = 1

Neighbor: FE80::FFE0:FFFF:FE4A:8E04
     Interface: Vlanif100
     Uptime: 00:01:18
     Expiry time: 00:01:31
     DR Priority: 1
     Generation ID: 0x7751638D
     Holdtime: 105 s
     LAN delay: 500 ms
     Override interval: 2500 ms
     Neighbor tracking: disabled
     PIM BFD-session: N
     Neighbor Secondary Address(es):
     FC00:0:0:2004::2
```

Table 8-67 Description of the **display pim ipv6 neighbor** command output

Item	Description
Total Number of Neighbors on this interface	Total number of PIM (IPv6) neighbors on an interface.
Neighbor	Address of a PIM (IPv6) neighbor.
Interface	Interface where the PIM (IPv6) neighbor resides.
Uptime	How long has the PIM (IPv6) neighbor been in Up state.
Expiry time	How soon the PIM (IPv6) neighbor will time out.
DR Priority	DR priority of the PIM (IPv6) neighbor.
Generation ID	Indicates the randomly generated 32-bit value of PIM (IPv6) neighbor.
Holdtime	Keepalive period of the PIM (IPv6) neighbor.
LAN delay	Delay in transmitting Prune messages.
Override interval	Interval for overriding the Prune action.
Neighbor tracking	Whether the neighbor tracking neighbor function is enabled.
PIM BFD-session	Whether a BFD session is set up.
Neighbor Secondary Address (es)	IPv6 address of the neighbor.

8.4.28 display pim ipv6 routing-table

Function

The **display pim ipv6 routing-table** command displays the PIM (IPv6) multicast routing table.

Format

display pim ipv6 routing-table [*ipv6-source-address* [**mask** *mask-length*] | *ipv6-group-address* [**mask** *mask-length*] | **flags** *flag-value* | **fsm** | **incoming-interface** { *interface-type interface-number* | **register** } | **mode** { **dm** | **sm** | **ssm** } | **outgoing-interface** { **exclude** | **include** | **match** } { *interface-type interface-number* | **none** | **register** }] * [**outgoing-interface-number** [*number*]]

display pim ipv6 routing-table brief [*ipv6-source-address* [**mask** *mask-length*] | *ipv6-group-address* [**mask** *mask-length*] | **incoming-interface** { *interface-type interface-number* | **register** }] *

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-group-address	Specifies the IPv6 address of a multicast group address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
mask *mask-length*	Specifies the mask length of a multicast source or group.	The value is an integer. The mask length of a multicast source ranges from 0 to 128. The mask length of a multicast group ranges from 8 to 128.
flags *flag-value*	Displays of routing entries of a specified type. *flag-value* specifies the flag of a routing entry.	-
fsm	Displays detailed information about the finite state machine (FSM).	-
incoming-interface	Displays the routing entry with the specified upstream interface.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Displays the register interface.	-
dm	Displays PIM-DM (IPv6) routing entries.	-
sm	Displays PIM-SM (IPv6) routing entries.	-
ssm	Displays PIM-SSM (IPv6) routing entries.	-

Parameter	Description	Value
outgoing-interface { **exclude** | **include** | **match** }	Displays the routing entries with or without a specified outbound interface. - exclude: displays the entries that do not contain the specified interface. - include: displays the entries that contain the specified interface. - match: displays the entries match the specified interface.	-
none	Displays the routing entry without the downstream interface.	-
outgoing-interface-number	Displays the number of the outbound interfaces of routing entries.	-
number	Specifies the number of the outbound interfaces to be queried.	-
brief	Displays only the name of upstream interface and the number of downstream interfaces of routing entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to:

- Check whether PIM (IPv6) has been configured successfully on the network.
- Check the inbound interfaces, outbound interfaces, flags, and other information in the routing entries to identify failure points when forwarding errors occur on the PIM (IPv6) network.

The PIM (IPv6) routing table includes both (*, G) and (S, G) entries. (*, G) entries are used to set up a rendezvous point tree (RPT), and (S, G) entries are used to set up a shortest path tree (SPT).

Table 8-68 lists the values of the **flags** *flag-value* parameter.

Table 8-68 Values of the *flag-value* parameter

Item	Description
act	Indicates that the multicast routing entry at which actual data arrives exists.
del	Indicates the multicast routing entry to be deleted.
exprune	Indicates that the entry on the RPT is pruned and no receiver on the RPT requests the information sent by the source.
ext	Indicates routing entries that contain downstream interfaces provided by other multicast routing protocols.
loc	Indicates routing entries on the switch directly connected to the network segment where the source resides.
niif	Indicates routing entries with unknown upstream interfaces.
nonbr	Indicates that the routing entry of the upstream neighbor address (link-local address) towards the RP or the source is not found.
none	Indicates routing entries without any flag.
rpt	Indicates the routing entries that are on the RPT but do not use the RPT data.
sg_rcvr	Indicates that the (S, G) receiver of S exists on the local switch and PIM (IPv6) is the owner of the downstream interface.
sgjoin	Indicates that the (S, G) receiver of S exists on the local switch and PIM (IPv6) is not the owner of the downstream interface.
spt	Indicates routing entries on the shortest path tree (SPT).
swt	Indicates routing entries during the SPT switchover.
upchg	Indicates a route change has occurred. The current entry uses the original upstream interface to forward data and waits for data received from a new interface.
wc	Indicates a (*, G) entry.

Example

Display the PIM (IPv6) multicast routing table.

```
<HUAWEI> display pim ipv6 routing-table
 VPN-Instance: public net
 Total 1 (*, G) entry; 1 (S, G) entry

 (*, FFE3::1)
     RP: FC00:0:0:1::1
     Protocol: pim-sm, Flag: WC
     UpTime: 00:57:31
     Upstream interface: NULL
         Upstream neighbor: NULL
```

```
        RPF prime neighbor: NULL
    Downstream interface(s) information:
    Total number of downstreams: 1
        1: Vlanif10
            Protocol: static, UpTime: 00:57:31, Expires: never

(FC00:0:0:2001::2, FFE3::1)
    RP: FC00:0:0:1::1
    Protocol: pim-sm, Flag: ACT WC
    UpTime: 00:04:24
        1: Vlanif20
        Upstream neighbor: FE80::A01:100:1
        RPF prime neighbor: FE80::A01:100:1
    Downstream interface(s) information:
    Upstream interface: Vlanif10
            Protocol: pim-dm, UpTime: 00:04:24, Expires:  -
```

Table 8-69 Description of the **display pim ipv6 routing-table** command output

Item	Description
Total 1 (*, G) entry; 1 (S, G) entry	Total number of the (S, G) entries and (*, G) entries in the PIM routing table.
(*, FFE3::1)	(*, G) entry in the PIM routing table.
RP	RP address.
Protocol	Type of PIM (IPv6) protocols, PIM-DM (IPv6), PIM-SM (IPv6), or PIM-SSM (IPv6).
Flag	Flag of a (S, G) entry or (*, G) entry in the PIM (IPv6) routing table.
UpTime	Lifetime of an interface.
Upstream interface	Upstream interface of a (S, G) entry or (*, G) entry.
Upstream neighbor	Upstream neighbor of a (S, G) entry or (*, G) entry.
RPF prime neighbor	RPF neighbor of a (S, G) entry or (*, G) entry. ● For a (*, G) entry, when the local device is an RP, the RPF neighbor is Null. ● For a (S, G) entry, when the local device is directly connected to the multicast source, the RPF neighbor is Null.

Item	Description
Downstream interface(s) information	Information about downstream interfaces, including: - Number of downstream interfaces - Names of downstream interfaces - Type of the PIM (IPv6) protocol configured on the downstream interfaces - Existing period and timeout period of downstream interfaces
Total number of downstreams	Number of downstream interfaces.
Vlanif10	Interface name.
Expires	Timeout period of an entry.

Display the brief information about PIM (IPv6) routing entries.

```
<HUAWEI> display pim ipv6 routing-table brief FF25::1
 VPN-Instance: public net
 Total 3 (*, G) entries; 3 (S, G) entries

 Total matched 1 (*, G) entry; 1 (S, G) entry

  00001. (FC00:0:0:2008::55, FF25::1)
       Upstream interface: Vlanif10
       Number of downstreams: 2
  00002. (*, FF25::1)
       Upstream interface: Vlanif10
       Number of downstreams: 2
```

Table 8-70 Description of the display pim ipv6 routing-table brief command output

Item	Description
Total 3 (*, G) entries; 3 (S, G) entries	Total number of the (S, G) entries and (*, G) entries in the PIM (IPv6) routing table.
Total matched 1 (*, G) entry; 1 (S, G) entry	Total number of the (S, G) entries and (*, G) entries that meet the query conditions in the PIM routing table.
00001. (FC00:0:0:2008::55, FF25::1)	(S, G) entry.
Number of downstreams	Number of downstream interfaces in (S, G) entries or (*, G) entries.

Display the number of the outbound interfaces of PIM (IPv6) routing entries.

```
<HUAWEI> display pim ipv6 routing-table outgoing-interface-number
 VPN-Instance: public net
```

```
Total 2 (*, G) entries; 0 (S, G) entry

(*, FF25::1)
    RP: FC00:0:0:2008::5:3:2 (local)
    Protocol: pim-sm, Flag: WC
    UpTime: 00:00:04
    Upstream interface: Register
        Upstream neighbor: NULL
        RPF prime neighbor: NULL
    Downstream interface(s) information:
    Total number of downstreams: 2

(*, FF25::2)
    RP: FC00:0:0:2008::5:3:2 (local)
    Protocol: pim-sm, Flag: WC
    UpTime: 00:00:05
    Upstream interface: Register
        Upstream neighbor: NULL
        RPF prime neighbor: NULL
    Downstream interface(s) information:
    Total number of downstreams: 2
```

8.4.29 display pim ipv6 rp-info

Function

The **display pim ipv6 rp-info** command displays information about the RP corresponding to a multicast group.

Format

display pim ipv6 rp-info [*ipv6-group-address*]

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies a multicast group address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display pim ipv6 rp-info** command displays information about the RP to which a multicast group corresponds. This command can help determine whether multicast forwarding errors are caused by faults of an RP.

Precautions

The RP information contains the information about the RP discovered through the BSR mechanism and static RP.

If the group address is not specified in this command, the corresponding RP information of all the multicast groups is displayed.

Example

Display the RP of multicast group FF1E::1.

```
<HUAWEI> display pim ipv6 rp-info ff1e::1
 VPN-Instance: public net
 BSR RP Address is: FE1E::1
     Priority: 192
     Uptime: 00:00:52
     Expires: 00:01:38
 RP mapping for this group is: FC00:0:0:2001::1 (local host)
```

Table 8-71 Description of the **display pim ipv6 rp-info** command output

Item	Description
VPN-Instance	VPN instance to which RP information belongs. **public net** indicates the public network instance.
BSR RP Address is	IP address of a dynamical RP
Priority	RP priority
Uptime	Period during which the RP exists
Expires	Time before an RP times out
RP mapping for this group is	Address of the RP to which multicast group corresponds

8.4.30 embedded-rp

Function

The **embedded-rp** command enables the embedded RP function.

The **undo embedded-rp** command disables the embedded RP function.

By default, the embedded RP function is enabled.

Format

embedded-rp [*basic-acl6-number*]

undo embedded-rp [*basic-acl6-number*]

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the number of the basic ACL.	The value is an integer that ranges from 2000 to 2999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The embedded RP function is enabled by default after PIM-SM (IPv6) is enabled. This function enables the switch to obtain the RP address from the IPv6 multicast address of a received multicast packet, so that the switch does not need to know the RP information beforehand.

By default, the switch can parse group addresses in the range of FF7x::/12. The value of x can be 0 or any integer in the range of 3 to F. When the switch receives a multicast packet with an IPv6 group address in this range, the switch can obtain the RP address from the IPv6 group address. This RP will replace the static RP or dynamically elected RP. If you do not want the switch to use RP information obtained from IPv6 multicast addresses of multicast packets, run the **undo embedded-rp** command to disable the embedded RP function.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If an IPv6 ACL is specified in the command, the final group address range for embedded RP is the intersection of the group address range specified by the IPv6 ACL and the default group address range. All the devices in the PIM (IPv6) domain must be configured with the same group address range.

The **embedded-rp** command and the **acl** command are used together.

- For the IPv6 numbered ACL, in the ACL6 view, you can set the source address range of multicast groups that is enabled with the embedded RP by specifying the **source** parameter in the **rule** command.
- For the IPv6 Named ACL, in the ACL6 view, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the address range of multicast groups that is specified by the **destination** parameter and with the time period that is specified by the **time-range** parameter.

This command is cyclical in nature. That is, the latest command overwrites the previous one, and takes effect.

Example

Enable the embedded RP function on multicast group ff73::.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2000
[HUAWEI-acl6-basic-2000] rule permit source ff73:: 12
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] embedded-rp 2000
```

8.4.31 graceful-restart (IPv6)

Function

The **graceful-restart** command enables PIM GR.

The **undo graceful-restart** command disables PIM GR.

By default, PIM GR is not enabled.

Format

graceful-restart

undo graceful-restart

Parameters

None

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a stack is used on the PIM-SM (IPv6) network, multicast data transmission is interrupted after an active/standby switchover occurs in the stack, because the slave switch on the new master device does not have PIM (IPv6) forwarding entries.

PIM GR enables the system to back up join and prune information in PIM (IPv6) routing entries to the new master device when an active/standby switchover is performed in the system. This ensures normal multicast data forwarding during restoration of the multicast distribution tree. For details about stack configuration, see Stack Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Device Management*.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

At least one interface must have PIM-SM (IPv6) enabled for the **graceful-restart** command to take effect.

Example

Enable PIM GR in the PIM-IPv6 view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] graceful-restart
```

8.4.32 graceful-restart period (IPv6)

Function

The **graceful-restart period** command configures the minimum PIM GR period.

The **undo graceful-restart period** command restores the default minimum PIM GR period.

By default, the minimum PIM GR period is 120 seconds.

Format

graceful-restart period *period*

undo graceful-restart period

Parameters

Parameter	Description	Value
period	Specifies the minimum PIM GR period.	The value is an integer that ranges from 90 to 3600 in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **graceful-restart period** command ensures the minimum time for maintaining forwarding entries.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

Unicast protocol GR forms the basis of PIM GR; therefore, the minimum PIM GR period should be longer than the corresponding unicast protocol GR period.

The PIM GR period also depends on the complexity of the network topology and increases with the expansion of unicast route capacity and multicast route capacity.

Example

Set the minimum PIM GR period in the PIM-IPv6 view to 150 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] graceful-restart
[HUAWEI-pim6] graceful-restart period 150
```

8.4.33 hello-option dr-priority (IPv6)

Function

The **hello-option dr-priority** command configures the designated router (DR) priority for the switch.

The **undo hello-option dr-priority** command restores the default DR priority.

By default, the DR priority for the switch is 1.

Format

hello-option dr-priority *priority*

undo hello-option dr-priority

Parameters

Parameter	Description	Value
priority	Specifies the DR priority of the switch.	The value is an integer that ranges from 0 to 4294967295. The greater the value, the higher the priority.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IPv6 PIM-SM network, switches on a shared network segment are candidates for the DR. The DR is responsible for the registering of the local multicast source and the joining of the receivers.

The DR is elected based on the priority and the IPv6 address. The switches send Hello messages carrying the priority for DR election. The switch with the highest priority becomes the DR. If the switches have the same priority, the switch with the largest IPv6 address becomes the DR.

If at least one switch in the network does not support Hello packets that contain the priority, the switch with the largest IPv6 address functions as the DR.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **hello-option dr-priority** command has the same function as the **pim ipv6 hello-option dr-priority** command in the interface view. By default, if the **pim ipv6 hello-option dr-priority** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM-IPv6 view, configure the DR priority of a switch to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] hello-option dr-priority 3
```

8.4.34 hello-option holdtime (IPv6)

Function

The **hello-option holdtime** command sets the timeout period for a switch to wait to receive Hello messages from its PIM neighbor.

The **undo hello-option holdtime** command restores the default configuration.

By default, the timeout period for a switch to wait to receive Hello messages from its PIM neighbor is 105 seconds.

Format

hello-option holdtime *interval*

undo hello-option holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout time during which a switch waits to receive a Hello message from its PIM neighbor.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the PIM (IPv6) network, after a switch receives a Hello message from its PIM neighbor, the switch starts a timer based on the Holdtime value in the Hello message. If the switch does not receive any Hello message from its PIM neighbor when the timer expires, it considers the neighbor invalid or unreachable.

The **hello-option holdtime (IPv6)** command sets the timeout period during which a PIM interface waits to receive the Hello message from its neighbor.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The timeout period must be greater than the interval for sending Hello messages. You can run the **timer hello (IPv6)** command to set the interval for sending Hello messages.

The **hello-option holdtime** command has the same function as the **pim ipv6 hello-option holdtime** command in the interface view. By default, if the **pim ipv6 hello-option holdtime** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM-IPv6 view, set the timeout interval to 120 seconds. The timeout interval is the period during which a switch waits to receive the Hello message from its PIM neighbor.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] hello-option holdtime 120
```

8.4.35 hello-option lan-delay (IPv6)

Function

The **hello-option lan-delay** command sets the delay in transmitting Prune message on the shared network segment.

The **undo hello-option lan-delay** command restores the default delay.

By default, the delay in transmitting Prune message on the shared network segment is 500 milliseconds.

Format

hello-option lan-delay *interval*

undo hello-option lan-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay in transmitting Prune message on the shared network segment.	The value is an integer that ranges from 1 to 32767, in milliseconds (ms).

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent switches carry **lan-delay** and **override-interval** values. The **lan-delay** parameter indicates the delay in transmitting messages in the LAN. If devices on the same link have different **lan-delay** values, the maximum value is used.

When a switch sends a Prune message to the upstream device in the same network segment, the other devices that still request multicast data need to send a Join message to the upstream device within the override-interval period.

The value of the Prune-Pending Timer (PPT) is the sum of **lan-delay** and **override-interval** values and refer to the delay from the current device receiving a Prune message from the downstream interface to performing the prune action. If the switch receives a Join message from the downstream interface before the PPT timer expires, it cancels the prune action.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If the delay in transmitting Prune message is too short, the upstream device will stop forwarding multicast packets before the downstream device determines whether to override the Prune action or not. Exercise caution when you run the **hello-option lan-delay** command.

The **hello-option lan-delay** command has the same function as the **pim ipv6 hello-option lan-delay** command in the interface view. By default, if the **pim ipv6 hello-option lan-delay** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the delay in transmitting Prune message on the shared network segment to 200 ms in the PIM-IPv6 view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] hello-option lan-delay 200
```

8.4.36 hello-option neighbor-tracking (IPv6)

Function

The **hello-option neighbor-tracking** command enables the neighbor tracking function.

The **undo hello-option neighbor-tracking** command restores the default configuration.

By default, the neighbor tracking function is not enabled.

Format

hello-option neighbor-tracking

undo hello-option neighbor-tracking

Parameters

None

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When sending a Hello message, the switch generates a Generation ID and encapsulates it into the message. The Generation ID changes only when the device status changes. In this case, the neighboring device detects the Generation ID change after receiving the Hello message and immediately sends a Join message to the device to update the neighbor relationship. If multiple devices on a shared network segment prepare to send Join messages to the same upstream PIM neighbor, only one device is allowed to send the Join message. After other devices detect the Join message, they do not send Join messages to the upstream neighbor. This means that the upstream neighbor cannot update neighbor relationships with downstream devices after a Generation ID change.

When the switch with neighbor tracking enabled detects Join messages from other devices, the switch still sends the Join messages to the same upstream PIM neighbor.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-SM (IPv6).

Neighbor tracking can be implemented only when this function is enabled on all devices on the shared network segment.

The **hello-option neighbor-tracking** command has the same function as the **pim ipv6 hello-option neighbor-tracking** command in the interface view. By default, if neighbor tracking is not used on an interface, the neighbor tracking configuration in the PIM-IPv6 view takes effect.

Example

In the PIM-IPv6 view, enable the downstream neighbor tracking function.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] hello-option neighbor-tracking
```

8.4.37 hello-option override-interval (IPv6)

Function

The **hello-option override-interval** command sets the interval for overriding the prune action in a Hello message.

The **undo hello-option override-interval** command restores the default interval.

By default, the interval for overriding the prune action in a Hello message is 2500 ms.

Format

hello-option override-interval *interval*

undo hello-option override-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for overriding the prune action in a Hello message.	The value is an integer that ranges from 1 to 65535, in milliseconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** values. The **override-interval** parameter refers to the period during which a downstream switch can override the prune action.

When a switch sends a Prune message to the upstream device in the same network segment, the other devices that still request multicast data need to send a Join message to the upstream device within the override-interval period.

If switches on the same link have different values, the maximum value is used.

The value of PPT is the sum of **lan-delay** and **override-interval** values. When receiving a Prune message from a downstream interface, the switch does not perform the prune action until the PPT expires. If the switch receives a Join message from the downstream interface before the PPT expires, it cancels the Prune action.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

The **hello-option override-interval** command has the same function as the **pim ipv6 hello-option override-interval** command in the interface view. By default, if the **pim ipv6 hello-option override-interval** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

In the PIM-IPv6 view, set the interval for denying the prune action in a Hello message to 2000 ms.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] hello-option override-interval 2000
```

8.4.38 holdtime assert (IPv6)

Function

The **holdtime assert** command sets the timeout period for all PIM interfaces to keep the Assert state on the local switch.

The **undo holdtime assert** command restores the default timeout.

By default, the timeout period for all PIM interfaces to keep the Assert state on the local switch is 180 seconds.

Format

holdtime assert *interval*

undo holdtime assert

Parameters

Parameter	Description	Value
interval	Specifies the time during which the PIM interface keeps the Assert state.	The value is an integer that ranges from 7 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the shared network segment connected to multiple PIM devices, if the same multicast packets reach these PIM devices and pass the RPF check, multiple copies of the same multicast packets are forwarded to this network segment. In this situation, these PIM devices need to initiate the assert mechanism. The device that wins assert election is responsible for multicast forwarding on the shared network segment. Other devices suppress multicast data forwarding and retain the Assert state for a period of time. After the timer for a PIM interface in the Assert state expires, the device that fails to be elected triggers a new round of election.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

The **holdtime assert** command has the same function as the **pim ipv6 holdtime assert** command in the interface view. By default, if the timeout period is not used on an interface, the timeout period configured in the PIM-IPv6 view is used.

Example

In the PIM-IPv6 view, set the interval during which a switch keeps the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] holdtime assert 100
```

8.4.39 holdtime join-prune (IPv6)

Function

The **holdtime join-prune** command sets the holdtime value in Join/Prune messages sent by all PIM interfaces. Devices that receive Join/Prune messages set the time during which the downstream interface keeps the Join or Prune state according to holdtime.

The **undo holdtime join-prune** command restores the default value.

By default, the holdtime value in Join/Prune messages sent by all PIM interfaces is 210 seconds.

Format

holdtime join-prune *interval*

undo holdtime join-prune

Parameters

Parameter	Description	Value
interval	Specifies the value of holdtime carried in Join/Prune messages sent by the local device.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Join/Prune message from the downstream device, the switch starts the hold timer. If this message carries group-join information and the switch does not receive subsequent Join/Prune messages from the downstream device when the timer expires, it suppresses multicast data forwarding to downstream interfaces of the specified group. If Join/Prune message carries group-prune information, the switch resumes multicast data forwarding to downstream interfaces when the hold timer expires.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

The **holdtime join-prune** command has the same function as the **pim ipv6 holdtime join-prune** command in the interface view. By default, if the holdtime value is not used on an interface, the holdtime value configured in the PIM-IPv6 view is used.

Example

In the PIM-IPv6 view, set the time during which the downstream interface of a switch keeps the Join or Prune state to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] holdtime join-prune 280
```

8.4.40 join-prune max-packet-length (IPv6)

Function

The **join-prune max-packet-length** command sets the maximum size of each Join/Prune message to be sent.

The **undo join-prune max-packet-length** command restores the default maximum size of each Join/Prune message to be sent.

By default, the maximum length of Join/Prune message sent by is 8100 bytes.

Format

join-prune max-packet-length *packet-length*

undo join-prune max-packet-length

Parameters

Parameter	Description	Value
packet-length	Specifies the maximum size of each PIM-SM Join/Prune message to be sent.	The value is an integer that ranges from 100 to 64000, in bytes.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the peer device has low performance and takes a long time to process a large Join/Prune message carrying a lot of (S, G) entries, the maximum size of each Join/Prune message can be reduced to relieve the burden on the peer device.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

If the maximum size specified in the **join-prune max-packet-length** command is greater than the interface MTU, the maximum size of each message to be sent is equal to the interface MTU.

Example

Set the maximum size of each Join/Prune message to be sent to 2100 bytes.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] join-prune max-packet-length 2100
```

8.4.41 join-prune periodic-messages queue-size (IPv6)

Function

The **join-prune periodic-messages queue-size** command sets the maximum number of (S, G) entries carried in a Join/Prune message that is sent every second.

The **undo join-prune periodic-messages queue-size** command restores the default maximum number of (S, G) entries carried in a Join/Prune message that is sent every second.

By default, a Join/Prune message that is sent every second contains 1020 entries.

Format

join-prune periodic-messages queue-size *queue-size*

undo join-prune periodic-messages queue-size

Parameters

Parameter	Description	Value
queue-size	Specifies the maximum number of (S, G) entries carried in a Join/Prune message that is sent every second.	The value is an integer that ranges from 16 to 4096.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the peer device has a low throughput, reduce the length of a queue for periodically sending messages to control the number of (S, G) entries. This setting allows the local device to send Join/Prune messages with a small number of (S, G) entries multiple times, preventing packet loss or route flapping.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

Example

Allow each Join/Prune message that is sent every second to carry a maximum of 2000 (S, G) entries.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] join-prune periodic-messages queue-size 2000
```

8.4.42 join-prune triggered-message-cache disable (IPv6)

Function

The **join-prune triggered-message-cache disable** command disables the Join/Prune message package function.

The **undo join-prune triggered-message-cache disable** command enables the Join/Prune message package function.

By default, the Join/Prune message package function is enabled.

Format

join-prune triggered-message-cache disable

undo join-prune triggered-message-cache disable

Parameters

None

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The system performs more efficiently when sending a package of Join/Prune messages than sending a large number of individual Join/Prune messages. A device sends Join/Prune messages in packages. To disable the package function, run the **join-prune triggered-message-cache disable** command.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

Example

Disable the Join/Prune message package function.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] join-prune triggered-message-cache disable
```

8.4.43 neighbor-check (IPv6)

Function

The **neighbor-check** command enables the PIM neighbor check function.

The **undo neighbor-check** command restores the default setting.

By default, the PIM neighbor check function is not enabled.

Format

neighbor-check { **receive** | **send** }

undo neighbor-check { **receive** | **send** }

Parameters

Parameter	Description	Value
receive	Checks whether the Join/Prune and Assert messages are received from a PIM neighbor. If not, these messages are discarded.	-
send	Checks whether the Join/Prune and Assert messages are sent to a PIM neighbor. If not, these messages are not sent.	-

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM devices send Join/Prune messages to the upstream PIM neighbor to perform join and prune actions and PIM neighbors often exchange Assert messages. To save system resources and protect security of Join/Prune messages and Assert messages, run the **neighbor-check** command to enable the PIM neighbor check function.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

You can specify both **receive** and **send** to enable the PIM neighbor check function for the received and sent Join/Prune and Assert messages.

This command is valid for only PIM-SM (IPv6).

Example

In the PIM-IPv6 view, enable the PIM neighbor check function for the received Join/Prune and Assert messages.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] neighbor-check receive
```

8.4.44 pim-ipv6

Function

The **pim-ipv6** command displays the PIM-IPv6 view.

The **undo pim-ipv6** command clears the configuration in the PIM-IPv6 view.

Format

pim-ipv6

undo pim-ipv6

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before performing PIM (IPv6) configurations, run the **pim-ipv6** command to enter the PIM-IPv6 view.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

NOTICE

In using the **undo pim-ipv6** command, enter Y or N to confirm the action. This command clears global PIM (IPv6) configurations in the current instance. Use this command with caution.

Example

Enter the PIM-IPv6 view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6]
```

8.4.45 pim ipv6 bfd

Function

The **pim ipv6 bfd** command configures PIM BFD (IPv6) parameters on an interface.

The **undo pim ipv6 bfd** command restores default PIM BFD (IPv6) parameters on an interface.

By default, the interval for transmitting BFD packets and interval for receiving BFD packets are 1000 ms, and the BFD detection multiplier is 3.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

pim ipv6 bfd { **min-tx-interval** *tx-value* | **min-rx-interval** *rx-value* | **detect-multiplier** *multiplier-value* }*

undo pim ipv6 bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** }*

undo pim ipv6 bfd { **min-tx-interval** *tx-value* | **min-rx-interval** *rx-value* | **detect-multiplier** *multiplier-value* }*

Parameters

Parameter	Description	Value
min-tx-interval *tx-value*	Specifies the interval for sending BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-rx-interval *rx-value*	Specifies the interval for receiving BFD packets.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Parameter	Description	Value
detect-multiplier *multiplier-value*	Specifies the local detection multiplier of BFD packets. - For a stable link, you can set the detection multiplier to a large value to avoid frequent link detection. - For an unstable link, a small detection multiplier may cause BFD session flapping. Therefore, it is recommended that you set the detection multiplier to a large value.	The value is an integer ranging from 3 to 50. The default value is 3.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you need to control detection parameters of BFD packets, run the **pim ipv6 bfd** command to configure the sending interval, receiving interval, and local detection multiplier for PIM BFD (IPv6) packets.

The **min-tx-interval**, **min-rx-interval**, and **detect-multiplier** parameters can be configured separately at two ends of a link so that the two ends can send or receive BFD packets at different rates. If there is no special requirement for the detection period and the link is stable, you are advised to configure the same parameter settings for the routing devices that have the same performance and are on the shared network segment.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

After BFD parameters are configured, PIM (IPv6) provides the address to be detected, the minimum sending interval and receiving interval of PIM BFD (IPv6) packets, and the local detection multiplier for BFD. The two ends enabled with BFD then negotiate the actual sending interval and receiving interval, and the detection period based on these configured parameters. During the detection phase, BFD notifies the route management (RM) module of the BFD session status and the RM module then notifies PIM (IPv6) of the session status.

If a link fault occurs, BFD quickly notifies the RM of the session status and the RM then notifies PIM (IPv6) of the session status. The PIM (IPv6) protocol deletes the status of the faulty interface, triggers a new DR or Assert election, and restores the forwarding of multicast data to the downstream interface. This shortens the period of multicast traffic interruption caused by the interface fault.

Precautions

To validate PIM BFD (IPv6), ensure that a BFD session has been set up and the session is in the Up state.

The two ends negotiate the actual sending interval and receiving interval, and detection period of BFD packets based on the following negotiation mechanism:

- The formula used to calculate the interval for sending PIM IPv6 BFD packets and the formula used to calculate the interval for receiving PIM IPv6 BFD packets are as follows:
  - Interval for sending PIM IPv6 BFD packets = Max (Local **min-tx-interval**, Remote **min-rx-interval**)
  - Interval for receiving PIM IPv6 BFD packets = Max (Remote **min-tx-interval**, Local **min-rx-interval**)
- The formula used to calculate the detection period is as follows:
  - Detection period = Remote **detect-multiplier** x Max (Remote **min-tx-interval**, Local **min-rx-interval**)

If a large parameter value is set, BFD will take a long time to detect a fault on a link. This may cause packet loss.

Example

Enable PIM BFD (IPv6) on VLANIF 100, and set both the minimum interval for sending BFD packets and the minimum interval for receiving BFD packets to 200 ms and the local detection multiplier to 5.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 sm
[HUAWEI-Vlanif100] pim ipv6 bfd enable
[HUAWEI-Vlanif100] pim ipv6 bfd min-tx-interval 200 min-rx-interval 200 detect-multiplier 5
```

Enable PIM BFD (IPv6) on GE0/0/1, and set both the minimum interval for sending BFD packets and the minimum interval for receiving BFD packets to 200 ms and the local detection multiplier to 5.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
```

```
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 sm
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 bfd enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 bfd min-tx-interval 200 min-rx-interval 200 detect-multiplier
5
```

8.4.46 pim ipv6 bfd enable

Function

The **pim ipv6 bfd enable** command enables PIM BFD (IPv6) on an interface.

The **undo pim ipv6 bfd enable** command disables PIM BFD (IPv6) on an interface.

By default, PIM BFD (IPv6) is disabled on an interface.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

pim ipv6 bfd enable

undo pim ipv6 bfd enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To minimize the impact of a fault on services and improve network availability, a network device is required to quickly detect a communications fault between adjacent devices so that the upper layer protocol can rectify the fault to ensure normal services.

On a PIM network, changes of link status between PIM neighbors will restart some PIM mechanisms, such as DR election or Assert winner election. For example, when the DR or Assert winner on a shared network segment fails, PIM neighbors on the network segment trigger DR or Assert winner re-election only when the PIM neighbor relationships time out. Multicast data transmission is interrupted before a new DR or Assert winner is elected. The multicast service interruption time is longer than or equal to the neighbor relationship timeout interval or Assert timer value, and is usually several seconds.

PIM BFD (IPv6) can detect link status changes on a shared network segment in milliseconds, enabling PIM devices to rapidly respond to failures of PIM neighbors. If a PIM BFD (IPv6)-capable interface does not receive any BFD packets from the DR or Assert winner within the detection interval, it considers that the DR or Assert winner has failed. Then BFD rapidly reports the session status to the route management (RM) module, which then reports the link status change to the PIM module. After receiving the notification, the PIM module triggers DR or Assert winner re-election immediately, without waiting for timeout of the neighbor relationship. This mechanism reduces the multicast service interruption time and improves reliability of multicast data transmission.

Pre-configuration Tasks

PIM BFD (IPv6) depends on the BFD protocol. Therefore, you need first to enable BFD globally to validate the PIM BFD (IPv6) function.

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Before configuring PIM BFD (IPv6), enable PIM-SM (IPv6) in the interface view. If the **undo pim ipv6 sm** command is run, IPv6 PIM-SM is disabled and the PIM BFD (IPv6) function is removed from the interface at the same time.

Example

Enable PIM BFD (IPv6) on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 sm
[HUAWEI-Vlanif100] pim ipv6 bfd enable
```

Enable PIM BFD (IPv6) on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 sm
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 bfd enable
```

8.4.47 pim ipv6 bsr-boundary

Function

The **pim ipv6 bsr-boundary** command configures the BSR boundary of a PIM-SM (IPv6) domain on an interface.

The **undo pim ipv6 bsr-boundary** command restores the default configuration.

By default, the BSR boundary of a PIM-SM (IPv6) domain is not set.

Format

pim ipv6 bsr-boundary

undo pim ipv6 bsr-boundary

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As the management core of the PIM-SM (IPv6) network, the BSR is responsible for sending collected RP-set information to PIM neighbors through Bootstrap messages.

You can divide a large PIM-SM (IPv6) network into multiple PIM-SM (IPv6) domains by configuring the bsr boundary on an interface. Each BSR then serves the local PIM-SM (IPv6) domain.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

The Bootstrap messages cannot traverse the BSR boundary but other multicast packets can.

Example

Configure the BSR boundary of a PIM-SM (IPv6) domain on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 bsr-boundary
```

Configure the BSR boundary of a PIM-SM (IPv6) domain on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
```

```
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 bsr-boundary
```

8.4.48 pim ipv6 dm

Function

The **pim ipv6 dm** command enables PIM-DM (IPv6) on an interface.

The **undo pim ipv6 dm** command restores the default configuration.

By default, PIM-DM (IPv6) is disabled on an interface.

Format

pim ipv6 dm

undo pim ipv6 dm

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM-DM (IPv6) is a multicast routing protocol in dense mode and applies to small-scale networks with densely-distributed group members.

After PIM-DM (IPv6) is enabled on an interface, the switch can set up the PIM neighbor relationship with the neighboring device. The switch then can process protocol packets received from PIM neighbors.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

PIM-DM (IPv6) and PIM-SM (IPv6) cannot be enabled simultaneously on the device.

If PIM-DM (IPv6) and MLD need to be enabled on the same interface, enable PIM-DM (IPv6), and then enable MLD.

Running the **pim ipv6 dm** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable PIM (IPv6) on the corresponding VLANIF interface first, and then enable MLD snooping in the VLAN. If MLD snooping is enabled in the VLAN first, PIM (IPv6) cannot be enabled on the VLANIF interface.

Example

Enable PIM-DM (IPv6) on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 dm
```

Enable PIM-DM (IPv6) on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 dm
```

8.4.49 pim ipv6 hello-option dr-priority

Function

The **pim ipv6 hello-option dr-priority** command sets the priority for the PIM interface that is elected as DR.

The **undo pim ipv6 hello-option dr-priority** command restores the default value of the priority.

By default, the priority for the PIM interface that is elected as DR is 1.

Format

pim ipv6 hello-option dr-priority *priority*

undo pim ipv6 hello-option dr-priority

Parameters

Parameter	Description	Value
priority	Specifies the priority of the PIM interface that is elected as DR.	The value is an integer that ranges from 0 to 4294967295. The greater the value, the higher the priority.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM (IPv6) network, devices on a shared network segment are candidates for the DR. The DR is responsible for the registering of the local multicast source and the joining of the receivers.

The DR is elected based on the priority and the IPv6 address. Switches send Hello messages carrying their priorities to each other, and the one with the highest priority becomes the DR. If the switches have the same priority, the switch with the largest IPv6 address becomes the DR.

If at least one device in the network does not support Hello packets that contain the priority, the device with the largest IPv6 address functions as the DR.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **pim ipv6 hello-option dr-priority** command has the same function as the **hello-option dr-priority (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 hello-option dr-priority** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the priority of VLANIF100 that is elected as DR to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 hello-option dr-priority 3
```

Set the priority of GE0/0/1 that is elected as DR to 3.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 hello-option dr-priority 3
```

8.4.50 pim ipv6 hello-option holdtime

Function

The **pim ipv6 hello-option holdtime** command sets the timeout period during which the PIM interface waits to receive the Hello message from its neighbor.

The **undo pim ipv6 hello-option holdtime** command restores the default value of the timeout.

By default, the timeout period during which the PIM interface waits to receive the Hello message from its neighbor is 105 seconds.

Format

pim ipv6 hello-option holdtime *interval*

undo pim ipv6 hello-option holdtime

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which the PIM interface waits to receive Hello messages from its neighbor.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a PIM (IPv6) network, after a switch receives a Hello message from its PIM neighbor, it starts a timer based on Holdtime value in the Hello message. If the switch does not receive any Hello message from its PIM neighbor when the timer expires, the switch considers the neighbor invalid or unreachable.

The **pim ipv6 hello-option holdtime** command sets the timeout period during which the PIM interface waits to receive the Hello message from its neighbor.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The timeout period must be greater than the interval for sending Hello messages, which is set using the **pim ipv6 time hello** command.

The **pim ipv6 hello-option holdtime** command has the same function as the **hello option holdtime (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 hello-option holdtime** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the timeout period during which VLANIF100 waits to receive Hello messages from its neighbor to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 hello-option holdtime 120
```

Set the timeout period during which GE0/0/1 waits to receive Hello messages from its neighbor to 120 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 hello-option holdtime 120
```

8.4.51 pim ipv6 hello-option lan-delay

Function

The **pim ipv6 hello-option lan-delay** command sets the delay in transmitting messages in a shared network in the interface view.

The **undo pim ipv6 hello-option lan-delay** command restores the default value of the delay.

By default, the delay in transmitting messages in the shared network is 500 ms.

Format

pim ipv6 hello-option lan-delay *interval*

undo pim ipv6 hello-option lan-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay in transmitting messages in the shared network.	The value is an integer that ranges from 1 to 32767, in milliseconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent switches carry **lan-delay** and **override-interval** values. The **lan-delay** parameter indicates the delay in transmitting messages in the LAN. If devices on the same link have different **lan-delay** values, the maximum value is used.

When a switch sends a Prune message to the upstream device in the same network segment, the other devices that still request multicast data need to send a Join message to the upstream device within the override-interval period.

The value of the Prune-Pending Timer (PPT) is the sum of **lan-delay** and **override-interval** values and refer to the delay from the current device receiving a Prune message from the downstream interface to performing the prune action. If the switch receives a Join message from the downstream interface before the PPT timer expires, it cancels the prune action.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

If the prune delay is set too short, the upstream device stops forwarding multicast packets before the downstream device overrides Prune messages of neighbors. Exercise caution when you run this command.

The function of this command in the interface view is the same as that of the **hello-option lan-delay (IPv6)** command in the PIM-IPv6 view. By default, if the configuration on the interface is not performed, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the delay in transmitting messages to 200 ms on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 hello-option lan-delay 200
```

Set the delay in transmitting messages to 200 ms on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 hello-option lan-delay 200
```

8.4.52 pim ipv6 hello-option neighbor-tracking

Function

The **pim ipv6 hello-option neighbor-tracking** command enables the neighbor tracking function in the interface view.

The **undo pim ipv6 hello-option neighbor-tracking** command restores the default configuration.

By default, the neighbor tracking function is not enabled.

Format

pim ipv6 hello-option neighbor-tracking

undo pim ipv6 hello-option neighbor-tracking

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When sending a Hello message, a switch generates a Generation ID and encapsulates it into the message. The Generation ID changes only when the device status changes. In this case, the neighboring device detects the Generation ID change after receiving the Hello message and immediately sends a Join message to the device to update the neighbor relationship. If multiple devices on the shared network segment prepare to send Join messages to the same upstream PIM neighbor, only one device is allowed to send the Join message. After other devices detect the Join message, they do not send Join messages to the upstream neighbor. This means that the upstream neighbor cannot update neighbor relationships with downstream devices after a Generation ID change.

After the neighbor tracking function is enabled, when the device detects Join messages from other devices, the device still sends the Join messages to the same upstream PIM neighbor.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-SM (IPv6).

The neighbor tracking function can be implemented on a shared network segment only when this function is enabled on all devices on the network segment.

The **pim ipv6 hello-option neighbor-tracking** command has the same function as the **hello-option neighbor-tracking (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 hello-option neighbor-tracking** command is not used, the configuration in the PIM-IPv6 view takes effect; otherwise, the configuration in the interface view takes effect.

Example

Enable the neighbor tracking function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 hello-option neighbor-tracking
```

Enable the neighbor tracking function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 hello-option neighbor-tracking
```

8.4.53 pim ipv6 hello-option override-interval

Function

The **pim ipv6 hello-option override-interval** command sets the interval carried in Hello messages for overriding the prune action on the interface.

The **undo pim ipv6 hello-option override-interval** command, restores the default configuration.

By default, the interval carried in Hello messages for overriding the prune action on the interface is 2500 milliseconds.

Format

pim ipv6 hello-option override-interval *interval*

undo pim ipv6 hello-option override-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval of overriding the prune action.	The value is an integer that ranges from 1 to 65535, in milliseconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello messages sent from switches carry **lan-delay** and **override-interval** values. The **override-interval** parameter refers to the period during which a downstream switch can override the prune action.

When a switch sends a Prune message to the upstream device in the same network segment, the other devices that still request multicast data need to send a Join message to the upstream device within the override-interval period.

If switches on the same link have different values, the maximum value is used.

The value of PPT is the sum of **lan-delay** and **override-interval** values. When receiving a Prune message from a downstream interface, the switch does not perform the prune action until the PPT expires. If the switch receives a Join message from the downstream interface before the PPT expires, it cancels the Prune action.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **pim ipv6 hello-option override-interval** command has the same function as the **hello-option override-interval (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 hello-option override-interval** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval for overriding the prune action in Hello messages to 2000 ms on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 hello-option override-interval 2000
```

Set the interval for overriding the prune action in Hello messages to 2000 ms on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 hello-option override-interval 2000
```

8.4.54 pim ipv6 holdtime assert

Function

The **pim ipv6 holdtime assert** command sets the timeout period during which a PIM interface keeps the Assert state.

The **undo pim ipv6 holdtime assert** command restores the default value of the timeout.

By default, the timeout period during which a PIM interface keeps the Assert state is 180 seconds.

Format

pim ipv6 holdtime assert *interval*

undo pim ipv6 holdtime assert

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which a PIM interface keeps the Assert state.	The value is an integer that ranges from 7 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the shared network segment connected to multiple PIM devices, if the same multicast packets reach these PIM devices and pass the RPF check, multiple copies of the same multicast packets are forwarded to this network segment. In this situation, these PIM routers need to initiate the assert mechanism. The router that wins assert election is responsible for multicast forwarding on the shared network segment. Other devices suppress multicast data forwarding and retain the Assert state for a period of time. After the timer for a PIM interface in the Assert state expires, the device that fails to be elected triggers a new round of election.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for PIM-SM (IPv6) and PIM-DM (IPv6).

The **pim ipv6 holdtime assert** command has the same function as the **holdtime assert (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 holdtime assert** command is not used, the value configured in the PIM-IPv6 view is used; otherwise, the value configured in the interface view is used.

Example

Set the timeout period for VLANIF100 to keep the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 holdtime assert 100
```

Set the timeout period for GE0/0/1 to keep the Assert state to 100s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 holdtime assert 100
```

8.4.55 pim ipv6 holdtime join-prune

Function

The **pim ipv6 holdtime join-prune** command sets the holdtime in a Join/Prune message sent by the PIM interface.

The **undo pim ipv6 holdtime join-prune** command restores the default value of the holdtime.

By default, the holdtime in a Join/Prune message sent by the PIM interface is 210 seconds.

Format

pim ipv6 holdtime join-prune *interval*

undo pim ipv6 holdtime join-prune

Parameters

Parameter	Description	Value
interval	Specifies the value of holdtime in a Join/Prune message sent by the PIM interface.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Join/Prune message from the downstream device, the switch starts the hold timer. If this message carries group-join information and the switch does not receive subsequent Join/Prune messages from the downstream device when the timer expires, it suppresses multicast data forwarding to downstream interfaces of the specified group. If Join/Prune message carries group-prune information, the switch resumes multicast data forwarding to downstream interfaces when the hold timer expires.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

The **pim ipv6 holdtime join-prune** command has the same function as the **holdtime join-prune (IPv6)** command in the PIM-IPv6 view. By default, if the **pim ipv6 holdtime join-prune** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the holdtime in a Join/Prune message sent by VLANIF100 to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 holdtime join-prune 280
```

Set the holdtime in a Join/Prune message sent by GE0/0/1 to 280 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 holdtime join-prune 280
```

8.4.56 pim ipv6 join-policy

Function

The **pim ipv6 join-policy** command enables the system to filter join information in Join/Prune messages.

The **undo pim ipv6 join-policy** command restores the default setting.

By default, join information in Join/Prune message is not filtered.

Format

pim ipv6 join-policy { **asm** *basic-acl6-number* | **ssm** *advanced-acl6-number* | *advanced-acl6-number* }

undo pim ipv6 join-policy [**asm** | **ssm**]

Parameters

Parameter	Description	Value
asm	Filters join information, with the group address in the ASM group address range.	-
basic-acl6-number	Specifies the basic ACL number.	The value is an integer that ranges from 2000 to 2999.
ssm	Filters join messages, with the group addresses within the SSM group address range and specified source address.	-
advanced-acl6-number	Specifies the advanced ACL number.	The value is an integer that ranges from 3000 to 3999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized users from joining multicast groups on the PIM-SM (IPv6) network by filtering join information in Join/Prune messages, run the **pim ipv6 join-policy** command.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

This command is valid for only IPv6 PIM-SM.

The **pim ipv6 join-policy** command and the **acl ipv6 (system view)** command are used together.

- If **asm** is specified, you can set the multicast group address range of join information in the basic ACL6 view by specifying the **source** parameter in the **rule (basic ACL6 view)** command.
- If **ssm** is specified, you can set the source address range and multicast group address range of join information in the advanced ACL6 view by respectively specifying the **source** parameter and **destination** parameter in the **rule (advanced ACL6 view)** command.

You must run the **multicast ipv6 routing-enable** command to enable the multicast function before using the command.

Example

Configure VLANIF100 to accept the join information with the group address FF25::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source ff25::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 join-policy asm 2001
```

Configure GE0/0/1 to accept the join information with the group address FF25::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source ff25::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 join-policy asm 2001
```

8.4.57 pim ipv6 neighbor-policy

Function

The **pim ipv6 neighbor-policy** command configures a policy for filtering PIM neighbors on an interface.

The **undo pim ipv6 neighbor-policy** command restores the default setting.

By default, PIM neighbors on the interface are not filtered.

Format

pim ipv6 neighbor-policy *basic-acl6-number*

undo pim ipv6 neighbor-policy

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the basic ACL number.	The value is an integer that ranges from 2000 to 2999.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized neighbors from being involved in the PIM protocol, run the **pim ipv6 neighbor-policy** command to configure a policy for filtering PIM neighbors and set the address range of PIM neighbors. The switch sets up neighbor relationships with the addresses matching the filtering rules and deletes the neighbors that do not match the filtering rules.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

The **pim ipv6 neighbor-policy** command and the **acl ipv6** command are used together. In the ACL view, set the address range of PIM neighbors by specifying **source** in the **rule** command.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

When configuring the neighbor filtering function on the interface, you must also configure the neighbor filtering function correspondingly on the PIM neighbor of the interface.

If the IPv6 address of a PIM neighbor that has established a neighbor relationship with the device is not in the configured range of valid neighbor IPv6 addresses, the device will no longer receive Hello messages from this PIM neighbor. When the holdtime of Hello messages expires, the neighbor relationship between the PIM device and the device is terminated.

Example

Configure VLANIF100 to set up the PIM neighbor relationship with the switch of the address FC00:0:0:2000::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00:0:0:2000::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 neighbor-policy 2001
```

Configure GE0/0/1 to set up the PIM neighbor relationship with the switch of the address FC00:0:0:2000::1.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00:0:0:2000::1 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 neighbor-policy 2001
```

8.4.58 pim ipv6 require-genid

Function

The **pim ipv6 require-genid** command configures a PIM interface to reject the Hello messages without the Generation ID.

The **undo pim ipv6 require-genid** command restores the default configuration.

By default, a PIM interface is allowed to receive the Hello messages without the Generation ID.

Format

pim ipv6 require-genid

undo pim ipv6 require-genid

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an interface is enabled with PIM, the switch generates a random number as the Generation ID of the Hello message. If the device status is updated, the switch generates a new Generation ID. When the switch finds that the Hello message received from a PIM neighbor contains a different Generation ID, it considers that the status of the PIM neighbor has changed.

To ensure that connected PIM neighbors work properly, run the **pim ipv6 require-genid** command to configure a PIM interface to reject the Hello messages without the Generation ID.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

Example

Configure VLANIF100 to reject the Hello messages without the Generation ID.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 require-genid
```

Configure GE0/0/1 to reject the Hello messages without the Generation ID.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 require-genid
```

8.4.59 pim ipv6 silent

Function

The **pim ipv6 silent** command enables the PIM silent (IPv6) function on an interface.

The **undo pim ipv6 silent** command cancels the PIM silent (IPv6) function on an interface.

By default, the PIM silent (IPv6) function is disabled on an interface.

Format

pim ipv6 silent

undo pim ipv6 silent

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To protect the switch against pseudo PIM Hello (IPv6) messages sent from malicious hosts, configure the **pim ipv6 silent** command on the interface directly connected to the host network segment to set the interface to PIM silent (IPv6) mode. Then the interface cannot receive or forward any PIM (IPv6) packet, and all PIM (IPv6) neighbors and PIM (IPv6) state machines on this interface are deleted. This interface becomes the DR, but the MLD function on the interface is not affected.

The PIM silent (IPv6) function applies only to the interface directly connected to a host network segment, and only one PIM switch can be connected to this network segment.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

Running the **pim ipv6 silent** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

If PIM BFD (IPv6) function is enabled on the interface, this command cannot be configured.

This command and **pim ipv6 timer dr-switch-delay** command are mutually exclusive.

NOTICE

After you run this command on an interface, the interface no longer receives or sends any PIM (IPv6) packets and other PIM (IPv6) functions on the interface become invalid. Confirm your action before using this command.

If a host network segment is connected to multiple switches and PIM silent (IPv6) is enabled on multiple interfaces, all these interfaces become static DRs. This causes multicast forwarding failures.

Example

Configure the PIM silent (IPv6) function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 silent
```

Configure the PIM silent (IPv6) function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 silent
```

8.4.60 pim ipv6 sm

Function

The **pim ipv6 sm** command enables PIM-SM (IPv6) on an interface.

The **undo pim ipv6 sm** command disables PIM-SM (IPv6).

By default, PIM-SM (IPv6) is disabled on an interface.

Format

pim ipv6 sm

undo pim ipv6 sm

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After PIM-SM (IPv6) is enabled on interfaces, devices can set up PIM neighbor relationships with each other and process protocol packets received from PIM neighbors.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

PIM-DM (IPv6) and PIM-SM (IPv6) cannot be enabled simultaneously on the device.

If PIM-SM (IPv6) and MLD need to be enabled on the same interface, enable PIM-SM (IPv6), and then enable MLD.

Running the **pim ipv6 sm** command failed on the VLANIF interface because Layer 2 multicast querier or report-suppress is enabled for this VLAN.

If both Layer 2 and Layer 3 multicast services are required in a VLAN, enable PIM (IPv6) on the corresponding VLANIF interface first, and then enable MLD snooping in the VLAN. If MLD snooping is enabled in the VLAN first, PIM (IPv6) cannot be enabled on the VLANIF interface.

Example

Enable PIM-SM (IPv6) on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 sm
```

Enable PIM-SM (IPv6) on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 sm
```

8.4.61 pim ipv6 state-refresh-capable

Function

The **pim ipv6 state-refresh-capable** command enables PIM-DM (IPv6) State-Refresh on an interface.

The **undo pim ipv6 state-refresh-capable** command disables PIM-DM (IPv6) State-Refresh.

By default, PIM-DM (IPv6) State-Refresh is enabled.

Format

pim ipv6 state-refresh-capable

undo pim ipv6 state-refresh-capable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM-DM (IPv6) State-Refresh is implemented by periodically sending State-Refresh messages in the network. After receiving a State-Refresh message, the switch in the pruned state resets the prune-status timer, preventing the downstream interface from forwarding packets.

After PIM-DM (IPv6) state-refresh is disabled, the interface starts to forward multicast data when the prune timer expires. The downstream routers that do not require the data send Prune messages. The process repeats and wastes a lot of network resources. Enabling PIM-DM (IPv6) State-Refresh can reduce traffic on the network.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-DM (IPv6).

Example

Disable PIM-DM (IPv6) State-Refresh on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo pim ipv6 state-refresh-capable
```

Disable PIM-DM (IPv6) State-Refresh on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] undo pim ipv6 state-refresh-capable
```

8.4.62 pim ipv6 timer dr-switch-delay

Function

The **pim ipv6 timer dr-switch-delay** command enables PIM DR switching delay and configures the delay on an interface. When the interface changed from a DR to a non-DR, the interface continues to forward data before the delay expires.

The **undo pim ipv6 timer dr-switch-delay** command disables PIM DR switching delay on the interface.

By default, when the interface changes from a DR to a non-DR, the interface stops forwarding data immediately.

Format

pim ipv6 timer dr-switch-delay *interval*

undo pim ipv6 timer dr-switch-delay

Parameters

Parameter	Description	Value
interval	Specifies the delay.	The value is an integer that ranges from 10 to 3600, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the DR on a shared network segment becomes the non-DR, original multicast forwarding entries will be deleted immediately, causing multicast data interruption in a short time. To solve the problem, set the DR switching delay. Original multicast forwarding entries still take effect until the delay is reached.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-SM (IPv6).

This command and **pim ipv6 silent** command are mutually exclusive.

Example

Enable PIM DR switching delay on VLANIF100 and set the delay to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
```

```
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 timer dr-switch-delay 20
```

Enable PIM DR switching delay on GE0/0/1 and set the delay to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 timer dr-switch-delay 20
```

8.4.63 pim ipv6 timer graft-retry

Function

The **pim ipv6 timer graft-retry** command sets the interval for retransmitting Graft messages on an interface.

The **undo pim ipv6 timer graft-retry** command restores the default value of the interval.

By default, the interval for retransmitting Graft messages on an interface is 3 seconds.

Format

pim ipv6 timer graft-retry *interval*

undo pim ipv6 timer graft-retry

Parameters

Parameter	Description	Value
interval	Specifies the interval of retransmitting Graft messages.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In PIM-DM (IPv6) mode, when a member joins a pruned group, the switch sends a Graft message and waits to receive an ACK message from the upstream switch. If the downstream switch does not receive the ACK message in the period configured through the command, the switch resends the Graft message until the switch receives the ACK message from the upstream switch.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-DM (IPv6).

Example

Set the interval for retransmitting Graft messages to 80s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 timer graft-retry 80
```

Set the interval for retransmitting Graft messages to 80s on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 timer graft-retry 80
```

8.4.64 pim ipv6 timer hello

Function

The **pim ipv6 timer hello** command sets the interval for sending Hello messages on an interface.

The **undo pim ipv6 timer hello** command restores the default value of the interval.

By default, the interval for sending Hello messages on an interface is 30 seconds.

Format

pim ipv6 timer hello *interval*

undo pim ipv6 timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Hello messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM devices periodically send Hello messages to maintain PIM neighbor relationships. You can run the **pim ipv6 timer hello** command to set the interval for sending Hello messages.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

The interval for sending Hello messages must be shorter than the timeout period of PIM neighbors. You can run the **pim ipv6 hello-option holdtime** command to set the timeout period of PIM neighbors.

The configuration is the same as the **timer hello (IPv6)** command in the PIM-IPv6 view. The configuration in the interface view takes precedence over the configuration in the PIM-IPv6 view. The value configured in the PIM-IPv6 view is used if no value is configured on the interface.

Example

Set the interval for sending Hello messages to 40 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 timer hello 40
```

Set the interval for sending Hello messages to 40 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 timer hello 40
```

8.4.65 pim ipv6 timer join-prune

Function

The **pim ipv6 timer join-prune** command sets the interval for periodically sending Join/Prune messages to the upstream device.

The **undo pim ipv6 timer join-prune** command restores the default interval.

By default, the interval for periodically sending Join/Prune messages to the upstream device is 60 seconds.

Format

pim ipv6 timer join-prune *interval*

undo pim ipv6 timer join-prune

Parameters

Parameter	Description	Value
interval	Specifies the interval at which Join/Prune messages are sent.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device sends join information to the upstream device, requesting the upstream device to forward multicast data. The device sends prune information to the upstream device, requesting the upstream device to stop forwarding multicast data. Join information and prune information are encapsulated in Join/Prune messages. The device periodically sends Join/Prune messages to the upstream device to update the forwarding status.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

The interval configured through this command must be shorter than the interval configured through the **pim ipv6 holdtime join-prune** command. The interval at which Join or Prune messages are sent must be shorter than the holdtime carried in Join/Prune messages.

The configuration is the same as that of the **timer join-prune (IPv6)** command in the PIM-IPv6 view. The system prefers the configuration in the interface view. The value configured in the PIM-IPv6 view is used if no value is configured on the interface.

Example

Set the interval for sending Join or Prune messages to 80 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 timer join-prune 80
```

Set the interval for sending Join or Prune messages to 80 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 timer join-prune 80
```

8.4.66 pim ipv6 triggered-hello-delay

Function

The **pim ipv6 triggered-hello-delay** command sets the maximum delay for triggering Hello messages.

The **undo pim ipv6 triggered-hello-delay** command restores the default maximum delay.

By default, the maximum delay for triggering Hello messages is 5 seconds.

Format

pim ipv6 triggered-hello-delay *interval*

undo pim ipv6 triggered-hello-delay

Parameters

Parameter	Description	Value
interval	Specifies the maximum delay for triggering Hello messages.	The value is an integer that ranges from 1 to 5, in seconds.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Conflicts will occur if multiple PIM devices sending Hello message at the same time. To avoid such conflicts, when a PIM device detects Hello messages on the network, it waits for a random delay that is smaller than the value configured using this command before sending a Hello message.

To avoid the conflict caused by multiple PIM devices sending Hello message at the same time, the PIM device automatically selects a random number smaller than the configured value as the delay. When detecting Hello messages in the network, the PIM device sends Hello message after the delay.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Example

Set the maximum delay for triggering the Hello message to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] pim ipv6 triggered-hello-delay 3
```

Set the maximum delay for triggering the Hello message to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] pim ipv6 triggered-hello-delay 3
```

8.4.67 probe-interval (IPv6)

Function

The **probe-interval** command sets the interval for a switch to send Probe messages (null Register message) to the RP.

The **undo probe-interval** command restores the default value of the interval.

By default, the interval for a switch to send Probe messages to the RP is 5 seconds.

Format

probe-interval *interval*

undo probe-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Probe messages to RP.	The value is an integer that ranges from 1 to 1799, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When receiving a Register-Stop message sent by the RP, the DR at the source side stops sending Register messages and enters the register suppression state.

During the register suppression, the DR at the source side sends Probe messages to notify the RP that the multicast source is still in the Active state. After the register suppression times out, the DR at the source side starts to send Register messages.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-SM (IPv6).

The interval set using the **probe-interval** command must be less than half the interval set using the **register-suppression-timeout (IPv6)** command.

Example

In the PIM-IPv6 view, set the interval for sending Probe messages to RP to 6 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] probe-interval 6
```

8.4.68 register-policy (IPv6)

Function

The **register-policy** command sets the rules used by an RP to filter Register messages.

The **undo register-policy** command restores the default setting.

By default, the rules for filtering Register messages are not configured.

Format

register-policy *advanced-acl6-number*

undo register-policy

Parameters

Parameter	Description	Value
advanced-acl6-number	Specifies the number of the advanced ACL that defines the rules for filtering packets based on source addresses or group addresses.	The value is an integer that ranges from 3000 to 3999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent the attack of invalid Register messages, you can configure devices to receive or deny Register messages according to the packet filtering rules.

If the ACL rejects an (S, G) entry contained in a Register message or the ACL does not filter this entry, the RP sends a Register-Stop message to the DR on the source side to stop the registration of this multicast data stream.

The **register-policy** command and the **acl ipv6** command are used together. In the ACL6 view, you can set the multicast source address range by specifying the **source** parameter in the **rule** command, and set the multicast group address range by specifying the **destination** parameter in the **rule** command.

The configurations of the IPv6 Named ACL and the advanced ACL are the same, and can implement filtering of both source addresses and multicast group addresses. The Named ACL can also be configured with the **time-range** parameter.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

NOTICE

When the **register-policy** command is used on the RP, only Register messages matching the rule of the ACL are received by the RP. If an undefined ACL is specified, the RP denies all Register messages.

This command is valid for only PIM-SM (IPv6).

The **register-policy** command takes effect for only subsequently received Register messages. The multicast entries that have been registered successfully are not deleted and can still be used for multicast data forwarding.

Example

Configure the RP to receive Register packets sent by the multicast source on the network segment FC00:0:0:2001::2/64 to the multicast group FF02:13::/64.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 3000
[HUAWEI-acl6-adv-3000] rule permit ipv6 source fc00:0:0:2001::2 64 destination ff02:13:: 64
[HUAWEI-acl6-adv-3000] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] register-policy 3000
```

8.4.69 register-source (IPv6)

Function

The **register-source** command specifies the source IPv6 address used by the source's DR to send Register messages.

The **undo register-source** command restores the default setting.

By default, the source IPv6 address used by the source's DR to send Register messages is not specified.

Format

register-source *ipv6-address*

undo register-source

Parameters

Parameter	Description	Value
ipv6-address	Specifies the global IPv6 unicast address of the registered source.	-

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the source IPv6 address for sending Register messages is no longer the only IPv6 address in the network for the RP device or the source IPv6 address is filtered out, errors occur in the registration process and extra traffic occupies bandwidth on the network. In this case, use the **register-source** command to specify an appropriate interface as the source IPv6 address for sending Register messages. Using the loopback address of the source's DR as the source IPv6 address is recommended.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Before specifying the source IPv6 unicast address for sending Register messages, enable PIM-SM.

Precautions

The command is effective only when the specified interface is in Up state.

Example

Specify the source IPv6 address used by the source's DR to send Register message as FC00:0:0:1101::1.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] register-source fc00:0:0:1101::1
```

8.4.70 register-suppression-timeout (IPv6)

Function

The **register-suppression-timeout** command sets the timeout period during which a switch keeps the register suppression state.

The **undo register-suppression-timeout** command restores the default timeout period.

By default, a switch keeps the register suppression state for 60 seconds.

Format

register-suppression-timeout *interval*

undo register-suppression-timeout

Parameters

Parameter	Description	Value
interval	Specifies the timeout period during which the switch keeps the register suppression state.	The value is an integer that ranges from 11 to 3600, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a Register-Stop message from the RP, the switch immediately stops sending Register messages and enters the register suppression state.

The **register-suppression-timeout** command determines how long the switch keeps the register suppression state. When the timeout period expires, the switch (source DR) starts to send Register messages to the RP.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid only for PIM-SM (IPv6).

If the timeout period is too short, the RP receives burst multicast data more frequently. If the timeout period is too long, there will be a long delay for a new receiver to join a group when an (S, G) entry on the RP times out.

You can use the **probe-interval (IPv6)** command to configure the switch to send null Register messages before the suppression timer times out. This configuration reduces burst Register messages and shortens the timeout period to reduce the delay for a new receiver to join a group.

Example

In the PIM-IPv6 view, set the timeout period during which the switch keeps the register suppression state to 70 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] register-suppression-timeout 70
```

8.4.71 reset pim ipv6 control-message counters

Function

The **reset pim ipv6 control-message counters** command resets the statistics about PIM (IPv6) control messages.

Format

reset pim ipv6 control-message counters [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the name and the number of an interface. It is used to reset the statistics about PIM (IPv6) control messages on a specified interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

If an interface with PIM (IPv6) enabled has been forwarding multicast packets for a long time, the switch stores statistics on a large number of control messages. You can run this command to reset statistics on control messages.

Example

Reset the statistics about PIM (IPv6) control messages on all interfaces.

```
<HUAWEI> reset pim ipv6 control-message counters
```

8.4.72 reset pim ipv6 routing-table

Function

The **reset pim ipv6 routing-table** command clears PIM status of the specified downstream interface of a specified PIM (IPv6) entry.

Format

reset pim ipv6 routing-table group *ipv6-group-address* **mask** *ipv6-group-mask-length* **source** *ipv6-source-address* **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
group *ipv6-group-address*	Specifies the group address of an IPv6 PIM entry.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.

Parameter	Description	Value
mask *ipv6-group-mask-length*	Specifies the mask length of an IPv6 multicast group address.	The value is an integer that ranges from 0 to 128.
source *ipv6-source-address*	Specifies the source address of an IPv6 PIM entry.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset pim ipv6 routing-table** command clears PIM status of the specified downstream interface of a specified PIM entry.

Configuration Impact

Using this command can clear the PIM status of the specified interface in a specified PIM entry. The command cannot be used to clear the MLD and static group join status on a specified interface.

Precautions

This command is valid for only PIM-SM (IPv6).

NOTICE

Clearing PIM status of the downstream interfaces can trigger sending of Join/Prune messages, which causes multicast service interruption.

Example

Clear PIM status of the downstream interface VLANIF100 of the (S, G) entry (FC00:0:0:2001::4,FF25::1).

```
<HUAWEI> reset pim ipv6 routing-table group ff25::1 mask 128 source fc00:0:0:2001::4 interface vlanif
100
```

8.4.73 source-lifetime (IPv6)

Function

The **source-lifetime** command specifies the timeout period of (S, G) entries on the switch.

The **undo source-lifetime** command restores the default value of the timeout period.

By default, the timeout period is 210 seconds.

Format

source-lifetime { *interval* | **infinity** } [**group-policy** *acl6-number*]

undo source-lifetime

undo source-lifetime { *interval* | **infinity** } [**group-policy** *acl6-number*]

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of (S, G) entries on the switch.	The value is an integer that ranges from 60 to 65535, in seconds.
infinity	Indicates that (S, G) entries on the switch will never age out.	-
group-policy	Specifies a group policy to determine to which the configured timeout period takes effect.	-
acl6-number	Specifies the number of a basic or advanced ACL.	The value is an integer that ranges from 2000 to 3999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch creates a timer for each (S, G) entry. The **source-lifetime** command is used to set the value of the timer. After receiving a multicast packet from S, the interface resets the timer. If the timer times out, the (S, G) entry is considered invalid.

- If you configure **source-lifetime** *interval*, the configured timeout period applies to all (S, G) entries.
- If you configure **source-lifetime** *interval* { **group-policy** *acl6-number* }:
  - If you specify an advanced ACL name in the command, the configured timeout period applies to the (S, G) entries in which the source and group addresses are permitted by the specified ACL.
  - If you specify a basic ACL number in the command, the configured timeout period applies to the (S, G) entries in which the source addresses are permitted by the specified ACL.
  - If you specify an advanced ACL number in the command, the configured timeout period applies to the (S, G) entries in which the source and group addresses are permitted by the specified ACL.
- If you configure **source-lifetime infinity**, all (S, G) entries will never age out.
- If you configure **source-lifetime infinity** { **group-policy** *acl6-number* }:
  - If you specify an advanced ACL name in the command, the (S, G) entries in which the source and group addresses are permitted by the specified ACL will never age out.
  - If you specify a basic ACL number in the command, the (S, G) entries in which the source addresses are permitted by the specified ACL will never age out.
  - If you specify an advanced ACL number in the command, the (S, G) entries in which the source and group addresses are permitted by the specified ACL will never age out.

If you run this command multiple times for the same range of multicast forwarding entries and specify *interval* and **infinity** respectively in the commands, **infinity** takes precedence over *interval*.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

Example

Set the timeout period of (S, G) entries on the switch to 200 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] source-lifetime 200
```

8.4.74 source-policy (IPv6)

Function

The **source-policy** command configures the switch to filter received multicast data packets based on source addresses or source/group addresses.

The **undo source-policy** command deletes the configuration.

By default, a switch does not filter received multicast data packets based on source addresses or source/group addresses.

Format

source-policy *acl6-number*

undo source-policy

Parameters

Parameter	Description	Value
acl6-number	Specifies number of the basic or advanced ACL.	The value is an integer that ranges from 2000 to 3999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent unauthorized source information from being advertised on the PIM network, run the **source-policy** command to configure the switch to filter received multicast data packets based on source addresses or source/group addresses.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

For the numbered ACL, the **source-policy** command and the **acl ipv6acl ipv6** command are used together.

- In the basic ACL6 view, you can set the source address range of multicast packets by specifying the **source** parameter in the **rule** command.
- In the advanced ACL6 view, you can set the source address range of multicast packets by specifying the **source** parameter in the **rule** command, and set the multicast group IPv6 address range by specifying the **destination** parameter in the **rule** command.

The configurations of the named ACL and advanced ACL are the same, and can filter both source addresses and group addresses. A named ACL can also be configured with the **time-range** parameter.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

Example

In the public network instance, configure the switch to receive multicast data packets with the source address of FC00:0:0:3121::1 and to discard those with the source address of FC00:0:0:3121::2.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source fc00:0:0:3121::1 128
[HUAWEI-acl6-basic-2001] rule deny source fc00:0:0:3121::2 128
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] source-policy 2001
```

8.4.75 spt-switch-threshold (IPv6)

Function

The **spt-switch-threshold** command sets the rate threshold of the multicast packets when the DR at the member side joins the SPT.

The **undo spt-switch-threshold** command restores the default value.

By default, the system performs SPT switchover on receiving the first multicast data packet through the RPT.

Format

spt-switch-threshold { *traffic-rate* | **infinity** } [**group-policy** { *basic-acl6-number* } [**order** *order-value*]]

undo spt-switch-threshold [*traffic-rate* | **infinity**] [**group-policy** { *basic-acl6-number* }]

Parameters

Parameter	Description	Value
traffic-rate	Specifies the threshold rate for the switchover from the RPT to the SPT. **NOTE** Setting this parameter may affect operation of multicast services. You are advised to use the default triggering condition. That is, an SPT switchover is triggered immediately after the first multicast data packet is received from the RPT. The default triggering condition can reduce the number of multicast packets forwarded on the RPT.	The value is an integer that ranges from 1 to 4194304, in kbit/s.
infinity	Indicates that the SPT switchover is never enabled.	-

Parameter	Description	Value
basic-acl6-number	Specifies an entry of the group-policy list. It works with the multicast group that matches *basic-acl6-number* to enable the threshold. *basic-acl6-number* specifies the number of the basic ACL that defines the range of multicast groups.	If the parameter is not set, the threshold is applied to all multicast groups. The value ranges from 2000 to 2999.
order *order-value*	Adjusts the order of the ACLs in the group-policy list. If a group matches multiple ACLs, the threshold is selected in the order specified by *order-value*. *order-value* specifies the updated number.	The value is an integer. The value is any value other than original one in the current group-policy list. If the parameter is not set, the order of the ACLs in the group-policy list does not change.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The source's DR encapsulates multicast packets in a Register message, and then transmits the unicast Register message to the RP. Then, the RP decapsulates the Register message and forwards the multicast packets to the receivers along the RPT. By default, when the RP or receiver's DR receives the first multicast packet, it initiates an SPT switchover to the source.

After the **spt-switch-threshold** command is executed on the receiver's DR, the receiver's DR periodically checks the forwarding rate of multicast packets. When the forwarding rate exceeds the threshold, the receiver's DR sends a Join messages to the source, triggering the SPT switchover.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

If this command is used several times for the same group, the first matched command takes effect.

This command is valid to all devices that may function as the DR at the member side, but is invalid to RPs.

Precautions

This command is valid for only PIM-SM (IPv6).

Example

Set the threshold to 4 kbit/s. If the transmission rate of packets from the source to the multicast group is higher than the threshold, the switch switches packets to the SPT towards the source.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] spt-switch-threshold 4
```

Add a group-policy: the ACL number, rate threshold, and order of the group-policy are 2010, 100 kbit/s, and 1 respectively.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2010
[HUAWEI-acl6-basic-2010] rule permit source ff02:: 96
[HUAWEI-acl6-basic-2010] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] spt-switch-threshold 100 group-policy 2010 order 1
```

8.4.76 ssm-policy (IPv6)

Function

The **ssm-policy** command sets the range of SSM group addresses.

The **undo ssm-policy** command restores the default configuration.

By default, the range of IPv6 SSM group addresses is FF3x::/32. (The value of x ranges from 0 to F.)

Format

ssm-policy *basic-acl6-number*

undo ssm-policy

Parameters

Parameter	Description	Value
basic-acl6-number	Specifies the number of the basic ACL that defines the range of SSM group addresses.	The value is an integer that ranges from 2000 to 2999.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the SSM group address range is FF3x::/32. The value of x ranges from 0 to F. You can run the **ssm-policy** command to specify the range of PIM SSM group addresses. All the PIM-SM (IPv6) interfaces consider that PIM SSM is enabled on all the multicast groups in the specified address range. The specified SSM group address range can exceed the default group address range.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If Multicast Listener Discovery version 2 (MLDv2) is used to add an (S, G) entry, this command does not take effect.

The **ssm-policy** command and the **acl ipv6acl ipv6** command are used together.

- For the numbered ACL6, in the ACL6 view, you can set the IPv6 address range of SSM multicast groups by specifying the **source** parameter in the **rule (basic ACL6 view)** command.
- For the named ACL6, in the ACL6 view, when the **rule (basic ACL6 view)** command is used to configure a filtering rule, the filtering rule is effective only with the multicast group address range that is specified by the **destination** parameter and with the time period that is specified by the **time-range** parameter.

This command is valid for only PIM-SM (IPv6).

Example

Set the range of PIM SSM multicast addresses to FF31:0:8192::/96.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2000
[HUAWEI-acl6-basic-2000] rule permit source ff31:0:8192:: 96
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] ssm-policy 2000
```

8.4.77 state-refresh-interval (IPv6)

Function

The **state-refresh-interval** command sets the interval for sending PIM State-Refresh messages.

The **undo state-refresh-interval** command restores the default value of the interval.

By default, the interval for sending PIM State-Refresh messages is 60 seconds.

Format

state-refresh-interval *interval*

undo state-refresh-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending PIM State-Refresh messages.	The value is an integer that ranges from 1 to 255, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On the PIM-DM (IPv6) network, the device periodically sends State-Refresh messages to update the timeout interval of the prune timer on the downstream device. By doing this, the interface that has no multicast requirements retains in prune state.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-DM (IPv6).

To prevent a pruned interface from forwarding packets when the Prune status times out, the interval for sending State-Refresh messages is shorter than the period for keeping the Prune status.

You can run the **holdtime join-prune (IPv6)** command to set the period during which the device keeps the Prune status.

This command takes effect only when it is run on the routers directly connected to the source.

Example

Set the interval for sending PIM State-Refresh messages to 70s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] state-refresh-interval 70
```

8.4.78 state-refresh-rate-limit (IPv6)

Function

The **state-refresh-rate-limit** command sets the minimum period to wait before receiving the next PIM State-Refresh message.

The **undo state-refresh-rate-limit** command restores the default value.

By default, the minimum period to wait to receive the next PIM State-Refresh message is 30 seconds.

Format

state-refresh-rate-limit *interval*

undo state-refresh-rate-limit

Parameters

Parameter	Description	Value
interval	Specifies the minimum period for waiting to receive the next PIM State-Refresh message.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch can receive multiple PIM State-Refresh messages in a short period. Some of the messages are the same. To avoid duplicate messages, you can run the **state-refresh-rate-limit** command to set the period to wait to receive the next State-Refresh message.

- Before the State-Refresh timer times out, the switch discards the received duplicate State-Refresh messages.
- After the State-Refresh timer times out, the switch can receive the next State-Refresh message.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-DM (IPv6).

Example

Set the minimum period to wait to receive the next PIM State-Refresh message to 45s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] state-refresh-rate-limit 45
```

8.4.79 state-refresh-ttl (IPv6)

Function

The **state-refresh-ttl** command sets the TTL value for sending PIM State-Refresh messages.

The **undo state-refresh-ttl** command restores the default value of the TTL.

By default, the TTL value for sending PIM State-Refresh messages is 255.

Format

state-refresh-ttl *ttl-value*

undo state-refresh-ttl

Parameters

Parameter	Description	Value
ttl-value	Specifies the minimum TTL value of the PIM state refresh message sent by an interface.	The value is an integer that ranges from 1 to 255.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving a State-Refresh message, the switch decreases the value of the TTL in the message by 1, and then sends the message to the downstream switch until the value of the TTL becomes 0. If the scale of the network is small, the message is delivered in a loop.

You can use the **state-refresh-ttl** command to set the value of the TTL according to the scale of the network.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-DM (IPv6).

This command takes effect only when it is run on the routers directly connected to the source.

Example

Set the TTL value for sending PIM State-Refresh messages to 45.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] state-refresh-ttl 45
```

8.4.80 static-rp (IPv6)

Function

The **static-rp** command configures a static RP.

The **undo static-rp** command restores the default configuration.

By default, no static RP is configured.

Format

static-rp *rp-address* [*basic-acl6-number*] [**preferred**]

undo static-rp *rp-address*

Parameters

Parameter	Description	Value
rp-address	Specifies address of a static RP.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
basic-acl6-number	Specifies the basic ACL that is used to control the range of multicast groups served by a static RP.	The value is an integer that ranges from 2000 to 2999.
preferred	Indicates that the static RP is preferred.	-

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When only one RP exists in the network, you can manually configure a static RP rather than a dynamic RP. This can reduce bandwidth used to exchange information between the C-RP and the BSR.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

If the address of the static RP is the address of an interface in the Up state on the local host, the local host acts as the static RP. PIM (IPv6) does not need to be enabled on the interface of the static RP.

If no ACL number is specified in the command, the static RP serves all the multicast groups. If an ACL is specified but the ACL does not contain any rules, the static RP serves all the multicast groups. If the specified ACL has rules configured, the static RP serves only the multicast groups permitted by the ACL.

If the command used to configure the static RP does not contain **preferred**, devices apply BSR mechanism to elect a dynamic RP. If the dynamic RP is not configured in the network or the dynamic RP is invalid, the static RP becomes valid. If the command used to configure static RP contains **preferred**, the static RP is preferred.

If this command is used many times, multiple static RPs are configured. In the case that multiple static RPs serve a group, the RP with the largest IPv6 address is selected to serve the group. If *rp-address* of the RPs is identical, the latest RP replaces the previous one.

Precautions

The **static-rp** command and the **acl ipv6** command are used together. In the ACL6 view, when the **rule** command is used to configure a filtering rule, you can set the address range of multicast groups that are served by the static RP by specifying the **source** parameter in the **rule** command. The filtering rule is effective only with the **source** parameter and the time period specified by the **time-range** parameter.

NOTE

Up to 50 static RPs can be configured by using this command repeatedly, but the same ACL cannot correspond to multiple static RPs. If the ACL is not referenced, only one static RP can be configured.

To make the static RP work normally, run the **static-rp** command on all devices in the PIM-SM (IPv6) domain.

Example

Configure the switch with the address of FC00:0:0:1111::1111 as the static RP in the PIM-SM (IPv6) domain.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] static-rp fc00:0:0:1111::1111
```

8.4.81 timer hello (IPv6)

Function

The **timer hello** command sets the interval at which the PIM switch sends Hello messages.

The **undo timer hello** command restores the default interval.

By default, the interval at which the PIM switch sends Hello messages is 30 seconds.

Format

timer hello *interval*

undo timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval at which Hello messages are sent.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PIM devices periodically send Hello messages to maintain PIM neighbor relationships. You can run the **pim ipv6 timer hello** command to set the interval for sending Hello messages.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Configuration Impact

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

The interval at which the PIM device sends Hello messages should be less than the timeout period of the PIM neighbor. You can run the **hello-option holdtime (IPv6)** command to set the timeout period of PIM neighbors.

The **timer hello** command has the same function as the **pim ipv6 timer hello** command in the interface view. By default, if the **pim ipv6 timer hello** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval at which PIM Hello messages are sent to 40s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] timer hello 40
```

8.4.82 timer join-prune (IPv6)

Function

The **timer join-prune** command configures the interval at which Join/Prune messages are sent to an upstream device.

The **undo timer join-prune** command restores the default interval.

By default, the interval at which Join/Prune messages are sent to an upstream device is 60 seconds.

Format

timer join-prune *interval*

undo timer join-prune

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending Join/Prune messages.	The value is an integer that ranges from 1 to 18000, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch sends join information to the upstream device, requesting the upstream device to forward multicast data. The switch sends prune information to the upstream device, requesting the upstream device to stop forwarding multicast data. Join information and prune information are encapsulated in Join/Prune messages. The PIM switch periodically sends Join/Prune messages to the upstream switch to update the forwarding status.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for both PIM-DM (IPv6) and PIM-SM (IPv6).

The interval configured using the **timer join-prune** command must be shorter than the interval configured using the **holdtime join-prune (IPv6)** command.

The **timer join-prune** command has the same function as the **pim ipv6 timer join-prune** command in the interface view. By default, if the **pim ipv6 timer join-prune** command is not used, the value configured in the PIM view is used; otherwise, the value configured in the interface view is used.

Example

Set the interval at which Join/Prune messages are sent to 80s.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] timer join-prune 80
```

8.4.83 timer spt-switch (IPv6)

Function

The **timer spt-switch** command sets the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from the RPT to the SPT.

The **undo timer spt-switch** command restores the default value of the interval.

By default, the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from the RPT to the SPT is 15 seconds.

Format

timer spt-switch *interval*

undo timer spt-switch

Parameters

Parameter	Description	Value
interval	Specifies the interval for checking whether the rate for transmitting multicast data exceeds the threshold before the switchover from RPT to SPT.	The value is an integer that ranges from 15 to 65535, in seconds.

Views

PIM-IPv6 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **timer spt-switch** command to set the interval for checking whether the rate for transmitting multicast data exceeds the threshold.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is valid for only PIM-SM (IPv6).

Before running this command, you must set the threshold for SPT switchover by using the **spt-switch-threshold (IPv6)** command; otherwise, the **timer spt-switch** command takes no effect.

Example

Set the interval for checking the rate for transmitting the multicast data before the switchover from RPT to SPT to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] pim-ipv6
[HUAWEI-pim6] timer spt-switch 30
```

8.5 MSDP Configuration Commands

8.5.1 Command Support

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.
S6700	Supported.

NOTE

Only S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the MSDP multi-instance feature.

8.5.2 cache-sa-enable

Function

The **cache-sa-enable** command enables the SA cache function on a switch. After receiving an SA message, the switch caches (S, G) information carried in the SA message.

The **cache-sa-disable** command disables the SA cache function.

The **undo cache-sa-enable** command disables the SA cache function.

By default, the SA cache function is enabled on a switch.

Format

cache-sa-enable

cache-sa-disable

undo cache-sa-enable

Parameters

None

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch enabled with the SA cache function locally saves (S, G) information carried in the received SA messages. When the switch receives requests for receiving multicast data, it directly obtains (S, G) information from the SA cache.

A switch no longer saves (S, G) information carried in the received SA messages locally after the **undo cache-sa-enable** or the **cache-sa-disable** command is run to disable the SA cache function. When the switch receives requests for receiving multicast data, it must wait for the SA messages sent by the MSDP peer in the next sending period. This may result in a delay in receiving multicast data.

Prerequisites

MSDP has been enabled using the **msdp** command.

Configuration Impact

When an RP receives a new (*, G) Join message,

- If the SA cache function is enabled, the RP searches the SA cache for the (S, G) information.
  - If the SA cache contains related (S, G) information, the RP directly joins the SPT with the root being S.
  - If the SA cache does not contain related (S, G) information, the RP does not process the received Join message.
- If the SA cache function is disabled, the RP processes the message in one of the following ways:
  - If the sending of SA Request messages is enabled, the RP sends an SA Request message to the specified MSDP peer and waits for the response.
  - If the sending of SA Request messages is disabled, the RP must wait for the SA message sent by the MSDP peer in the next sending period.

Precautions

The **cache-sa-disable** and **undo cache-sa-enable** commands' configurations are both **undo cache-sa-enable** in the configuration file.

Example

Disable the SA cache function on the switch.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] undo cache-sa-enable
```

8.5.3 display default-parameter msdp

Function

The **display default-parameter msdp** command displays default configurations about MSDP.

Format

display default-parameter msdp

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command still displays the default configurations even after the MSDP parameters are changed. You can use this command to check the consistency of default configurations about MSDP parameters on MSDP peers.

Example

Display default configurations about MSDP.

```
<HUAWEI> display default-parameter msdp
  MSDP View Default Configurations:
  ---------------------------------
  Cache-sa-enable: enabled
  Msdp description:
  Encap-data-enable: disabled
  Request-sa-enable: disabled
  Sa-request-policy: disabled
  Sa-policy: disabled
  Connect-retry-period: 30 s
  Minimum TTL: 0
```

Table 8-72 Description of the **display default-parameter msdp** command output

Item	Description
MSDP View Default Configurations	Default configurations in the MSDP view.

Item	Description
Cache-sa-enable	Whether SA cache is enabled. By default, SA cache is enabled. This parameter is configured using the **cache-sa-enable** command.
Msdp description	Whether MSDP peer description is configured. By default, no description is configured for an MSDP peer. This parameter is configured using the **peer description (MSDP)** command.
Encap-data-enable	Whether encapsulating multicast data packets into the SA message is enabled. By default, an SA message does not encapsulate any multicast packet. This parameter is configured using the **encap-data-enable** command.
Request-sa-enable	Whether sending an SA Request message immediately when a Join message is received. By default, when receiving a Join message, the switch waits for the SA message in the next period instead of sending an SA Request message to its MSDP peer. This parameter is configured using the **peer request-sa-enable** command.
Sa-request-policy	Whether the filtering rule for responding to the SA Request message is configured. By default, the switch is not configured with any filtering rule for responding to the SA Request message and responds to all SA Request messages from all MSDP peers. This parameter is configured using the **peer sa-request-policy** command.
Sa-policy	Whether the filtering rule for receiving or forwarding the SA message is configured. By default, the switch does not filter the received or forwarded SA messages. This parameter is configured using the **peer sa-policy** command.

Item	Description
Connect-retry-period	Interval for retrying to set up a TCP connection between MSDP peers. By default, the interval for retrying to set up an MSDP peer relationship is 30 seconds. This parameter is configured using the **timer retry** command.
Minimum TTL	TTL value of SA messages that are encapsulated with multicast data. By default, the TTL value of SA messages that are encapsulated with multicast data is 0. This parameter is configured using the **peer minimum-ttl** command.

8.5.4 display msdp brief

Function

The **display msdp brief** command displays summary information about the status of MSDP peers.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **brief** [**state** { **connect** | **down** | **listen** | **shutdown** | **up** }]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only the public network instance is displayed.	-
state	Displays summary information about the MSDP peers in specified status.	-
connect	Indicates the MSDP peers in Connect state.	-

Parameter	Description	Value
down	Indicates the MSDP peers in Down state.	-
listen	Indicates the MSDP peers in Listen state.	-
shutdown	Indicates the MSDP peers in Shutdown state.	-
up	Indicates the MSDP peers in Up state.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After MSDP peers establish a TCP connection, the **display msdp brief** command can be used to display the brief information about the remote MSDP peer, such as the address, AS number, the number of (S, G) entries, and the status of the TCP connection.

Precautions

This command displays summary information about the status of MSDP peers only when the MSDP peer has been configured.

MSDP specifies that the peer with the higher IP address acts as the server and listens at port 639. The peer with the lower IP address acts as client and enables the connection. If the connection fails, the client enables the connection again.

Example

Display summary information about MSDP peers.

```
<HUAWEI> display msdp brief
MSDP Peer Brief Information
  Configured   Up          Listen      Connect     Shutdown     Down
  2            2           0           0           0            0

  Peer's Address     State     Up/Down time    AS     SA Count   Reset Count
  192.168.3.2        Up        01:07:08        ?      8          0
  192.168.5.1        Up        00:16:39        ?      13         0
```

Table 8-73 Description of the **display msdp brief** command output

Item	Description
MSDP Peer Brief Information	summary information about MSDP peers.
Configured	Total number of configured MSDP peers.
Up	Number of MSDP peers in Up state.
Listen	Number of MSDP peers in Listen state.
Connect	Number of MSDP peers in Connect state.
Shutdown	Number of MSDP peers in Shutdown state.
Down	Number of MSDP peers in Down state.
Peer's Address	Address of the peer. This parameter is configured using the **peer connect-interface (MSDP)** command.
State	Status of the MSDP session. ● Up: The connection is set up and is in Up state. ● Listen: The local device acts as the server and is in Listen state. The connection is not set up. ● Connect: The local device acts as the client and is in Connect state. The connection is not set up. ● Shutdown: The MSDP peer is in Shutdown state. ● Down: The connection fails.
Up/Down time	Time when the session becomes Up or Down. The time format is as follows: ● Time that is shorter than or equal to 24 hours: hour: minute: second. ● Time that is longer than 24 hours but shorter than or equal to one week: day: hour. ● Time that is longer than one week: week: day.
AS	The AS number of the MSDP peer. A question mark (?) indicates that the AS number cannot be obtained.
SA Count	Number of (S, G) entries in the SA cache.
Reset Count	Resetting times, including the resetting because the Notification message is received or Holdtimer times out.

8.5.5 display msdp control-message counters

Function

The **display msdp control-message counters** command displays statistics about MSDP messages.

Format

display msdp control-message counters [**peer** *peer-address* | **message-type** { **source-active** | **sa-request** | **sa-response** | **keepalive** | **notification** | **traceroute-request** | **traceroute-reply** | **data-packets** | **unknown-type** }] *

Parameters

Parameter	Description	Value
peer *peer-address*	Specifies IP address of MSDP peer. If **peer** *peer-address* is specified, only statistics about the MSDP messages received, sent, and discarded on a specified MSDP peer are displayed.	The value is in dotted decimal notation.
message-type	Specifies MSDP message types. If **message-type** is specified, only statistics about the MSDP messages received, sent, and discarded of a specified type are displayed.	-
source-active	Displays the statistics about Source-Active messages on the interface.	-
sa-request	Displays the statistics about Source-Active Request messages on the interface.	-
sa-response	Displays the statistics about Source-Active Response messages on the interface.	-
keepalive	Displays the statistics about KeepAlive messages on the interface.	-
notification	Displays the statistics about Notification messages on the interface.	-
traceroute-request	Displays the statistics about Traceroute Request messages on the interface.	-
traceroute-reply	Displays the statistics about Traceroute Reply messages on the interface.	-
data-packets	Displays the statistics about data packets on the interface.	-

Parameter	Description	Value
unknown-type	Displays the statistics about unknown type messages on the interface.	-

Usage Guidelines

Usage Scenario

This command helps you learn MSDP running status by displaying statistics about received, sent, and discarded MSDP messages.

Precautions

This command displays statistics about MSDP messages only when the MSDP peer has been configured.

Example

Display statistics about the MSDP messages that are received, sent, and discarded by the peer 192.168.3.3.

```
<HUAWEI> display msdp control-message counters peer 192.168.3.3
 MSDP message counters for peer: 192.168.3.3
                         Received        Sent            Invalid
 Source-Active              0              0               0
 Source-Active Request      0              0               0
 Source-Active Response     0              0               0
 KeepAlive                 48             49               0
 Notification               0              1               0
 Traceroute Request         0              -               -
 Traceroute Reply           0              -               -
 Data Packets               0              0               0
 Unknown Type               1              -               1
```

Table 8-74 Description of the **display msdp control-message counters peer 192.168.3.3** command output

Item	Description
MSDP message counters for peer	IP addresses of MSDP peers.
Received	Number of received messages.
Sent	Number of sent messages.
Invalid	Number of invalid messages.

Item	Description
Source-Active	Source-Active message: carries multiple (S, G) entries and is transmitted among several RPs; encapsulates PIM-SM multicast data.
Source-Active Request	Source-Active Request message: requests (S, G) list of a specified group G to reduce the delay in joining the group.
Source-Active Response	Source-Active Response message: responds to SA request messages.
KeepAlive	Keepalive message: maintains MSDP peer connections. Keepalive packets are sent only when no other protocol packets are exchanged between MSDP peers.
Notification	Notification message.
Traceroute Request	Traceroute Request message: traces and detects the RPF path along which SA messages are transmitted.
Traceroute Reply	Traceroute Reply message: traces and detects the RPF path along which SA messages are transmitted.
Data Packets	Data packets.
Unknown Type	Unknown type message.

8.5.6 display msdp invalid-packet

Function

The **display msdp invalid-packet** command displays statistics about invalid MSDP messages received by a device and details of these messages.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet** [**peer** *peer-address* | **message-type** { **keepalive** | **notification** | **sa-request** | **sa-response** | **source-active** }] *

display msdp invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays statistics about invalid MSDP messages received in all VPN instances. If **vpn-instance** or **all-instance** is not specified, only the public network instance is displayed.	-
peer *peer-address*	Displays statistics about invalid MSDP messages received from a specified peer. *peer-address* specifies an MSDP peer address.	The address is in dotted decimal notation.
message-type	Displays statistics about invalid MSDP messages of a specific type.	-
keepalive	Displays statistics about invalid Keepalive messages.	-
notification	Displays statistics about invalid Notification messages.	-
sa-request	Displays statistics about invalid Source-Active Request messages.	-
sa-response	Displays statistics about invalid Source-Active Response messages.	-
source-active	Displays statistics about invalid Source-Active messages.	-
packet-number	Displays details about a specified number of invalid MSDP messages recently received. If this parameter is not specified, details about all invalid MSDP messages.	The value is an integer that ranges from 1 to 100.
verbose	Displays details about invalid MSDP messages.	-

1: Monitoring level

Usage Guidelines

You can run the **display msdp invalid-packet** command to view statistics and details of invalid MSDP messages for fault location and rectification.

If MSDP peer relationships fail to be set up on a multicast network, you can run the **display msdp invalid-packet** command first to check whether devices have received invalid MSDP messages. If the command output contains statistics about invalid MSDP messages, run the **display msdp invalid-packet** [*packet-number*] **verbose** command to view details of invalid MSDP messages to locate the fault.

You can run the following related commands to view information about specific invalid MSDP messages:

- Run the **display msdp** [**vpn-instance** *vpn-instance-name* | **all-instance**] **invalid-packet** command to view statistics about invalid MSDP messages received in a specified VPN instance or in all VPN instances.
- Run the **display msdp invalid-packet peer** *peer-address* command to view statistics about invalid MSDP messages received from a specified peer.
- Run the **display msdp invalid-packet** *packet-number* **verbose** command to view details of invalid MSDP messages recently received. Currently, details of a maximum of 100 invalid MSDP messages can be displayed.

Example

Display statistics about invalid MSDP messages received by a device.

```
<HUAWEI> display msdp invalid-packet peer 192.168.1.1

            Statistics of invalid packets for public net:
-------------------------------------------------------------------
MSDP SA invalid packet:
Fault Length            : 0           Bad Length-x            : 0
Bad Sprefix             : 0           Invalid Multicast Group : 0
Invalid Multicast Source: 0           Bad Encap Data          : 0
Illegal RP Addr         : 0           RP Loop                 : 0

MSDP SA Response invalid packet:
Fault Length            : 0           Bad Length-x            : 0
Bad Sprefix             : 0           Invalid Multicast Group : 0
Invalid Multicast Source: 0           Illegal RP Addr         : 0
RP Loop                 : 0

MSDP SA Request invalid packet:
Fault Length            : 0           Invalid Multicast Group : 0

MSDP Keep Alive invalid packet:
Fault Length            : 0

MSDP Notification invalid packet:
Fault Length            : 0
-------------------------------------------------------------------
```

Table 8-75 Description of the **display msdp invalid-packet peer 192.168.1.1** command output

Item	Description
Statistics of invalid packets for public net	Statistics about invalid MSDP messages in the public network instance.

Item	Description
MSDP SA invalid packet	Invalid Source-Active messages.
Fault Length	Messages with invalid lengths.
Bad Length-x	Messages with invalid Length-x fields.
Bad Sprefix	Messages with invalid Sprefix fields.
Invalid Multicast Group	Messages with invalid multicast group addresses.
Invalid Multicast Source	Messages with invalid multicast source addresses.
Bad Encap Data	Messages with invalid data encapsulated.
Illegal RP Addr	Messages with illegal Rendezvous Point addresses.
RP Loop	Messages whose Rendezvous Point addresses are local addresses.
MSDP SA Response invalid packet	Invalid Source-Active Response messages.
MSDP SA Request invalid packet	Invalid Source-Active Request messages.
MSDP Keep Alive invalid packet	Invalid Keepalive messages.
MSDP Notification invalid packet	Invalid Notification messages.

Display details of a specific invalid MSDP message recently received.

```
<HUAWEI> display msdp invalid-packet 1 verbose
       Detailed information of invalid packets
-----------------------------------------------------
Packet information (Index 1):
-----------------------------------------------------
Peer                :  10.2.2.2
Time                :  2010-6-9 11:25:46 UTC-08:00
Message Length      :  22
Invalid Type        :  Invalid Addr List
0000: 00 01 00 02 00 69 00 13 00 04 00 00 00 64 00 02
0010: 00 04 81 f4 09 c4
-----------------------------------------------------
```

Table 8-76 Description of the **display msdp invalid-packet 1 verbose** command output

Item	Description
Detailed information of invalid packets	Details about invalid MSDP messages.

Item	Description
Packet information (Index 1)	Sequence number of the invalid MSDP message (numbered in the opposite order that the message is received, for example, the index of the last received message is 1, the index of the last but one message is 2, and so on).
Peer	IP address of the peer that sends the invalid MSDP message.
Time	Time when the invalid MSDP message is received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is configured through the **clock timezone** command; DST indicates that the daylight saving time is configured through **clock daylight-saving-time** command.
Message Length	Length of the invalid MSDP message.
Invalid Type	Type of the invalid MSDP message.
0000: 00 01 00 02 00 69 00 13 00 04 00 00 00 64 00 02 0010: 00 04 81 f4 09 c4	Contents of the invalid MSDP message.

8.5.7 display msdp peer-status

Function

The **display msdp peer-status** command displays the detailed information about MSDP peers.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **peer-status** [*peer-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only the public network instance is displayed.	-
peer-address	Specifies the address of a remote MSDP peer. If this parameter is not specified, information about all the MSDP peers in the instance is displayed.	The address is in dotted decimal notation.

Usage Guidelines

Usage Scenario

After MSDP peers establish a TCP connection, the **display msdp peer-status** command can be used to display the detailed information about a specified MSDP peer, such as the interface status, interface configuration, policy for filtering messages, and number of messages.

Precautions

This command displays the detailed information about a specified MSDP peer only when the MSDP peer has been configured.

Example

Display the detailed information about the MSDP peer 10.110.11.11.

```
<HUAWEI> display msdp peer-status 10.110.11.11
 MSDP Peer 10.110.11.11, AS 100
 Description:
 Information about connection status:
   State: Up
   Up/down time: 14:41:08
   Resets: 0
   Connection interface: LoopBack0 (10.110.11.22)
   Number of sent/received messages: 867/947
   Number of discarded output messages: 0
   Elapsed time since last connection or counters clear: 14:42:40
```

```
Information about (Source, Group)-based SA filtering policy:
  Import policy: none
  Export policy: none
  Local Export policy: none
Information about SA-Requests:
  Policy to accept SA-Request messages: none
  Sending SA-Requests status: disable
Minimum TTL to forward SA with encapsulated data: 0
SAs learned from this peer: 0, SA-cache maximum for the peer: none
Input queue size: 0, Output queue size: 0
Counters for MSDP message:
  Count of RPF check failure: 0
  Incoming/outgoing SA messages: 0/0
  Incoming/outgoing SA requests: 0/0
  Incoming/outgoing SA responses: 0/0
  Incoming/outgoing data packets: 0/0
Peer authentication: unconfigured
Peer authentication type: none
```

Table 8-77 Description of the **display msdp peer-status** command output

Item	Description
MSDP Peer	Address of the peer. This parameter is configured using the **peer connect-interface (MSDP)** command.
AS	AS number of the MSDP peer. A question mark (?) indicates that the AS number cannot be obtained.
Description	Description of the verbose information.
Information about connection status	Information of connection status.
