dhcp-server	Specifies the packets sent by DHCP servers.	-
igmp	Specifies IGMP packets.	-
nd	Specifies IPv6 ND packets.	-
pim	Specifies PIM protocol packets.	-
all	Specifies all devices in a stack if a stack is established or the local device if no stack is established.	-
mcu	Specifies the main control board.	-
slot *slot-id*	● Specifies a slot ID if stacking is not configured. ● Specifies a stack ID if stacking is configured.	The value must be set according to the device configuration.

1: Monitoring level

Usage Guidelines

After adaptive CPCAR adjustment for protocol packets is enabled, you can run this command to view the historical adaptive CPCAR adjustment records of protocol packets. The information includes the adjustment time, CPCAR adjustments, and reason for the adjustments.

You can use this command to check a maximum of 100 latest historical records.

Example

Display historical adaptive CPCAR adjustment records of protocol packets.

```
<HUAWEI> display cpu-defend dynamic-adjust history-record all
Dynamic-adjust history-record on mainboard:
-----------------------------------------------------------------------------------------

Adjustment time     Packet type     Default/Previous/Current(kbps) Reason
2019-04-22 11:00:41 arp-request-uc  384/672/720                CPCAR drop
packet
2019-04-22 10:59:41 arp-request-uc  384/624/672                CPCAR drop

```

Table 14-31 Description of the **display cpu-defend dynamic-adjust history-record** command output

Item	Description
Dynamic-adjust history-record on mainboard	Historical adaptive CPCAR adjustment records of protocol packets on the main control board.
Adjustment time	Time when the CPCAR value was adjusted.
Packet type	Type of protocol packets.

Item	Description
Default/Previous/ Current(kbps)	- **Default**: default CPCAR value (in kbit/s) - **Previous**: CPCAR value after the last adjustment (in kbit/s) - **Current**: current CPCAR value (in kbit/s)
Reason	Reason for the adjustment: - **CPCAR drop packet**: Packet loss occurred due to CPCAR exceeding. - **CPU queue drop packet**: Packet loss occurred in the CPU queue. - **CPU overload**: The CPU was overloaded. - **Set default**: CPCAR was restored to the default value.
Dynamic-adjust history-record on slot 0	Historical adaptive CPCAR adjustment records of protocol packets in a slot.

14.2.42 display cpu-defend dynamic-car history-record

Function

The **display cpu-defend dynamic-car history-record** command displays historical records on dynamic adjustment of the default CIR value of protocol packets.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display cpu-defend dynamic-car history-record

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the default CIR value is set, you can run this command to view the historical records of adjusting the CPCAR value of protocol packets from 64 kbit/s to a specific value.

The granularity of each adjustment is 64 kbit/s on the switch. If the default CPCAR value is greater than 64 kbit/s, the adjustments from 64 kbit/s to the default CPCAR value are only recorded but do not take effect.

You can use this command to check a maximum of 100 latest historical records.

Example

Display the historical records on dynamic adjustment of the default CIR value of protocol packets.

```
<HUAWEI> display cpu-defend dynamic-car history-record
 Global status : Enable
 -------------------------------------------------------------------------------
 Time                Protocol    Packet-type     Slot  CIR(Kbps)   Status
 -------------------------------------------------------------------------------
 2012-08-24 11:28:10  arp        arp-reply       0     128         Success
 2012-08-24 11:28:08  arp        arp-request     0     128         Success
 2012-08-24 11:27:37  arp        arp-reply       0     64          Success
 2012-08-24 11:27:37  arp        arp-request     0     64          Success
-------------------------------------------------------------------------------
```

Table 14-32 Description of the display cpu-defend dynamic-car history-record command output

Item	Description
Global status	The device is enabled to dynamically adjust the default CIR value of protocol packets. To enable the device to dynamically adjust the default CIR value of protocol packets, run the **cpu-defend dynamic-car enable** command.
Time	Timestamps of the default CIR value of protocol packets that is dynamically adjusted.
Protocol	Protocol name. To configure a protocol, run the **cpu-defend dynamic-car** [**arp** | **vrrp**] command.
Packet-type	Packet type.
Slot	ID of the stack where the default CIR value is dynamically adjusted. The value indicates the slot ID if stacking is not configured.

Item	Description
CIR(Kbps)	Dynamically adjusted default CIR value, in kbit/s. If the default CIR value restores to the original default CIR value, NA is displayed. **NOTE** When the rate of sending packets to the CPU is too large, the CPU becomes overloaded. The device restores the original default CIR value for protocol packets and this field is displayed as NA.
Status	Result of dynamic adjustment. The value can be: ● success: indicates that the adjustment succeeds. ● fail: indicates that the adjustment fails. ● conflict: indicates that the adjusted default CIR value conflicts the configured CIR value. The CIR value configured by users takes effect.

14.2.43 display cpu-defend host-car statistics

Function

The **display cpu-defend host-car statistics** command displays the number of packets discarded in user-level rate limiting.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display cpu-defend host-car [**mac-address** *mac-address*] **statistics** [**slot** *slot-id*]

Parameters

Parameter	Description	Value
mac-address *mac-address*	Indicates the number of discarded packets from the specified MAC address.	-
slot *slot-id*	Indicates the number of packets discarded by the specified slot.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To view the number of packets discarded in the user-level rate limiting, run this command.

Precautions

- Before using this command, run the **cpu-defend host-car enable** command to enable user-level rate limiting.
- If the number of discarded packets is 0, the index is not displayed.

Example

Display the number of packets discarded in the user-level rate limiting.

```
<HUAWEI> display cpu-defend host-car statistics
slot 0
car-id                          car-drop
----------------------------------------------
3192                              740385
3347                                   7
4133                              529474
4471                              529477
5075                              529476
5836                              529474
6046                             1001218
```

Table 14-33 Description of the display cpu-defend host-car statistics command output

Item	Description
slot	Slot ID.
car-id	Bucket ID for rate limiting.
car-drop	Number of dropped packets whose rate exceeds the CAR. To configure the CAR value, run the **cpu-defend host-car** [**mac-address** *mac-address* | **car-id** *car-id*] **pps** *pps-value* command.

14.2.44 display cpu-defend policy

Function

The **display cpu-defend policy** command displays the attack defense policy configuration.

Format

display cpu-defend policy [*policy-name*]

Parameters

Parameter	Description	Value
policy-name	Displays the configuration of a specified attack defense policy. ● If *policy-name* is specified, information about the specified attack defense policy is displayed. ● If *policy-name* is not specified, information about all attack defense policies is displayed.	The attack defense policy must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After an attack defense policy is created, you can run the **display cpu-defend policy** command to view the stack ID that the attack defense policy is applied to and configurations of the attack defense policy.

Example

Display information about all attack defense policies.

```
<HUAWEI> display cpu-defend policy
  ----------------------------------------------------------------
 Name  : default
 Related slot : <3>
  ----------------------------------------------------------------
 Name  : test
 Description : defend_arp_attack
 Related slot : <mcu>
```

Display information about the attack defense policy named **test**.

```
<HUAWEI> display cpu-defend policy test
 Description : defend_arp_attack
```

```
Related slot : <0>
Configuration :
  Whitelist 1 ACL number : 2002
  Blacklist 1 ACL number : 2001
  Car packet-type arp-request : CIR(128)  CBS(24064)
  Deny packet-type arp-reply
  Port-type eni packet-type arp-request
  Linkup-car packet-type  ftp : CIR(5000)  CBS(940000)
```

Table 14-34 Description of the display cpu-defend policy command output

Item	Description
Name	Name of an attack defense policy. To configure an attack defense policy, run the **cpu-defend policy** command.
Description	Description of an attack defense policy. To configure a description for an attack defense policy, run the **description** command.
Related slot	Slot ID or stack ID that an attack defense policy is applied to. When mcu is displayed, it indicates the main control board.
Whitelist 1 ACL number	Number of an ACL defined in whitelist 1. To configure a whitelist, run the **whitelist** command.
Blacklist 1 ACL number	Number of an ACL defined in blacklist 1. To configure a blacklist, run the **blacklist** command.
Car packet-type arp-request	CIR values of ARP Request packets. To set the CIR values for ARP Request packets, run the **car** command.
Deny packet-type arp-reply	ARP Reply packets are discarded. To configure the device to discard ARP Reply packets, run the **deny** command.
Port-type eni packet-type arp-request	ARP Request packets are sent to the CPU through ENI ports.
Linkup-car packet-type ftp	CIR values of FTP packets after an FTP connection is set up. To set the CIR values of FTP packets after an FTP connection is set up, run the **linkup-car** and **cpu-defend application-apperceive enable** commands.

14.2.45 display cpu-defend port-type

Function

The **display cpu-defend port-type** command displays physical interfaces of Network-to-Network Interface (NNI), User-to-Network Interface (UNI), and Enhanced Network Interface (ENI) types.

NOTE

Only the S6735-S, S6720S-EI and S6720-EI support this command.

Format

display cpu-defend port-type slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	• This parameter specifies the slot ID if stacking is not configured. • This parameter specifies the stack ID if a stack is configured.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After specifying interfaces types for sending protocol packets using the **port type** { **uni** | **eni** | **nni** } and **port-type** { **uni** | **eni** | **nni** } **packet-type** *type* commands, you can run the **display cpu-defend port-type** command to view types of interfaces on the device.

Example

Display interface types in stack 0.

```
<HUAWEI> display cpu-defend port-type slot 0
 Uni Port :
 Eni Port :
 Nni Port :GigabitEthernet0/0/1-22
```

Table 14-35 Description of the display cpu-defend port-type command output

Item	Description
Uni Port	The interface is a user-side interface on the device.
Eni Port	The interface is an interface connected to another switch or user.
Nni Port	The interface is a network-side interface on the device.

14.2.46 display cpu-defend rate

Function

The **display cpu-defend rate** command displays the rate of sending protocol packets to the CPU.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display cpu-defend rate [**packet-type** *packet-type*] { **all** | **slot** *slot-id* }

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies a packet type.	The supported packet type depends on the device.
all	Indicates all switches in a stack if stack is enabled, or the switch itself if stack is disabled.	-
slot *slot-id*	● This parameter specifies the slot ID if stacking is not configured. ● This parameter specifies the stack ID if stack is enabled.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display cpu-defend rate** command to view the rate of sending protocol packets to the CPU when checking the configuration of an attack defense policy. In this way, you can determine which type of protocols may attack the CPU based on the rate.

NOTE

To ensure normal operation of other services and protect the CPU, the rate of incremental protocol packets is calculated only in a specified period after you run the **display cpu-defend rate** command and displayed on the terminal. After you run this command, a message is displayed to wait for a while.

Example

Display the rate of ARP Reply packets sent from the switch to the CPU.

```
<HUAWEI> display cpu-defend rate packet-type arp-reply slot 0
Info: Please wait for a moment....
Cpu-defend rate on slot 0:
-------------------------------------------------------------------------------
Packet Type          Pass(bps)    Drop(bps)       Pass(pps)       Drop(pps)
-------------------------------------------------------------------------------
arp-reply              49504       86496            91             159
-------------------------------------------------------------------------------
```

Table 14-36 Description of the **display cpu-defend rate** command output

Item	Description
Packet Type	Packet type.
Pass(bps)	Number of forwarded bits within one second.
Drop(bps)	Number of discarded bits within one second.
Pass(pps)	Number of forwarded packets within one second.
Drop(pps)	Number of discarded packets within one second.

14.2.47 display cpu-defend statistics

Function

The **display cpu-defend statistics** command displays statistics on packets sent to the CPU.

Format

display cpu-defend statistics [**packet-type** *packet-type*] [**all** | **slot** *slot-id*]

NOTE

The S1720GW-E and S1720GWR-E do not support this command.

Parameters

Parameter	Description	Value
packet-type *packet-type*	Displays statistics about the specified type of packets. *packet-type* specifies the packet type. ● If *packet-type* is specified, statistics on the specified type of protocol packets are displayed. ● If *packet-type* is not specified, statistics on all protocol packets are displayed.	The value depends on the protocol types supported by the device. **NOTE** You can specify the **ftp** parameter to view IPv6 FTP packet statistics.
all	Displays packet statistics about all the member switches in a stack if stacking is enabled or on the local switch if stacking is disabled. If **all** and **slot** are not specified, the CAR statistics on the master switch in a stack are displayed.	-
slot *slot-id*	● Specifies the slot ID if stacking is not configured. ● Specifies the stack ID if stacking is configured.	The value depends on the actual configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display cpu-defend statistics** command displays statistics on packets sent to the CPU, including the number of forwarded and discarded packets. This helps the network administrator configure attack defense policies.

Precautions

If neither **all** nor **slot** is specified, the CAR statistics on the master switch in a stack are displayed.

Example

Display CAR statistics on the switch. (S5731-H used as an example)

```
<HUAWEI> display cpu-defend statistics
 Statistics on slot 0:
-----------------------------------------------------------------------------
Packet Type         Pass(Packet/Byte)   Drop(Packet/Byte)  Last-dropping-time
-----------------------------------------------------------------------------
arp-miss                       0                0                 -
                            0                0
arp-reply                      0                0                 -
                            0                0
arp-request                     0                0                 -
                            0                0
......
```

Display CAR statistics on the switch. (S5720-LI used as an example)

```
<HUAWEI> display cpu-defend statistics
 Statistics on mainboard:

-------------------------------------------------------------------------------
telnet                     0           0
-------------------------------------------------------------------------------
```

NOTE

The preceding information is an example. The displayed packet type depends on the actual situation.

Table 14-37 Description of the **display cpu-defend statistics** command output

Item	Description
Statistics on slot 0	CAR statistics about protocol packets on a specified switch or stack. **NOTE** On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, you cannot view packet statistics on interfaces of the master switch in a stack.
Statistics on mainboard	CAR statistics about protocol packets on the MCU.
Linkup statistics on slot 0	CAR statistics about protocol packets collected when the protocol connection is established.
Packet Type	Packet type.

Item	Description
Pass(Packet/Byte)	Number of passed packets or bytes. **NOTE** The S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S does not support packet statistics collection based on the number of bytes.
Drop(Packet/Byte)	Number of dropped packets or bytes. **NOTE** When the length exceeds 11 digits, the end of the value is displayed as **k**, indicating that the value is multiplied by 1000. When the length exceeds 14 digits, the end of the value is displayed as **m**, indicating that the value is multiplied by 1000000. When the length exceeds 17 digits, the end of the value is displayed as **g**, indicating that the value is multiplied by 1000000000. Statistics on discarded packets cannot be collected for the standby and slave switches in a stack, which cover the following switch models: S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S
Last-dropping-time	Last time statistics about dropped packets were collected.

14.2.48 host-car disable

Function

The **host-car disable** command disables user-level rate limiting on interfaces.

The **undo host-car disable** command enables user-level rate limiting on interfaces.

By default, user-level rate limiting is enabled on all interfaces.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

host-car disable

undo host-car disable

Parameters

None

Views

GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch performs user-level rate limiting on the users connecting to all interfaces. If you are sure that the users connecting to an interface are secure, you can disable user-level rate limiting on this interface.

Precautions

- Before using this command, run the **cpu-defend host-car enable** command to enable user-level rate limiting.
- After user-level rate limiting is disabled on an interface, the switch does not limit the rate of packets received from the specified user MAC address and cannot protect the interface against attacks. In addition, the packets of the same type sent from other users may be affected.
- Disable user-level rate limiting on network-side interfaces to prevent DHCP and ARP packets from being discarded.

Example

Disable user-level rate limiting on the interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] host-car disable
```

14.2.49 linkup-car

Function

The **linkup-car** command sets the CPCAR value for packets of a protocol connection, including the Committed Information Rate (CIR) and Committed Burst Size (CBS).

The **undo linkup-car** command restores the default CPCAR rate limit.

Table 14-38 lists the default CIR and CBS values for the setup of BGP, BGP4+, FTP, IPv6 FTP, HTTP, HTTPS, IKE, IPSEC-ESP, ISIS, OSPF, OSPFv3, SSH, TELNET, and TFTP connections; the CIR and CBS for sending packets of IP-CLOUD connections are 2048 kbit/s and 385024 bytes respectively.

Format

linkup-car packet-type { **bgp** | **bgp4plus** | **ftp** | **ftpv6** | **http** | **https** | **ike** | **ip-cloud** | **ipsec-esp** | **isis** | **ospf** | **ospfv3** | **ssh** | **telnet** | **tftp** } **cir** *cir-value* [**cbs** *cbs-value*]

undo linkup-car packet-type { **bgp** | **bgp4plus** | **ftp** | **ftpv6** | **http** | **https** | **ike** | **ip-cloud** | **ipsec-esp** | **isis** | **ospf** | **ospfv3** | **ssh** | **telnet** | **tftp** }

NOTE

- Only the S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **bgp** parameter.
- Only the S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **https** parameter.
- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **bgp4plus** and **isis** parameter.
- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **ospfv3** parameter.
- Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6735-S, S6720-EI, and S6720S-EI support the **ike** parameter.
- Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **ipsec-esp** parameter.
- Only the S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5720S-LI, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **ospf** parameter.
- Only the S200, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H support the **ip-cloud** parameter.

Parameters

Parameter	Description	Value
bgp	Indicates that the protocol type is BGP.	-
bgp4plus	Indicates that the protocol type is BGP4+.	-
ftp	Indicates that the protocol type is FTP.	-

Parameter	Description	Value
ftpv6	Indicates that the protocol type is IPv6 FTP.	-
http	Indicates that the protocol type is HTTP.	-
https	Indicates that the protocol type is HTTPS.	-
ike	Indicates that the protocol type is IKE. This parameter does not take effect in non-NAT scenarios.	-
ip-cloud	Indicates that the protocol type is IP-CLOUD.	-
ipsec-esp	Indicates that the protocol type is IPSEC-ESP. **ipsec-esp** specified in the **linkup-car** command indicates the type of the protocol used by IPsec EVPN, and **ipsec-esp** specified in the **car** command indicates the type of the protocol used by OSPFv3.	-
isis	Indicates that the protocol type is ISIS.	-
ospf	Indicates the protocol type is OSPF.	-
ospfv3	Indicates the protocol type is OSPFv3.	-
ssh	Indicates the protocol type is SSH.	-
telnet	Indicates the protocol type is TELNET.	-
tftp	Indicates the protocol type is TFTP.	-
cir *cir-value*	Specifies the CIR value.	The value is an integer that ranges from 64 to 65535, in kbit/s.

Parameter	Description	Value
cbs *cbs-value*	Specifies the CBS value.	The value is an integer that ranges from 10000 to 4294967295, in bytes. If the **cbs** is not set, the default *cbs-value* is 188 times the *cir-value*.

Views

Attack defense policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The default CPCAR value of BGP, BGP4+, FTP, IPv6 FTP, HTTP, HTTPS, IP-CLOUD, ISIS, OSPFv3, OSPF, IKE, IPSEC-ESP, SSH, TFTP, or TELNET protocol is small. When a switch uses these protocols to transfer files or set up connections with other hosts or devices, the number of protocol packets sharply increases in a short period. When the packet rate exceeds the limit, the protocol packets are dropped. The switch may also undergo attacks of other protocols. This affects data transmission and causes service interruption.

You can run the **cpu-defend application-apperceive** command to enable active link protection, ensuring normal operation of these protocols related services when attacks occur. When a connection is set up, the switch sends packets at the rate of the CPCAR value configured using the **linkup-car** command. The CPCAR value can be set as required.

Follow-up Procedure

Run the **cpu-defend application-apperceive enable** command to enable ALP to enable the rate limit set using the **linkup-car** command. By default, ALP is enabled on FTP, IPv6 FTP, HTTP, IP-CLOUD, HTTPS, IKE, IPSEC-ESP, TFTP, SSH, and TELNET packets and disabled on BGP, BGP4+, ISIS, OSPF, and OSPFv3 packets.

Precautions

You are advised to run the **display cpu-defend configuration** command to check the CIR value supported by the protocol being used before running the **linkup-car** command to set the rate limit.

BGP, BGP4+, ISIS, OSPF, and OSPFv3 are disabled when the configuration is initialized. You can set the rate limit using the **car** command before the protocols are enabled and the **linkup-car** command after connections are set up and ALP is enabled.

You can set a shared CPCAR value for packets of FTP, IPv6 FTP, SSH, TFTP connections on S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-

H, and S5736-S. For example, the **linkup-car packet-type ftp cir** *cir-value* [**cbs** *cbs-value*] command specifies the CPCAR value for FTP packets when an FTP connection is set up, and also specifies the CPCAR value for packets of IPv6 FTP, SSH, TFTP connections.

Table 14-38 Default CIR and CBS values

Product	CIR	CBS
SS1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI	• FTP, IPv6 FTP, HTTP, SSH, TFTP: 1024 kbit/s • IKE: 64 kbit/s • IPSEC-ESP: 320 kbit/s • OSPF: 512 kbit/s • TELNET: 64 kbit/s	• FTP, IPv6 FTP, HTTP, SSH, TFTP: 192512 bytes • IKE: 12032 bytes • IPSEC-ESP: 60160 bytes • OSPF: 96256 bytes • TELNET: 12032 bytes

Example

Set the CIR and CBS for BGP packets to 1000 kbit/s and 100000 bytes.

```
<HUAWEI> system-view
[HUAWEI] cpu-defend policy test
[HUAWEI-cpu-defend-policy-test] linkup-car packet-type bgp cir 1000 cbs 100000
```

14.2.50 port type

Function

The **port type** command configures the interface type. The interface type can be Network-to-Network Interface (NNI), User-to-Network Interface (UNI), or Enhanced Network Interface (ENI).

The **undo port type** command cancels the configuration.

By default, the interface type is NNI.

NOTE

Only the S6735-S, S6720S-EI and S6720-EI support this command.

Format

port type { **uni** | **eni** | **nni** }

undo port type

Parameters

Parameter	Description	Value
uni	Indicates that the interface is a user-side interface on the device.	-
eni	Indicates that the interface is connected to another switch or user. An ENI supports all protocols that are supported by an UNI.	-
nni	Indicates that the interface is a network-side interface on the device. An NNI supports all protocol packets.	-

Views

40GE interface view, GE interface view, XGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, protocol packets that can be sent to the CPU are controlled by an ACL. If protocol packets are sent to the device, packets received by interfaces cannot be differentiated.

If an interface is attacked and the user disables the device to send packets, packets cannot be sent from other interfaces, affecting communications of the device. If an interface is attacked and the user does not disable the device to send packets, attack packets occupy resources and valid packets cannot be sent.

For example, OSPF is enabled on an interface and OSPF packets are sent to the device. If a non-OSPF interface is attacked, attack packets will occupy resources and valid OSPF packets cannot be forwarded. As a result, OSPF negotiation becomes slow or fails.

The **port type** command specifies the interface types according to the interface location. Interfaces of different types support different protocols and send only the packets of the supported protocols to the CPU. This reduces the workload of the CPU and provides flexible ways to protect the CPU.

Precautions

If you run the **port type** command multiple times, only the latest configuration takes effect.

Follow-up Procedure

This command differentiates packets from different types of interfaces so that the attack packets are denied and valid packets are forwarded. If an attack occurs, you can run the **deny** command to discard packets of a specified type or run the **car** command to limit the rate of a specified type of protocol packets.

Example

Configure GE0/0/1 as an NNI.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port type nni
```

14.2.51 port-type

Function

The **port-type** command maps interfaces to protocol types. The type can be User-to-Network Interface (UNI), Enhanced Network Interface (ENI), or Network-to-Network Interface (NNI).

The **undo port-type** command cancels the configuration.

By default, the type of interface sending protocol packets to the CPU is displayed using the **display cpu-defend configuration** command.

NOTE

Only the S6735-S, S6720S-EI and S6720-EI support this command.

Format

port-type { **uni** | **eni** | **nni** } **packet-type** *packet-type*

undo port-type [**uni** | **eni** | **nni**] **packet-type** *packet-type*

Parameters

Parameter	Description	Value
uni	Indicates that the interface is a user-side interface on the device.	-

Parameter	Description	Value
eni	Indicates that the interface is connected to another switch or user. An ENI supports all protocols that are supported by an UNI.	-
nni	Indicates that the interface is a network-side interface on the device. An NNI supports all protocol packets.	-
packet-type *packet-type*	Specifies the protocol supported by an interface type. A protocol is mapped to only one interface type.	The supported packet type depends on the device.

Views

Attack defense policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, protocol packets that can be sent to the CPU are controlled by an ACL. If protocol packets are sent to the device, packets received by interfaces cannot be differentiated.

If an interface is attacked and the user disables the device to send packets, packets cannot be sent from other interfaces, affecting communications of the device. If an interface is attacked and the user does not disable the device to send packets, attack packets occupy resources and valid packets cannot be sent.

The **port-type** command maps interfaces to protocol types. The **port type** command specifies the interface types according to port locations. By using the two commands, the interfaces send only the packets of the supported protocols. This reduces the workload of CPU and provides ways to flexibly protect the CPU.

NOTE

Protocol packets are not supported by the UNI, ENI, or NNI interfaces. These protocol packets are sent to the CPU for processing from any interface on the device.

Procedure

After you run the **port type** command to configure interface types, run the **port-type** command to specify the protocols supported by the interfaces and the method to process the protocol packets.

Precautions

If you run the **port-type** command multiple times, only the latest configuration takes effect because a protocol is mapped to only one interface type.

Follow-up Procedure

This command differentiates packets from different types of interfaces so that the attack packets are denied and valid packets are forwarded. If an attack occurs, you can run the **deny** command to discard a specified type of packets. When receiving packets of the type, the interfaces discard these packets. You can also run the **car (attack defense policy view)** command to limit the rate of attack packets of a specified type.

Example

Configure UNI interfaces to send ARP Reply packets to the CPU.

```
<HUAWEI> system-view
[HUAWEI] cpu-defend policy test
[HUAWEI-cpu-defend-policy-test] port-type uni packet-type arp-reply
[HUAWEI-cpu-defend-policy-test] quit
[HUAWEI] cpu-defend-policy test global
```

14.2.52 reset auto-defend attack-source

Function

The **reset auto-defend attack-source** command clears information about attack sources.

Format

reset auto-defend attack-source [**history**] [**slot** *slot-id*]

Parameters

Parameter	Description	Value
history	Deletes history attack source information. If **history** is not specified, all existing attack source information is deleted.	-
slot *slot-id*	- This parameter specifies the slot ID if stacking is not configured. - This parameter specifies the stack ID if stacking is enabled. If **slot** *slot-id* is not specified, information about attack sources is cleared.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view the latest attack source information on the device, run the **reset auto-defend attack-source** command to delete the existing attack source information, wait for a period, and run the **display auto-defend attack-source** command.

To delete history attack source information, run the **reset auto-defend attack-source history** command.

Precautions

After the **reset auto-defend attack-source** command is run, information about attack sources is cleared and cannot be restored.

Example

Delete existing attack source information on the device.

```
<HUAWEI> system-view
[HUAWEI] reset auto-defend attack-source
```

14.2.53 reset auto-defend attack-source trace-type

Function

The **reset auto-defend attack-source trace-type** command clears the counter of packets traced after attack source tracing based on source MAC addresses, source IP addresses, or source ports+VLANs is configured.

Format

reset auto-defend attack-source trace-type { **source-mac** [*mac-address*] | **source-ip** [*ipv4-address* | **ipv6** *ipv6-address*] | **source-portvlan** [**interface** *interface-type interface-number* **vlan-id** *vlan-id* [**cvlan-id** *cvlan-id*]] } [**slot** *slot-id*]

Parameters

Parameter	Description	Value
source-mac [*mac-address*]	Clears the counter of packets traced after attack source tracing based on source MAC addresses is configured. If *mac-address* is specified, the counter of traced packets sent from the specified MAC address is cleared.	The value of *mac-address* is in H-H-H format. An H contains 1 to 4 hexadecimal numbers.
source-ip [*ipv4-address* | **ipv6** *ipv6-address*]	Clears the counter of packets traced after attack source tracing based on source IP addresses is configured. If an ip-address is specified, the counter of traced packets sent from the specified IP address is cleared. ● *ipv4-address* specifies the IPv4 address of an interface. ● **ipv6** *ipv6-address* specifies the IPv6 address of an interface.	● The value of *ipv4-address* is in dotted decimal notation. ● The value of *ipv6-address* is in format X:X:X:X:X:X:X:X. The total length is 128 bit, which is divided into eight groups. The 16 bits of each group are represented by four hexadecimal characters.
source-portvlan [**interface** *interface-type interface-number* **vlan-id** *vlan-id* [**cvlan-id** *cvlan-id*]]	Clears the counter of packets traced after attack source tracing based on source ports+VLANs is configured. If a port or VLAN is specified, the counter of traced packets sent from the specified port or VLAN is cleared. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. ● **vlan-id** *vlan-id* specifies the ID of the VLAN. ● **cvlan-id** *cvlan-id* specifies the inner VLAN ID in a QinQ packet.	*vlan-id* is an integer that ranges from 1 to 4094. *cvlan-id* is an integer that ranges from 1 to 4094.

Parameter	Description	Value
slot *slot-id*	- This parameter specifies the slot ID if stacking is not configured. - This parameter specifies the stack ID if stack is enabled.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view information about attack sources in a specified period, run the **reset auto-defend attack-source** command to clear existing information about attack sources and run the **display auto-defend attack-source** command. However, the **reset auto-defend attack-source** clears information about all attack sources. You can run the **reset auto-defend attack-source trace-type** command to clear information about specified attack sources.

Precautions

After the **reset auto-defend attack-source trace-type** command is run, information about attack sources is cleared and cannot be restored.

Example

Clear the counter of traced packets sent from IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] reset auto-defend attack-source trace-type source-ip 10.1.1.1
```

14.2.54 reset auto-port-defend statistics

Function

The **reset auto-port-defend statistics** command deletes packet statistics on port attack defense.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset auto-port-defend statistics [**all** | **slot** *slot-id*]

Parameters

Parameter	Description	Value
all	Deletes packet statistics of port attack defense on the interfaces of all stacked switches in a stack environment or on all interfaces of the local switch in a non-stack environment. If **all** or **slot** *slot-id* is not specified, packet statistics on the master device (stack configured) or local device (stack not configured) are deleted.	-
slot *slot-id*	● The value indicates the slot ID if stacking is not configured. ● The value indicates the stack ID when stack is configured.	The value depends on the device configuration.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before viewing packet statistics of port attack defense in a certain period, delete existing packet statistics, and then run the **display auto-port-defend statistics** command to collect the latest statistics.

Precautions

The deleted packet statistics cannot be restored.

Example

Delete packet statistics on the interfaces of the device.

```
<HUAWEI> reset auto-port-defend statistics
```

14.2.55 reset cpu-defend dynamic-car history-record

Function

The **reset cpu-defend dynamic-car history-record** command clears history records on dynamic adjustment of the default CIR value of protocol packets.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset cpu-defend dynamic-car history-record

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **reset cpu-defend dynamic-car history-record** command to clear the previous records and run the **display cpu-defend dynamic-car history-record** command to view the history records on dynamic adjustment of the default CIR value of protocol packets in a specified period.

Precautions

The **reset cpu-defend dynamic-car history-record** command clears history records on dynamic adjustment of the default CIR value of protocol packets and the records cannot be restored.

Example

Clear the history records on dynamic adjustment of the default CIR value of protocol packets.

```
<HUAWEI> reset cpu-defend dynamic-car history-record
```

14.2.56 reset cpu-defend host-car statistics

Function

The **reset cpu-defend host-car statistics** command clears packet statistics in the user-level rate limiting.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

reset cpu-defend host-car [**mac-address** *mac-address*] **statistics** [**slot** *slot-id*]

Parameters

Parameter	Description	Value
mac-address *mac-address*	Clears statistics on the packets from the specified MAC address.	-
slot *slot-id*	Clears packet statistics on the specified slot.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Before viewing the latest packet statistics in the user-level rate limiting, run this command to clear existing packet statistics.

NOTICE

Packet statistics cannot be restored after they are deleted. Exercise caution when you use the command.

Example

Clear packet statistics in user-level rate limiting.

```
<HUAWEI> reset cpu-defend host-car statistics
```

14.2.57 reset cpu-defend statistics

Function

The **reset cpu-defend statistics** command clears statistics on packets sent to the CPU.

Format

reset cpu-defend statistics [**packet-type** *packet-type*] [**all** | **slot** *slot-id*]

NOTE

The S1720GW-E and S1720GWR-E do not support this command.

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies the protocol type of packets. *packet-type* specifies the packet type. ● If **packet-type** *packet-type* is specified, the statistics on the specified type of protocol packets are cleared. ● If **packet-type** *packet-type* is not specified, the statistics on all protocol packets are cleared.	The supported packet type depends on the device.
all	This parameter indicates all switches in a stack if stacking is enabled, or the switch itself if stack is disabled. If **all** and **slot** are not specified, the CAR statistics on the master switch in a stack are cleared.	-
slot *slot-id*	● This parameter specifies the slot ID if stacking is not configured. ● This parameter specifies the stack ID if stacking is enabled.	The value must be set according to the device configuration.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view statistics on the packets sent to the CPU in a specified period, run the **reset cpu-defend statistics** command to clear existing statistics and run the **display cpu-defend statistics** command.

Precautions

The deleted packet statistics cannot be restored.

Example

Clear statistics on BGP packets sent to the CPU.

```
<HUAWEI> reset cpu-defend statistics packet-type bgp slot 0
```

14.2.58 user-defined-flow

Function

The **user-defined-flow** command configures a user-defined flow.

The **undo user-defined-flow** command deletes a user-defined flow.

By default, no user-defined flow is configured.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

user-defined-flow *flow-id* **acl** *acl-number*

undo user-defined-flow *flow-id*

Parameters

Parameter	Description	Value
flow-id	Specifies the ID of the user-defined flow.	The value is an integer that ranges from 1 to 8.
acl *acl-number*	Specifies the number of an Access Control List (ACL). The ACL referenced by a user-defined flow on the device can be a basic ACL, an advanced ACL, or a Layer 2 ACL.	The value is an integer that ranges from 2000 to 4999. • 2000 to 2999: basic ACLs • 3000 to 3999: advanced ACLs • 4000 to 4999: Layer 2 ACLs

Views

Attack defense policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When unknown attacks occur on the network, you can run the **user-defined-flow** command to bind an ACL rule with a user-defined flow. Then you can run the **car user-defined-flow** *flow-id* **cir** *cir-value* [**cbs** *cbs-value*] command to limit the rate of flows with the specific characteristic or run the **deny user-defined-flow** *flow-id* command to discard these flows.

Precautions

If an ACL containing the deny action is applied to the user-defined flow, packets matching the ACL are discarded.

The priority of user-defined flows is higher than that of dynamic link protection. That is, if a user-defined flow is configured on a device and packets match the user-defined flow, dynamic link protection does not take effect on the packets.

Example

Specify ACL 2001 as the rule of user-defined flow 2.

```
<HUAWEI> system-view
[HUAWEI] cpu-defend policy test
[HUAWEI-cpu-defend-policy-test] user-defined-flow 2 acl 2001
```

14.2.59 whitelist

Function

The **whitelist** command configures a whitelist.

The **undo whitelist** command deletes a whitelist.

By default, no whitelist is configured.

Format

whitelist *whitelist-id* **acl** *acl-number*

undo whitelist *whitelist-id*

Parameters

Parameter	Description	Value
whitelist-id	Specifies the ID of a whitelist.	The value is an integer that ranges from 1 to 8.

Parameter	Description	Value
acl *acl-number*	Specifies the number of an Access Control List (ACL). The ACL referenced by a whitelist on the device can be a basic ACL, an advanced ACL, or a Layer 2 ACL.	The value is an integer that ranges from 2000 to 4999. ● 2000 to 2999: basic ACLs ● 3000 to 3999: advanced ACLs ● 4000 to 4999: Layer 2 ACLs

Views

Attack defense policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can create a whitelist and add users with specified characteristic to the whitelist. The device processes packets sent from users in the whitelist first. You can set the attributes of the whitelist flexibly by defining ACL rules.

A maximum of 8 whitelists can be configured in an attack defense policy on the device.

Precautions

If an ACL containing the deny action is applied to the whitelist, packets sent from users in the whitelist are discarded.

For X series cards, the packets from users in the whitelist are preferentially sent to the CPU at a high rate, and the **display cpu-defend statistics** command cannot collect statistics on these packets.

Example

Specify ACL 2002 as the rule of whitelist 2.

```
<HUAWEI> system-view
[HUAWEI] cpu-defend policy test
[HUAWEI-cpu-defend-policy-test] whitelist 2 acl 2002
```

14.3 MFF Configuration Commands

14.3.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.3.2 display mac-forced-forwarding

Function

The **display mac-forced-forwarding** command displays the MFF configuration.

Format

display mac-forced-forwarding { **network-port** | **vlan** *vlan-id* }

Parameters

Parameter	Description	Value
network-port	Displays network interface information.	-
vlan *vlan-id*	Displays the MFF configuration in a specified VLAN.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mac-forced-forwarding** command displays the MFF network interface information and MFF configuration in a specified VLAN.

NOTE

When the **user-bind static** command is executed to configure a static binding entry for a non-DHCP user, at least **ip-address** and **vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*] must be specified. In this case, the MFF entry that has the same IP address and VLAN ID as the static binding entry can be deleted when the static binding entry is deleted.

Example

Display information about the MFF network interface.

```
<HUAWEI> display mac-forced-forwarding network-port
--------------------------------------------------------------------------------
```

```
VLAN ID                Network-ports
-------------------------------------------------------------------------------
VLAN 10                GigabitEthernet0/0/1
                       GigabitEthernet0/0/2
                       GigabitEthernet0/0/3
VLAN 100               GigabitEthernet0/0/4
                       GigabitEthernet0/0/5
```

Table 14-39 Description of the display mac-forced-forwarding network-port command output

Item	Description
VLAN ID	ID of the VLAN that the network interface belongs to.
Network-ports	Network interface.

Display the MFF configuration in VLAN 100.

```
<HUAWEI> display mac-forced-forwarding vlan 100
[Vlan 100] MFF host total count = 3
-------------------------------------------------------------------------------
Servers        192.168.1.2
               192.168.1.3
-------------------------------------------------------------------------------
User IP        User MAC          Gateway IP       Gateway MAC
-------------------------------------------------------------------------------
192.168.1.10   00e0-fc01-0001    192.168.1.254    00e0-fc02-0001
192.168.1.11   00e0-fc01-0002    192.168.1.254    00e0-fc02-0001
192.168.1.12   00e0-fc01-0003    192.168.1.252    00e0-fc02-0003
-------------------------------------------------------------------------------
```

Table 14-40 Description of the display mac-forced-forwarding vlan command output

Item	Description
MFF host total count	Number of users in VLAN 100.
Servers	IP addresses of servers in VLAN 100.
User IP	IP addresses of users in VLAN 100.
User MAC	MAC addresses of users in VLAN 100.
Gateway IP	Gateway IP address.
Gateway MAC	Gateway MAC address.

14.3.3 mac-forced-forwarding arp-trigger

Function

The **mac-forced-forwarding arp-trigger** command enables an EAN to add or update an MFF entry when receiving an ARP packet from a user.

The **undo mac-forced-forwarding arp-trigger** command disables an EAN from adding or updating an MFF entry when receiving an ARP packet from a user.

By default, the EAN does not add or update an MFF entry when receiving an ARP packet from a user.

Format

mac-forced-forwarding arp-trigger

undo mac-forced-forwarding arp-trigger

Parameters

N/A

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a data center, users and virtual machine (VM) servers are isolated at Layer 2 on EAN devices using MFF. If a VM connects to another EAN and does not send DHCP request packets after migrating between servers, the backup binding table may exist on the new EAN device and the original EAN may still reserve the MFF entry. This cannot ensure security of Layer 2 isolation and Layer 3 communication between users and servers. Run the **mac-forced-forwarding arp-trigger** command on the new EAN to enable it to check binding entries when receiving an ARP packet from the user. If an entry matches the user, the EAN updates the MFF entry. If no entry matches the user, the EAN adds a new entry. The EAN broadcasts the ARP packet to all network interfaces when receiving the first ARP packet regardless of whether the user entry exists.

Prerequisite

MFF has been enabled in the system view and VLAN view using the **mac-forced-forwarding enable** command.

Example

Enable the EAN to add or update the MFF entries when receiving an ARP packet from a user in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding arp-trigger
```

14.3.4 mac-forced-forwarding dumb-terminal-compatible

Function

The **mac-forced-forwarding dumb-terminal-compatible** command configures a device to forward the ARP packets from the gateway to dumb terminals.

The **undo mac-forced-forwarding dumb-terminal-compatible** command disables a device from forwarding the ARP packets from the gateway to dumb terminals.

By default, a device does not forward the ARP packets from gateway to dumb terminals.

Format

mac-forced-forwarding dumb-terminal-compatible

undo mac-forced-forwarding dumb-terminal-compatible

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the MFF device connects to dumb terminals (which do not actively send ARP request packets or send ARP request packets at a long interval), the MFF device must transparently transmit the ARP packets from gateway to dumb terminals after the MFF entries are aged out; otherwise, the user ARP entries on gateway are aged out and user services are interrupted. Therefore, when the MFF device connects to dumb terminals, the MFF device needs to be configured to transparently transmit the ARP packets from gateway to dumb terminals.

Prerequisites

Global MFF has been enabled using the **mac-forced-forwarding enable** command.

Precautions

After the MFF device is configured to transparently transmit ARP packets to dumb terminals, run the **mac-forced-forwarding static-gateway** command to configure an IP address for the static gateway; otherwise, this function does not take effect.

After this function is enabled, the MFF device searches the static binding table when receiving ARP request packets from the gateway (configured using the **user-bind static** command):

- If the outbound interface is found in the static binding table, the device forwards the ARP request packets through this interface.
- If the outbound interface is not found in the static binding table, the device broadcasts the ARP request packets in the VLAN. In this situation, all users in the VLAN can receive the ARP packets.

Example

Configure a device to transparently transmit ARP packets from gateway to dumb terminals in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] mac-forced-forwarding enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding dumb-terminal-compatible
```

14.3.5 mac-forced-forwarding enable

Function

The **mac-forced-forwarding enable** command enables MFF.

The **undo mac-forced-forwarding enable** command disables MFF.

By default, MFF is disabled.

Format

mac-forced-forwarding enable

undo mac-forced-forwarding enable

Parameters

None

Views

System view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Many networks require that the gateway monitor data traffic and isolate users. MFF isolates users at Layer 2 and connects users at Layer 3 on the same network segment. MFF enables traffic to be forwarded through the gateway. This implements traffic monitoring and accounting and ensures network security.

Precautions

You can run the **mac-forced-forwarding enable** command in the VLAN view and perform other configurations only after you enable MFF globally in the system view.

After MFF is disabled in the system view, other MFF configurations are automatically deleted.

MFF cannot be enabled in a VLAN where the super VLAN or VLANIF interface is configured.

MFF cannot be enabled in a sub-VLAN where the super VLAN and VLANIF interface are configured.

The MFF function is implemented based on ARP proxy, whereas the EAI function is implemented based on ARP request packet forwarding. Therefore, the two functions conflict with each other. If you have enabled both MFF and EAI in the same VLAN, the MFF function takes effect.

NOTE

When you enable MFF, if ACL resources are insufficient, the MFF function does not take effect.

MFF cannot be configured in the super-VLAN.

When DHCP relay is configured in a super VLAN, MFF cannot be enabled in its sub-VLANs.

Example

Enable MFF in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] mac-forced-forwarding enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
```

14.3.6 mac-forced-forwarding gateway-detect

Function

The **mac-forced-forwarding gateway-detect** command enables timed gateway detection and sets the gateway detection interval.

The **undo mac-forced-forwarding gateway-detect** command disables timed gateway detection.

By default, timed gateway detection is enabled and the default gateway detection interval is 30s.

Format

mac-forced-forwarding gateway-detect [**interval** *interval-time*]

undo mac-forced-forwarding gateway-detect

Parameters

Parameter	Description	Value
interval *interval-time*	Indicates the gateway detection interval.	The value is an integer that ranges from 30 to 17280, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a practical network, services may be interrupted for a long time because the MFF-enabled device cannot immediately detect the gateway MAC address change. Timed gateway detection can solve this problem. After the detection function is enabled (enabled by default), the MFF-enabled device scans recorded gateway information every *interval-time* seconds. For each gateway recorded, the MFF-enabled device uses user information to construct an ARP request packet and sends it to the network interface. The MFF-enabled device then learns the gateway MAC address from the ARP reply packet. If the gateway MAC address changes, the MFF-enabled device immediately updates the gateway information and broadcasts gratuitous ARP packets to users. Users can update the gateway address.

Prerequisites

MFF has been enabled in a VLAN using the **mac-forced-forwarding enable** command.

Precautions

When detecting multiple gateway addresses, the MFF-enabled device sends an ARP reply packet with the first gateway address by default.

After MFF is enabled, timed gateway detection does not take effect if no ARP request packet is received from the user or gateway or if no user is authorized by the DHCP server to access the network.

If a gateway fails, traffic between users will be blocked. To avoid this situation, the device considers a gateway invalid if it does not receive a response from the gateway after five detection attempts. The device then deletes the MAC address entry of the invalid gateway. If the gateway detection interval is changed during a detection, the number of detection times is accumulated.

Example

Enable timed gateway detection in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] mac-forced-forwarding enable
[HUAWEI-vlan10] mac-forced-forwarding gateway-detect
```

14.3.7 mac-forced-forwarding igmp-query discard

Function

The **mac-forced-forwarding igmp-query discard** command configures an MFF-enabled device to discard the IGMP Query messages from users when both MFF and IGMP snooping are enabled in a VLAN.

The **undo mac-forced-forwarding igmp-query discard** command disables an MFF-enabled device from discarding the IGMP Query messages from users when both MFF and IGMP snooping are enabled in a VLAN.

By default, an MFF-enabled device does not discard the IGMP Query messages from users when both MFF and IGMP snooping are enabled in a VLAN.

Format

mac-forced-forwarding igmp-query discard

undo mac-forced-forwarding igmp-query discard

Parameters

None.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

After MFF and IGMP snooping are enabled in a VLAN, the IGMP Query messages are broadcast in the VLAN. To prevent IGMP Query message broadcasting, use the **mac-forced-forwarding igmp-query discard** command.

Example

Configure an MFF-enabled device to discard the IGMP Query messages from users in VLAN10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] mac-forced-forwarding igmp-query discard
```

14.3.8 mac-forced-forwarding ipv6-isolate

Function

The **mac-forced-forwarding ipv6-isolate** command configures the user-side inbound interface on a device to discard IPv6 packets.

The **undo mac-forced-forwarding ipv6-isolate** command disables a device from discarding IPv6 packets from users.

By default, the user-side inbound interface on a device does not discard IPv6 packets from users.

Format

mac-forced-forwarding ipv6-isolate

undo mac-forced-forwarding ipv6-isolate

Parameters

None.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **mac-forced-forwarding ipv6-isolate** command is used, the user-side inbound interface on a device discards the IPv6 packets from users to prevent IPv6 packets from being broadcast on the VLAN. If the device does not discard IPv6 packets, users can learn the MAC addresses of each other, which makes MFF user isolation function invalid.

Prerequisites

The MFF function has been enabled in the system view and the VLAN view.

The VLAN contains at least one network-side interface.

Example

Configure the user-side inbound interface on a device to discard IPv6 packets from users.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding ipv6-isolate
```

14.3.9 mac-forced-forwarding network-port

Function

The **mac-forced-forwarding network-port** command configures an interface as a network interface.

The **undo mac-forced-forwarding network-port** command restores the interface to be a user interface.

By default, an interface is a user interface.

Format

mac-forced-forwarding network-port

undo mac-forced-forwarding network-port

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To make MFF in a VLAN effective, ensure that at least one network interface belongs to the VLAN. Therefore, configure network interfaces for MFF.

The interface that is connected to the gateway and other network devices is configured as a network interface.

Precautions

MFF has been enabled in the system view using the **mac-forced-forwarding enable** command. Regardless of whether MFF is enabled in the VLAN that an interface belongs to, the interface can be configured as a network interface.

Multiple interfaces can be configured as network interfaces.

Example

Configure GE0/0/1 as a network interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] mac-forced-forwarding network-port
Info: This operation may take a few seconds. Please wait for a moment.....
```

14.3.10 mac-forced-forwarding network-port-arp-trigger

Function

The **mac-forced-forwarding network-port-arp-trigger** command enables the network interface on an EAN to delete an MFF entry when the network port receives an ARP packet.

The **undo mac-forced-forwarding network-port-arp-trigger** command disables the network interface on an EAN from deleting an MFF entry when the network port receives an ARP packet.

By default, the network interface on an EAN does not delete the MFF entry when receiving an ARP packet.

Format

mac-forced-forwarding network-port-arp-trigger

undo mac-forced-forwarding network-port-arp-trigger

Parameters

N/A

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a data center, users and VM servers are isolated at Layer 2 on EAN devices using MFF. If a VM connects to another EAN after migrating between servers, and the binding table on the original EAN is not aged out, the original EAN considers the VM an MFF host. If an attacker accesses users or sends ARP request packets using the IP address and MAC address of the VM, the original EAN allows the request. Attacks are not defended. After you run the **mac-forced-forwarding network-port-arp-trigger** command on the original EAN, the original EAN determines that the VM has migrated to another EAN and deletes the MFF entry mapping the VM when receiving ARP packets from this VM.

Prerequisites

MFF has been enabled in the system view and VLAN view using the **mac-forced-forwarding enable** command.

Example

Enable the network interface on an EAN to delete an MFF entry when receiving an ARP packet.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding network-port-arp-trigger
```

14.3.11 mac-forced-forwarding server

Function

The **mac-forced-forwarding server** command configures the IP address for a server on the MFF network.

The **undo mac-forced-forwarding server** command deletes the configured IP address of a server.

By default, no IP address is configured for servers.

Format

mac-forced-forwarding server *server-ip* &<1–10>

undo mac-forced-forwarding server { *server-ip* | **all** }

Parameters

Parameter	Description	Value
server-ip	Specifies the IP address for a server.	The value is in dotted decimal notation. **NOTE** This IP address must be a class A, B, or C address. If the IP address is a class A address, it cannot be in the format 0.x.x.x.
all	Specifies IP addresses for all servers.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to the gateway, application servers such as the DHCP, multicast, or another server may be deployed on a network. You can configure IP addresses for application servers and set a list of accessible application servers on the MFF-enabled device.

- When a network interface on the MFF-enabled device receives an ARP request from a specified application server, the MFF-enabled device responds with the user MAC address by default. The packets sent from the server to the user are directly forwarded without passing through the gateway.
- If the MFF-enabled device is configured to transparently transmit ARP request packets, the device responds with the gateway MAC address. The packets sent from the server to the user are forwarded through the gateway.

Prerequisites

MFF has been enabled in a VLAN using the **mac-forced-forwarding enable** command.

Precautions

When the number of configured servers reaches the upper limit 10, run the **undo mac-forced-forwarding server** { *server-ip* | **all** } command to delete unneeded servers before you configure new servers.

NOTE

This command is required only when the application servers and clients are in the same VLAN.

Example

Configure IP address 192.168.1.2 for a server in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding server 192.168.1.2
```

14.3.12 mac-forced-forwarding static-gateway

Function

The **mac-forced-forwarding static-gateway** command configures a static gateway IP address in a VLAN.

The **undo mac-forced-forwarding static-gateway** command cancels the configuration.

By default, no static gateway IP address is configured in a VLAN.

Format

mac-forced-forwarding static-gateway *ip-address* &<1-16>

undo mac-forced-forwarding static-gateway { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the static gateway IP address in a VLAN. A maximum of 16 static gateway IP addresses in a VLAN can be specified in this command.	The value is in dotted decimal notation. **NOTE** This IP address must be a class A, B, or C address. If the IP address is a class A address, it cannot be in the format 0.x.x.x.
all	Deletes all static gateway IP addresses in the VLAN.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The static gateway is applicable when users are configured with static IP addresses. These users cannot dynamically obtain gateway information through DHCP packets. In this case, configure a static gateway address for each VLAN. After you run the **mac-forced-forwarding static-gateway** command, the users who are not authorized by the DHCP server can use the static gateway address to access the network. The users who are authorized by the DHCP server can still access the original gateway.

Prerequisites

Global MFF has been enabled using the **mac-forced-forwarding enable** command.

Precautions

If a static gateway IP address is changed, users will fail to access the network. The MAC address in the ARP table on the client belongs to the old gateway. After a new gateway is configured, the ARP entry on client is not updated immediately (that is, the MAC address in ARP table is not updated to the new gateway's MAC address). Therefore, the user cannot access the network.

Example

Configure static gateway IP address 10.1.1.10 in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mac-forced-forwarding enable
[HUAWEI-vlan100] mac-forced-forwarding static-gateway 10.1.1.10
```

14.3.13 mac-forced-forwarding user-detect transparent

Function

The **mac-forced-forwarding user-detect transparent** command enables transparent transmission of ARP request packets.

The **undo mac-forced-forwarding user-detect transparent** command disables transparent transmission of ARP request packets.

By default, transparent transmission of ARP request packets is disabled.

Format

mac-forced-forwarding user-detect transparent

undo mac-forced-forwarding user-detect transparent

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In MFF networking, if the gateway performs accounting for users based on the online duration, the gateway must know whether a user is online at a specified moment. By default, the MFF-enabled device sends ARP reply packets in response to ARP request packets sent from the gateway. The MFF-enabled device can always send ARP reply packets as long as the MFF entry is not aged out. As a result, the gateway always considers users online even if they have gone offline.

To solve this problem, configure the MFF-enabled device to transparently transmit ARP request packets sent from the gateway to the user. Then, the MFF-enabled device does not respond to the ARP packets. If the gateway does not receive the ARP reply packet from a user, the gateway considers that the user has gone offline. The gateway can monitor the user status in a timely manner and correctly perform accounting.

Prerequisites

Global MFF has been enabled using the **mac-forced-forwarding enable** command.

Precautions

In other scenarios, use the default configuration.

Example

Enable transparent transmission of ARP request packets in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] mac-forced-forwarding enable
[HUAWEI-vlan10] mac-forced-forwarding user-detect transparent
```

14.4 Attack Defense Configuration Commands

14.4.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.4.2 anti-attack abnormal enable

Function

The **anti-attack abnormal enable** command enables defense against malformed packet attacks.

The **undo anti-attack abnormal enable** command disables defense against malformed packet attacks.

The **anti-attack abnormal disable** command disables defense against malformed packet attacks.

By default, defense against malformed packet attacks is enabled.

Format

anti-attack abnormal enable

undo anti-attack abnormal enable

anti-attack abnormal disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The malformed packet attack is to send malformed IP packets to the system. If such an attack occurs, the system may break down when processing the malformed IP packets. To prevent the system from breaking down and to ensure normal network services, run the **anti-attack abnormal enable** command to enable defense against malformed packets.

The device detects malformed packets after defense against malformed packets is enabled.

The device directly discards packets of the following types:

- Flood attacks from IP null payload packets
- Attacks from IGMP null payload packets
- LAND attacks
- Smurf attacks
- Attacks from packets with invalid TCP flag bits

Precautions

You can also run the **anti-attack enable** command in the system view to enable attack defense against all attack packets including malformed packets.

Example

Enable defense against malformed packet attacks.

```
<HUAWEI> system-view
[HUAWEI] anti-attack abnormal enable
```

14.4.3 anti-attack enable

Function

The **anti-attack enable** command enables defense against all attack packets.

The **undo anti-attack enable** command disables defense against all attack packets.

The **anti-attack disable** command disables defense against all attack packets.

By default, defense against all attack packets is enabled.

Format

anti-attack enable

undo anti-attack enable

anti-attack disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Different types of attacks on a network cause high device usage or system breakdown, affecting network services. To prevent the system from breaking down and to ensure normal network services, run the **anti-attack enable** command to enable defense against all attack packets.

Precautions

Running the **anti-attack enable** command is equivalent to running all of the following commands:

- **anti-attack abnormal enable**
- **anti-attack fragment enable**
- **anti-attack tcp-syn enable**
- **anti-attack udp-flood enable**
- **anti-attack icmp-flood enable**

Example

Enable defense against all attack packets.

```
<HUAWEI> system-view
[HUAWEI] anti-attack enable
```

14.4.4 anti-attack fragment enable

Function

The **anti-attack fragment enable** command enables defense against packet fragment attacks.

The **undo anti-attack fragment enable** command disables defense against packet fragment attacks.

The **anti-attack fragment disable** command disables defense against packet fragment attacks.

By default, defense against packet fragment attacks is enabled.

Format

anti-attack fragment enable

undo anti-attack fragment enable

anti-attack fragment disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker sends error packet fragments to a device, the device consumes a large number of resources to process the error packet fragments, affecting normal services. To prevent the system from breaking down and to ensure normal network services, run the **anti-attack fragment enable** command to enable defense against packet fragment attacks.

The device detects error packet fragments after defense against error packet fragments is enabled. If the device detects error packet fragments, the device limits the rate of these fragments to ensure that the device CPU works properly.

Precautions

You can also run the **anti-attack enable** command in the system view to enable attack defense against all attack packets including packet fragments.

Example

Enable defense against packet fragment attacks.

```
<HUAWEI> system-view
[HUAWEI] anti-attack fragment enable
```

14.4.5 anti-attack fragment car

Function

The **anti-attack fragment car** command sets the rate limit of packet fragments.

The **undo anti-attack fragment car** command restores the rate limit of packet fragments.

By default, the rate limit of packet fragments is 155000000 bit/s.

Format

anti-attack fragment car cir *cir*

undo anti-attack fragment car

Parameters

Parameter	Description	Value
cir *cir*	Specifies the committed information rate (CIR) of packet fragments.	The value is an integer that ranges from 8000 to 155000000, in bit/s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After defense against packet fragment attacks is enabled, run the **anti-attack fragment car** command to set the rate limit of packet fragments. If the rate of received packet fragments exceeds the rate limit, the device discards excess packet fragments to ensure that the device CPU works properly.

Prerequisites

Defense against packet fragment attacks has been enabled using the **anti-attack fragment enable** command.

Example

Set the rate limit of packet fragments to 8000 bit/s.

```
<HUAWEI> system-view
[HUAWEI] anti-attack fragment enable
[HUAWEI] anti-attack fragment car cir 8000
```

14.4.6 anti-attack icmp-flood enable

Function

The **anti-attack icmp-flood enable** command enables defense against ICMP flood attacks.

The **undo anti-attack icmp-flood enable** command disables defense against ICMP flood attacks.

The **anti-attack icmp-flood disable** command disables defense against ICMP flood attacks.

By default, defense against ICMP flood attacks is enabled.

Format

anti-attack icmp-flood enable

undo anti-attack icmp-flood enable

anti-attack icmp-flood disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker sends a large number of ICMP request packets to the target host in a short time, the target host is busy with these ICMP request packets. As a result, the target host is overloaded and cannot process normal services. To prevent ICMP flood attacks, run the **anti-attack icmp-flood enable** command to enable defense against ICMP flood attacks.

The device detects ICMP flood attack packets after defense against ICMP flood attacks is enabled. If the device detects ICMP flood attack packets, the device limits the rate of these ICMP flood attack packets to ensure that the device CPU works properly.

Precautions

You can also run the **anti-attack enable** command in the system view to enable attack defense against all attack packets including ICMP flood attack packets.

Example

Enable defense against ICMP flood attacks.

```
<HUAWEI> system-view
[HUAWEI] anti-attack icmp-flood enable
```

14.4.7 anti-attack icmp-flood car

Function

The **anti-attack icmp-flood car** command sets the rate limit of ICMP flood attack packets.

The **undo anti-attack icmp-flood car** command restores the default rate limit of ICMP flood attack packets.

By default, the rate limit of ICMP flood attack packets is 155000000 bit/s.

Format

anti-attack icmp-flood car cir *cir*

undo anti-attack icmp-flood car

Parameters

Parameter	Description	Value
cir *cir*	Specifies the committed information rate (CIR) of ICMP flood attack packets.	The value is an integer that ranges from 8000 to 155000000, in bit/s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After defense against ICMP flood attacks is enabled, run the **anti-attack icmp-flood car** command to set the rate limit of ICMP flood attack packets. If the rate of received ICMP flood attack packets exceeds the rate limit, the device discards excess ICMP flood attack packets to ensure that its CPU works properly.

Prerequisites

Defense against ICMP flood attacks has been enabled using the **anti-attack icmp-flood enable** command.

Example

Set the rate limit of ICMP flood attack packets to 8000 bit/s.

```
<HUAWEI> system-view
[HUAWEI] anti-attack icmp-flood enable
[HUAWEI] anti-attack icmp-flood car cir 8000
```

14.4.8 anti-attack tcp-syn enable

Function

The **anti-attack tcp-syn enable** command enables defense against TCP SYN flood attacks.

The **undo anti-attack tcp-syn enable** command disables defense against TCP SYN flood attacks.

The **anti-attack tcp-syn disable** command disables defense against TCP SYN flood attacks.

By default, defense against TCP SYN flood attacks is enabled.

Format

anti-attack tcp-syn enable

undo anti-attack tcp-syn enable

anti-attack tcp-syn disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An attacker sends a SYN packet to a target host to initiate a TCP connection but does not respond to the SYN-ACK sent from the target host. If the target host receives no ACK packet from the attacker, it keeps waiting for the ACK packet. A half-open connection is formed. The attacker keeps sending SYN packets, so many half-open connections are set up on the target host. This wastes a large number of resources. To prevent TCP SYN flood attacks, run the **anti-attack tcp-syn enable** command to enable defense against TCP SYN flood attacks.

The device detects TCP SYN flood attack packets after defense against TCP SYN flood attacks is enabled. If the device detects TCP SYN flood attack packets, the device limits the rate of these TCP SYN flood attack packets to ensure that the device CPU works properly.

Precautions

You can also run the **anti-attack enable** command in the system view to enable attack defense against all attack packets including TCP SYN flood attack packets.

Example

Enable defense against TCP SYN flood attacks.

```
<HUAWEI> system-view
[HUAWEI] anti-attack tcp-syn enable
```

14.4.9 anti-attack tcp-syn car

Function

The **anti-attack tcp-syn car** command sets the rate limit at which TCP SYN packets are received.

The **undo anti-attack tcp-syn car** command restores the default rate limit at which TCP SYN packets are received.

By default, the rate limit at which TCP SYN packets are received is 155000000 bit/s.

Format

anti-attack tcp-syn car cir *cir*

undo anti-attack tcp-syn car

Parameters

Parameter	Description	Value
cir *cir*	Specifies the committed information rate (CIR) at which TCP SYN packets are received.	The value is an integer that ranges from 8000 to 155000000, in bit/s.

Views

System view

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker sends a large number of UDP packets to the target host in a short time, the target host is busy with these UDP packets. As a result, the target host is overloaded and cannot process normal services. To prevent UDP flood attacks, run the **anti-attack udp-flood enable** command to enable defense against UDP flood attacks.

The device detects UDP flood attack packets after defense against UDP flood attacks is enabled. The device directly discards UDP flood attack packets.

Precautions

You can also run the **anti-attack enable** command in the system view to enable attack defense against all attack packets including UDP flood attack packets.

Example

Enable defense against UDP flood attacks.

```
<HUAWEI> system-view
[HUAWEI] anti-attack udp-flood enable
```

14.4.11 display anti-attack statistics

Function

The **display anti-attack statistics** command displays statistics about attack packets of a specified type.

If no parameter is specified, the **display anti-attack statistics** command displays statistics about attack packets of all types.

Format

display anti-attack statistics [**abnormal** | **fragment** | **tcp-syn** | **udp-flood** | **icmp-flood**]

Parameters

Parameter	Description	Value
abnormal	Displays statistics about malformed packets.	-
fragment	Displays statistics about defense against packet fragments.	-
tcp-syn	Displays statistics about defense against TCP SYN flood attacks.	-
udp-flood	Displays statistics about defense against UDP flood attacks.	-
icmp-flood	Displays statistics about defense against ICMP flood attacks.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display anti-attack statistics** command displays statistics on attack packets of the following types: malformed packet attack, packet fragment attack, TCP SYN flood attack, UDP flood attack, ICMP flood attack.

Example

Display attack defense statistics.

```
<HUAWEI> display anti-attack statistics
Packets Statistic Information:
-------------------------------------------------------------------------------
AntiAtkType  TotalPacketNum        DropPacketNum         PassPacketNum
        (H)        (L)        (H)        (L)        (H)        (L)
-------------------------------------------------------------------------------
URPF         0          0          0          0          0          0
Abnormal     0          0          0          0          0          0
Fragment     0          0          0          0          0          0
Tcp-syn      0          58         0          0          0          58
Udp-flood    0          0          0          0          0          0
Icmp-flood   0          0          0          0          0          0
-------------------------------------------------------------------------------
```

Table 14-41 Description of the display anti-attack statistics command output

Item	Description
Packets Statistic Information	Attack defense statistics.
AntiAtkType	Attack defense type: - URPF: URPF check (The device does not support this parameter.) - Abnormal: defense against malformed packets - Fragment: defense against packet fragments - Tcp-syn: defense against TCP SYN flood attacks - Udp-flood: defense against UDP flood attacks - Icmp-flood: defense against ICMP flood attacks
TotalPacketNum	Total number of packets.
DropPacketNum	Number of discarded packets.

Item	Description
PassPacketNum	Number of forwarded packets.
(H)	Highest-order bit display.
(L)	Lowest-order bit display.

14.4.12 reset anti-attack statistics

Function

The **reset anti-attack statistics** command clears attack defense statistics.

Format

reset anti-attack statistics [**abnormal** | **fragment** | **tcp-syn** | **udp-flood** | **icmp-flood**]

Parameters

Parameter	Description	Value
abnormal	Clears statistics about defense against malformed packets.	-
fragment	Clears statistics about defense against packet fragments.	-
tcp-syn	Clears statistics about defense against TCP SYN flood attacks.	-
udp-flood	Clears statistics about defense against UDP flood attacks.	-
icmp-flood	Clears statistics about defense against ICMP flood attacks.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

If no attack defense is specified, statistics about all types of attack defense are cleared.

NOTICE

The cleared statistics cannot be restored. Exercise caution when you use the command.

Example

Clear statistics about defense against malformed packets.

```
<HUAWEI> reset anti-attack statistics abnormal
```

14.5 Traffic Suppression and Storm Control Configuration Commands

14.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.5.2 broadcast-suppression (interface view)

Function

The **broadcast-suppression** command sets the maximum traffic rate of broadcast packets that can pass through an interface in the inbound direction.

The **undo broadcast-suppression** command restores the default maximum traffic rate of broadcast packets that can pass through an interface in the inbound direction.

By default, the rate of broadcast packets is suppressed by bandwidth percentage, and the percentage rate limit is 10%.

Format

broadcast-suppression { *percent-value* | **cir** *cir-value* [**cbs** *cbs-value*] | **packets** *packets-per-second* }

undo broadcast-suppression

Parameters

Parameter	Description	Value
percent-value	Specifies the percentage of bandwidth occupied by broadcast packets on an interface. If loopback detection is enabled on an interface, the interface rate is set by user. If loopback detection is not enabled on an interface, the interface rate is automatically negotiated. You can run the **display this interface** command in the interface view to check the interface rate (value of the **Speed** field).	The value is an integer and the value range is as follows: ● 40GE interface: 0 to 100 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S ● Other interfaces: 0 to 100

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through. **NOTE** Traffic suppression based on **cir** is more precise than that based on **packets**. To specify the **cir** parameter, ensure that the traffic suppression mode set in the system view is **bits**.	The value is an integer, in kbit/s. The value range is as follows: ● Ethernet interface: 0 to 100000 ● GE interface: 0 or 16 to 1000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 1000000 for the others ● XGE interface: 0 or 16 to 10000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 10000000 for the others ● 25GE interface: 0 to 25000000 ● MultiGE interface: 0 to X, X indicates the negotiated bandwidth ● 40GE interface: 0 to 40000000 ● 100GE interface: 0 to 100000000 ● Port group: 0 to 100000000 **NOTE** When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1000000.

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the maximum size of traffic that can pass through.	The value is an integer. For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: The value ranges from 10000 to 65535, in bytes. For other models: The value ranges from 10000 to 4294967295, in bytes. By default, the CBS value is 188 times the CIR value.

Parameter	Description	Value
packets *packets-per-second*	Specifies the number of packets transmitted per second. **NOTE** To specify the **packets** parameter, ensure that the traffic suppression mode set in the system view is **packets**.	The value is an integer and the value range is as follows: - Ethernet interface: 0 to 148810 - GE interface: 0 to 1488100 - XGE interface: 0 to 14881000 - MultiGE interface: 0 to X. X indicates the negotiated bandwidth - 25GE interface: 0 to 37202500 - 40GE interface: 0 to 59524000 - 100GE interface: 0 to 148810000 - Port group: 0 to 148810000 **NOTE** - For S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the configured value is less than 24, traffic suppression is performed based on 24. If the configured value is greater than or equal to 24, traffic suppression is performed based on the configured value. - When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1488100.

Default Level

2: Configuration level

Usage Guidelines

Usage Guidelines

The accumulating broadcast packets on the network occupy more and more network resources. This affects normal operation of services on the network.

To prevent broadcast storms, you can use the **broadcast-suppression** command to set the threshold of broadcast traffic that an interface allows to pass through. When the broadcast traffic rate reaches the rate limit, the system discards excess broadcast packets to control the traffic rate in a proper range.

Precautions

If the rate limit in bit/s is set for a type of packets on an interface, the rate limit in pps cannot be set for other types of packets on the same interface. In a similar manner, if the rate limit in pps is set for a type of packets on an interface, the rate limit in bit/s cannot be set for other types of packets on the same interface.

Setting the bandwidth percentage is the same as setting the rate limit in pps. Take an interface of 1 Gbit/s as an example. If the bandwidth percentage is set to 50%, the device converts the bandwidth percentage to rate limit in pps as follows: (1000 x (50/100) x 1000 x 1000)/(84 x 8). In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

NOTE

If a packet rate limit is configured for a type of packets on an interface, the percentage rate limit for other types of packets is converted into the packet rate limit.

Example

Set the broadcast packet rate to 100000 pps on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] broadcast-suppression packets 100000
```

14.5.3 broadcast-suppression block outbound

Function

The **broadcast-suppression block outbound** command blocks outgoing broadcast packets on an interface.

The **undo broadcast-suppression block outbound** command unblocks outgoing broadcast packets on an interface.

By default, an interface does not block outgoing broadcast packets.

Format

broadcast-suppression block outbound

undo broadcast-suppression block outbound

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Guidelines

After an interface receives a broadcast packet, it broadcasts the packet to all users in the same VLAN. This may cause information leak. For example, if an unauthorized user is connected to an interface in a VLAN, an unauthorized user obtains a host's address from broadcast packets and uses the address to attack the host. To prevent information leak, use the **broadcast-suppression block outbound** command to block outgoing broadcast packets on an interface if users connected to the interface do not need to receive broadcast packets. For example, if users on an interface seldom change and require high security, you can use this command on the interface.

Precautions

The **broadcast-suppression block outbound** command is applicable only to interfaces on which users do not need to receive broadcast packets. This command will affect network operations if it is used on an interface where users need to receive broadcast packets.

Traffic suppression can be configured for incoming and outgoing packets on an interface, and the configurations are independent of each other. On an interface, you can use the **broadcast-suppression** command to limit the rate of incoming broadcast packets and use the **broadcast-suppression block outbound** command to block outgoing broadcast packets.

Example

Block outgoing broadcast packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] broadcast-suppression block outbound
```

14.5.4 broadcast-suppression (VLAN view)

Function

The **broadcast-suppression** command sets the rate limit for broadcast packets in a VLAN.

The **undo broadcast-suppression** command cancels broadcast packets suppression in a VLAN.

By default, broadcast packets are not suppressed in a VLAN.

Format

broadcast-suppression *threshold-value*

undo broadcast-suppression

Parameters

Parameter	Description	Value
threshold-value	Specifies the rate limit of broadcast packets.	The value is an integer that ranges from 64 to 10000000, in kbit/s.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

The accumulating broadcast packets on the network occupy more and more network resources. This affects normal operation of services on the network.

After you run the **broadcast-suppression** command, the device limits the rate of broadcast packets based on the configured rate limit. If the rate limit is exceeded, the device discards excess broadcast packets.

Example

Set the rate limit to 1000 kbit/s for broadcast packets in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] broadcast-suppression 1000
```

14.5.5 display flow-suppression interface

Function

The **display flow-suppression interface** command displays the traffic suppression configuration on an interface.

Format

display flow-suppression interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type* *interface-number*	Specifies the type and number of an interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command can display the traffic suppression for broadcast, unknown multicast, known multicast, unknown unicast, and known unicast packets on the interface, including rate limiting mode and rate limit value.

Example

Display the traffic suppression configuration on GE0/0/1.

```
<HUAWEI> display flow-suppression interface gigabitethernet 0/0/1
 storm type         rate mode   set rate value
-------------------------------------------------------------------------------
 unknown-unicast    percent      percent: 90%
 multicast          percent      percent: 90%
 broadcast          percent      percent: 90%
 known-unicast      percent      percent: 100%
 known-multicast    percent      percent: 100%
-------------------------------------------------------------------------------
```

Table 14-42 Description of the display flow-suppression interface command output

Item	Description
storm type	Traffic type: - unknown-unicast: unknown unicast traffic - multicast: unknown multicast traffic - broadcast: broadcast traffic - known-unicast: known-unicast traffic - known-multicast: known-multicast traffic
rate mode	Type of the rate limit. - pps: packet mode - percent: percentage mode
set rate value	Configured rate limit. The rate can be set by the following commands: - **broadcast-suppression** - **multicast-suppression** - **unicast-suppression** - **known-unicast-suppression** - **known-multicast-suppression**

14.5.6 display storm-control

Function

The **display storm-control** command displays information about storm control on an interface.

Format

display storm-control [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. - *interface-type* specifies the type of the interface. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command can display the storm control for broadcast, unknown multicast, and unknown unicast packets on the interface, such as packet mode, storm control action, and packet status.

Example

Display information about storm control on GE0/0/1.

```
<HUAWEI> display storm-control interface gigabitethernet 0/0/1
PortName     Type      Rate      Mode Action   Punish-  Trap Log Int Last-
                    (Min/Max)            Status             Punish-Time
-----------------------------------------------------------------------------
GE0/0/1      Multicast 1000      Pps  Block    Normal   Off  On  90  -
                    /2000
GE0/0/1      Broadcast 1000      Pps  Block    Normal   Off  On  90  -
                    /2000
GE0/0/1      Unicast   1000      Pps  Block    Normal   Off  On  90  -
                    /2000
```

Table 14-43 Description of the display storm-control command output

Item	Description
PortName	Interface name.
Type	Packet type. ● Broadcast packets ● Unknown Multicast packets ● Unknown Unicast packets To configure the type of packets on which storm control is performed, run the **storm-control** command.
Rate	● Min: lower rate threshold ● Max: upper rate threshold To configure the rates, run the **storm-control** command.

Item	Description
Mode	Storm control mode. - Kbps: CIR in kbit/s - Pps: packets in pps - %: percentage in % To configure the storm control mode, run the **storm-control** command.
Action	Storm control action. - Block: blocks packets. - Err-down: shuts down the interface. - None: No action is configured. To configure a storm control action, run the **storm-control action** command.
Punish-Status	Status of the interface. - Block: When the rate of receiving packets is greater than the value of **MaxRate** and the storm control action is **block**, the status of the interface is **block**. - Normal: Packets are normally forwarded. - Err-down: When the rate of receiving packets is greater than the value of **MaxRate** and the storm control action is **error-down**, the status of the interface is **error-down**.
Trap	Whether the alarm function for storm control is enabled. - on: The alarm function for storm control is enabled. - off: The alarm function for storm control is disabled. To configure the alarm function for storm control, run the **storm-control enable trap** command.
Log	Whether the log function for storm control is enabled. - on: The log function for storm control is enabled. - off: The log function for storm control is disabled. To configure the alarm function for storm control, run the **storm-control enable log** command.
Int	Interval for detecting storms, in seconds. The default value is 5.
Last-Punish-Time	Last time storm control is performed.

14.5.7 icmp rate-limit

Function

The **icmp rate-limit** command sets the rate threshold of ICMP packets.

The **undo icmp rate-limit** command restores the default rate threshold of ICMP packets.

By default, the rate limits of ICMP packets in the system and on an interface depend on the product model. The value is 128 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, and 190 on the other models, in pps.

Format

icmp rate-limit { **total** | **interface** *interface-type interface-number1* [**to** *interface-number2*] } **threshold** *threshold-value*

undo icmp rate-limit { **total** | **interface** *interface-type interface-number1* [**to** *interface-number2*] }

Parameters

Parameter	Description	Value
total	Specifies the total rate threshold in the system.	-
interface *interface-type interface-number1* **to** *interface-number2*	Specifies the type and number of an interface. • *interface-type* specifies the interface type. • *interface-number1* specifies the number of the first interface. • **to** *interface-number2* specifies the number of the last interface. The value of *interface-number2* must be greater than the value of *interface-number1*. *interface-number1* and *interface-number2* specify the range of interfaces.	-

Parameter	Description	Value
threshold *threshold-value*	Specifies the rate threshold of ICMP packets.	The value ranges from 0 to 1000, in pps. **NOTE** The value 0 indicates that the rate of ICMP packets is not limited.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Guidelines

A network often undergoes ICMP packet attacks. If a switch receives a large number of broadcast ICMP request packets on user-side interfaces, these packets are sent to the switch CPU for processing. Then the CPU usage becomes high, affecting other services on the switch. You can use the **icmp rate-limit** command to prevent the switch from being attacked by ICMP packets.

After the rate limit function is configured for ICMP packets on an interface, the system automatically discards excess ICMP packets when the number of ICMP packets sent by an interface every second exceeds the rate threshold.

Precautions

Before setting the rate threshold of ICMP packets, use the **icmp rate-limit enable** command to enable the rate limit function for ICMP packets.

Example

Set the rate threshold of ICMP packets on GE0/0/1 to GE0/0/5 to 20 pps.

```
<HUAWEI> system-view
[HUAWEI] icmp rate-limit interface gigabitethernet 0/0/1 to 0/0/5 threshold 20
```

14.5.8 icmp rate-limit enable

Function

The **icmp rate-limit enable** command enables the traffic suppression function for ICMP packets.

The **undo icmp rate-limit enable** command disables the traffic suppression function for ICMP packets.

By default, the traffic suppression function for ICMP packets is disabled.

Format

icmp rate-limit enable

undo icmp rate-limit enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Attackers may send a large number of ICMP packets to attack a network. If the device sends all the received ICMP packets to the CPU for processing, a lot of CPU usage resources are occupied and other services may be abnormal. To prevent ICMP packet attacks, you can configure the device to suppress ICMP packets.

Before configuring traffic suppression for ICMP packets on an interface, run the **undo icmp-reply fast** command to disable the ICMP reply fast function.

Example

Enable the traffic suppression function for ICMP packets.

```
<HUAWEI> system-view
[HUAWEI] icmp rate-limit enable
```

14.5.9 known-multicast-suppression

Function

The **known-multicast-suppression** command sets the maximum traffic volume of known multicast packets that can pass through an interface.

The **undo known-multicast-suppression** allows all known multicast packets to pass.

By default, known multicast packets are not suppressed.

NOTE

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S do not support this command.

Format

known-multicast-suppression { *percent-value* | **cir** *cir-value* [**cbs** *cbs-value*] | **packets** *packets-per-second* }

undo known-multicast-suppression

Parameters

Parameter	Description	Value
percent-value	Specifies the percentage of bandwidth occupied by broadcast packets on an interface. If loopback detection is enabled on an interface, the interface rate is set by user. If loopback detection is not enabled on an interface, the interface rate is automatically negotiated. You can run the **display this interface** command in the interface view to check the interface rate (value of the **Speed** field).	The value is an integer and the value range is as follows: - 40GE interface: 0 to 100 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S - Other interfaces: 0 to 100

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through. **NOTE** Traffic suppression based on **cir** is more precise than that based on **packets**. To specify the **cir** parameter, ensure that the traffic suppression mode set in the system view is **bits**.	The value is an integer, in kbit/s. The value range is as follows: ● Ethernet interface: 0 to 100000 ● GE interface: 0 to 1000000 ● XGE interface: 0 to 10000000 ● 25GE interface: 0 to 25000000 ● MultiGE interface: 0 to X, X indicates the negotiated bandwidth ● 40GE interface: 0 to 40000000 ● 100GE interface: 0 to 100000000 ● Port group: 0 to 100000000 **NOTE** When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1000000.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the maximum size of traffic that can pass through.	The value is an integer that ranges from 10000 to 4294967295, in bytes. By default, the CBS value is 188 times the CIR value.

Parameter	Description	Value
packets *packets-per-second*	Specifies the number of packets transmitted per second. **NOTE** To specify the **packets** parameter, ensure that the traffic suppression mode set in the system view is **packets**.	The value is an integer and the value range is as follows: ● Ethernet interface: 0 to 148810 ● GE interface: 0 to 1488100 ● XGE interface: 0 to 14881000 ● MultiGE interface: 0 to X. X indicates the negotiated bandwidth ● 25GE interface: 0 to 37202500 ● 40GE interface: 0 to 59524000 ● 100GE interface: 0 to 148810000 ● Port group: 0 to 148810000 **NOTE** ● For S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the configured value is less than 24, traffic suppression is performed based on 24. If the configured value is greater than or equal to 24, traffic suppression is performed based on the configured value. ● When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1488100.

Views

Ethernet interface view, 40GE interface view, 100GE interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **known-multicast-suppression** command to set the threshold of known multicast traffic that an interface allows to pass through. When the known multicast traffic volume exceeds the threshold, the system discards the excess known multicast packets to control the traffic volume of known multicast packets to a proper range.

Precautions

Setting the bandwidth percentage is the same as setting the rate limit in pps. Take an interface of 1 Gbit/s as an example. If the bandwidth percentage is set to 50%, the device converts the bandwidth percentage to rate limit in pps as follows: (1000 x (50/100) x 1000 x 1000)/(84 x 8). In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

NOTE

If a packet rate limit is configured for a type of packets on an interface, the percentage rate limit for other types of packets is converted into the packet rate limit.

Example

known Set the maximum known multicast packet rate to 100000 pps on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] known-multicast-suppression packets 100000
```

14.5.10 known-unicast-suppression

Function

The **known-unicast-suppression** command sets the maximum traffic volume of known unicast packets that can pass through an interface.

The **undo known-unicast-suppression** allows all known unicast packets to pass.

By default, known unicast packets are not suppressed.

NOTE

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S do not support this command.

Format

known-unicast-suppression { *percent-value* | **cir** *cir-value* [**cbs** *cbs-value*] | **packets** *packets-per-second* }

undo known-unicast-suppression

Parameters

Parameter	Description	Value
percent-value	Specifies the percentage of bandwidth occupied by broadcast packets on an interface. If loopback detection is enabled on an interface, the interface rate is set by user. If loopback detection is not enabled on an interface, the interface rate is automatically negotiated. You can run the **display this interface** command in the interface view to check the interface rate (value of the **Speed** field).	The value is an integer and the value range is as follows: • 40GE interface: 0 to 100 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S • Other interfaces: 0 to 100

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through. **NOTE** Traffic suppression based on **cir** is more precise than that based on **packets**. To specify the **cir** parameter, ensure that the traffic suppression mode set in the system view is **bits**.	The value is an integer, in kbit/s. The value range is as follows: - Ethernet interface: 0 to 100000 - GE interface: 0 to 1000000 - XGE interface: 0 to 10000000 - 25GE interface: 0 to 25000000 - MultiGE interface: 0 to X, X indicates the negotiated bandwidth - 40GE interface: 0 to 40000000 - 100GE interface: 0 to 100000000 - Port group: 0 to 100000000 **NOTE** When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1000000.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the maximum size of traffic that can pass through.	The value is an integer that ranges from 10000 to 4294967295, in bytes. By default, the CBS value is 188 times the CIR value.

Parameter	Description	Value
packets *packets-per-second*	Specifies the number of packets transmitted per second. **NOTE** To specify the **packets** parameter, ensure that the traffic suppression mode set in the system view is **packets**.	The value is an integer and the value range is as follows: ● Ethernet interface: 0 to 148810 ● GE interface: 0 to 1488100 ● XGE interface: 0 to 14881000 ● MultiGE interface: 0 to X. X indicates the negotiated bandwidth ● 25GE interface: 0 to 37202500 ● 40GE interface: 0 to 59524000 ● 100GE interface: 0 to 148810000 ● Port group: 0 to 148810000 **NOTE** ● For S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the configured value is less than 24, traffic suppression is performed based on 24. If the configured value is greater than or equal to 24, traffic suppression is performed based on the configured value. ● When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1488100.

Views

Ethernet interface view, 40GE interface view, 100GE interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **known-unicast-suppression** command to set the threshold of known multicast traffic that an interface allows to pass through. When the known unicast traffic rate exceeds the rate limit, the system discards excess known unicast packets to control the traffic volume in a proper range.

Precautions

Setting the bandwidth percentage is the same as setting the rate limit in pps. Take an interface of 1 Gbit/s as an example. If the bandwidth percentage is set to 50%, the device converts the bandwidth percentage to rate limit in pps as follows: (1000 x (50/100) x 1000 x 1000)/(84 x 8). In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

NOTE

If a packet rate limit is configured for a type of packets on an interface, the percentage rate limit for other types of packets is converted into the packet rate limit.

Example

#Set the maximum known unicast packet rate to 100000 pps on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] known-unicast-suppression packets 100000
```

14.5.11 multicast-suppression (interface view)

Function

The **multicast-suppression** command sets the maximum traffic volume of unknown multicast packets that can pass through an interface.

The **undo multicast-suppression** allows all unknown multicast packets to pass.

By default, unknown multicast packets are not suppressed.

Format

multicast-suppression { *percent-value* | **cir** *cir-value* [**cbs** *cbs-value*] | **packets** *packets-per-second* }

undo multicast-suppression

Parameters

Parameter	Description	Value
percent-value	Specifies the percentage of bandwidth occupied by broadcast packets on an interface. If loopback detection is enabled on an interface, the interface rate is set by user. If loopback detection is not enabled on an interface, the interface rate is automatically negotiated. You can run the **display this interface** command in the interface view to check the interface rate (value of the **Speed** field).	The value is an integer and the value range is as follows: ● 40GE interface: 0 to 100 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S ● Other interfaces: 0 to 100

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through. **NOTE** Traffic suppression based on **cir** is more precise than that based on **packets**. To specify the **cir** parameter, ensure that the traffic suppression mode set in the system view is **bits**.	The value is an integer, in kbit/s. The value range is as follows: ● Ethernet interface: 0 to 100000 ● GE interface: 0 or 16 to 1000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 1000000 for the others ● XGE interface: 0 or 16 to 10000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 10000000 for the others ● 25GE interface: 0 to 25000000 ● MultiGE interface: 0 to X, X indicates the negotiated bandwidth ● 40GE interface: 0 to 40000000 ● 100GE interface: 0 to 100000000 ● Port group: 0 to 100000000 **NOTE** When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1000000.

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the maximum size of traffic that can pass through.	The value is an integer. For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: The value ranges from 10000 to 65535, in bytes. For other models: The value ranges from 10000 to 4294967295, in bytes. By default, the CBS value is 188 times the CIR value.

Parameter	Description	Value
packets *packets-per-second*	Specifies the number of packets transmitted per second. **NOTE** To specify the **packets** parameter, ensure that the traffic suppression mode set in the system view is **packets**.	The value is an integer and the value range is as follows: ● Ethernet interface: 0 to 148810 ● GE interface: 0 to 1488100 ● XGE interface: 0 to 14881000 ● MultiGE interface: 0 to X. X indicates the negotiated bandwidth ● 25GE interface: 0 to 37202500 ● 40GE interface: 0 to 59524000 ● 100GE interface: 0 to 148810000 ● Port group: 0 to 148810000 **NOTE** ● For S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the configured value is less than 24, traffic suppression is performed based on 24. If the configured value is greater than or equal to 24, traffic suppression is performed based on the configured value. ● When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1488100.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an increasing number of unknown multicast packets are transmitted on a network, more network resources are occupied and services are affected.

To prevent broadcast storms, you can use the **multicast-suppression** command to set the threshold of unknown multicast traffic that an interface allows to pass through. When the unknown multicast traffic volume exceeds the threshold, the system discards the excess unknown multicast packets to control the traffic volume of unknown multicast packets to a proper range.

Precautions

Setting the bandwidth percentage is the same as setting the rate limit in pps. Take an interface of 1 Gbit/s as an example. If the bandwidth percentage is set to 50%, the device converts the bandwidth percentage to rate limit in pps as follows: (1000 x (50/100) x 1000 x 1000)/(84 x 8). In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

NOTE

If a packet rate limit is configured for a type of packets on an interface, the percentage rate limit for other types of packets is converted into the packet rate limit.

For S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, unknown multicast traffic suppression does not take effect on unknown multicast packets with the reserved addresses (224.0.0.x/24, 224.0.1.x/24, 239.x.x.x/8, and ff0x::/12).

Example

Set the maximum unknown multicast packet rate to 100000 pps on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] multicast-suppression packets 100000
```

14.5.12 multicast-suppression block outbound

Function

The **multicast-suppression block outbound** command configures an interface to block outgoing unknown multicast packets.

The **undo multicast-suppression block outbound** command cancels the configuration.

By default, outgoing unknown multicast packets are not blocked on an interface.

Format

multicast-suppression block outbound

undo multicast-suppression block outbound

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an interface receives an unknown multicast packet, the interface broadcasts the packet to all users in the same VLAN. This may cause information leak. For example, if an unauthorized user is connected to an interface in a VLAN, the unauthorized user obtains the host address in unknown multicast packets by listening to unknown multicast packets and uses the host address to attack the host. To prevent information leak, use the **multicast-suppression block outbound** command to block outgoing unknown multicast packets on an interface if users connected to the interface do not need to receive unknown multicast packets.

Precautions

The **multicast-suppression block outbound** command is applicable only to interfaces where users do not need to receive unknown multicast packets. This command will affect network operations if it is used on an interface where users need to receive unknown multicast packets.

Traffic suppression can be configured for incoming and outgoing packets on an interface, and the configurations are independent of each other. On an interface, you can use the **multicast-suppression** command to limit the rate of incoming unknown multicast packets and use the **multicast-suppression block outbound** command to block outgoing unknown multicast packets.

Example

Block outgoing unknown multicast packets onGE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] multicast-suppression block outbound
```

14.5.13 storm-control

Function

The **storm-control** command enables storm control for broadcast packets, unknown multicast packets, and unknown unicast packets on an interface.

The **undo storm-control** command disables storm control.

By default, storm control is disabled on interfaces.

Format

storm-control { **broadcast** | **multicast** | **unicast** } **min-rate** *min-rate-value* **max-rate** *max-rate-value*

storm-control { **broadcast** | **multicast** | **unicast** } **min-rate cir** *min-rate-value-cir* **max-rate cir** *max-rate-value-cir* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

storm-control { **broadcast** | **multicast** | **unicast** } **min-rate percent** *min-rate-value-percent* **max-rate percent** *max-rate-value-percent* (Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.)

undo storm-control { **broadcast** | **multicast** | **unicast** | **all-packets** }

Parameters

Parameter	Description	Value
broadcast	Enables storm control for broadcast packets.	-
multicast	Enables storm control for unknown multicast packets.	-
unicast	Enables storm control for unknown unicast packets.	-

Parameter	Description	Value
min-rate *min-rate-value*	Specifies the lower threshold in packet rate limit mode. If the value of *min-rate-value* is specified, packets received by an interface are forwarded when the rate of receiving packets is smaller than the value of *min-rate-value* in storm detection.	The value is an integer, in pps. The value range is as follows: ● Ethernet interface: 1 to 148810 ● GE interface: 1 to 1488100 ● MultiGE interface: 1 to X. X indicates the negotiated bandwidth ● XGE interface: 1 to 14881000 ● 25GE interface: 1 to 14881000 ● 40GE interface: 1 to 59524000 ● 100GE interface: 1 to 148810000 ● Port group: 1 to 148810000 **NOTE** The given value range for port groups is the maximum one. The actually delivered value range depends on the minimum value range allowed by member interfaces in a port group. The actual value range depends on the auto-negotiated rates.

Parameter	Description	Value
min-rate cir *min-rate-value-cir*	Specifies the lower threshold in byte rate limit mode. If the value of *min-rate-value-cir* is specified, packets received by an interface are forwarded when the rate of receiving packets is smaller than the value of *min-rate-value-cir* in storm detection.	The value is an integer, in kbit/s. The value range is as follows: ● Ethernet interface: 1 to 100000 ● GE interface: 1 to 1000000 ● XGE interface: 1 to 10000000 ● 25GE interface: 1 to 14881000 ● 40GE interface: 1 to 40000000 ● 100GE interface: 1 to 100000000 ● Port group: 1 to 100000000 **NOTE** The given value range for port groups is the maximum one. The actually delivered value range depends on the minimum value range allowed by member interfaces in a port group. The actual value range depends on the auto-negotiated rates.
min-rate percent *min-rate-value-percent*	Specifies the lower threshold in percentage rate limit mode. If the value of *min-rate-value-percent* is specified, packets received by an interface are forwarded when the rate of receiving packets is lower than the value of *min-rate-value-percent* in storm detection.	The value is an integer, in percentage. The value ranges from 1 to 100.

Parameter	Description	Value
max-rate *max-rate-value*	Specifies the upper threshold in packet rate limit mode. Storm control is performed on an interface when the rate of receiving packets on the interface is greater than the value of *max-rate-value* in storm detection.	The value is an integer, in pps. The value range is as follows: - Ethernet interface: 1 to 148810 - GE interface: 1 to 1488100 - MultiGE interface: 1 to X. X indicates the negotiated bandwidth - XGE interface: 1 to 14881000 - 25GE interface: 1 to 14881000 - 40GE interface: 1 to 59524000 - 100GE interface: 1 to 148810000 - Port group: 1 to 148810000 **NOTE** The given value range for port groups is the maximum one. The actually delivered value range depends on the minimum value range allowed by member interfaces in a port group. The actual value range depends on the auto-negotiated rates.

Parameter	Description	Value
max-rate cir *max-rate-value-cir*	Specifies the upper threshold in byte rate limit mode. If the value of *max-rate-value-cir* is specified, storm control is performed on an interface when the rate of receiving packets on the interface is greater than the value of *max-rate-value-cir* in storm detection.	The value is an integer, in kbit/s. The value range is as follows: ● Ethernet interface: 1 to 100000 ● GE interface: 1 to 1000000 ● XGE interface: 1 to 10000000 ● 25GE interface: 1 to 14881000 ● 40GE interface: 1 to 40000000 ● 100GE interface: 1 to 100000000 ● Port group: 1 to 100000000 **NOTE** The given value range for port groups is the maximum one. The actually delivered value range depends on the minimum value range allowed by member interfaces in a port group. The actual value range depends on the auto-negotiated rates.
max-rate percent *max-rate-value-percent*	Specifies the upper threshold in percentage rate limit mode. If the value of *max-rate-value-percent* is specified, storm control is performed on an interface when the rate of receiving packets on the interface is greater than the value of *max-rate-value-percent* in storm detection.	The value is an integer, in percentage. The value ranges from 1 to 100.

Parameter	Description	Value
all-packets	Disables storm control for all the broadcast packets, unknown multicast packets, and unknown unicast packets.	-

Views

Ethernet interface view, 40GE interface view, 100GE interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the average rate of receiving packets on an interface is greater than the value of *max-rate-value*, *max-rate-value-cir*, or *max-rate-value-percent* in storm detection, storm control is performed on the packets.

NOTE

The storm detection interval can be set using the **storm-control interval** command.

Storm control actions include **block** and **shutdown**, which can be configured using the **storm-control action** command. If the action is **block** on an interface, packets on the interface are unblocked when the rate of receiving packets on the interface is smaller than the value of *min-rate-value*, *min-rate-value-cir* or *min-rate-value-percent*; if the action is **shutdown** on an interface, run the **undo shutdown** command to enable the interface.

Precautions

For S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S5736-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I, when detecting unicast packets, a switch does not distinguish unknown unicast packets from known unicast packets. The packet rate detected is the sum of the rates of unknown and known unicast packets. When the storm control action is block, the switch blocks only the unknown unicast packets. This rule also applies to multicast packets.

You cannot configure storm control and traffic suppression simultaneously on an interface. For example, if you configure traffic suppression for unknown multicast packets, unknown unicast packets, or broadcast packets (including 100% traffic suppression for broadcast packets) on an interface, then you cannot configure storm control for broadcast packets simultaneously on the interface.

After storm control is configured on an interface, the device does not check the VLAN IDs of packets when performing check on the packets. That is, the device performs storm control on all the packets no matter whether the VLANs of the packets are allowed by the interface.

Example

Perform storm control on broadcast packets received on GE0/0/1. In the storm detection interval, perform storm control on packets when the rate of receiving packets on an interface is greater than 8000 pps and forward packets when the rate of receiving packets on an interface is smaller than 5000 pps.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] storm-control broadcast min-rate 5000 max-rate 8000
```

14.5.14 storm-control action

Function

The **storm-control action** sets the storm control action to **error-down** or **block**.

The **undo storm-control action** command cancels the configuration.

By default, no storm control action is configured.

Format

storm-control action { **block** | **error-down** }

undo storm-control action

NOTE

The following models do not support the **error-down** parameter:

S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S6720S-S, S5735S-H, S5736-S

Parameters

Parameter	Description	Value
block	Blocks packets.	-
error-down	Shuts down an interface.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

You can control data packets and prevent flooding by running the **storm-control action** command to configure a storm control action and the **storm-control** command to set the upper and lower thresholds.

In a storm detection interval, when the average rate of receiving broadcast packets, unknown multicast packets, and unknown unicast packets is greater than the value of the specified upper threshold, packets are blocked or the interface is shut down.

If the storm control action on an interface is **block**, the interface is restored when the traffic falls below the lower threshold.

If the storm control action is **error-down**, the interface can be recovered using either of the following methods:

- Manual recovery (after an Error-Down event occurs):

  If a few interfaces need to be recovered, run the **shutdown** and **undo shutdown** commands in the interface view. Alternatively, run the **restart** command in the interface view to restart the interfaces.
- Automatic recovery (before an Error-Down event occurs):

  If a large number of interfaces need to be recovered, manual recovery is time consuming and some interfaces may be omitted. To avoid this problem, run the **error-down auto-recovery cause storm-control interval** *interval-value* command in the system view to enable automatic interface recovery and set the recovery delay time. Run the **display error-down recovery** command to view information about automatic interface recovery.

  NOTE

  This method does not take effect on interfaces that are already in Error-Down state. It is effective only on interfaces that enter the Error-Down state after this configuration is complete.

Precautions

For S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S5736-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I, when detecting unicast packets, a switch does not distinguish unknown unicast packets from known unicast packets. The packet rate detected is the sum of the rates of unknown and known unicast packets. When the storm control action is block, the switch blocks only the unknown unicast packets. This rule also applies to multicast packets.

Example

Configure the storm control action is **block** on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] storm-control action block
```

14.5.15 storm-control enable

Function

The **storm-control enable** command configures the system to record logs or report traps during storm control.

The **undo storm-control enable** command configures the system not to record logs or report traps during storm control.

By default, the system does not record logs or report traps.

Format

storm-control enable { **log** | **trap** }

undo storm-control enable { **log** | **trap** }

Parameters

Parameter	Description	Value
log	Enables the log function.	-
trap	Enables the trap function.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

After storm control is configured, the switch monitors the broadcast, unknown multicast, and unknown unicast packets received on an interface. When the packet rate within a detection interval exceeds the upper limit, the switch executes the storm control action (block packets or shut down the interface) on the interface. This may affect services. You can configure the log or trap for storm control so that the administrator can quickly take actions to protect the switch.

- After the logging function is enabled for storm control, the storm control log information is recorded in the **STORMCTRL** log of the SECE module.
- After the trap function is enabled for storm control, the trap is SECE_1.3.6.1.4.1.2011.5.25.32.4.1.14.1 hwXQoSStormControlTrap.

Example

Enable the trap reporting function during storm control on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] storm-control broadcast min-rate 3000 max-rate 5000
[HUAWEI-GigabitEthernet0/0/1] storm-control action block
[HUAWEI-GigabitEthernet0/0/1] storm-control enable trap
```

14.5.16 storm-control interval

Function

The **storm-control interval** command sets the storm detection interval.

The **undo storm-control interval** command restores the default storm detection interval.

By default, the storm detection interval is 5s.

Format

storm-control interval *interval-value*

undo storm-control interval

Parameters

Parameter	Description	Value
interval-value	Specifies the storm detection interval.	The value is an integer that ranges from 1 to 180, in seconds. The default value is 5s.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Before using the **storm-control interval** command to set the storm detection interval, run the **storm-control** command in the interface view to configure storm control. Otherwise, the storm detection interval does not take effect.

Example

Configure storm control and set the storm detection interval to 10 seconds on GE0/0/1. Block broadcast packets when the rate of receiving broadcast packets is greater than 5000 pps and forward the packets when the rate of receiving broadcast packets is smaller than 3000 pps in 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] storm-control broadcast min-rate 3000 max-rate 5000
[HUAWEI-GigabitEthernet0/0/1] storm-control action block
[HUAWEI-GigabitEthernet0/0/1] storm-control interval 10
```

14.5.17 storm-control whitelist protocol

Function

The **storm-control whitelist protocol** command adds specified protocol packets to the traffic suppression and storm control whitelist.

The **undo storm-control whitelist protocol** command deletes specified protocol packets from the traffic suppression and storm control whitelist.

By default, no protocol packet is not added to the traffic suppression and storm control whitelist.

NOTE

This command is supported only on the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S.

Format

storm-control whitelist protocol { **arp-request** | **bpdu** | **dhcp** | **igmp** | **rip** }*

undo storm-control whitelist protocol { **arp-request** | **bpdu** | **dhcp** | **igmp** | **rip** }*

Parameters

Parameter	Description	Value
arp-request	Adds ARP packets to the traffic suppression and storm control whitelist.	-
bpdu	Adds BPDU packets to the traffic suppression and storm control whitelist.	-
dhcp	Adds DHCP packets to the traffic suppression and storm control whitelist.	-
igmp	Adds IGMP packets to the traffic suppression and storm control whitelist.	-
rip	Adds RIP packets to the traffic suppression and storm control whitelist.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To free specified protocol packets from traffic suppression and storm control, you can run the **storm-control whitelist protocol** command to add these packets to the traffic suppression and storm control whitelist.

Precautions

- The **storm-control whitelist protocol** command configuration takes effect only on protocol packets in the inbound direction of an interface. It does not take effect on the packets that are blocked in the outbound direction of an interface using the **broadcast-suppression block outbound**, **multicast-suppression block outbound**, and **unicast-suppression block outbound**.
- The **storm-control whitelist protocol** command configuration does not take effect on broadcast packets that are suppressed using the **broadcast-suppression** command in the VLAN view.
- After the **qos lr inbound whitelist protocol** command is run to add specified protocol packets to the whitelist for inbound interface-based rate limiting, traffic suppression and storm control do not take effect on these protocol packets in the inbound direction of the corresponding interface.

Example

Add BPDU packets to the traffic suppression and storm control whitelist.

```
<HUAWEI> system-view
[HUAWEI] storm-control whitelist protocol bpdu
```

14.5.18 suppression mode

Function

The **suppression mode** command sets the global traffic suppression mode.

The **undo suppression mode** command restores the default traffic suppression mode.

By default, the global traffic suppression mode is **packets**.

NOTE

Only the SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, and S5736-S support this command.

Format

suppression mode { **by-packets** | **by-bits** }

undo suppression mode

Parameters

Parameter	Description	Value
by-packets	Sets the traffic suppression mode to **packets**.	-
by-bits	Sets the traffic suppression mode to **bits**.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The default traffic suppression mode on an interface is **packets**. To precisely control traffic rate, run the **suppression mode** command in the system view to set the traffic suppression mode to **bits**.

Precautions

If the **packets** mode has been set on an interface and the **bits** mode is set in the system view, the device automatically converts the traffic rate values and suppresses traffic based on **bits**. For example, if the maximum rate of broadcast packets allowed by a GE interface is set to 1000 pps, the device converts the traffic rate value as follows: 1000 x 84 x 8 = 672000 bits = 672 Kbit. In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

If the traffic suppression mode set in the system view is **packets**, the **cir** parameter cannot be specified when you set the maximum traffic rate on an interface.

If the traffic suppression mode set in the system view is **bits**, the **packets** parameter cannot be specified when you set the maximum traffic rate on an interface.

Example

Set the traffic suppression mode to **by-bits**.

```
<HUAWEI> system-view
[HUAWEI] suppression mode by-bits
Warning: All Interface supression mode will be changed. Continue? [Y/N]:y
```

14.5.19 unicast-suppression (interface view)

Function

The **unicast-suppression** command sets the maximum traffic volume of unknown unicast packets that can pass through an interface.

The **undo unicast-suppression** allows all unknown unicast packets to pass.

By default, unknown unicast packets are not suppressed.

Format

unicast-suppression { *percent-value* | **cir** *cir-value* [**cbs** *cbs-value*] | **packets** *packets-per-second* }

undo unicast-suppression

Parameters

Parameter	Description	Value
percent-value	Specifies the percentage of bandwidth occupied by broadcast packets on an interface. If loopback detection is enabled on an interface, the interface rate is set by user. If loopback detection is not enabled on an interface, the interface rate is automatically negotiated. You can run the **display this interface** command in the interface view to check the interface rate (value of the **Speed** field).	The value is an integer and the value range is as follows: • 40GE interface: 0 to 100 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S • Other interfaces: 0 to 100

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through. **NOTE** Traffic suppression based on **cir** is more precise than that based on **packets**. To specify the **cir** parameter, ensure that the traffic suppression mode set in the system view is **bits**.	The value is an integer, in kbit/s. The value range is as follows: - Ethernet interface: 0 to 100000 - GE interface: 0 or 16 to 1000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 1000000 for the others - XGE interface: 0 or 16 to 10000000 for the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, 0 to 10000000 for the others - 25GE interface: 0 to 25000000 - MultiGE interface: 0 to X, X indicates the negotiated bandwidth - 40GE interface: 0 to 40000000 - 100GE interface: 0 to 100000000 - Port group: 0 to 100000000 **NOTE** When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1000000.

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the maximum size of traffic that can pass through.	The value is an integer. For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: The value ranges from 10000 to 65535, in bytes. For other models: The value ranges from 10000 to 4294967295, in bytes. By default, the CBS value is 188 times the CIR value.

Parameter	Description	Value
packets *packets-per-second*	Specifies the number of packets transmitted per second. **NOTE** To specify the **packets** parameter, ensure that the traffic suppression mode set in the system view is **packets**.	The value is an integer and the value range is as follows: ● Ethernet interface: 0 to 148810 ● GE interface: 0 to 1488100 ● XGE interface: 0 to 14881000 ● MultiGE interface: 0 to X. X indicates the negotiated bandwidth ● 25GE interface: 0 to 37202500 ● 40GE interface: 0 to 59524000 ● 100GE interface: 0 to 148810000 ● Port group: 0 to 148810000 **NOTE** ● For S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the configured value is less than 24, traffic suppression is performed based on 24. If the configured value is greater than or equal to 24, traffic suppression is performed based on the configured value. ● When an interface is configured with an optical module, the value range is determined by the rate of the optical module. For example, when an XGE interface is configured with a GE optical module, the value range is 0 to 1488100.

Views

Ethernet interface view, 40GE interface view, 100GE interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, port group view, Eth-Trunk member interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an increasing number of unknown unicast packets are transmitted on the network, more network resources are occupied and services are affected.

To prevent broadcast storms, you can use the **unicast-suppression** command to set the threshold of unicast traffic that an interface allows to pass through. When the unknown unicast traffic rate exceeds the rate limit, the system discards excess unknown unicast packets to control the traffic volume in a proper range.

Precautions

Setting the bandwidth percentage is the same as setting the rate limit in pps. Take an interface of 1 Gbit/s as an example. If the bandwidth percentage is set to 50%, the device converts the bandwidth percentage to rate limit in pps as follows: (1000 x (50/100) x 1000 x 1000)/(84 x 8). In the preceding formula, 84 is the average length of packets (including the 60-byte packet body, 20-byte frame spacing, and 4-byte check information), and 8 is the number of bits in a byte.

NOTE

If a packet rate limit is configured for a type of packets on an interface, the percentage rate limit for other types of packets is converted into the packet rate limit.

Example

#Set the maximum unknown unicast packet rate to 100000 pps on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] unicast-suppression packets 100000
```

14.5.20 unicast-suppression block outbound

Function

The **unicast-suppression block outbound** command configures an interface to block outgoing unknown unicast packets.

The **undo unicast-suppression block outbound** command cancels the configuration.

By default, an interface does not block outgoing unknown unicast packets.

Format

unicast-suppression block outbound

undo unicast-suppression block outbound

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an interface receives an unknown unicast packet, the interface broadcasts the packet to all users in the same VLAN. This may cause information leak. For example, if an unauthorized user is connected to an interface in a VLAN, the unauthorized user obtains a host's address from unknown unicast packets and uses the address to attack the host. To prevent information leak, use the **unicast-suppression block outbound** command to block unknown unicast packets on an interface if users connected to the interface do not need to receive broadcast packets. For example, if users on an interface seldom change and require high security, you can use this command on the interface.

Precautions

The **unicast-suppression block outbound** command is applicable only to interfaces where users do not need to receive unknown unicast packets. This command will affect network operations if it is used on an interface where users need to receive unknown packets.

Traffic suppression can be configured for incoming and outgoing packets on an interface, and the configurations are independent of each other. On an interface, use the **unicast-suppression** command to limit the rate of incoming unknown unicast packets and the **unicast-suppression block outbound** command to block outgoing unknown unicast packets.

Example

Block outgoing multicast packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] unicast-suppression block outbound
```

14.6 ARP Security Configuration Commands

14.6.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.6.2 arp anti-attack check user-bind alarm enable

Function

The **arp anti-attack check user-bind alarm enable** command enables the alarm function for ARP packets discarded by DAI.

The **undo arp anti-attack check user-bind alarm enable** command disables the alarm function for ARP packets discarded by DAI.

By default, the alarm function for ARP packets discarded by DAI is disabled.

Format

arp anti-attack check user-bind alarm enable

undo arp anti-attack check user-bind alarm enable

Parameters

None

Views

Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view, VLAN view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DAI is enabled, if you want to receive an alarm when a large number of ARP packets are discarded by DAI, you can run the **arp anti-attack check user-bind alarm enable** command. After the alarm function is enabled, the device sends an alarm when the number of discarded ARP packets exceeds the threshold.

Prerequisites

DAI has been enabled using the **arp anti-attack check user-bind enable** command in the corresponding view.

Follow-up Procedure

The alarm threshold is set by the **arp anti-attack check user-bind alarm threshold** command.

Precautions

If you run this command in multiple views, the configuration will take effect in the following sequence: BD view > interface view > VLAN view.

Example

Enable the alarm function for ARP packets discarded by DAI on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind alarm enable
```

14.6.3 arp anti-attack check user-bind alarm threshold

Function

The **arp anti-attack check user-bind alarm threshold** command sets the alarm threshold for ARP packets discarded by DAI.

The **undo arp anti-attack check user-bind alarm threshold** command restores the default alarm threshold for ARP packets discarded by DAI.

By default, the alarm threshold for ARP packets discarded by DAI is 100 packets.

Format

arp anti-attack check user-bind alarm threshold *threshold*

undo arp anti-attack check user-bind alarm threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold for the ARP packets discarded by DAI.	The value is an integer that ranges from 1 to 1000.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view, VLAN view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use this command to set the alarm threshold for ARP packets discarded by DAI. After the alarm threshold is set, the device sends an alarm when the number of ARP packets discarded by DAI exceeds this threshold.

Prerequisites

DAI has been enabled using the **arp anti-attack check user-bind enable** command in the corresponding view, and the alarm function for ARP packets discarded by DAI has been enabled using the **arp anti-attack check user-bind alarm enable** command in the corresponding view.

Precautions

The **arp anti-attack check user-bind alarm threshold** command takes effect in the system view only when DAI and the alarm function for ARP packets discarded by DAI are enabled in the interface, BD, or VLAN view. The global alarm threshold takes effect on all interfaces, BDs, or VLANs enabled with the two functions.

The priority configured in the interface, BD, or VLAN view is higher than that configured globally. If the alarm threshold on an interface is not configured, the global alarm threshold is used.

Example

Set the alarm threshold for ARP packets discarded by DAI on GE0/0/1 to 200.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind alarm enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind alarm threshold 200
```

14.6.4 arp anti-attack check user-bind check-item (interface view)

Function

The **arp anti-attack check user-bind check-item** command configures check items for ARP packet check based on binding entries on an interface.

The **undo arp anti-attack check user-bind check-item** command restores the default check items.

By default, the check items consist of IP address, MAC address, and VLAN ID.

Format

arp anti-attack check user-bind check-item { **ip-address** | **mac-address** | **vlan** } *

undo arp anti-attack check user-bind check-item

Parameters

Parameter	Description	Value
ip-address	Indicates that the device checks IP addresses in ARP packets.	-
mac-address	Indicates that the device checks MAC addresses in ARP packets.	-
vlan	Indicates that the device checks VLAN IDs in ARP packets.	-

Views

Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device receives an ARP packet, it compares the source IP address, source MAC address, and VLAN ID of the ARP packet with binding entries. If the ARP packet matches a binding entry, the device considers the ARP packet valid and allows the packet to pass through. If the ARP packet matches no binding entry, the device considers the ARP packet invalid and discards the packet.

To allow some special ARP packets that match only one or two items in binding entries to pass through, use the **arp anti-attack check user-bind check-item** command to configure the device to check ARP packets according to one or two specified items in binding entries.

Prerequisites

DAI has been enabled on the interface using the **arp anti-attack check user-bind enable** command.

Precautions

Check items configured for ARP packet check based on binding entries do not take effect on hosts that are configured with static binding entries. These hosts check ARP packets based on all items in static binding entries.

Example

Configure GE0/0/1 to check IP addresses in ARP packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind check-item ip-address
```

14.6.5 arp anti-attack check user-bind check-item (VLAN or BD view)

Function

The **arp anti-attack check user-bind check-item** command configures check items for ARP packet check based on binding entries in a VLAN or BD.

The **undo arp anti-attack check user-bind check-item** command restores the default check items.

By default, the check items consist of IP address, MAC address, and interface number.

Format

arp anti-attack check user-bind check-item { **ip-address** | **mac-address** | **interface** } *

undo arp anti-attack check user-bind check-item

Parameters

Parameter	Description	Value
ip-address	Indicates that the device checks IP addresses in ARP packets.	-
mac-address	Indicates that the device checks MAC addresses in ARP packets.	-
interface	Indicates that the device checks interface numbers in ARP packets.	-

Views

VLAN view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device receives an ARP packet, it compares the source IP address, source MAC address, and interface number of the ARP packet with binding entries. If the ARP packet matches a binding entry, the device considers the ARP packet valid and allows the packet to pass through. If the ARP packet matches no binding entry, the device considers the ARP packet invalid and discards the packet.

To allow some special ARP packets that match only one or two items in binding entries to pass through, configure the device to check ARP packets according to one or two specified items in binding entries.

Prerequisites

DAI has been enabled in the VLAN or BD using the **arp anti-attack check user-bind enable** command.

Precautions

Check items configured for ARP packet check based on binding entries do not take effect on hosts that are configured with static binding entries. These hosts check ARP packets based on all items in static binding entries.

Example

Configure the device to check IP addresses in ARP packets from VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] arp anti-attack check user-bind enable
[HUAWEI-vlan100] arp anti-attack check user-bind check-item ip-address
```

14.6.6 arp anti-attack check user-bind enable

Function

The **arp anti-attack check user-bind enable** command enables dynamic ARP inspection (DAI) for an interface, BD, or VLAN to check ARP packets against binding entries.

The **undo arp anti-attack check user-bind enable** command disables DAI for an interface, BD, or VLAN.

By default, DAI is disabled for an interface, BD, or VLAN.

Format

arp anti-attack check user-bind enable

undo arp anti-attack check user-bind enable

Parameters

None

Views

Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view, BD view, VLAN view

NOTE

DAI can be enabled in the BD view only for the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To defend against MITM attacks and prevent authorized users' data from being intercepted, run the **arp anti-attack check user-bind enable** command to enable DAI. When a device receives an ARP packet, it compares the source IP address, source MAC address, interface number, BD, and VLAN ID of the ARP packet with binding entries. If the ARP packet matches a binding entry, the device considers the ARP packet valid and allows the packet to pass through. If the ARP packet matches no binding entry, the device considers the ARP packet invalid and discards the packet.

DAI can be enabled in the interface view, BD view, or VLAN view. When DAI is enabled in the interface view, the device checks all ARP packets received on the interface against binding entries. When DAI is enabled in the VLAN view or BD view, the device checks ARP packets received on interfaces belong to the VLAN or BD based on binding entries.

Follow-up Procedure

Run the **arp anti-attack check user-bind check-item (interface view)** or **arp anti-attack check user-bind check-item (VLAN or BD view)** command to configure check items for ARP packet check based on binding entries.

Precautions

When resources are sufficient, DAI can be enabled in a maximum of 400 VLANs.

After DAI is configured, the function of disabling the VLANIF interface from sending ARP packets destined for other devices to the CPU is ineffective on the VLANIF interface.

Example

Enable DAI on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack check user-bind enable
```

Enable DAI in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] arp anti-attack check user-bind enable
```

14.6.7 arp anti-attack entry-check enable

Function

The **arp anti-attack entry-check enable** command enables ARP entry fixing.

The **undo arp anti-attack entry-check enable** command disables ARP entry fixing.

By default, ARP entry fixing is disabled.

Format

arp anti-attack entry-check { **fixed-mac** | **fixed-all** | **send-ack** } **enable**

undo arp anti-attack entry-check [**fixed-mac** | **fixed-all** | **send-ack**] **enable**

Parameters

Parameter	Description	Value
fixed-mac	Indicates ARP entry fixing in **fixed-mac** mode. When receiving an ARP packet, the device discards the packet if the MAC address does not match the MAC address in the corresponding ARP entry. If the MAC address in the ARP packet matches that in the corresponding ARP entry while the interface number or VLAN ID does not match that in the ARP entry, the device updates the interface number or VLAN ID in the ARP entry.	-
fixed-all	Indicates ARP entry fixing in **fixed-all** mode. When the MAC address, interface number, and VLAN ID of an ARP packet match those in the corresponding ARP entry, the device updates other information about the ARP entry.	-
send-ack	Indicates ARP entry fixing in **send-ack** mode. When the device receives an ARP packet with a changed MAC address, interface number, or VLAN ID, it does not immediately update the corresponding ARP entry. Instead, the device sends a unicast ARP Request packet to the user with the IP address mapped to the original MAC address in the ARP entry, and then determines whether to change the MAC address, VLAN ID, or interface number in the ARP entry depending on the response from the user.	-

Views

System view, VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To defend against ARP address spoofing attacks, enable ARP entry fixing. The **fixed-mac**, **fixed-all**, and **send-ack** modes are applicable to different scenarios and are mutually exclusive:

- The **fixed-mac** mode applies to networks where user MAC addresses are unchanged but user access locations often change. When a user connects to a different interface on the device, the device updates interface information in the ARP entry of the user timely.
- The **fixed-all** mode applies to networks where user MAC addresses and user access locations are fixed.
- The **send-ack** mode applies to networks where user MAC addresses and user access locations often change.

Precautions

After ARP entry fixing is enabled, the function that updates ARP entries when MAC address entries change (configured by the **mac-address update arp** command) becomes invalid.

In **send-ack** mode, the device can record a maximum of 100 ARP entries in the ARP Request packets intended to trigger ARP entry modification.

If you run the **arp anti-attack entry-check enable** command in the system view, ARP entry fixing is enabled on all interfaces. If you run the **arp anti-attack entry-check enable** command in the interface view, ARP entry fixing is enabled on the specified interface.

If ARP entry fixing is enabled globally and on a VLANIF interface simultaneously, the configuration on the VLANIF interface takes precedence over the global configuration.

Example

Enable ARP entry fixing and specify the **fixed-mac** mode.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack entry-check fixed-mac enable
```

14.6.8 arp anti-attack gateway-duplicate enable

Function

The **arp anti-attack gateway-duplicate enable** command enables ARP gateway anti-collision.

The **undo arp anti-attack gateway-duplicate enable** command disables ARP gateway anti-collision.

By default, ARP gateway anti-collision is disabled.

Format

arp anti-attack gateway-duplicate enable

undo arp anti-attack gateway-duplicate enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker forges the gateway address to send ARP packets with the source IP address being the gateway IP address on the LAN where the gateway is located, ARP entries on hosts in the LAN record the incorrect gateway address. As a result, all traffic from user hosts to the gateway is sent to the attacker and the attacker can intercept user data, causing network access failures of these hosts.

To defend against attacks from bogus gateways, run the **arp anti-attack gateway-duplicate enable** command to enable ARP gateway anti-collision on gateways to which user hosts directly connect. A gateway considers that an ARP gateway collision occurs when it receives an ARP packet meeting either of the following conditions:

- The source IP address of the ARP packet is the same as the IP address of the VLANIF interface matching the inbound interface of the packet.
- The source IP address of the ARP packet is the virtual IP address of the inbound interface, but the source MAC address is not the VRRP virtual MAC address.

The gateway generates an ARP anti-collision entry and discards the received ARP packets with the same source MAC address and VLAN ID as those of the ARP packet within a specified period of time. This function prevents ARP packets with a bogus gateway address from being broadcast in a VLAN.

Precautions

The device supports a maximum of 100 ARP anti-collision entries. When the maximum number is exceeded, the gateway cannot prevent new ARP gateway collision attacks.

After DAI is configured, the function of disabling the VLANIF interface from sending ARP packets destined for other devices to the CPU is ineffective on the VLANIF interface.

Example

Enable ARP gateway anti-collision.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack gateway-duplicate enable
```

14.6.9 arp anti-attack log-trap-timer

Function

The **arp anti-attack log-trap-timer** command sets the interval for sending ARP alarms.

The **undo arp anti-attack log-trap-timer** command restores the default setting.

The default interval for sending alarms is 0, indicating that the device does not send ARP alarms.

Format

arp anti-attack log-trap-timer *time*

undo arp anti-attack log-trap-timer

Parameters

Parameter	Description	Value
time	Specifies the interval for sending ARP alarms.	The value is an integer that ranges from 0 to 1200, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After rate limiting on ARP packets based on source IP addresses is enabled, if the number of ARP packets the device receives per second exceeds the limit, the device discards the excess ARP packets. The device considers the excess ARP packets as potential attacks. The device sends ARP alarms indicating potential attacks to the NMS. To avoid excessive alarms when ARP attacks occur, reduce the alarm quantity by setting a proper interval for sending alarms.

Precautions

In the insecure environment, you are advised to extend the interval for sending ARP alarms. This prevents excessive ARP alarms. In the secure environment, you are advised to shorten the interval for sending ARP alarms. This facilitates fault rectification in real time.

After the interval is set, the device discards alarms generates in this interval; therefore, some faults cannot be rectified in real time.

The command takes effect only on the alarm for ARP rate limit based on source IP addresses (corresponding to **arp speed-limit source-ip**). The other ARP alarms are generated at a fixed interval of 5 seconds.

Example

Set the interval for sending ARP alarms to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack log-trap-timer 20
```

14.6.10 arp anti-attack packet-check

Function

The **arp anti-attack packet-check** command enables ARP packet validity check and specifies check items.

The **undo arp anti-attack packet-check** command disables ARP packet validity check.

By default, ARP packet validity check is disabled.

Format

arp anti-attack packet-check { **ip** | **dst-mac** | **sender-mac** } *

undo arp anti-attack packet-check [**ip** | **dst-mac** | **sender-mac**] *

Parameters

Parameter	Description	Value
ip	Indicates ARP packet validity check based on the IP address.	-
dst-mac	Indicates ARP packet validity check based on the destination MAC address.	-
sender-mac	Indicates ARP packet validity check based on the source MAC address.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To avoid ARP attacks, you can use the **arp anti-attack packet-check** command to enable ARP packet validity check on an access device or a gateway to filters out

ARP packets with invalid IP addresses or MAC addresses. The device checks validity of an ARP packet based on each or any combination of the following items:

- Source and destination IP addresses: The device checks the source and destination IP addresses in an ARP packet. If the source or destination IP address is all 0s, all 1s, or a multicast IP address, the device discards the packet as an invalid packet. The device checks both the source and destination IP addresses in an ARP Reply packet but checks only the source IP address in an ARP Request packet.
- Source MAC address: The device compares the source MAC address in an ARP packet with that in the Ethernet frame header. If they are the same, the packet is valid. If they are different, the device discards the packet.
- Destination MAC address: The device compares the destination MAC address in an ARP packet with that in the Ethernet frame header. If they are the same, the packet is valid. If they are different, the device discards the packet.

Precautions

Generally, packets with different source and destination MAC addresses in the ARP packet and Ethernet frame header are allowed by the ARP protocol. When an attack occurs, capture and analyze packets. If the attack is initiated by using inconsistent source or destination MAC addresses in the ARP packet and Ethernet frame header, enable ARP packet validity check based on the source or destination MAC address.

If you run the **arp anti-attack packet-check sender-mac** command multiple times, all the check items specified in these commands take effect.

Example

Enable ARP packet validity check and configures the device to check the source MAC address in an ARP packet.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack packet-check sender-mac
```

14.6.11 arp anti-attack rate-limit

Function

The **arp anti-attack rate-limit** command sets the maximum rate and rate limiting duration of ARP packets globally, in a VLAN, or on an interface, and enables the function of discarding all ARP packets received from the interface when the rate of ARP packets exceeds the limit on an interface.

The **undo arp anti-attack rate-limit** command restores the default maximum rate and rate limiting duration of ARP packets globally, in a VLAN, or on an interface, and allows the device to send ARP packets to the CPU again.

By default, a maximum of 100 ARP packets are allowed to pass per second, and the function of discarding all ARP packets received from the interface when the rate of ARP packets exceeds the limit is disabled.

Format

System view, VLAN view

arp anti-attack rate-limit packet *packet-number* [**interval** *interval-value*]

undo arp anti-attack rate-limit

Interface view

arp anti-attack rate-limit packet *packet-number* [**interval** *interval-value* | **block-timer** *timer*] *

undo arp anti-attack rate-limit

Parameters

Parameter	Description	Value
packet *packet-number*	Specifies the maximum rate of sending ARP packets, that is, the number of ARP packets allowed to pass through in the rate limiting duration.	The value is an integer that ranges from 1 to 16384. The default value is 100.
interval *interval-value*	Specifies the rate limiting duration of ARP packets.	The value is an integer that ranges from 1 to 86400, in seconds. The default value is 1 second.
block-timer *timer*	Specifies the duration for blocking ARP packets.	The value is an integer that ranges from 5 to 864000, in seconds.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After rate limit on ARP packets is enabled, run the **arp anti-attack rate-limit** command to set the maximum rate and rate limiting duration of ARP packets globally, in a VLAN, or on an interface. In the rate limiting duration, if the number of received ARP packets exceeds the limit, the device discards the excess ARP packets.

If the parameter **block-timer** *timer* is specified, the device discards all ARP packets received in the duration specified by *timer*.

Prerequisites

Rate limit on ARP packets has been enabled globally, in a VLAN, or on an interface using the **arp anti-attack rate-limit enable** command.

Precautions

If the maximum rate and rate limiting duration are configured in the system view, VLAN view, and interface view at the same time, the device uses the configurations in the interface view, VLAN view, and system view in order.

NOTE

The **arp anti-attack rate-limit** command takes effect only on ARP packets sent to the CPU for processing in **none-block** mode, and does not affect ARP packet forwarding by the chip. In **block** mode, the device discards subsequent ARP packets on an interface only when the number of ARP packets sent to the CPU exceeds the limit.

Example

Configure Layer 2 interface GE0/0/1 to allow 200 ARP packets to pass through in 10 seconds, and configure GE0/0/1 to discard all ARP packets in 60 seconds when the number of ARP packets exceeds the limit.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit packet 200 interval 10 block-timer 60
```

Configure Layer 3 interface GE0/0/1 to allow 200 ARP packets to pass through in 10 seconds, and configure GE0/0/1 to discard all ARP packets in 60 seconds when the number of ARP packets exceeds the limit.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit packet 200 interval 10 block-timer 60
```

14.6.12 arp anti-attack rate-limit alarm enable

Function

The **arp anti-attack rate-limit alarm enable** command enables the alarm function for ARP packets discarded when the rate of ARP packets exceeds the limit.

The **undo arp anti-attack rate-limit alarm enable** command disables the alarm function for ARP packets discarded when the rate of ARP packets exceeds the limit.

By default, the alarm function for ARP packets discarded when the rate of ARP packets exceeds the limit is disabled.

Format

arp anti-attack rate-limit alarm enable

undo arp anti-attack rate-limit alarm enable

Parameters

None

Views

System view, VLAN view, Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Usage Guidelines

Usage Scenario

After rate limit on ARP packets is enabled, if you want the device to generate alarms for excessive discarded ARP packets, run the **arp anti-attack rate-limit alarm enable** command. When the number of discarded ARP packets exceeds the alarm threshold, the device generates an alarm.

You can set the alarm threshold using the **arp anti-attack rate-limit alarm threshold** command.

Prerequisites

Rate limit on ARP packets has been enabled using the **arp anti-attack rate-limit enable** command.

Example

Enable rate limit on ARP packets globally and enable the alarm function.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack rate-limit enable
[HUAWEI] arp anti-attack rate-limit alarm enable
```

Enable rate limit for the ARP packets on Layer 2 interface GE0/0/1 and enable the alarm function.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm enable
```

Enable rate limit for the ARP packets on Layer 3 interface GE0/0/1 and enable the alarm function.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm enable
```

14.6.13 arp anti-attack rate-limit alarm threshold

Function

The **arp anti-attack rate-limit alarm threshold** command sets the alarm threshold of ARP packets discarded when the rate of ARP packets exceeds the limit.

The **undo arp anti-attack rate-limit alarm threshold** command restores the default alarm threshold.

By default, the alarm threshold of ARP packets discarded when the rate of ARP packets exceeds the limit is 100.

Format

arp anti-attack rate-limit alarm threshold *threshold*

undo arp anti-attack rate-limit alarm threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold of ARP packets discarded when the rate of ARP packets exceeds the limit.	The value is an integer that ranges from 1 to 16384.

Views

System view, VLAN view, Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **arp anti-attack rate-limit alarm threshold** command to set the alarm threshold. When the number of discarded ARP packets exceeds the alarm threshold, the device generates an alarm.

Prerequisites

Rate limit on ARP packets has been enabled using the **arp anti-attack rate-limit enable** command, and the alarm function has been enabled using the **arp anti-attack rate-limit alarm enable** command.

Example

Enable rate limit on ARP packets globally, enable the alarm function, and set the alarm threshold to 50.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack rate-limit enable
[HUAWEI] arp anti-attack rate-limit alarm enable
[HUAWEI] arp anti-attack rate-limit alarm threshold 50
```

Enable rate limit for the ARP packets on Layer 2 interface GE0/0/1, enable the alarm function, and set the alarm threshold to 50.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm threshold 50
```

Enable rate limit for the ARP packets on Layer 3 interface GE0/0/1, enable the alarm function, and set the alarm threshold to 50.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm enable
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit alarm threshold 50
```

14.6.14 arp anti-attack rate-limit enable

Function

The **arp anti-attack rate-limit enable** command enables rate limit on ARP packets.

The **undo arp anti-attack rate-limit enable** command disables rate limit on ARP packets.

By default, rate limiting on ARP packets is disabled.

Format

arp anti-attack rate-limit enable

undo arp anti-attack rate-limit enable

Parameters

None

Views

System view, VLAN view, Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

The device has no sufficient CPU resource to process other services when processing a large number of ARP packets. To protect CPU resources of the device, limit the rate of ARP packets.

You can run the **arp anti-attack rate-limit enable** command to enable rate limit on ARP packets. When the rate of ARP packets exceeds the limit, excess ARP packets are discarded. To set the rate limit and rate limiting duration of ARP packets, run the **arp anti-attack rate-limit** command.

After the optimized ARP reply function (disabled by default) is enabled using the **undo arp optimized-reply disable** command, rate limiting on ARP packets globally, in a VLAN, or on an Interface does not take effect.

Example

Enable rate limit on ARP packets globally.

```
<HUAWEI> system-view
[HUAWEI] arp anti-attack rate-limit enable
```

Enable rate limit for the ARP packets on Layer 2 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
```

Enable rate limit for the ARP packets on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp anti-attack rate-limit enable
```

14.6.15 arp trust source

Function

The **arp trust source** command enables ARP gateway protection for the specified IP address.

The **undo arp trust source** command disables ARP gateway protection for the specified IP address.

By default, ARP gateway protection is disabled.

Format

arp trust source *ip-address*

undo arp trust source { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the protected gateway IP address.	The value is in dotted decimal notation.
all	Disables ARP gateway protection for all IP addresses in the current view.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker poses as a gateway to send ARP packets, other users on the network consider the attacker to be a gateway, causing a communication interruption between authorized users and gateway. This situation will also happen if a user incorrectly sets the host IP address as the gateway address. To prevent such bogus gateway attacks, configure ARP gateway protection on the device's interfaces connected to the gateway. When the ARP packets from a gateway address reach a device:

- The interfaces with gateway protection enabled can receive and forward the ARP packets.
- The interfaces without gateway protection enabled discard the ARP packets.

Precautions

A maximum of 8 protected gateway addresses can be specified on each interface, and 32 can be specified on the entire device. If the same gateway IP address is specified on different interfaces, the system considers that multiple protected gateway IP addresses have been configured.

Example

Enable ARP gateway protection on GE0/0/1 and set the protected gateway IP address to 10.10.10.1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp trust source 10.10.10.1
```

14.6.16 arp gratuitous-arp send enable

Function

The **arp gratuitous-arp send enable** command enables gratuitous ARP packet sending.

The **undo arp gratuitous-arp send enable** command disables gratuitous ARP packet sending.

By default, gratuitous ARP packet sending is disabled.

Format

arp gratuitous-arp send enable

undo arp gratuitous-arp send enable

Parameters

None

Views

System view, VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker forges the gateway address to send ARP packets to other user hosts, ARP entries on the hosts record the incorrect gateway address. As a result, the gateway cannot receive data sent from the hosts. You can enable gratuitous ARP packet sending on the gateway. Then the gateway sends gratuitous ARP packets at intervals to update the ARP entries of authorized users so that the ARP entries contain the correct MAC address of the gateway.

By default, the device sends a gratuitous ARP packet every 60 seconds after this function is enabled. You can also set the interval using the **arp gratuitous-arp send interval** command.

Precautions

After you run the **arp gratuitous-arp send enable** command in the system view, gratuitous ARP packet sending is enabled on all VLANIF interfaces.

After you run the **undo arp gratuitous-arp send enable** command in the system view, gratuitous ARP packet sending is disabled on all VLANIF interfaces.

Example

Enable gratuitous ARP packet sending on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] arp gratuitous-arp send enable
```

14.6.17 arp gratuitous-arp send interval

Function

The **arp gratuitous-arp send interval** command sets the interval for sending gratuitous ARP packets.

The **undo arp gratuitous-arp send interval** command restores the default interval for sending gratuitous ARP packets.

By default, the interval for sending gratuitous ARP packets is 60 seconds.

Format

arp gratuitous-arp send interval *interval-time*

undo arp gratuitous-arp send interval

Parameters

Parameter	Description	Value
interval-time	Specifies the interval for sending gratuitous ARP packets.	The value is an integer that ranges from 1 to 86400, in seconds.

Views

System view, VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the device sends a gratuitous ARP packet every 60 seconds after gratuitous ARP sending is enabled. You can set the interval for sending gratuitous ARP packets using the **arp gratuitous-arp send interval** command.

If you set the interval in the system view, the configuration takes effect on all VLANIF interfaces. If you set the interval in both the system view and VLANIF interface view, the configuration on the VLANIF interface takes precedence over the global configuration.

Prerequisites

Gratuitous ARP packet sending has been enabled using the **arp gratuitous-arp send enable** command.

Example

Set the interval for sending gratuitous ARP packets to 100 seconds on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] arp gratuitous-arp send enable
[HUAWEI-Vlanif10] arp gratuitous-arp send interval 100
```

14.6.18 arp learning dhcp-trigger

Function

The **arp learning dhcp-trigger** command enables ARP learning triggered by DHCP.

The **undo arp learning dhcp-trigger** command disables ARP learning triggered by DHCP.

By default, ARP learning triggered by DHCP is disabled.

Format

arp learning dhcp-trigger

undo arp learning dhcp-trigger

Parameters

None

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When many DHCP users connect to a network device, the device needs to learn and maintain many ARP entries. This affects device performance.

To address this issue, you can configure ARP learning triggered by DHCP on the gateway. When the DHCP server assigns an IP address to a user, the device generates a DHCP snooping binding table and generates an ARP entry for the user based on the binding table. When DHCP snooping binding entries are deleted, ARP entries are also deleted.

Prerequisites

- DHCP has been enabled globally using the **dhcp enable** command in the system view.

- DHCP snooping has been enabled globally using the **dhcp snooping enable** command in the system view.
- DHCP snooping has been enabled using the **dhcp snooping enable** command in the view of the interface or VLAN through which a user goes online.

Precautions

When both VRRP and DHCP relay are configured on the network, neither the **dhcp snooping enable** command nor the **arp learning dhcp-trigger** command can be configured on the VRRP master and backup devices.

The VLANIF interface must be assigned an IP address on the same network segment as that of a user.

DHCP snooping for wireless users is deployed on APs. The AC enabled with DHCP snooping does not process DHCP packets of wireless users. Therefore, ARP learning takes effect only for wired users.

Example

Enable ARP learning triggered by DHCP on VLANIF 100 and assign an IP address on the same network segment as that of a user.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp snooping enable
[HUAWEI] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.0.1 255.255.255.0
[HUAWEI-Vlanif100] arp learning dhcp-trigger
```

14.6.19 arp learning disable

Function

The **arp learning disable** command disables an interface from learning dynamic ARP entries.

The **undo arp learning disable** command enables an interface to learn dynamic ARP entries.

By default, an interface is enabled to learn dynamic ARP entries.

Format

arp learning disable

undo arp learning disable

Parameters

None

Views

VLANIF interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure security and facilitate management, you can enable an interface to learn or disable an interface from learning dynamic ARP entries. You can also use the **arp learning strict** or **arp learning strict** commands to strictly control ARP entry learning on an interface.

Precautions

If an interface is disabled from learning ARP entries, the network will be interrupted.

If an interface has learned some dynamic ARP entries, the system does not delete these entries after the interface is disabled from learning dynamic ARP entries. You can manually delete or reserve these learned dynamic ARP entries (deleted by the **reset arp** command).

Example

Disable VLANIF10 from learning dynamic ARP entries.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] arp learning disable
```

14.6.20 arp learning strict (interface view)

Function

The **arp learning strict** command enables strict ARP learning on the interface.

The **undo arp learning strict** command restores the global configuration on the interface.

By default, strict ARP learning is disabled on the interface.

Format

arp learning strict { **force-enable** | **force-disable** | **trust** }

undo arp learning strict

Parameters

Parameter	Description	Value
force-enable	Indicates that strict ARP learning is enabled.	-

Parameter	Description	Value
force-disable	Indicates that strict ARP learning is disabled.	-
trust	Indicates that the configuration of strict ARP learning is the same as the global configuration. **NOTE** The effect of the **trust** parameter is the same as the effect of the **undo arp learning strict** command.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If many user hosts send a large number of ARP packets to a device simultaneously, or attackers send bogus ARP packets to the device, the following problems occur:

- Processing ARP packets consumes many CPU resources. The device learns many invalid ARP entries, which exhaust ARP entry resources and prevent the device from learning ARP entries for ARP packets from authorized users. Consequently, communication of authorized users is interrupted.
- After receiving bogus ARP packets, the device incorrectly modifies the ARP entries. As a result, authorized users cannot communicate with each other.

To avoid the preceding problems, enable strict ARP learning on the gateway. This function indicates that the device learns only ARP entries for ARP Reply packets in response to ARP Request packets sent by itself, but does not allow the device to learn the ARP entries for the ARP packets received from other devices. In this way, the device can defend against most ARP attacks.

Prerequisites

On an Ethernet interface working in Layer 2 mode, the **undo portswitch** command has been run to switch the interface to Layer 3 mode.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support switching between Layer 2 and Layer 3 modes.

Precautions

The configuration on an interface takes precedence over the global configuration.

When ARP attacks occur on many interfaces of the device, you can run the **arp learning strict** command to enable strict ARP learning globally.

Example

Enable strict ARP learning on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] arp learning strict force-enable
```

Enable strict ARP learning on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp learning strict force-enable
```

14.6.21 arp learning strict (system view)

Function

The **arp learning strict** command enables strict ARP learning.

The **undo arp learning strict** command disables strict ARP learning.

By default, strict ARP learning is disabled.

Format

arp learning strict

undo arp learning strict

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If many user hosts send a large number of ARP packets to a device simultaneously, or attackers send bogus ARP packets to the device, the following problems occur:

- Processing ARP packets consumes many CPU resources. The device learns many invalid ARP entries, which exhaust ARP entry resources and prevent the device from learning ARP entries for ARP packets from authorized users. Consequently, communication of authorized users is interrupted.

- After receiving bogus ARP packets, the device incorrectly modifies the ARP entries. As a result, authorized users cannot communicate with each other.

To avoid the preceding problems, enable strict ARP learning on the gateway. This function indicates that the device learns only ARP entries for ARP Reply packets in response to ARP Request packets sent by itself. In this way, the device can defend against most ARP attacks.

Precautions

The configuration on an interface takes precedence over the global configuration.

Example

Enable strict ARP learning.

```
<HUAWEI> system-view
[HUAWEI] arp learning strict
```

14.6.22 arp optimized-passby enable

Function

The **arp optimized-passby enable** command configures the device not to send ARP packets destined for other devices to the CPU.

The **undo arp optimized-passby enable** command configures the device to send ARP packets destined for other devices to the CPU.

By default, a device does not send ARP packets destined for other devices to the CPU.

Format

arp optimized-passby enable

undo arp optimized-passby enable

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an interface receives a large number of ARP packets whose destination IP addresses are different from the IP address of this interface and sends these ARP packets to the CPU for processing, the CPU usage is high and the CPU cannot process services properly.

To prevent this issue, you can configure the device to directly forward ARP packets destined for other devices without sending them to the CPU. This improves the device's capability of defending against ARP flood attacks.

Precautions

If any of the following configurations is performed, the configuration of disabling the device from sending ARP packets destined for other devices to the CPU does not take effect on a VLANIF interface:

- Run the **arp anti-attack gateway-duplicate enable** to enable ARP gateway anti-collision.
- Run the **arp ip-conflict-detect enable** command to enable IP address conflict detection.
- Run the **arp anti-attack check user-bind enable** command to enable the dynamic ARP inspection (DAI) function.
- Run the **dhcp snooping arp security enable** command to enable the egress ARP inspection (EAI) function.
- Run the **arp over-vpls enable** command to enable proxy ARP on a VPLS network.
- Run the **arp-proxy enable** command to enable routed proxy ARP.
- Run the **arp-proxy inner-sub-vlan-proxy enable** command to enable intra-VLAN proxy ARP.
- Run the **arp-proxy inter-sub-vlan-proxy enable** command to enable inter-VLAN proxy ARP.
- Perform an NAC-related configuration. For details, see the *User Access and Authentication Configuration Guide*.

Example

Configure the device to send ARP packets destined for other devices to the CPU.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo arp optimized-passby enable
```

14.6.23 arp optimized-reply disable

Function

The **arp optimized-reply disable** command disables the optimized ARP reply function.

The **undo arp optimized-reply disable** command enables the optimized ARP reply function.

By default, the optimized ARP reply function is enabled.

Format

arp optimized-reply disable

undo arp optimized-reply disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a stack of multiple switches functions as an access gateway, the stack can receive a large number of ARP packets requesting for the stack's interface MAC address. If all these ARP Request packets are sent to the master switch, the CPU usage of the switch increases, and other services are affected.

To address the preceding problem, enable optimized ARP reply, which improves the switch's capability of defending against ARP flood attack. After this function is enabled, the stack performs the following operations:

- When receiving an ARP Request packet of which the destination IP address is the local interface address, the switch where the interface is located directly returns an ARP Reply packet.
- When a stack system receives an ARP Request packet of which the destination IP address is not the local interface address and intra-VLAN proxy ARP is enabled on the master switch, the switch where the interface is located checks whether the ARP Request packet meets the proxy condition. If so, the switch returns an ARP Reply packet. If not, the switch discards the packet.

NOTE

The optimized ARP reply function can be configured on a stand-alone fixed switch, but does not take effect.

By default, the optimized ARP reply function is enabled. After a device receives an ARP Request packet, the device checks whether an ARP entry corresponding to the source IP address of the ARP Request packet exists.

- If there is a corresponding ARP entry, the stack performs optimized ARP reply to this ARP Request packet.
- If there is no corresponding ARP entry, the stack does not perform optimized ARP reply to this ARP Request packet.

Precautions

- The optimized ARP reply function does not take effect for ARP Request packets with double VLAN tags.
- The optimized ARP reply function takes effect for ARP Request packets sent by wireless users.
- The optimized ARP reply function takes effect only for the ARP Request packets received by VLANIF interfaces, VBDIF interfaces, Eth-Trunk sub-interfaces, and physical sub-interfaces. The optimized ARP reply function does not take effect for the ARP Request packets sent from the VLANIF interfaces of super VLANs. The optimized ARP reply function takes effect for the ARP Request packets sent from the VLANIF interfaces of MUX VLANs, but it do not take effect when the ARP request packet carries the Group VLAN or Separate VLAN.

  NOTE

  The optimized ARP reply function takes effect only for the ARP Request packets received by the Eth-Trunk sub-interfaces and physical sub-interfaces of the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.
- The optimized ARP reply function does not take effect globally or on interfaces after you run any of the following commands:
  - **ip address** *ip-address* { *mask* | *mask-length* } **sub**: configures secondary IP addresses for interfaces.
  - **arp anti-attack gateway-duplicate enable**: enables the ARP gateway anti-collision function.
  - **arp ip-conflict-detect enable**: enables IP address conflict detection.
  - **arp anti-attack check user-bind enable**: enables dynamic ARP inspection (DAI).

    NOTE

    When DAI is enabled in the physical interface view, the optimized ARP reply function does not take effect on the device where the physical interface resides. When DAI is enabled in the Eth-Trunk view or VLAN view, the optimized ARP reply function does not take effect globally.
  - **dhcp snooping arp security enable**: enables egress ARP inspection (EAI).
  - **arp over-vpls enable**: enables ARP proxy on the device on a VPLS network.
  - **arp-proxy enable**: configures the routed ARP proxy function.
  - **arp-proxy inter-sub-vlan-proxy enable** configures inter-VLAN proxy ARP function.
- After the optimized ARP reply function is enabled, the following functions become invalid:
  - ARP rate-limiting based on source MAC addresses (configured using the **arp speed-limit source-mac** command)
  - ARP rate-limiting based on source IP addresses (configured using the **arp speed-limit source-ip** command)
  - Global ARP rate-limiting, ARP rate-limiting in VLANs, as well as ARP rate-limiting on interfaces (configured using the **arp anti-attack rate-limit enable** command)

Example

Disable the optimized ARP reply function.

```
<HUAWEI> system-view
[HUAWEI] arp optimized-reply disable
```

14.6.24 arp over-vpls enable

Function

The **arp over-vpls enable** command enables ARP proxy on a device in a VPLS network.

The **undo arp over-vpls enable** command disables ARP proxy on a device in a VPLS network.

By default, ARP proxy is disabled on a device in a VPLS network.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support this command.

Format

arp over-vpls enable

undo arp over-vpls enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent bogus ARP packets at the PW side from being broadcast to the AC side on a VPLS network, enable ARP proxy over VPLS on a PE.

ARP packets at the PW side are sent to the CPU for processing.

- If the ARP packets are ARP request packets and the destination IP addresses in the packets match DHCP snooping binding entries, the device constructs ARP reply packets based on the DHCP snooping binding entries and sends them to the requester at the PW side.

- If the ARP packets are not ARP request packets or the destination IP addresses in the packets match no DHCP snooping binding entry, the device forwards these ARP packets to the destination.

Precautions

Before using this command, ensure that DHCP snooping on the device in a VPLS network is enabled using the **dhcp snooping over-vpls enable** command.

After DAI is configured, the function of disabling the VLANIF interface from sending ARP packets destined for other devices to the CPU is ineffective on the VLANIF interface.

Example

Enable ARP proxy on a device in a VPLS network.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping over-vpls enable
[HUAWEI] arp over-vpls enable
```

14.6.25 arp snooping anti-attack check enable

Function

The **arp snooping anti-attack check enable** command enables ARP snooping detection on an interface.

The **undo arp snooping anti-attack check enable** command disables ARP snooping detection on an interface.

By default, ARP snooping detection is disabled on an interface.

Format

arp snooping anti-attack check enable

undo arp snooping anti-attack check enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group interface

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If forged ARP packets are sent in a man-in-the-middle (MITM) attack, two communicating devices learn an incorrect address mapping of each other and the data of authorized users is intercepted by the attacker. To prevent this problem, you can enable ARP snooping detection on the device. After ARP snooping detection is enabled, the device compares the source IP address, source MAC address, port number, and VLAN information in a received ARP packet with those in the ARP snooping table. If no ARP snooping entry with the same source IP address and VLAN information as the ARP packet is found, the device creates an ARP snooping entry. If an ARP snooping entry with the same source IP address and VLAN information is found and other information matches, the device determines that the user who sends the ARP packet is a valid user and allows the ARP packet to pass. If an ARP snooping entry with the same source IP address and VLAN information is found but other information does not match, the device discards the ARP packet.

Prerequisites

Before running this command, ensure that you have completed the following configurations:

1. Run the **arp snooping enable** command in the system view to enable ARP snooping globally.
2. Run the **arp snooping anti-attack entry-check enable** command in the system view to enable ARP snooping entry fixing.
3. Run the **arp snooping enable** command in the interface view to enable ARP snooping on an interface.

Example

Enable ARP snooping detection on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] arp snooping enable
[HUAWEI] arp snooping anti-attack entry-check fixed-mac enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp snooping enable
[HUAWEI-GigabitEthernet0/0/1] arp snooping anti-attack check enable
```

14.6.26 arp snooping anti-attack entry-check enable

Function

The **arp snooping anti-attack entry-check enable** command enables ARP snooping entry fixing.

The **undo arp snooping anti-attack entry-check enable** command disables ARP snooping entry fixing.

By default, ARP snooping entry fixing is disabled.

Format

arp snooping anti-attack entry-check { **fixed-mac** | **fixed-all** | **send-ack** } **enable**

undo arp snooping anti-attack entry-check [**fixed-mac** | **fixed-all** | **send-ack**] **enable**

Parameters

Parameter	Description	Value
fixed-mac	Indicates ARP snooping entry fixing in **fixed-mac** mode. When receiving an ARP packet, the device discards the packet if its MAC address does not match the MAC address in the corresponding ARP snooping entry. If the MAC address in the ARP packet matches that in the corresponding ARP snooping entry while the interface information does not match that in the ARP snooping entry, the device updates the interface information in the ARP snooping entry.	-
fixed-all	Indicates ARP snooping entry fixing in **fixed-all** mode. When the MAC address and interface information of an ARP packet match those in the corresponding ARP snooping entry, the device updates other information in the ARP snooping entry.	-

Parameter	Description	Value
send-ack	Indicates ARP snooping entry fixing in **send-ack** mode. When the device receives an ARP packet with a changed MAC address or different interface information, it does not immediately update the corresponding ARP snooping entry. Instead, the device sends a unicast ARP Request packet to the user corresponding to the original MAC address in the ARP snooping entry. If the device receives an ARP Reply packet from the user, the device does not update the ARP snooping entry. If the device does not receive an ARP Reply packet from the user, the device sends a unicast ARP Request packet to the user corresponding to the new MAC address. Regardless of whether the device receives an ARP Reply packet from this user, the device updates the ARP snooping entry based on the ARP packets sent from the user if this user continuously sends ARP Request packets to the device.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an attacker forges ARP packets, the device learns incorrect ARP snooping entries. As a result, users cannot receive data packets. To prevent this problem, you can enable the ARP snooping entry fixing function on the device. Once the device enabled with this function learns an ARP snooping entry, it does not update the ARP snooping entry, only updates some information in the ARP snooping entry, or sends a unicast ARP Request packet to check the validity of the new ARP snooping entry. The device provides three ARP snooping entry fixing modes, which are applicable to different scenarios.

- **fixed-mac**: This mode applies to networks where user MAC addresses are unchanged but user access locations often change. When a user connects to a different interface on the device, the device updates interface information in the ARP snooping entry of the user timely.
- **fixed-all**: This mode applies to networks where user MAC addresses and user access locations are fixed.
- **send-ack**: This mode applies to networks where user MAC addresses and user access locations often change.

Prerequisites

ARP snooping has been enabled by running the **arp snooping enable** command in the system view.

Precautions

- An ARP snooping entry is created based on the source IP address and VLAN information of an ARP packet. Therefore, ARP snooping entry fixing is performed only when the source IP address and VLAN information of an ARP packet are the same as those in an existing ARP snooping entry.
- The three ARP snooping entry fixing modes are mutually exclusive.
- Before disabling ARP snooping entry fixing, ensure that ARP snooping detection is disabled on all interfaces.

Example

Enable ARP snooping entry fixing and specify the **fixed-mac** mode.

```
<HUAWEI> system-view
[HUAWEI] arp snooping enable
[HUAWEI] arp snooping anti-attack entry-check fixed-mac enable
```

14.6.27 arp snooping enable

Function

The **arp snooping enable** command enables ARP snooping.

The **undo arp snooping enable** command disables ARP snooping.

By default, ARP snooping is disabled on the device.

Format

arp snooping enable

undo arp snooping enable

Parameters

None

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During video network O&M, the NMS needs to obtain the IP addresses and MAC addresses of NEs to draw a network topology for subsequent O&M. For LLDP-incapable NEs, you can configure the ARP snooping function on the access switch. This function enables the device to obtain the IP addresses and MAC addresses of NEs from the ARP packets sent from the NEs, and generate ARP snooping entries.

After ARP snooping is enabled, the device sends the received ARP packets to the CPU. The CPU analyzes the ARP packets to obtain the source IP address, source MAC address, VLAN ID, and inbound interface of the packets, and creates an ARP snooping entry to record user information.

After an ARP snooping entry is created, it ages after 900 seconds by default. An ARP snooping entry is created based on the source IP address and VLAN information of an ARP packet. If no ARP snooping entry matches the source IP address and VLAN information of a received ARP packet, the device creates a new ARP snooping entry. If the source IP address and VLAN information of a received ARP packet are the same as those in an existing ARP snooping entry, the device updates the MAC address and interface information in the entry and resets the aging timer.

Precautions

- You must enable ARP snooping in the system view, and then enable ARP snooping in a VLAN or on an interface.
- When a switch is managed by the analyzer, you need to enable ARP snooping globally and on an interface so that the analyzer can parse user access port information.

Example

Enable ARP snooping on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] arp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp snooping enable
```

Enable ARP snooping in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] arp snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] arp snooping enable
```

14.6.28 arp snooping detect default-ip

Function

The **arp snooping detect default-ip** command configures the source IP address of ARP probe packets sent by the device.

The **undo arp snooping detect default-ip** command restores the default setting.

By default, the source IP address of ARP probe packets is 0.0.0.0.

Format

arp snooping detect default-ip *ip-address*

undo arp snooping detect default-ip

Parameters

Parameter	Description	Value
ip-address	Specifies the source IP address of ARP probe packets.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After generating ARP snooping entries, the device performs ARP probe on the entries that are about to be aged out. By default, the device sends ARP probe packets with the source IP address being 0.0.0.0. After a terminal obtains an IP address when going online, it also sends an ARP probe packet with the source IP address being all 0s to check whether the obtained IP address conflicts with other IP addresses. If the terminal receives an all-0 ARP packet, the terminal considers that an IP address conflict occurs and therefore re-applies for an IP address. In this case, you need to run this command to change the source IP address of the device's ARP probe packets to prevent terminals from repeatedly applying for IP addresses.

Configuration Impact

If this command is run more than once, the latest configuration overrides the previous one.

Precautions

You are advised to set the IP address to be different from the IP address of the user gateway.

Example

Set the source IP address of ARP probe packets to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] arp snooping detect default-ip 10.1.1.1
```

14.6.29 arp snooping detect ignored-ip

Function

The **arp snooping detect ignored-ip** command configures the device not to perform ARP probe for ARP snooping entries of a specified IP address.

The **undo arp snooping detect ignored-ip** command restores the default setting.

By default, the device performs ARP probe for ARP snooping entries of all IP addresses.

Format

arp snooping detect ignored-ip *ip-address*

undo arp snooping detect ignored-ip { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address for ARP probe.	The value is in dotted decimal notation.
all	Performs ARP probe for all IP addresses.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The device performs ARP probe for the generated ARP snooping entries that are about to age. Specifically, it sends ARP probe packets with the source IP addresses being all 0s and the destination IP addresses being the IP addresses of the entries that are about to age. If the peer device is a gateway, it identifies the received ARP packets as gratuitous ARP packets sent by itself, performs IP address conflict detection, and frequently generates conflict alarms and logs. To prevent this problem, you can run the **arp snooping detect ignored-ip** command to configure the device not to perform ARP probe for ARP snooping entries of a specified IP address.

Example

Disable ARP probe for ARP snooping entries of the IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] arp snooping detect ignored-ip 10.1.1.1
```

14.6.30 arp speed-limit source-mac

Function

The **arp speed-limit source-mac** command sets the maximum rate of ARP packets based on source MAC addresses.

The **undo arp speed-limit source-mac** command restores the default setting.

By default, the maximum rate of ARP packets from each source MAC address is set to 0, that is, the rate of ARP packets is not limited based on source MAC addresses.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp speed-limit source-mac [*mac-address*] **maximum** *maximum*

undo arp speed-limit source-mac [*mac-address*]

Parameters

Parameter	Description	Value
mac-address	Specifies the source MAC address. If this parameter is specified, the rate of ARP packets from the MAC address is limited. If this parameter is not specified, the rate of ARP packets from each MAC address is limited.	The value is in the H-H-H format. H is a hexadecimal number of 1 to 4 digits.
maximum *maximum*	Specifies the maximum rate of ARP packets from a specified MAC address.	The integer form, in pps, is as follows: ● S5731-S, S5731S-S: 0 to 16384 ● S5731-H, S5731S-H: 0 to 61440 ● S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S: 0 to 65536 ● S6735-S, S6720-EI, S6720S-EI: 0 to 131072 ● S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M: 0 to 4096 ● S5735-S, S5735S-S, S5735-S-I: 0 to 8180 ● S2730S-S: 0 to 2048

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When processing a large number of ARP packets with fixed source MAC addresses but variable source IP addresses, the CPU is overloaded and ARP entries are exhausted. To prevent this problem, limit the rate of ARP packets based on source MAC addresses.

After the **arp speed-limit source-mac** command is run, the device collects statistics on ARP packets from a specified source MAC address. If the number of

ARP packets from a specified source IP address per second exceeds the threshold, the device discards the excess ARP packets.

Precautions

Limiting the rate of all ARP packets is not recommended. You are advised to find out the attack source according to packet statistics, and then limit the rate of ARP packets from the specified source MAC address.

If the source MAC address is not specified, the rate of ARP packets from each MAC address is limited. If the rate of ARP packets from each source IP address is set using the **arp speed-limit source-ip** command at the same time and the rate is the same as that set using the **arp speed-limit source-mac** command, both commands take effect. When receiving ARP packets from a fixed source, the device limits the rate of these packets based on the maximum rate set by the **arp speed-limit source-mac** command.

After the optimized ARP reply function (disabled by default) is enabled using the **undo arp optimized-reply disable** command, rate limiting on ARP packets based on the source MAC address does not take effect.

Example

Set the maximum rate of ARP packets from any source MAC address to 100 pps.

```
<HUAWEI> system-view
[HUAWEI] arp speed-limit source-mac maximum 100
```

Set the maximum rate of ARP packets from a specified MAC address 0-0-1 to 50 pps.

```
<HUAWEI> system-view
[HUAWEI] arp speed-limit source-mac 0-0-1 maximum 50
```

14.6.31 arp speed-limit source-ip

Function

The **arp speed-limit source-ip** command sets the maximum rate of ARP packets based on the source IP address.

The **undo arp speed-limit source-ip** command restores the default setting.

By default, the device allows a maximum of 30 ARP packets from the same source IP address to pass through per second.

Format

arp speed-limit source-ip [*ip-address*] **maximum** *maximum*

undo arp speed-limit source-ip [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the source IP address. If this parameter is specified, the rate of ARP packets from the IP address is limited. If this parameter is not specified, the rate of ARP packets from each IP address is limited.	The value is in dotted decimal notation.
maximum *maximum*	Specifies the maximum rate of ARP packets from a specified source IP address. **NOTE** If the rate of all ARP packets is limited, a large value is recommended because valid packets may be discarded if the value is small. However, a too large value will deteriorate the system performance. If an IP address initiates attacks, you can set the maximum number of ARP Miss messages triggered by packets from this IP address to a small value.	The integer form, in pps, is as follows: ● SS1720GW-E, S1720GWR-E, S2730S-S, S5720-LI, S5720S-LI: 0 to 2048 ● S5720I-SI, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M: 0 to 4096 ● S5735-S, S5735S-S, S5735-S-I: 0 to 8180 ● S5731-S, S5731S-S: 0 to 16384 ● S5731-H, S5731S-H: 0 to 61440 ● S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S: 0 to 65536 ● S5735S-H, S5736-S: 0 to 20000 ● S6735-S, S6720-EI, S6720S-EI: 0 to 131072

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When processing a large number of ARP packets with fixed IP addresses (for example, the ARP packets with the same source IP addresses but frequently changing MAC addresses or outbound interfaces), the CPU is overloaded and cannot process other services. To prevent this problem, limit the rate of ARP packets based on the source IP address.

After the **arp speed-limit source-ip** command is run, the device collects statistics on ARP packets based on the source IP address. If the number of ARP packets from a specified source IP address per second exceeds the threshold, the device discards the excess ARP packets.

Precautions

Limiting the rate of all ARP packets is not recommended. You are advised to find out the attack source according to packet statistics, and then limit the rate of ARP packets from the specified source IP address.

When you confirm that the network is secure, set the rate limit to 0 to increase ARP learning speed. After the rate limit is set to 0, the device does not limit the ARP packet rate based on source IP addresses.

If the source IP address is not specified, the rate of ARP packets from each IP address is limited. If the rate of ARP packets from each source MAC address is set using the **arp speed-limit source-mac** command at the same time and the rate is the same as that set using the **arp speed-limit source-ip** command, both commands take effect. When receiving ARP packets from a fixed source, the device limits the rate of these packets based on the maximum rate set by the **arp speed-limit source-mac** command.

After the optimized ARP reply function (disabled by default) is enabled using the **undo arp optimized-reply disable** command, rate limiting on ARP packets based on the source IP address does not take effect.

Example

Set the maximum rate of ARP packets from a source IP address to 100 pps.

```
<HUAWEI> system-view
[HUAWEI] arp speed-limit source-ip maximum 100
```

Set the maximum rate of ARP packets from a specified IP address 10.0.0.1 to 50 pps.

```
<HUAWEI> system-view
[HUAWEI] arp speed-limit source-ip 10.0.0.1 maximum 50
```

14.6.32 arp validate (interface view)

Function

The **arp validate** command enables MAC address consistency check in an ARP packet on an interface. This function compares the source and destination MAC addresses in ARP packets with those in the Ethernet frame header.

The **undo arp validate** command disables MAC address consistency check in an ARP packet on an interface.

By default, MAC address consistency check in an ARP packet is disabled.

Format

arp validate { **source-mac** | **destination-mac** } *

undo arp validate { **source-mac** | **destination-mac** } *

Parameters

Parameter	Description	Value
source-mac	Indicates that the device compares the source MAC address in a received ARP packet with that in the Ethernet frame header.	-
destination-mac	Indicates that the device compares the destination MAC address in a received ARP packet with that in the Ethernet frame header.	-

Views

Ethernet interface view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view, VE interface view

Default Level

2: Configuration level

Usage Guidelines

The MAC address consistency check function for ARP packets prevents attacks from bogus ARP packets in which the source and destination MAC addresses are different from those in the Ethernet frame header. This function is usually configured on gateways.

After the **arp validate** command is run, the gateway checks the MAC address consistency in an ARP packet before ARP learning. If the source and destination MAC addresses in an ARP packet are different from those in the Ethernet frame header, the device discards the packet as an attack. If the source and destination MAC addresses in an ARP packet are the same as those in the Ethernet frame header, the device performs ARP learning.

When using this command, note the following points:

- If **source-mac** is specified:
  - When receiving an ARP Request packet, the device checks only the source MAC address consistency.
  - When receiving an ARP Reply packet, the device checks only the source MAC address consistency.
- If **destination-mac** is specified:

  - When receiving an ARP Request packet, the device does not check the destination MAC address consistency because the ARP Request packet is broadcast.
  - When receiving an ARP Reply packet, the device checks the destination MAC address consistency.
- If **source-mac** and **destination-mac** are specified:
  - When receiving an ARP Request packet, the device checks only the source MAC address consistency.
  - When receiving an ARP Reply packet, the device checks the source and destination MAC address consistency.

Example

Enable MAC address consistency check in an ARP packet on Layer 2 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp validate source-mac destination-mac
```

Enable MAC address consistency check in an ARP packet on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp validate source-mac destination-mac
```

14.6.33 arp-fake expire-time

Function

The **arp-fake expire-time** command sets the aging time of temporary ARP entries.

The **undo arp-fake expire-time** command restores the default aging time of temporary ARP entries.

By default, the aging time of temporary ARP entries is 3 seconds.

Format

arp-fake expire-time *expire-time*

undo arp-fake expire-time

Parameters

Parameter	Description	Value
expire-time	Specifies the aging time of temporary ARP entries.	The value is an integer that ranges from 1 to 36000, in seconds.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view, VLANIF interface view, VBDIF interface view, VE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

When IP packets trigger ARP Miss messages, the device generates temporary ARP entries and sends ARP Request packets to the destination network.

- In the aging time of temporary ARP entries:
  - Before receiving an ARP reply packet, the device discards the IP packets matching the temporary ARP entry and does not generate ARP Miss messages.
  - After receiving an ARP Reply packet, the device generates a correct ARP entry to replace the temporary entry.
- When temporary ARP entries age out, the device clears them. If no ARP entry matches the IP packets forwarded by the device, ARP Miss messages and temporary ARP entries are repeatedly generated

When a device undergoes an ARP Miss attack, you can run the **arp-fake expire-time** command to extend the aging time of temporary ARP entries to reduce the frequency of triggering ARP Miss messages and minimize the impact on the device.

Example

Set the aging time of temporary ARP entries to 10 seconds on VLANIF10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] arp-fake expire-time 10
```

Set the aging time of temporary ARP entries to 10 seconds on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-fake expire-time 10
```

14.6.34 arp-limit

Function

The **arp-limit** command sets the maximum number of ARP entries that an interface can dynamically learn.

The **undo arp-limit** command deletes the maximum number of ARP entries that an interface can dynamically learn.

By default, the maximum number of ARP entries that an interface can dynamically learn is the same as the number of ARP entries supported by the device.

Format

VLANIF interface, VBDIF interface, VE sub-interface, Layer 3 interface, and Ethernet sub-interface:

arp-limit maximum *maximum*

undo arp-limit

VE sub-interface, Layer 2 interface and port group:

arp-limit vlan *vlan-id1* [**to** *vlan-id2*] **maximum** *maximum*

undo arp-limit vlan *vlan-id1* [**to** *vlan-id2*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support Layer 3 interfaces and sub-interfaces.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support VE sub-interfaces.

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Specifies the ID of a VLAN from which the maximum number of ARP entries an interface can dynamically learn is limited. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. *vlan-id1* and *vlan-id2* specify a range of VLANs. If **to** *vlan-id2* is not specified, the device limits the maximum number of ARP entries an interface dynamically learns from the VLAN *vlan-id1*. If **to** *vlan-id2* is specified, the device limits the maximum number of ARP entries an interface dynamically learns from each VLAN from *vlan-id1* to *vlan-id2*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094.

Parameter	Description	Value
maximum *maximum*	Specifies the maximum number of ARP entries that an interface can dynamically learn.	The integer form, is as follows: - SS1720GW-E, S1720GWR-E, S2730S-S, S5720-LI, S5720S-LI: 1 to 2048 - S5720I-SI, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M: 1 to 4096 - S5735-S, S5735S-S, S5735-S-I: 1 to 8000 - S5731-S, S5731S-S: 1 to 16384 - S5731-H, S5731S-H: 1 to 61440 - S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S: 1 to 65536 - S5735S-H, S5736-S: 1 to 20000 - S6735-S, S6720-EI, S6720S-EI: 1 to 131072

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent ARP entries from being exhausted by ARP attacks from a host connecting to an interface on the device, set the maximum number of ARP entries that the interface can dynamically learn. When the number of the ARP entries learned by a specified interface reaches the maximum number, no dynamic ARP entry can be added.

Precautions

If the number of ARP entries learned by an interface exceeds the maximum number, the device neither learns new ARP entries nor clears the learned ARP entries. Instead, the device asks users to delete the excess ARP entries.

If the **arp-limit vlan** *vlan-id1* **to** *vlan-id2* **maximum** *maximum* command is run more than once, the following situations are available:

- If **maximum** *maximum* is the same in multiple command instances, all configurations take effect. For example, if the **arp-limit vlan 10 to 30 maximum 200** command and then the **arp-limit vlan 35 to 40 maximum 200** command are run, both configurations take effect. If the VLAN ranges specified in multiple command instances are overlapping, the system automatically merges the VLAN ranges. For example, if the **arp-limit vlan 50 to 80 maximum 200** command and then the **arp-limit vlan 70 to 100 maximum 200** command are run, both configurations take effect, and the system merges the configurations into **arp-limit vlan 50 to 100 maximum 200**.
- If **maximum** *maximum* is different in multiple command instances, the latest configuration overrides the previous one for the same VLAN range. For example, if the **arp-limit vlan 10 to 30 maximum 200** command and then the **arp-limit vlan 15 to 25 maximum 300** command are run, the system automatically divides the configurations into **arp-limit vlan 10 to 14 maximum 200**, **arp-limit vlan 15 to 25 maximum 300**, and **arp-limit vlan 26 to 30 maximum 200**.

Example

Configure that VLANIF 10 can dynamically learn a maximum of 20 ARP entries.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] arp-limit maximum 20
```

Configure that Layer 3 interface GE0/0/1 can dynamically learn a maximum of 20 ARP entries.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-limit maximum 20
```

Configure that Layer 2 interface GE0/0/1 can dynamically learn a maximum of 20 ARP entries corresponding to VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp-limit vlan 10 maximum 20
```

14.6.35 arp-miss anti-attack rate-limit

Function

The **arp-miss anti-attack rate-limit** command sets the maximum rate and rate limiting duration of ARP Miss messages globally, in a VLAN, or on an interface.

The **undo arp-miss anti-attack rate-limit** command restores the default maximum rate and rate limiting duration of ARP Miss messages globally, in a VLAN, or on an interface.

By default, the device can process a maximum of 100 ARP Miss messages per second.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp-miss anti-attack rate-limit packet *packet-number* [**interval** *interval-value*]

undo arp-miss anti-attack rate-limit

Parameters

Parameter	Description	Value
packet *packet-number*	Specifies the maximum rate of ARP Miss messages, that is, the number of ARP Miss messages the device processes in the rate limiting duration.	The value is an integer that ranges from 1 to 16384. The default value is 100.
interval *interval-value*	Specifies the rate limiting duration of ARP Miss messages.	The value is an integer that ranges from 1 to 86400, in seconds. The default value is 1 second.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After rate limit on ARP Miss messages is enabled, you can set maximum rate and rate limiting duration of ARP Miss messages globally, in a VLAN, or on an interface. If the number of ARP Miss messages triggered by IP packets in the rate limiting duration exceeds the limit, the device does not process the excess ARP Miss packets and discards the IP packets triggering the excess ARP Miss messages.

Prerequisites

Rate limit on ARP Miss messages has been enabled globally, in a VLAN, or on an interface using the **arp-miss anti-attack rate-limit enable** command.

Precautions

If rate limit on ARP Miss messages is configured in the system view, VLAN view, and interface view, the device uses the configurations in the interface view, VLAN view, and system view in order.

Example

Configure the device to process a maximum of 200 ARP Miss messages triggered by IP packets from Layer 2 interface GE0/0/1 in 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit packet 200 interval 10
```

Configure the device to process a maximum of 200 ARP Miss messages triggered by IP packets from Layer 3 interface GE0/0/1 in 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit packet 200 interval 10
```

14.6.36 arp-miss anti-attack rate-limit alarm enable

Function

The **arp-miss anti-attack rate-limit alarm enable** command enables the alarm function for ARP Miss messages discarded when the rate of ARP Miss messages exceeds the limit.

The **undo arp-miss anti-attack rate-limit alarm enable** command disables the alarm function for ARP Miss messages discarded when the rate of ARP Miss messages exceeds the limit.

By default, the alarm function is disabled.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp-miss anti-attack rate-limit alarm enable

undo arp-miss anti-attack rate-limit alarm enable

Parameters

None

Views

System view, VLAN view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

2: Configuration level

Usage Guidelines

Usage Scenario

After rate limit on ARP Miss messages is enabled, if you want that the device can generate alarms to notify the network administrator of a large number of discarded excess ARP Miss messages, run the **arp-miss anti-attack rate-limit alarm enable** command. When the number of discarded ARP Miss packets exceeds the alarm threshold, the device generates an alarm.

You can set the alarm threshold using the **arp-miss anti-attack rate-limit alarm threshold** command.

Prerequisites

Rate limit on ARP Miss messages has been enabled using the **arp-miss anti-attack rate-limit enable** command.

Example

Enable the alarm function for ARP Miss messages discarded when the rate of ARP Miss messages exceeds the limit on Layer 2 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm enable
```

Enable the alarm function for ARP Miss messages discarded when the rate of ARP Miss messages exceeds the limit on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm enable
```

14.6.37 arp-miss anti-attack rate-limit alarm threshold

Function

The **arp-miss anti-attack rate-limit alarm threshold** command sets the alarm threshold for ARP Miss messages discarded when the rate of ARP Miss packets exceeds the limit.

The **undo arp-miss anti-attack rate-limit alarm threshold** command restores the default alarm threshold.

By default, the alarm threshold for ARP Miss packets discarded is 100.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp-miss anti-attack rate-limit alarm threshold *threshold*

undo arp-miss anti-attack rate-limit alarm threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold for ARP Miss messages discarded when the rate of ARP Miss messages exceeds the limit.	The value is an integer that ranges from 1 to 16384, in pps.

Views

System view, VLAN view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **arp-miss anti-attack rate-limit alarm threshold** command to set the alarm threshold. When the number of discarded ARP Miss packets exceeds the alarm threshold, the device generates an alarm.

Prerequisites

Rate limit on ARP Miss messages has been enabled using the **arp-miss anti-attack rate-limit enable** command, and the alarm function has been enabled using the **arp-miss anti-attack rate-limit alarm enable** command.

Example

Enable rate limit on ARP Miss messages globally, enable the alarm function, and set the alarm threshold to 200.

```
<HUAWEI> system-view
[HUAWEI] arp-miss anti-attack rate-limit enable
```

```
[HUAWEI] arp-miss anti-attack rate-limit alarm enable
[HUAWEI] arp-miss anti-attack rate-limit alarm threshold 200
```

Enable rate limit on ARP Miss messages on Layer 2 interface GE0/0/1, enable the alarm function, and set the alarm threshold to 200.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm threshold 200
```

Enable rate limit on ARP Miss messages on Layer 3 interface GE0/0/1, enable the alarm function, and set the alarm threshold to 200.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm enable
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit alarm threshold 200
```

14.6.38 arp-miss anti-attack rate-limit enable

Function

The **arp-miss anti-attack rate-limit enable** command enables rate limit on ARP Miss messages globally, in a VLAN, or on an interface.

The **undo arp-miss anti-attack rate-limit enable** command disables rate limit on ARP Miss messages globally, in a VLAN, or on an interface.

By default, rate limit on ARP Miss messages is disabled globally, in a VLAN, or on an interface.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp-miss anti-attack rate-limit enable

undo arp-miss anti-attack rate-limit enable

Parameters

None

Views

System view, VLAN view, GE interface view, 40GE interface view, XGE interface view, 25GE interface view, 100GE interface view, MultiGE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a host sends a large number of IP packets with unresolvable destination IP addresses to attack a device, that is, if the device has a route to the destination IP address of a packet but has no ARP entry matching the next hop of the route, the device triggers a large number of ARP Miss messages. IP packets triggering ARP Miss messages are sent to the CPU for processing. The device generates a large number of temporary ARP entries and sends many ARP Request packets to the network, consuming a large number of CPU and bandwidth resources.

To avoid the preceding problems, configure rate limit on ARP Miss messages globally, in a VLAN, or on an interface. The device collects statistics on ARP Miss messages. If the number of ARP Miss messages generated within the rate limiting duration exceeds the threshold (the maximum number of ARP Miss messages), the gateway discards the IP packets triggering the excess ARP Miss messages.

Follow-up Procedure

Run the **arp-miss anti-attack rate-limit** command to set the maximum rate and rate limiting duration of ARP Miss messages.

Example

Enable rate limit on ARP Miss messages on Layer 2 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
```

Enable rate limit on ARP Miss messages on Layer 3 interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] arp-miss anti-attack rate-limit enable
```

14.6.39 arp-miss speed-limit source-ip

Function

The **arp-miss speed-limit source-ip** command sets the maximum number of ARP Miss messages based on source IP addresses and specifies the mode for processing ARP Miss packets.

The **undo arp-miss speed-limit source-ip** command restores the default setting.

By default, the device processes a maximum of 30 ARP Miss messages triggered by IP packets from the same source IP address per second.

If the number of ARP Miss messages triggered by IP packets from the same source IP address per second exceeds the limit, the device discards the excess ARP Miss messages, that is, the device discards the excess ARP Miss packets. The device then uses the **block** mode to discard all ARP Miss packets from the source IP address within 5 seconds by default.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

arp-miss speed-limit source-ip *ip-address* [**mask** *mask*] **maximum** *maximum* [**none-block** | **block timer** *timer*]

arp-miss speed-limit source-ip maximum *maximum*

undo arp-miss speed-limit source-ip [*ip-address* [**mask** *mask*]]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support [**none-block** | **block timer** *timer*].

Parameters

Parameter	Description	Value
ip-address	Specifies the source IP address. If this parameter is specified, the maximum number of ARP Miss messages triggered by packets from this IP address is limited. If this parameter is not specified, the maximum number of ARP Miss messages triggered by packets from each IP address is limited.	The value is in dotted decimal notation.
mask *mask*	Specifies the mask of the IP address. If this parameter is specified, the maximum number of ARP Miss messages triggered by packets from IP addresses in the network segment is limited.	The value is an integer that ranges from 1 to 32.

Parameter	Description	Value
maximum *maximum*	Specifies the maximum number of ARP Miss messages based on the source IP address. **NOTE** If the maximum number of ARP Miss messages triggered by packets from each IP address is limited, a large value is recommended for this parameter because a small value may cause discarding of valid packets. However, a too large value will deteriorate the system performance. If an IP address initiates attacks, you can set the maximum number of ARP Miss messages triggered by packets from this IP address to a small value.	The integer form, in pps, is as follows: ● SS1720GW-E, S1720GWR-E, S2730S-S, S5720-LI, S5720S-LI: 0 to 2048 ● S5720I-SI, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M: 0 to 4096 ● S5735-S, S5735S-S, S5735-S-I: 0 to 8000 ● S5731-S, S5731S-S: 0 to 16384 ● S5731-H, S5731S-H: 0 to 61440 ● S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S: 0 to 65536 ● S5735S-H, S5736-S: 0 to 20000 ● S6735-S, S6720-EI, S6720S-EI: 0 to 131072 **NOTE** If the maximum rate of ARP Miss messages is set to 0, ARP Miss messages are not rate-limited based on source IP addresses.
none-block	Indicates that ARP Miss packets are processed in **none-block** mode. If the number of ARP Miss messages triggered by IP packets from a source IP address per second exceeds the limit, the CPU of the device discards the excess ARP Miss messages, that is, the CPU discards the excess ARP Miss packets.	-

Parameter	Description	Value
block timer *timer*	Indicates that ARP Miss packets are processed in **block** mode. If the number of ARP Miss messages triggered by IP packets from a source IP address per second exceeds the limit, the device discards the excess ARP Miss messages and delivers an ACL to enable the chip to discard all packets that are sent from this source IP address within the period specified by *timer*. When the period specified by *timer* expires, the ACL ages out and the chip does not discard ARP Miss packets from the source IP address and sends them to the CPU for processing.	The value ranges from 5 to 864000, in seconds. The default value is 5 seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of ARP Miss messages triggered by IP packets from a source IP address per second exceeds the limit, the device considers that an attack is initiated from the source IP address. If the ARP Miss message processing mode is set to **block**, the device discards excess ARP Miss packets from this source IP address and delivers an ACL to discard all subsequent packets sent from this source IP address. If the ARP Miss message processing mode is set to **none-block**, the device only discards excess ARP Miss packets.

The administrator can use the **arp-miss speed-limit source-ip** command to set the maximum number of ARP Miss packets and specify the mode for processing ARP Miss packets based on the actual network environment.

If the number of ARP Miss messages triggered by IP packets from a source IP address per second exceeds the limit, the device considers that an attack is initiated from the source IP address. The administrator can use the **arp-miss speed-limit source-ip** command to set the maximum number of ARP Miss messages that the device can process within a specified duration, protecting the system resources and ensuring proper running of other services.

Precautions

You can set the maximum number of ARP Miss messages for a maximum of 512 IP addresses.

If the ARP Miss packet processing mode is set to **none-block**, the device discards ARP Miss packets triggering excess ARP Miss messages to reduce CPU load. The non-block action can cause a high CPU usage, and the block action uses ACL resources. The default ARP Miss packet processing mode is recommended.

In the process of setting the maximum number of ARP Miss messages based on source IP addresses, if the ARP Miss packet processing mode is not specified, the device use the default processing mode **block**.

When the maximum number of ARP Miss packets exceeds the limit, the delivered ACL discards only the ARP Miss packets from the source IP address. Other packets can still be sent to the CPU.

A maximum of 16 ACLs can be delivered to the chip to discard ARP Miss packets from a specified IP address or network segment. When the device delivers 16 ACLs and all ACLs do not age out, and the number of ARP Miss packets from other IP addresses or network segments per second exceeds the limit, the device does not deliver any ACL to discard all subsequent packets and the CPU discards excess ARP packets.

NOTE

The S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S cannot deliver ACLs to discard ARP Miss packets.

Example

Set the maximum number of ARP Miss messages triggered by each source IP address per second to 60.

```
<HUAWEI> system-view
[HUAWEI] arp-miss speed-limit source-ip maximum 60
```

Set the maximum number of ARP Miss messages triggered by the IP address 10.0.0.1 per second to 100, and set the maximum number of ARP Miss messages triggered by other source IP addresses per second to 60.

```
<HUAWEI> system-view
[HUAWEI] arp-miss speed-limit source-ip maximum 60
[HUAWEI] arp-miss speed-limit source-ip 10.0.0.1 maximum 100
```

14.6.40 display arp anti-attack arpmiss-record-info

Function

The **display arp anti-attack arpmiss-record-info** command displays information recorded by the device when rate limit on ARP Miss messages is triggered.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display arp anti-attack arpmiss-record-info [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Displays the IP address of discarded ARP Miss packets.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After rate limit on ARP Miss messages is triggered, the device discards excess ARP Miss messages. You can run this command to view information recorded by the device when rate limit on ARP Miss messages is triggered. The information helps locate and rectify faults.

The device can record a maximum of 256 records about rate limit on ARP Miss messages. If a new round of rate limit on ARP Miss messages is triggered when the number of records reaches 256, the device takes the following actions:

1. If the source IP address of the attacker already exists in a record, the device updates the block time in the record using the discarding time of the new ARP Miss message.
2. If the source IP address of the attacker does not exist in any record, the device deletes the first record and adds a new record for this attacker.

Example

Display information recorded by the device when rate limit on ARP Miss messages is triggered.

```
<HUAWEI> display arp anti-attack arpmiss-record-info
Interface    IP address      Attack time          Block time          Aging-time
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
The number of record(s) in arp-miss table is 0
```

Table 14-44 Description of the display arp anti-attack arpmiss-record-info command output

Item	Description
Interface	Interface where ARP Miss packets are discarded.
IP address	Source IP address of discarded ARP Miss packets.
Attack time	First time when rate limit on ARP Miss messages is triggered, that is, time when the number of ARP Miss messages exceeds the limit.
Block time	Last time when the device discards the ARP Miss messages of the attacker.
Aging-time	Period during which the device discards ARP Miss packets. If the ARP Miss packet processing mode is set to **none-block**, the values of **Block time** and **Aging-time** are both 0. If the ARP Miss packet processing mode is set to **block**, the value of **Aging-time** is configured by the **arp-miss speed-limit source-ip** command, and the default value is 5 seconds.

14.6.41 display arp anti-attack configuration check user-bind

Function

The **display arp anti-attack configuration check user-bind** command displays the configuration of DAI in a VLAN or on an interface.

Format

display arp anti-attack configuration check user-bind [**vlan** [*vlan-id*] | **interface** [*interface-type interface-number*]]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays DAI configuration in the specified VLAN. If *vlan-id* is not specified, the DAI configurations in all VLANs are displayed.	*vlan-id* is an integer that ranges from 1 to 4094.

Parameter	Description	Value
interface [*interface-type interface-number*]	Displays DAI on the specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If *interface-type interface-number* is not specified, the DAI configurations on all interfaces are displayed. If neither **vlan** [*vlan-id*] nor **interface** [*interface-type interface-number*] is specified, the DAI configurations in all VLANs and on all interfaces are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the configuration of DAI in a VLAN or on an interface, including whether the function is enabled, check items, whether the alarm function is enabled for discarded ARP packets, and alarm threshold.

Only after DAI and the alarm function are enabled, output of this command is displayed.

Example

Display DAI configuration on GE0/0/1.

```
<HUAWEI> display arp anti-attack configuration check user-bind interface gigabitethernet 0/0/1
 arp anti-attack check user-bind enable
 arp anti-attack check user-bind alarm enable
 arp anti-attack check user-bind alarm threshold 50
 arp anti-attack check user-bind check-item ip-address
```

Display ARP check configurations in all VLANs and on all interfaces.

```
<HUAWEI> display arp anti-attack configuration check user-bind
#
```

```
vlan 2
 arp anti-attack check user-bind enable
 arp anti-attack check user-bind check-item ip-address
#
vlan 3
 arp anti-attack check user-bind enable
#
GigabitEthernet0/0/1
 arp anti-attack check user-bind enable
 arp anti-attack check user-bind alarm enable
 arp anti-attack check user-bind alarm threshold 50
 arp anti-attack check user-bind check-item ip-address
#
```

Table 14-45 Description of the display arp anti-attack configuration check user-bind command output

Item	Description
arp anti-attack check user-bind enable	DAI has been enabled. You can run the **arp anti-attack check user-bind enable** command to enable DAI.
arp anti-attack check user-bind alarm enable	The alarm function for ARP packets discarded by DAI has been enabled. You can run the **arp anti-attack check user-bind alarm enable** command to enable the alarm function.
arp anti-attack check user-bind alarm threshold 50	Alarm threshold of discarded ARP packets matching no binding entry. You can run the **arp anti-attack check user-bind alarm threshold** command to set the alarm threshold.
arp anti-attack check user-bind check-item ip-address	Only the IP address is checked during ARP packet check based on binding entries. You can run the **arp anti-attack check user-bind check-item** command or **arp anti-attack check user-bind check-item** command to specify the check item for ARP packet check based on binding entries.

14.6.42 display arp anti-attack configuration

Function

The **display arp anti-attack configuration** command displays the ARP anti-attack configuration.

Format

display arp anti-attack configuration { **arp-rate-limit** | **arp-speed-limit** | **entry-check** | **arpmiss-rate-limit** | **arpmiss-speed-limit** | **gateway-duplicate** | **log-trap-timer** | **packet-check** | **all** } (Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-

L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **arpmiss-rate-limit**, **arpmiss-speed-limit** and **gateway-duplicate**.)

Parameters

Parameter	Description	Value
arp-rate-limit	Displays the configuration of rate limit on ARP packets globally, in a VLAN, or on an interface.	-
arp-speed-limit	Displays the configuration of rate limit on ARP packets based on the source IP address or source MAC address.	-
entry-check	Displays the ARP entry fixing mode.	-
arpmiss-rate-limit	Displays the configuration of rate limit on ARP Miss messages globally, in a VLAN, or on an interface.	-
arpmiss-speed-limit	Displays the configuration of rate limit on ARP Miss messages based on the source IP address.	-
gateway-duplicate	Displays whether gateway anti-collision is enabled.	-
log-trap-timer	Displays the interval for sending ARP alarms.	-
packet-check	Displays whether ARP packet validity check is enabled.	-
all	Displays all ARP anti-attack configurations.	-

Usage Guidelines

After all ARP anti-attack functions are configured, you can run this command to check all configurations.

Example

Display the configuration of rate limit on ARP packets based on the source IP address or source MAC address.

```
<HUAWEI> display arp anti-attack configuration arp-speed-limit
ARP speed-limit for source-MAC configuration:
MAC-address         suppress-rate(pps)(rate=0 means function disabled)
-------------------------------------------------------------------------------
All                 0
-------------------------------------------------------------------------------
The number of configured specified MAC address(es) is 0, spec is
512.
ARP speed-limit for source-IP configuration:
IP-address          suppress-rate(pps)(rate=0 means function disabled)
-------------------------------------------------------------------------------
10.1.1.1            100
Others              0
-------------------------------------------------------------------------------
The number of configured specified IP address(es) is 1, spec is 512.
```

Display the configuration of rate limit on ARP Miss messages based on the source IP address.

```
<HUAWEI> display arp anti-attack configuration arpmiss-speed-limit
 ARP miss speed-limit for source-IP configuration:
 IP-address          suppress-rate(pps)(rate=0 means function disabled)
 -------------------------------------------------------------------------
 10.0.0.30/32        400
 Others              0
 -------------------------------------------------------------------------
 The number of configured specified IP address(es) is 1, spec is 512.
```

Display the ARP entry fixing mode.

```
<HUAWEI> display arp anti-attack configuration entry-check
 ARP anti-attack entry-check mode:
 Vlanif      Mode
-------------------------------------------------------------------------------
 All         send-ack
-------------------------------------------------------------------------------
```

Display all ARP anti-attack configurations.

```
<HUAWEI> display arp anti-attack configuration all
ARP anti-attack packet-check configuration:
-------------------------------------------------------------------------------
Sender-MAC checking function: disable
Dst-MAC checking function: disable
IP checking function: disable
-------------------------------------------------------------------------------

ARP gateway-duplicate anti-attack function: disabled

ARP anti-attack log-trap-timer: 0 second(s)
(The log and trap timer of speed-limit, default is 0 and means disabled.)

ARP anti-attack entry-check mode:
Vlanif      Mode
-------------------------------------------------------------------------------
```

```
All         disabled
-------------------------------------------------------------------------------

ARP rate-limit configuration:
-------------------------------------------------------------------------------
Global configuration:
Interface configuration:
  GigabitEthernet0/0/10 :
    arp anti-attack rate-limit enable
    arp anti-attack rate-limit packet 10 interval 1
VLAN configuration:
-------------------------------------------------------------------------------

ARP miss rate-limit configuration:
-------------------------------------------------------------------------------
Global configuration:
Interface configuration:
VLAN configuration:
-------------------------------------------------------------------------------

ARP speed-limit for source-MAC configuration:
MAC-address         suppress-rate(pps)(rate=0 means function disabled)
-------------------------------------------------------------------------------
All                 0
-------------------------------------------------------------------------------
The number of configured specified MAC address(es) is 0, spec is 512.

ARP speed-limit for source-IP configuration:
IP-address          suppress-rate(pps)(rate=0 means function disabled)
-------------------------------------------------------------------------------
All                 0
-------------------------------------------------------------------------------
The number of configured specified IP address(es) is 0, spec is 512.

ARP miss speed-limit for source-IP configuration:
IP-address          suppress-rate(pps)(rate=0 means function disabled)
-------------------------------------------------------------------------------
All                 500
-------------------------------------------------------------------------------
The number of configured specified IP address(es) is 0, spec is 512.
```

Table 14-46 Description of the display arp anti-attack configuration all command output

Item	Description
ARP anti-attack packet-check configuration	Whether ARP packet validity check is enabled. ● **Sender-mac checking function** indicates that the source MAC address is checked. ● **Dst-mac checking function** indicates that the destination MAC address is checked. ● **Ip checking function** indicates that the IP address is checked. You can run the **arp anti-attack packet-check** command to enable ARP packet validity check.
ARP gateway-duplicate anti-attack function	Whether ARP gateway anti-collision is enabled. You can run the **arp anti-attack gateway-duplicate enable** command to enable ARP gateway anti-collision.

Item	Description
ARP anti-attack log-trap-timer	Interval for sending ARP alarms You can run the **arp anti-attack log-trap-timer** command to set the interval for sending ARP alarms.
ARP anti-attack entry-check mode	ARP entry fixing mode. **Vlanif** specifies the interface to which the ARP entry fixing mode is applied. The modes include: - fixed-mac - fixed-all - send-ack - disabled You can run the **arp anti-attack entry-check enable** command to set the ARP entry fixing mode.
ARP rate-limit configuration	Configuration of rate limit on ARP packets. - **Global configuration** indicates the global configuration of rate limit on ARP packets. - **Interface configuration** indicates the configuration of rate limit on ARP packets on an interface. - **Vlan configuration** indicates the configuration of rate limit on ARP packets in a VLAN. You can run the **arp anti-attack rate-limit** command to configure rate limit on ARP packets.
ARP miss rate-limit configuration	Configuration of rate limit on ARP Miss messages. - **Global configuration** indicates the global configuration of rate limit on ARP Miss messages. - **Interface configuration** indicates the configuration of rate limit on ARP Miss messages on an interface. - **Vlan configuration** indicates the configuration of rate limit on ARP Miss messages in a VLAN. You can run the **anti-attack rate-limit** command to configure rate limit on ARP Miss messages.
ARP speed-limit for source-MAC configuration	Rate limit on ARP packets based on the source MAC address. You can run the **arp speed-limit source-mac** command to configure rate limit on ARP packets based on the source MAC address.
ARP speed-limit for source-IP configuration	Rate limit on ARP packets based on the source IP address. You can run the **arp speed-limit source-ip** command to configure rate limit on ARP packets based on the source IP address.

Item	Description
ARP miss speed-limit for source-IP configuration	Rate limit on ARP Miss messages based on source IP addresses. You can run the **arp-miss speed-limit source-ip** command to configure rate limit on ARP Miss messages based on the source IP address.
The number of configured specified MAC address(es) is 0, spec is 512.	Number (0) of the configured source MAC addresses based on which the rate of ARP packets or ARP Miss messages is limited, and the maximum value (512) allowed.
The number of configured specified IP address(es) is 1, spec is 512.	Number (1) of the configured source IP addresses based on which the rate of ARP packets or ARP Miss messages is limited, and the maximum value (512) allowed.
MAC-address	Rate limit on ARP packets based on a specified MAC address. ● **ALL** indicates all MAC addresses. ● **Others** indicates other MAC addresses except for the specified MAC address.
IP-address	Rate limit on ARP packets and ARP Miss messages based on a specified IP address. ● **ALL** indicates all IP addresses. ● **Others** indicates other IP addresses except for the specified IP address.
suppress-rate	Rate limit on ARP packets and ARP Miss messages. Value 0 indicates that the rate limit function is disabled for ARP packets and ARP Miss messages. You can run the **arp anti-attack rate-limit packet** *packet-number* command to configure the rate limit of ARP packets, and run the **arp-miss anti-attack rate-limit packet** *packet-number* command to configure the rate limit of ARP Miss messages.

14.6.43 display arp anti-attack gateway-duplicate item

Function

The **display arp anti-attack gateway-duplicate item** command displays ARP gateway anti-collision entries.

Format

display arp anti-attack gateway-duplicate item

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After ARP gateway anti-collision is enabled, you can run this command to view ARP anti-collision entries.

Example

Display ARP gateway anti-collision entries.

```
<HUAWEI> display arp anti-attack gateway-duplicate item
 Interface              IP address       MAC address      VLANID   Aging time
-------------------------------------------------------------------------------
 GigabitEthernet0/0/1    10.1.1.1         00e0-fc12-3456  2        150
 GigabitEthernet0/0/2    10.1.1.2         00e0-fc12-3478  2        170
-------------------------------------------------------------------------------
The number of record(s) in gateway conflict table is 2
```

Table 14-47 Description of the display arp anti-attack gateway-duplicate item command output

Item	Description
Interface	Inbound interface of ARP packets.
IP address	IP address of the gateway.
MAC address	Source MAC address of ARP packets.
VLANID	VLAN ID of ARP packets.
Aging time	Aging time of entries. The maximum value is 180 seconds. This parameter cannot be configured.

14.6.44 display arp anti-attack packet-check statistics

Function

The **display arp anti-attack packet-check statistics** command displays the statistics on invalid ARP packets that are filtered out during ARP packet validity check.

Format

display arp anti-attack packet-check statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After ARP packet validity check is enabled, if you want to view the statistics on invalid ARP packets that are filtered out, you can run this command.

Example

Display the statistics on invalid ARP packets that are filtered out in ARP packet validity check is displayed.

```
<HUAWEI> display arp anti-attack packet-check statistics
Number of ARP packet(s) checked:                        5
Number of ARP packet(s) dropped by sender-mac checking: 0
Number of ARP packet(s) dropped by dst-mac checking:    0
Number of ARP packet(s) dropped by src-ip checking:     2
Number of ARP packet(s) dropped by dst-ip checking:     0
```

Table 14-48 Description of the display arp anti-attack packet-check statistics command output

Item	Description
Number of ARP packet(s) checked	Number of ARP packets whose validity is checked.
Number of ARP packet(s) dropped by sender-mac checking	Number of invalid ARP packets that are filtered out because the source MAC address in the packet is different from that in the Ethernet frame header.
Number of ARP packet(s) dropped by dst-mac checking	Number of invalid ARP packets that are filtered out because the destination MAC address in the packet is different from that in the Ethernet frame header.
Number of ARP packet(s) dropped by src-ip checking	Number of invalid ARP packets with invalid source IP addresses that are filtered out.

Item	Description
Number of ARP packet(s) dropped by dst-ip checking	Number of invalid ARP packets with invalid destination IP addresses that are filtered out.

14.6.45 display arp anti-attack statistics check user-bind interface

Function

The **display arp anti-attack statistics check user-bind interface** command displays the statistics on discarded ARP packets matching no binding entry.

Format

display arp anti-attack statistics check user-bind interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. Where, ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After dynamic ARP inspection (DAI) is enabled in the interface view, you can run this command to check statistics about discarded ARP packets matching no binding entry on the interface. If the alarm function for ARP packets discarded by

DAI is enabled, you can also check statistics about discarded ARP packets matching no binding entry on the interface after the latest alarm is generated.

Precautions

- If DAI is enabled only in the VLAN view, this command cannot be run to display statistics about discarded ARP packets matching no binding entry on the interfaces in the VLAN.
- This command cannot check statistics about discarded ARP packets matching no binding entry on the management interface.

Example

Display the statistics on discarded ARP packets matching no binding entry on GE0/0/1.

```
<HUAWEI> display arp anti-attack statistics check user-bind interface gigabitethernet 0/0/1
 Dropped ARP packet number is 966
 Dropped ARP packet number since the latest warning is 605
```

Table 14-49 Description of the display arp anti-attack statistics check user-bind interface command output

Item	Description
Dropped ARP packet number is 966	Number of discarded ARP packets matching no DHCP snooping binding entry.
Dropped ARP packet number since latest warning is 605	Statistics on discarded ARP packets matching no DHCP snooping binding entry after the latest alarm is generated.

14.6.46 display arp learning strict

Function

The **display arp learning strict** command displays strict ARP learning globally and on all interfaces.

Format

display arp learning strict

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After strict ARP learning is configured, you can run this command to check the configuration.

Example

Display strict ARP learning globally and on all interfaces.

```
<HUAWEI> display arp learning strict
The global configuration:arp learning strict
 Interface                          LearningStrictState
------------------------------------------------------------
 Vlanif100                          force-disable
 Vlanif200                          force-enable
------------------------------------------------------------
 Total:2
 Force-enable:1
 Force-disable:1
```

Table 14-50 Description of the display arp learning strict command output

Item	Description
The global configuration	Global strict ARP learning. The value **arp learning strict** indicates that strict ARP learning has been enabled. If the parameter is left blank, strict ARP learning is disabled. You can run the **arp learning strict** command to enable strict ARP learning.
Interface	Interface name.
LearningStrictState	Strict ARP learning. ● The value **force-enable** indicates that strict ARP learning is enabled. ● The value **force-disable** indicates that strict ARP learning is disabled. You can run the **arp learning strict** command to enable strict ARP learning.
Total	Total number of interfaces to which strict ARP learning is applied.
Force-enable	Number of the interfaces on which strict ARP learning is enabled.
Force-disable	Number of the interfaces on which strict ARP learning is disabled.

14.6.47 display arp optimized-passby status

Function

The **display arp optimized-passby status** command displays whether the device is configured not to send ARP packets destined for other devices to the CPU and whether the configuration takes effect.

Format

display arp optimized-passby status interface vlanif *vlanif-id* **slot** *slot-id*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interface vlanif *vlanif-id*	Displays whether the device is configured not to send ARP packets destined for other devices to the CPU and whether the configuration takes effect on a specified VLANIF interface.	The value is an integer and the value range depends on the range of existing VLANIF interfaces. You can enter ? to obtain the range of VLANIF interface numbers.
slot *slot-id*	Displays whether the device is configured not to send ARP packets destined for other devices to the CPU and whether the configuration takes effect in a specified slot.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an interface receives a large number of ARP packets whose destination IP addresses are different from the IP address of this interface and sends these ARP packets to the CPU for processing, the CPU usage is high and the CPU cannot process services properly.

To prevent this issue, you can configure the device to directly forward ARP packets destined for other devices without sending them to the CPU. This improves the device's capability of defending against ARP flood attacks.

When the device is configured not to send ARP packets destined for other devices to the CPU, the configuration does not take effect if a conflict configuration exists on the device. You can use the **display arp optimized-passby status** command to check whether the device is configured not to send ARP packets destined for other devices to the CPU and whether the configuration takes effect. For details about conflict configurations, see **arp optimized-passby enable**.

Example

Display whether the device is configured not to send ARP packets destined for other devices to the CPU and whether the configuration takes effect on VLANIF 100.

```
<HUAWEI> display arp optimized-passby status interface Vlanif 100 slot 0
Current configuration:Enable
Actual        status:Inactive
Related configuration:
   NAC configuration (for example, dot1x enable)
```

Table 14-51 Description of the **display arp optimized-passby status** command output

Item	Description
Current configuration	Whether the device is configured not to send ARP packets destined for other devices to the CPU. ● Enable: The device is configured not to send ARP packets destined for other devices to the CPU. ● Disable: The device is configured to send ARP packets destined for other devices to the CPU.
Actual status	Whether the configuration of disabling the device from sending ARP packets destined for other devices to the CPU takes effect. ● Inactive ● Active
Related configuration	Conflict configuration. For details, see **arp optimized-passby enable**.

14.6.48 display arp optimized-reply statistics

Function

The **display arp optimized-reply statistics** command displays statistics on optimized ARP Reply packets.

Format

display arp optimized-reply statistics [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	- This parameter specifies the slot ID if stacking is not configured. - This parameter specifies the stack ID if stacking is enabled.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check statistics on optimized ARP Reply packets after the optimized ARP reply function is enabled on the device.

Example

Display statistics on optimized ARP Reply packets.

```
<HUAWEI> display arp optimized-reply statistics
Slot           Received          Processed            Dropped
---------------------------------------------------------------
0                    11                 9                 7
```

Table 14-52 Description of the display arp optimized-reply statistics command output

Item	Description
Slot	Stack ID.
Received	Number of ARP Request packets entering the processing procedure of the optimized ARP reply function.
Processed	Number of optimized ARP Reply packets.
Dropped	Number of ARP Request packets discarded.

14.6.49 display arp optimized-reply status

Function

The **display arp optimized-reply status** command displays the status of the optimized ARP reply function.

Format

display arp optimized-reply status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the status of the optimized ARP reply function.

Example

Check the status of the optimized ARP reply function.

```
<HUAWEI> display arp optimized-reply status
Current configuration:Disable
Actual         status:Inactive
Related configuration:
   arp optimized-reply disable
   arp anti-attack check user-bind enable
   arp anti-attack gateway-duplicate enable
```

Table 14-53 Description of the display arp optimized-reply status command output

Item	Description
Current configuration	Configuration of the optimized ARP reply function. - Enable - Disable To set this field, run the **arp optimized-reply disable** command.

Item	Description
Actual status	Status of the optimized ARP reply function. - Active - Inactive
Related configuration	Configuration that results in the invalid optimized ARP reply function. If the optimized ARP reply function has taken effect, this field is not displayed.

14.6.50 display arp packet statistics

Function

The **display arp packet statistics** command displays the statistics on ARP packets.

Format

display arp packet statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To locate and rectify ARP faults, you can run this command to view the statistics on ARP packets.

This command displays the ARP packet statistics on the active switch in a stack system.

Example

Display the statistics on ARP packets.

```
<HUAWEI> display arp packet statistics
ARP Pkt Received: sum 420066
ARP Received In Message-cache: sum 0
ARP-Miss Msg Received: sum 0
ARP Learnt Count: sum 5
ARP Pkt Discard For Limit: sum 0
ARP Pkt Discard For SpeedLimit: sum 0
```

```
ARP Pkt Discard For Proxy Suppress: sum 179578
ARP Pkt Discard For Other: sum 90347
ARP-Miss Msg Discard For SpeedLimit: sum 0
ARP Discard In Message-cache For SpeedLimit: sum 0
ARP-Miss Msg Discard For Other: sum 0
```

Table 14-54 Description of the display arp packet statistics command output

Item	Description
ARP Pkt Received	Number of the received ARP packets.
ARP Received In Message-cache	Number of ARP packets received within each second when a switch encapsulates multiple ARP request packets into one packet.
ARP-Miss Msg Received	Total number of ARP Miss messages triggered by ARP Miss packets sent to the CPU.
ARP Learnt Count	Times of ARP learning.
ARP Pkt Discard For Limit	Number of ARP packets discarded due to the ARP entry limit. To configure the maximum number of dynamic ARP entries that an interface can learn, run the **arp-limit** command.
ARP Pkt Discard For SpeedLimit	Number of ARP packets discarded when the number of ARP packets from a specified source IP address exceeds the limit. To configure a rate limit for ARP packets based on the source IP address, run the **arp speed-limit source-ip** command.
ARP Pkt Discard For Proxy Suppress	Number of packets discarded for the speed limit.
ARP Pkt Discard For Other	Number of the packets discarded due to other causes.
ARP-Miss Msg Discard For SpeedLimit	Number of ARP Miss messages discarded when the number of ARP Miss messages triggered by IP packets from a specified source IP address exceeds the limit.
ARP Discard In Message-cache For SpeedLimit	Number of ARP packets discarded due to software rate limit when a switch encapsulates multiple ARP request packets into one packet. To configure a rate limit for ARP Miss messages based on the source IP address, run the **arp-miss speed-limit source-ip** command.

Item	Description
ARP-Miss Msg Discard For Other	Number of the ARP Miss messages discarded due to other causes.

14.6.51 display arp-limit

Function

The **display arp-limit** command displays the maximum number of ARP entries that an interface can dynamically learn.

Format

display arp-limit [**interface** *interface-type interface-number*[*.subinterface-number*]] [**vlan** *vlan-id*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support sub-interface.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*[*.subinterface-number*]	Specifies the type and number of an interface. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number. • *subinterface-number* specifies the sub-interface number.	-
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the maximum number of ARP entries that an interface can dynamically learn is set, you can run this command to check the configuration.

If **interface** *interface-type interface-number*[*.subinterface-number*] and **vlan** *vlan-id* are specified, you can view the maximum number of ARP entries that the specified interface can dynamically learn in the specified VLAN. If the two parameters are not specified, the maximum number of ARP entries that each interface can dynamically learn is displayed.

Example

Display the number of ARP entries that each interface can dynamically learn.

```
<HUAWEI> display arp-limit
 Interface              LimitNum       VlanID         LearnedNum(Mainboard)
-------------------------------------------------------------------------
 Vlanif100              1000          0                0
 GigabitEthernet0/0/1    16384          10               0
 -------------------------------------------------------------------------
 Total:2
```

Table 14-55 Description of the display arp-limit command output

Item	Description
Interface	Interface name.
LimitNum	Maximum number of ARP entries that an interface can dynamically learn. To configure the maximum number of dynamic ARP entries that an interface can learn, run the **arp-limit** command.
VlanID	ID of the VLAN that the interface belongs to.
LearnedNum(Mainboard)	Number of ARP entries that an interface has learned.

14.6.52 display arp-miss speed-limit source-ip

Function

The **display arp-miss speed-limit source-ip** command displays the configuration of rate limit on ARP Miss message based on the source IP address.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display arp-miss speed-limit source-ip

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After ARP Miss rate limiting based on source IP address is configured, you can run this command to check the configuration.

Example

Display the configuration of rate limit on ARP Miss messages based on the source IP address.

```
<HUAWEI> display arp-miss speed-limit source-ip
 Slot     SuppressType   SuppressValue
 ---------------------------------------------------
 0        ARP-miss       600
```

Table 14-56 Description of the display arp-miss speed-limit source-ip command output

Item	Description
Slot	- The value indicates the slot ID if stacking is not configured. - The value indicates the stack ID if stacking is configured.
SuppressType	Suppression type.

Item	Description
SuppressValue	Maximum rate of ARP Miss messages from a specified source IP address. To configure a rate limit for ARP Miss messages based on the source IP address, run the **arp-miss speed-limit source-ip** command.

14.6.53 display arp snooping

Function

The **display arp snooping** command displays ARP snooping entries.

Format

display arp snooping { **all** \| **interface** *interface-type interface-number* \| **vlan** *vlan-id* \| **ip-address** *ip-address* \| **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays all ARP snooping entries.	-
interface *interface-type interface-number*	Displays the ARP snooping entry of a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
vlan *vlan-id*	Displays the ARP snooping entry of a specified VLAN.	The value is an integer in the range from 1 to 4094.
ip-address *ip-address*	Displays the ARP snooping entry of a specified IP address.	The value is in dotted decimal notation.

Parameter	Description	Value
mac-address *mac-address*	Displays the ARP snooping entry of a specified MAC address.	The value is a 12-digit hexadecimal number, in the format of H-H-H. Each H is 4 digits. If an H contains fewer than 4 digits, the left-most digits are padded with zeros. For example, e0 is displayed as 00e0. The MAC address cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After ARP snooping is enabled, the device generates ARP snooping entries that contain the IP address, MAC address, VLAN ID, inbound interface, and aging time. You can run the **display arp snooping** command to view the ARP snooping entries.

Example

Display all ARP snooping entries.

```
<HUAWEI> display arp snooping all
VLAN/CEVLAN     IP ADDRESS     MAC ADDRESS     INTERFACE     EXPIRE(S)
---------------------------------------------------------------------
2/-            192.168.10.1   xxxx-xxxx-xxx1  Eth1/0/0      20
2/-            192.168.10.2   xxxx-xxxx-xxx2  Eth1/0/0      10
13/-            10.1.1.1       xxxx-xxxx-xxx3  Eth-Trunk0    18
12/10            172.16.1.1     xxxx-xxxx-xxx4  40GE5/0/4     5
---------------------------------------------------------------------
Total Count:4
```

Table 14-57 Description of the **display arp snooping** command output

Item	Description
VLAN/CEVLAN	VLAN information.
IP ADDRESS	IP address.
MAC ADDRESS	MAC address.

Item	Description
INTERFACE	Inbound interface.
EXPIRE(S)	Aging time.

14.6.54 reset arp anti-attack packet-check statistics

Function

The **reset arp anti-attack packet-check statistics** command clears the statistics on invalid ARP packets that are filtered out during ARP packet validity check.

Format

reset arp anti-attack packet-check statistics

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to clear existing statistics, and run the **display arp anti-attack packet-check statistics** command to view the statistics on follow-up invalid ARP packets that are filtered out.

Example

Clear the statistics on invalid ARP packets that are filtered out in ARP packet validity check.

```
<HUAWEI> reset arp anti-attack packet-check statistics
```

14.6.55 reset arp anti-attack statistics check user-bind

Function

The **reset arp anti-attack statistics check user-bind** command clears the statistics on discarded ARP packets matching no binding entry.

Format

reset arp anti-attack statistics check user-bind interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. Where, - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

User view, system view

Default Level

2: Configuration level

Usage Guidelines

After DAI is enabled and some ARP packets matching no binding entry are discarded, you can run this command to clear the statistics on the discarded ARP packets.

Example

Clear the statistics on discarded ARP packets on GE0/0/1.

```
<HUAWEI> reset arp anti-attack statistics check user-bind interface gigabitethernet 0/0/1
```

14.6.56 reset arp anti-attack statistics rate-limit

Function

The **reset arp anti-attack statistics rate-limit** command clears the statistics on ARP packets discarded when the rate of ARP packets exceeds the limit.

Format

reset arp anti-attack statistics rate-limit

Parameters

None

Views

User view, system view

Default Level

2: Configuration level

Usage Guidelines

After rate limit on ARP packets is enabled globally, the device discards the excess packets when the rate of ARP packets exceeds the limit. You can run this command to clear the statistics on the discarded ARP packets.

Example

Clear the statistics on ARP packets discarded when the rate of ARP packets exceeds the limit.

```
<HUAWEI> reset arp anti-attack statistics rate-limit
```

14.6.57 reset arp optimized-reply statistics

Function

The **reset arp optimized-reply statistics** command clears statistics on optimized ARP Reply packets.

Format

reset arp optimized-reply statistics [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID.	The value must be set according to the device configuration.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

To collect statistics on optimized ARP Reply packets on the device, you can run the **reset arp optimized-reply statistics** [**slot** *slot-id*] command to clear statistics on optimized ARP Reply packets of the device.

Example

Clears statistics on optimized ARP Reply packets.

```
<HUAWEI> reset arp optimized-reply statistics
```

14.6.58 reset arp packet statistics

Function

The **reset arp packet statistics** command clears the statistics on ARP packets.

Format

reset arp packet statistics

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can run the **display arp packet statistics** command to display the statistics on ARP packets. To obtain correct statistics, run the **reset arp packet statistics** command to clear existing statistics first.

The **reset arp packet statistics** command clears the ARP packet statistics on the active switch in a stack system.

Example

Clear the statistics on all ARP packets.

```
<HUAWEI> reset arp packet statistics
```

14.6.59 reset arp snooping

Function

The **reset arp snooping** command clears ARP snooping entries.

Format

reset arp snooping { **all** | **interface** *interface-type interface-number* | **vlan** *vlan-id* | **ip-address** *ip-address* | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Clears all ARP snooping entries.	-
interface *interface-type interface-number*	Clears ARP snooping entries on an interface that has the specified interface type and number. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
vlan *vlan-id*	Clears ARP snooping entries in a specified VLAN.	The value is an integer in the range from 1 to 4094.
ip-address *ip-address*	Clears ARP snooping entries of the specified IP address.	The value is in dotted decimal notation.
mac-address *mac-address*	Clears ARP snooping entries of the specified MAC address.	The value is in H-H-H format, in which H is a hexadecimal number of 1 to 4 bits, such as 00e0 and fc01. If you enter less than four alphanumeric characters, 0s are added before the input digits. For example, if e0 is entered, 00e0 is displayed. The MAC address cannot be FFFF-FFFF-FFFF, 0000-0000-0000, and a multicast MAC address.

Views

User view

Default Level

3: Management level

Usage Guidelines

To view ARP snooping entries in a specified period, you need to generate new ARP snooping entries from a specified time. You can run the **reset arp snooping** command to clear ARP snooping entries.

Example

Clear ARP snooping entries.

```
<HUAWEI> reset arp snooping all
```

14.7 Port Security Configuration Commands

14.7.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.7.2 display mac-address sec-config

Function

The **display mac-address sec-config** command displays secure static MAC address entries.

Format

display mac-address sec-config [**vlan** *vlan-id* | *interface-type interface-number*] * [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the secure static MAC address entries in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Displays the secure static MAC address entries on a specified interface.	-

Parameter	Description	Value
verbose	Displays detailed information about secure static MAC address entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After secure static MAC address entries are configured by the command **port-security mac-address**, you can run the **display mac-address sec-config** command to check these entries.

Example

Display all secure static MAC address entries.

```
<HUAWEI> display mac-address sec-config
-------------------------------------------------------------------------------
MAC Address    VLAN/VSI/BD                   Learned-From        Type
-------------------------------------------------------------------------------
xxxx-xxxx-xxx1 100/-/-                       GE0/0/1             sec-config

-------------------------------------------------------------------------------
Total items displayed = 1
```

Table 14-58 Description of the display mac-address sec-config command output

Item	Description
MAC Address	Destination MAC address in a secure static MAC address entry.
VLAN/VSI/BD	ID of the VLAN, name of the VSI, or the ID of the BD that a MAC address belongs to.
Learned-From	Interface that learns a MAC address.
Type	Type of a MAC address entry. The value is **sec-config**, which indicates a secure static MAC address.

14.7.3 display mac-address security

Function

The **display mac-address security** command displays secure dynamic MAC address entries.

Format

display mac-address security [**vlan** *vlan-id* | *interface-type interface-number*] * [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays secure dynamic MAC address entries in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Displays secure dynamic MAC address entries with a specified outbound interface. - *interface-type* specifies the type of the outbound interface. - *interface-number* specifies the number of the outbound interface.	-
verbose	Displays detailed information about secure dynamic MAC address entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After port security is enabled on an interface by using the **port-security enable** command, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries. The learned secure dynamic MAC address entries are deleted after the device restarts.

After configuring the port security function, you can run the **display mac-address security** command to check whether the learned secure dynamic MAC address entries are correct.

Follow-up Procedure

If the displayed secure dynamic MAC address entries are invalid, run the **undo mac-address security** command to delete secure dynamic MUX MAC address entries.

Precautions

If you run the **display mac-address security** command without parameters, all secure dynamic MAC address entries are displayed.

If the MAC address table does not contain any secure dynamic MAC address entry, no information is displayed.

When the device has a large number of secure dynamic MAC address entries, it is recommended that you specify parameters in the command to filter the output information. Otherwise, the following problems may occur due to excessive output information:

- The displayed information is repeatedly refreshed, so you cannot find the required information.
- The system traverses and retrieves information for a long time, and does not respond to any request.

Example

Display all secure dynamic MAC address entries.

```
<HUAWEI> display mac-address security
-------------------------------------------------------------------------------
MAC Address    VLAN/VSI/BD                   Learned-From        Type
-------------------------------------------------------------------------------
xxxx-xxxx-xxx1 100/-/-                       GE0/0/1             security
xxxx-xxxx-xxx2 200/-/-                       GE0/0/2             security

-------------------------------------------------------------------------------
Total items displayed = 2
```

Display detailed information about all secure dynamic MAC address entries in VLAN 10.

```
<HUAWEI> display mac-address security vlan 10 verbose
-------------------------------------------------------------------------------
MAC Address : xxxx-xxxx-xxx1          VLAN : 10
Learned-From: GE0/0/1               Type : security
Aging-Time  : 200s

-------------------------------------------------------------------------------
Total items displayed = 1
```

Table 14-59 Description of the display mac-address security command output

Item	Description
MAC Address	Destination MAC address in a secure dynamic MAC address entry.
VLAN/VSI/BD	ID of the VLAN, name of the VSI, or the ID of the BD that a MAC address belongs to.
Learned-From	Interface that learns a MAC address.
Type	Type of a MAC address entry. The value is **security**, which indicates a secure dynamic MAC address.
Aging-Time	How soon a secure dynamic MAC address entry will be aged out.

14.7.4 display mac-address sticky

Function

The **display mac-address sticky** command displays sticky VLAN MAC address entries.

Format

display mac-address sticky [**vlan** *vlan-id* | *interface-type interface-number*] * [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays sticky MAC address entries in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Displays sticky MAC address entries with a specified outbound interface. ● *interface-type* specifies the type of the outbound interface. ● *interface-number* specifies the number of the outbound interface.	-

Parameter	Description	Value
verbose	Displays detailed information about sticky MAC address entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The MAC address table of the switch stores MAC addresses of other devices. When forwarding an Ethernet frame, the switch searches the MAC address table for the outbound interface according to the destination MAC address and VLAN ID in the Ethernet frame.

After port security is enabled on an interface by using the **port-security enable** command, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries. The learned secure dynamic MAC address entries are deleted after the switch restarts. If the sticky MAC function is also enabled on the interface by using the **port-security mac-address sticky** command, secure dynamic MAC address entries change to sticky MAC address entries. Sticky MAC address entries are not deleted after the switch restarts.

To check the sticky MAC configuration or the learned sticky MAC address entries, run the **display mac-address sticky** command.

Follow-up Procedure

If the displayed sticky MAC address entries are invalid, run the **undo mac-address sticky** command to delete sticky MAC address entries.

Precautions

If you run the **display mac-address sticky** command without parameters, all sticky MAC address entries are displayed.

If the MAC address table does not contain any sticky MAC address, no information is displayed.

When the switch has a large number of sticky MAC address entries, it is recommended that you specify parameters in the command to filter the output information. Otherwise, the following problems may occur due to excessive output information:

- The displayed information is repeatedly refreshed, so you cannot find the required information.

- The system traverses and retrieves information for a long time, and does not respond to any request.

Example

Display all sticky MAC address entries.

```
<HUAWEI> display mac-address sticky
-------------------------------------------------------------------------------
MAC Address    VLAN/VSI/BD                    Learned-From        Type
-------------------------------------------------------------------------------
xxxx-xxxx-xxx1 100/-/-                        GE0/0/1             sticky
xxxx-xxxx-xxx2 200/-/-                        GE0/0/2             sticky

-------------------------------------------------------------------------------
Total items displayed = 2
```

Display detailed information about all sticky MAC address entries in VLAN 10.

```
<HUAWEI> display mac-address sticky vlan 10 verbose
-------------------------------------------------------------------------------
MAC Address : xxxx-xxxx-xxx1           VLAN : 10
Learned-From: GE0/0/1                 Type : sticky

-------------------------------------------------------------------------------
Total items displayed = 1
```

Table 14-60 Description of the display mac-address sticky command output

Item	Description
MAC Address	MAC address in a sticky MAC address entry.
VLAN/VSI/BD	ID of the VLAN, name of the VSI, or the ID of the BD that a MAC address belongs to.
Learned-From	Interface that learns a MAC address.
Type	Type of a MAC address entry. The value is **sticky**, which indicates a sticky MAC address.

14.7.5 display mac-address sticky-config

Function

The **display mac-address sticky-config** command displays MAC address entries of the Sticky-Config type.

Format

display mac-address sticky-config [**vlan** *vlan-id* | *interface-type interface-number*] * [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays MAC address entries in a specified VLAN.	The value is an integer in the range from 1 to 4094.
interface-type interface-number	Displays MAC address entries with a specified outbound interface. ● *interface-type* specifies the type of the outbound interface. ● *interface-number* specifies the number of the outbound interface.	-
verbose	Displays detailed information about MAC address entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After secure static MAC address entries are configured using the **port-security mac-address sticky-config** command, you can run the **display mac-address sticky-config** command to check these entries.

Follow-up Procedure

After you run this command to check MAC address entries of the Sticky-Config type and consider that a MAC address entry is invalid, you can run the **undo port-security mac-address** [**sticky-config**] *mac-address* **vlan** *vlan-id* command to delete it.

Precautions

If you run the **display mac-address sticky-config** command without specifying any parameters, all MAC address entries of the Sticky-Config type are displayed.

If the MAC address table does not contain any MAC address of the Sticky-Config type, no information is displayed in the command output.

When the device has a large number of MAC address entries of the Sticky-Config type, it is recommended that you specify parameters in the command to filter the output information. If you do not specify these parameters, the following faults may occur:

- The displayed information is repeatedly refreshed, so you cannot find the required information.
- The system traverses and retrieves information for a long time, and does not respond to any request.

Example

Display all MAC address entries of the Sticky-Config type.

```
<HUAWEI> display mac-address sticky-config
-------------------------------------------------------------------------------
MAC Address    VLAN/VSI/BD                    Learned-From        Type
-------------------------------------------------------------------------------
0022-0022-0033 100/-/-                      GE0/0/1            sticky-config
0000-0000-0001 200/-/-                      GE0/0/2            sticky-config
-------------------------------------------------------------------------------
Total items displayed = 2
```

Display detailed information about all MAC address entries of the Sticky-Config type in VLAN 10.

```
<HUAWEI> display mac-address sticky-config vlan 10 verbose
-------------------------------------------------------------------------------
MAC Address : 0000-0000-0001           VLAN : 10
Learned-From: GE0/0/1                  Type : sticky-config

-------------------------------------------------------------------------------
Total items displayed = 1
```

Table 14-61 Description of the **display mac-address sticky-config** command output

Item	Description
MAC Address	MAC address in a MAC address entry of the Sticky-Config type.
VLAN/VSI/BD	ID of the VLAN, name of the virtual switch instance (VSI), or ID of the BD to which the MAC address belongs.
Learned-From	Interface that learns a MAC address.
Type	Type of a MAC address entry. The value is **sticky-config**, which indicates a MAC address of the Sticky-Config type.

14.7.6 display port-security

Function

The **display port-security** command displays the port security configuration.

Format

display port-security [*interface-type interface-number*]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays the port security configuration on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view information about interfaces configured with port security, including the number of MAC addresses that can be learned, number of learned MAC addresses, and actions configured on the interfaces.

After an interface enters the error-down state, you need to check the traffic that triggers this state. To facilitate troubleshooting, you can run this command to view the MAC address of the end user that triggers the error-down state of the interface and the VLAN to which the end user belongs.

Example

Display the port security configuration.

```
<HUAWEI> display port-security
Interface        MaxMacNum  CurrentMacNum  ProtectAction
InSecureMac:Vlan
Eth-Trunk17      1          0              Restrict       -
GE0/0/1     1          0            Shutdown       xxxx-xxxx-xxxx:100
GE0/0/2     1          0            Protect        -
```

Table 14-62 Description of the **display port-security** command output

Item	Description
Interface	Interface name.
MaxMacNum	Maximum number of MAC addresses that can be learned by the interface.
CurrentMacNum	Number of MAC addresses that have been learned by the interface.
ProtectAction	Action configured on the interface, which can be configured using the **port-security protect-action** command. Actions include: ● **Protect**: indicates that packets are discarded. ● **Restrict**: indicates that packets are discarded and a trap is generated. ● **Shutdown**: indicates that the interface is set to the error-down state and a trap is generated.
InSecureMac:Vlan	MAC address of the end user that triggers the **Shutdown** action and the VLAN to which the end user belongs after the action is set to **Shutdown**.

14.7.7 port-security aging-time

Function

The **port-security aging-time** command sets the aging time of secure dynamic MAC addresses on an interface.

The **undo port-security aging-time** command restores the default configuration.

By default, secure dynamic MAC addresses will not be aged out.

Format

port-security aging-time *time* [**type** { **absolute** | **inactivity** }]

undo port-security aging-time

NOTE

The S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I do not support **inactivity** parameter.

Parameters

Parameter	Description	Value
time	Specifies the aging time of secure dynamic MAC addresses.	The value is an integer that ranges from 1 to 1440, in minutes.
type	Specifies the type of the aging time.	The default type is **absolute**, indicating the absolute aging time.
absolute	Indicates the absolute aging time. After the aging time of secure dynamic MAC addresses is set, the system calculates the lifetime of each MAC address every minute. If the lifetime of a MAC address plus 1 is greater than or equal to *time* minutes, the secure dynamic MAC address is aged immediately. If the lifetime is smaller than *time* minutes, the system determines whether to delete the secure dynamic MAC address after 1 minute.	-
inactivity	Indicates the relative aging time. After the relative aging time is set to *time* minutes, the system checks traffic from each secure dynamic MAC address every 1 minute. If there is traffic, the aging is not performed. If no traffic is received from a secure dynamic MAC address, this MAC address is aged out after *time* minutes.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **port-security enable** command to enable port security on an interface, MAC address entries learned by the interface are saved in the MAC address table as secure dynamic MAC addresses. The learned secure dynamic MAC addresses will not be aged by default. When the number of learned MAC addresses reaches the limit, the interface cannot learn new MAC addresses.

If MAC addresses learned by an interface can be trusted only for a certain period, run the **port-security aging-time** command to set the aging time of secure dynamic MAC addresses on the interface. Then secure dynamic MAC addresses can be aged out and the interface can learn new MAC addresses.

Prerequisites

Port security is enabled on the interface.

Precautions

If you run the **port-security aging-time** command multiple times in the same interface view, only the latest configuration takes effect.

S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S6720S-S, S5735S-H, S5736-S, S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, S6730S-S: After an interface learns the secure dynamic MAC address of a user, the user connects to another interface (the original interface does not go Down) and the other interfaces continuously receive traffic with the source MAC address. The MAC address of the original interface is not aged out. As a result, the user cannot connect to the interface again. To solve this problem, you can set the aging time of secure dynamic MAC addresses on the interface.

Example

Set the aging time of secure dynamic MAC addresses on GE0/0/1 to 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security aging-time 30
```

14.7.8 port-security enable

Function

The **port-security enable** command enables the port security function on an interface.

The **undo port-security enable** command disables the port security function on an interface.

By default, port security is disabled on an interface.

Format

port-security enable

undo port-security enable

Parameters

None

Views

GE interface view, Ethernet interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After port security is enabled on an interface, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries. By default, secure dynamic MAC addresses will not be aged out. If the aging time of secure dynamic MAC address entries is set, these entries will be aged out. After the device restarts, secure dynamic MAC address entries are lost and need to be relearned. You can also create secure static MAC addresses which do not age out.

Port security has the following functions:

- Prevent unauthorized guests from using their computers to connect to an enterprise network.
- Prevent employees of a company from moving their computers without permission.

Precautions

- The total number of MAC addresses on interfaces enabled with port security cannot exceed 4096. For example, if the numbers of MAC addresses learned on interfaces 1, 2, 3, and 4 are 1000 respectively, interface 5 can learn a maximum of 96 MAC addresses.
- The protection action, secure static MAC addresses, and sticky MAC function can be configured only after port security is enabled.
- Port security and MAC address limiting conflict on an interface; therefore, the **port-security enable** and **mac-limit maximum** commands cannot be used on the same interface.
- Port security and MUX VLAN conflict on an interface; therefore, the **port-security enable** and **port mux-vlan enable** commands are not advised to be used on the same interface.

- Port security and GVRP conflict on an interface; therefore, the **port-security enable** and **gvrp** commands cannot be used on the same interface.
- Port security and generating snooping MAC entries conflict on an interface; therefore, the **port-security enable** and **user-bind ip sticky-mac** commands cannot be used on the same interface.
- If port security is enabled after MAC address learning is disabled using the **mac-address learning disable** command, the dynamic port security function does not take effect. If port security is enabled before MAC address learning is disabled on an interface, the device no longer learns MAC addresses on the interface, but secure MAC addresses that have been learned are reserved (including secure static MAC addresses).
- When multiple NAC users are online under one interface, if you want to enable port security function on the interface, you need to first run the **port-security max-mac-num** command to set the maximum number of MAC addresses learned by the interface, and then run the **port-security enable** command. Otherwise, only one user is reserved and other users are logged out.
- When both NAC authentication and port security are enabled on an interface, MAC addresses that fail to be authenticated are not converted to secure MAC addresses. Instead, they are learned as authentication MAC addresses on the interface. After authentication succeeds, the MAC addresses are converted to secure MAC addresses.

Example

Enable port security on GigabitEthernet0/0/2.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/2
[HUAWEI-GigabitEthernet0/0/2] port-security enable
```

14.7.9 port-security mac-address

Function

The **port-security mac-address** command configures a static secure MAC address.

The **undo port-security mac-address** command deletes a static secure MAC address.

By default, no static secure MAC address is configured.

Format

port-security mac-address *mac-address* **vlan** *vlan-id*

undo port-security mac-address *mac-address* **vlan** *vlan-id*

Parameters

Parameter	Description	Value
mac-address	Specifies a static secure MAC address.	The value is in the format of H-H-H, in which H is a hexadecimal number of 1 to 4 digits. The value cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.
vlan *vlan-id*	Specifies the ID of a VLAN.	The value is an integer in the range from 1 to 4094.

2: Configuration level

Usage Guidelines

Usage Scenario

After port security is enabled on an interface using the **port-security enable** command, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries.

When the interface becomes Down or the device is reset, static secure MAC addresses are not affected, and dynamic secure MAC addresses need to be learned again. Static secure MAC addresses are not aged out. Static secure MAC addresses have a higher priority than dynamic secure MAC addresses.

Prerequisites

Port security has been enabled by using the **port-security enable** command on the interface.

Precautions

Running the **port-security mac-address** *mac-address* **vlan** *vlan-id* command multiple times configures multiple static secure MAC addresses.

A static secure MAC address cannot be a VRRP virtual MAC address or system MAC address.

Example

Configure a static secure MAC address entry on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security mac-address 00e0-fc12-3456 vlan 10
```

14.7.10 port-security mac-address sticky-config

Function

The **port-security mac-address** command configures a static secure MAC address of the Sticky-Config type.

The **undo port-security mac-address** command deletes a static secure MAC address of the Sticky-Config type.

By default, no static secure MAC address of the Sticky-Config type is configured.

Format

port-security mac-address sticky-config *mac-address* **vlan** *vlan-id*

undo port-security mac-address sticky-config *mac-address* **vlan** *vlan-id*

Parameters

Parameter	Description	Value
mac-address	Specifies a static secure MAC address.	The value is in the format of H-H-H, in which H is a hexadecimal number of 1 to 4 digits. The value cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.
vlan *vlan-id*	Specifies the ID of a VLAN.	The value is an integer in the range from 1 to 4094.

Usage Guidelines

Usage Scenario

After port security is enabled on an interface using the **port-security enable** command, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries.

When the interface becomes Down or the device is reset, static secure MAC addresses are not affected, and dynamic secure MAC addresses need to be learned again. Static secure MAC addresses are not aged out. Static secure MAC addresses have higher priority than dynamic secure MAC addresses. You can run this command to configure a static secure MAC address of the Sticky-Config type.

Prerequisites

1. Port security has been enabled using the **port-security enable** command.
2. The sticky MAC function on an interface has been enabled using the **port-security mac-address sticky** command.

Precautions

You can manually configure one or more static secure MAC address entries of the Sticky-Config type. You run the **port-security mac-address sticky-config** *mac-address* **vlan** *vlan-id* command multiple times to configure multiple static secure MAC address entries of the Sticky-Config type.

A static secure MAC address of the Sticky-Config type cannot be a VRRP virtual MAC address or a system MAC address.

Example

Configure a static secure MAC address entry of the Sticky-Config type on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security mac-address sticky
[HUAWEI-GigabitEthernet0/0/1] port-security mac-address sticky-config 00e0-fc12-3456 vlan 10
```

14.7.11 port-security mac-address sticky

Function

The **port-security mac-address sticky** command enables the sticky MAC function on an interface.

The **undo port-security mac-address sticky** command disables the sticky MAC function on an interface.

By default, the sticky MAC function is disabled on an interface.

Format

port-security mac-address sticky [*mac-address* **vlan** *vlan-id*]

undo port-security mac-address sticky [*mac-address* **vlan** *vlan-id*]

Parameters

Parameter	Description	Value
mac-address	Specifies the MAC address in a sticky MAC address entry. **NOTE** This parameter is not supported in the port group view.	The value is in the format of H-H-H, in which H is a hexadecimal number of 1 to 4 digits. A MAC address cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.
vlan *vlan-id*	Specifies the ID of a VLAN. **NOTE** This parameter is not supported in the port group view.	The value is an integer in the range from 1 to 4094.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view,MultiGE interface view,40GE interface view,100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After port security is enabled on an interface using the **port-security enable** command, MAC address entries learned by the interface are stored in the MAC address table as secure dynamic MAC address entries.

After the sticky MAC function is enabled on an interface, the dynamic MAC addresses learned by the interface change to sticky MAC addresses.

Before the number of sticky MAC addresses reaches the limit on the interface, the MAC addresses learned subsequently are still converted into sticky MAC addresses. When the number of sticky MAC addresses reaches the limit, non-sticky MAC addresses are discarded. In addition, the system determines whether to send a trap message based on the configuration of the interface protection mode.

After enabling the sticky MAC function on an interface using the **port-security mac-address sticky** command, you can run the **port-security mac-address sticky** *mac-address* **vlan** *vlan-id* command to manually configure a sticky MAC address entry.

The sticky MAC function has the following functions:

- Prevent non-employees from using their own computers to access the company intranet without the permission of the network administrator.
- Prevent employees from moving network devices or computers of the company without the permission of the network administrator.

Prerequisites

Port security has been enabled by using the **port-security enable** command on the interface.

Precautions

Running the **undo port-security mac-address sticky** command will convert the sticky MAC addresses on the interface into secure dynamic MAC addresses.

The configuration information is not displayed after you run the **port-security mac-address sticky** *mac-address* **vlan** *vlan-id* command to configure sticky MAC address entries.

Manually configured and auto-generated sticky MAC address entries are automatically saved in a .ztbl or .ctbl file every 10 minutes. Alternatively, you can run the **save** command to manually save them. The saved file is not discarded after the device restarts. The file name must be the same as that of the system configuration file. For example, if the name of the system configuration file is test.cfg, the name of the sticky MAC address entry file must be test.ctbl. Otherwise, sticky MAC address entries will fail to be restored after the device restarts.

If you run the **port-security mac-address sticky** *mac-address* **vlan** *vlan-id* command multiple times, multiple sticky MAC address entries are configured.

A sticky MAC address cannot be a VRRP virtual MAC address or a system MAC address.

Example

Enable the sticky MAC function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security mac-address sticky
```

14.7.12 port-security max-mac-num

Function

The **port-security max-mac-num** command sets the maximum number of secure MAC addresses that can be learned on an interface.

The **undo port-security max-mac-num** command restores the default maximum number of secure MAC addresses that can be learned on an interface.

By default, only one MAC address can be learned on an interface.

Format

port-security max-mac-num *max-number*

undo port-security max-mac-num

Parameters

Parameter	Description	Value
max-number	Specifies the maximum number of secure MAC addresses that can be learned by an interface.	The value is an integer that ranges from 1 to 1024.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling port security on an interface, you can run the **port-security max-mac-num** command to limit the number of MAC addresses that the interface can learn. If the switch receives packets with a nonexistent source MAC address after the number of secure MAC addresses reaches the limit, the switch considers that the packets are sent from an unauthorized user, regardless of whether the destination MAC address of packets is valid, and takes the action configured using the **port-security protect-action** command on the interface. This prevents untrusted users from accessing these interfaces, improving security of the switch and the network.

Precautions

- The total number of MAC addresses on interfaces enabled with port security cannot exceed 4096. For example, if the numbers of MAC addresses learned on interfaces 1, 2, 3, and 4 are 1000 respectively, interface 5 can learn a maximum of 96 MAC addresses.
- If the sticky MAC function is disabled, *max-number* limits the number of secure dynamic MAC addresses learned by the interface and secure static MAC addresses configured manually.
- If the sticky MAC function is enabled, *max-number* limits the number of sticky MAC addresses learned by the interface, and sticky MAC addresses and secure static MAC addresses configured manually.
- When multiple NAC users are online under one interface, if you want to enable port security function on the interface, you need to first run the **port-security max-mac-num** command to set the maximum number of MAC addresses learned by the interface, and then run the **port-security enable**

command. Otherwise, only one user is reserved and other users are logged out.

- If you run the **port-security max-mac-num** command multiple times in the same interface view, only the latest configuration takes effect.

Example

Set the maximum number of MAC addresses that can be learned by GigabitEthernet0/0/1 to 5.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security max-mac-num 5
```

14.7.13 port-security protect-action

Function

The **port-security protect-action** command configures the protection action to be used when the number of learned MAC addresses on an interface exceeds the upper limit or static MAC address flapping is detected.

The **undo port-security protect-action** command restores the default protection action.

The default protection action is **restrict**.

Format

port-security protect-action { **protect** | **restrict** | **shutdown** }

undo port-security protect-action

Parameters

Parameter	Description	Value
protect	● The interface discards packets with source MAC addresses that are not in the MAC address table when the number of learned MAC addresses exceeds the upper limit. ● The interface discards packets with the flapping MAC address when static MAC address flapping occurs.	-

Parameter	Description	Value
restrict	● The interface discards packets with source MAC addresses that are not in the MAC address table and sends a trap message when the number of learned MAC addresses exceeds the upper limit. ● The interface discards packets with the flapping MAC address and sends a trap message when static MAC address flapping occurs.	-
shutdown	● The interface goes ERROR DOWN and sends a trap message when the number of learned MAC addresses exceeds the upper limit. ● The interface goes ERROR DOWN and sends a trap message when static MAC address flapping occurs.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling port security, you can run the **port-security protect-action** command to configure the protection action performed on the interface when the number of learned MAC addresses on the interface exceeds the upper limit or static MAC address flapping is detected.

The default action **restrict** is recommended. If the action is set to **shutdown** on an interface connected to a downstream device, the interface discards packets from trusted MAC addresses. Select the **shutdown** action only when the interface is directly connected to a user terminal.

Prerequisites

Port security has been enabled by using the **port-security enable** command on the interface.

Precautions

The interface takes protection actions when detecting static MAC address flapping only after the **port-security static-flapping protect** command is executed.

If the protection action is set to **shutdown**, the interface automatically goes ERROR DOWN when the number of learned MAC addresses exceeds the limit or static MAC address flapping is detected. In addition, the interface status will not be automatically recovered. In this case, you can run the **error-down auto-recovery cause port-security interval** *interval-value* command in the system view to enable an interface in Error-Down state to come back up automatically.

If you run the **port-security protect-action** command multiple times in the same interface view, only the latest configuration takes effect.

If both port security and traffic policy-based VLAN translation are configured on the following switch models, an interface forwards protocol packets with source MAC addresses not in the MAC address table when the number of learned MAC addresses exceeds the limit: S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S,

Example

Set the protection action on GE0/0/1 to **protect**.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port-security enable
[HUAWEI-GigabitEthernet0/0/1] port-security protect-action protect
```

14.7.14 port-security static-flapping protect

Function

The **port-security static-flapping protect** command enables static MAC address flapping detection.

The **undo port-security static-flapping protect** command disables static MAC address flapping detection.

By default, static MAC address flapping detection is disabled.

Format

port-security static-flapping protect

undo port-security static-flapping protect

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Secure MAC addresses are also static MAC addresses. When an interface receives a packet of which the source MAC address exists in the static MAC address table on another interface, the interface discards this packet. This will affect user services. For example, after the sticky MAC address function is enabled on GE0/0/1, PC1 is connected to the device through this interface. In this way, the MAC address of PC1 is stored in the static MAC address entry of GE0/0/1. If PC1 is then connected to the device through GE0/0/2, GE0/0/2 discards the packets sent from PC1. In this case, you can enable static MAC address flapping detection. The device then performs the configured action on GE0/0/2.

Precautions

Static MAC address flapping detection needs to be enabled only on the interfaces with port security enabled.

Example

Enable static MAC address flapping detection.

```
<HUAWEI> system-view
[HUAWEI] port-security static-flapping protect
```

14.7.15 undo mac-address security

Function

The **undo mac-address security** command deletes secure MAC address entries. Secure MAC address entries include dynamic and static secure MAC address entries and sticky MAC address entries.

Format

undo mac-address { **sec-config** | **security** | **sticky** } [*interface-type interface-number* | **vlan** *vlan-id*] *

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the outbound interface in a secure MAC address entry to be deleted.	-
vlan *vlan-id*	Specifies the VLAN ID in a secure MAC address entry to be deleted.	The value is an integer that ranges from 1 to 4094.
sec-config	Deletes static secure MAC address entries.	-
security	Deletes dynamic secure MAC address entries, that is, MAC address entries learned by an interface enabled with port security.	-
sticky	Deletes sticky MAC address entries, that is, MAC address entries learned by an interface enabled with the sticky MAC function.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After port security is enabled on an interface, dynamic MAC address entries learned by the interface turn into secure MAC address entries. Secure MAC address entries are not aged out. After the number of MAC address entries learned by an interface reaches the limit, the interface cannot learn new MAC address entries. Packets matching no MAC address entry are broadcast, wasting bandwidth resources. This command can delete useless secure MAC address entries to release the MAC address table space.

You can delete some of secure MAC address entries as required. For example:

- If you do not specify *interface-type interface-number*, the command deletes MAC address entries of the specified type on all interfaces.
- If you do not specify **vlan** *vlan-id*, the command deletes MAC address entries of the specified type in all VLANs.

Example

Delete all static secure MAC address entries.

```
<HUAWEI> system-view
[HUAWEI] undo mac-address sec-config
```

Delete all dynamic secure MAC address entries on gigabitethernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] undo mac-address security gigabitethernet 0/0/1
```

Delete all sticky MAC address entries.

```
<HUAWEI> system-view
[HUAWEI] undo mac-address sticky
```

14.8 DHCP Snooping Configuration Commands

14.8.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.8.2 arp dhcp-snooping-detect enable

Function

The **arp dhcp-snooping-detect enable** command enables association between the Address Resolution Protocol (ARP) and Dynamic Host Configuration Protocol (DHCP) snooping.

The **undo arp dhcp-snooping-detect enable** command disables association between ARP and DHCP snooping.

By default, association between ARP and DHCP snooping is disabled.

Format

arp dhcp-snooping-detect enable

undo arp dhcp-snooping-detect enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a DHCP client sends a DHCP Release message to release its IP address, the DHCP snooping-enabled device immediately deletes the binding entry of the DHCP client. If a DHCP client is abnormally disconnected and cannot send a DHCP Release message, the DHCP snooping-enabled device cannot immediately delete the binding entry of the DHCP client.

If association between ARP and DHCP snooping is enabled using this command and no ARP entry corresponding to the IP address in the DHCP snooping binding entry is found, the DHCP snooping-enabled device performs an ARP probe on the IP address. If no user is detected for consecutive four times, the DHCP snooping-enabled device deletes the DHCP snooping binding entry corresponding to the IP address. (The probe interval is 20 seconds, and the probe times and probe interval are fixed values and cannot be modified.) If the DHCP snooping-enabled device supports the DHCP relay function, this device then sends a DHCP Release message in place of the DHCP client to notify the DHCP server to release the IP address.

Prerequisites

Before association between the ARP and DHCP snooping is enabled, ensure that an IP address configured on the device is on the same network segment as the IP address of the client for ARP probe.

Example

Enable association between ARP and DHCP snooping on the device.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] arp dhcp-snooping-detect enable
```

14.8.3 dhcp option82 append vendor-specific

Function

The **dhcp option82 append vendor-specific** command inserts the Sub9 suboption into Option 82.

The **undo dhcp option82 append vendor-specific** command restores the default configuration.

By default, Sub9 suboption is not inserted into the Option 82 field of DHCP messages.

Format

dhcp option82 append vendor-specific

undo dhcp option82 append vendor-specific

Parameters

None

Views

Interface view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **dhcp option82 append vendor-specific** command is run on a DHCP relay agent or DHCP snooping device, the device will insert the Sub9 suboption into the Option 82 field of a received DHCP message. When this DHCP message is forwarded to the DHCP server, the server obtains the DHCP client location information from the Sub9 suboption.

The Sub9 suboption has old and new formats. The old format contains the vendor ID, for example, hwid. The new format does not contain the vendor ID.

Both the **dhcp option82 append vendor-specific** and **dhcp option82 vendor-specific format** commands can insert the Sub9 into the Option 82 field of the DHCP message, except that the Sub9 formats are different:

- **dhcp option82 append vendor-specific**: inserts the Sub9 of the new format. The new format includes the location information such as the node identifier, node chassis ID, node slot ID, node port number, and user VLAN.
- **dhcp option82 vendor-specific format**: inserts the Sub9 of the old format. The old format includes the DHCP client information such as user IP address and device name.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

- When both the **dhcp option82 append vendor-specific** and **dhcp option82 vendor-specific format** commands are run, the **dhcp option82 append vendor-specific** command takes effect.
- The Sub9 suboption can be inserted into Option 82 only when the Sub9 format is the same as the DHCP packet format. If the formats are different:
  - If the **dhcp option82 vendor-specific format** command has been run, the Sub9 of the new format cannot be inserted into Option 82.
  - If the **dhcp option82 append vendor-specific** command has been run, whether the Sub9 of the old format can be inserted depends on the Option 82 insertion method (which is configured using the **dhcp option82 enable** command).
    - When the Option 82 insertion method is Insert, the Sub9 is not inserted.
    - When the Option 82 insertion method is Rebuild, the Sub9 is reconstructed and then inserted into Option 82.

- The total length of the Option 82 field cannot exceed 255 bytes.

Example

Insert the Sub9 suboption into the Option 82 field of DHCP messages.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 append vendor-specific
```

14.8.4 dhcp option82 enable

Function

The **dhcp option82 enable** command enables a device to insert the Option 82 field to a DHCP message.

The **undo dhcp option82 enable** command disables a device from inserting the Option 82 field to a DHCP message.

By default, a device does not insert the Option 82 field to a DHCP message.

Format

In the interface view, BD view and port group view

dhcp option82 { **insert** | **rebuild** } **enable**

undo dhcp option82 { **insert** | **rebuild** } **enable**

In the VLAN view

dhcp option82 { **insert** | **rebuild** } **enable interface** *interface-type interface-number1* [**to** *interface-number2*]

undo dhcp option82 { **insert** | **rebuild** } **enable interface** *interface-type interface-number1* [**to** *interface-number2*]

Parameters

Parameter	Description	Value
insert	Enables a device to insert the Option 82 field to a DHCP message.	-
rebuild	Enables a device to forcibly insert the Option 82 field to a DHCP message.	-

Parameter	Description	Value
interface *interface-type interface-number1* [**to** *interface-number2*]	Specifies the interface type and number. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	If this command is run in the VLAN view, the specified interface must have been added to the VLAN.

Views

VLAN view, Ethernet interface view, GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Option 82 field records the location of a DHCP client. A device inserts the Option 82 field to a DHCP Request message to notify the DHCP server of the DHCP client location. The DHCP server can assign an IP address and other configurations to the DHCP client, ensuring DHCP client security.

The device inserts the Option 82 field to a DHCP message in two modes:

- Insert mode: Upon receiving a DHCP Request message without the Option 82 field, the device inserts the Option 82 field. If the DHCP Request message contains the Option 82 field, the device checks whether the Option 82 field contains the remote ID. If so, the device retains the Option 82 field; if not, the device inserts the remote ID.
- Rebuild mode: Upon receiving a DHCP Request message without the Option 82 field, the device inserts the Option 82 field. If the DHCP Request message contains the Option 82 field, the device deletes the original Option 82 field and inserts the Option 82 field set by the administrator.

The device handles the reply packets from the DHCP server in the same way regardless of whether the Insert or Rebuild method is used.

- The DHCP reply packets contain Option 82:
  - If the DHCP request packets received by the device do not contain Option 82, the device deletes Option 82 from the DHCP reply packets, and forwards the packets to the DHCP client.
  - If the DHCP request packets contain Option 82, the device changes the Option 82 format in the DHCP reply packets into the Option 82 format in the DHCP request packets, and forwards the packets to the DHCP client.
- If the DHCP reply packets do not contain Option 82, the device directly forwards the packets.

NOTE

The physical interface can insert Option82 to the DHCP packets directly forwarded, but does not insert Option82 to the DHCP packets forwarded through a tunnel.

Prerequisites

DHCP snooping has been enabled on the device, or the device has been configured as a DHCP relay agent.

Precautions

- When receiving a DHCP Request message, the device checks whether the field GIADDR in the packet is 0. If so, the **dhcp option82 enable** command takes effect; if not, this command does not take effect.
- DHCP Option 82 must be configured on the user-side of a device; otherwise, the DHCP messages sent to the DHCP server will not carry Option 82.

Example

Enable the device to insert the Option 82 field to DHCP messages on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 insert enable
```

14.8.5 dhcp option82 encapsulation

Function

The **dhcp option82 encapsulation** command configures suboptions inserted into the DHCP Option 82 field.

The **undo dhcp option82 encapsulation** command restores the default suboptions inserted into the DHCP Option 82 field.

By default, the circuit-id (CID), remote-id (RID), subscriber-id (SID), and Sub9 suboptions are inserted into the DHCP Option 82 field in the system view.

By default, suboptions of the DHCP Option 82 field are not inserted in other views.

Format

dhcp option82 encapsulation { **circuit-id** | **remote-id** | **subscriber-id** | **vendor-specific-id** } *

undo dhcp option82 encapsulation

Parameters

Parameter	Description	Value
circuit-id	Inserts the circuit-id suboption.	-
remote-id	Inserts the remote-id suboption.	-

Parameter	Description	Value
subscriber-id	Inserts the subscriber-id (SID) suboption.	-
vendor-specific-id	Inserts the vendor-specific suboption in the Sub9 field.	-

Views

System view, VLAN view, interface view, BD view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This function applies to a DHCP relay agent or a DHCP snooping-enabled device. The Option 82 field records the location of a DHCP client. A device inserts the Option 82 field to a DHCP Request message to notify the DHCP server of the DHCP client location. The DHCP server can assign an IP address and other configurations to the DHCP client, ensuring DHCP client security. The administrator can run this command to configure the device to insert one or more of the circuit-id suboption, remote-id suboption, subscriber-id suboption, and vendor-specific suboption in the Sub9 field into the DHCP Option 82 field. After the command is run, suboptions that are not configured to be inserted are not inserted into the DHCP Option 82 field by default.

Prerequisites

The DHCP function has been enabled in the system view using the **dhcp enable** command.

Example

Insert the circuit-id suboption into the DHCP Option 82 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp option82 encapsulation circuit-id
```

14.8.6 dhcp option82 format

Function

The **dhcp option82 format** command configures the format of the Option 82 field in a DHCP message.

The **undo dhcp option82 format** command restores the default format of the Option 82 field in a DHCP message.

By default, the Option 82 field in a DHCP message is in the format of **default**.

Format

dhcp option82 [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] [**circuit-id** | **remote-id**] **format** { **default** | **common** | **extend** | **user-defined** *text* }

undo dhcp option82 [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] [**circuit-id** | **remote-id**] **format**

Parameters

Parameter	Description	Value
circuit-id	Indicates the circuit ID (CID) in the Option 82 field. If the CID is not specified, the format of the Option 82 field is **default**.	-
remote-id	Indicates the remote ID (RID) in the Option 82 field. If the RID is not specified, the format of the Option 82 field is **default**.	-
default	Indicates the default format of the Option 82 field. ● CID format: interface name:svlan.cvlan host name/0/0/0/0/0, in ASCII format ● RID format: device MAC address, in hexadecimal notation	-
common	Indicates the common format of the Option 82 field. ● CID format: {eth|trunk}slot ID/subcard ID/ port ID:svlan.cvlan host name0/0/0/0/0, in ASCII format ● RID format: device MAC address (6 bytes), in ASCII format	-
extend	Indicates the extended format of the Option 82 field. ● CID format: circuit-id type (0) + length (4) + S-VLAN ID (2 bytes) + slot ID (5 bits) + subslot ID (3 bits) + port (1 byte), in hexadecimal notation ● RID format: remote-id type (0) + length (6) + device MAC address (6 bytes), in hexadecimal notation In the CID and RID formats, the values without a unit are fixed values of the fields; the values with a unit indicate the field lengths.	-

Parameter	Description	Value
user-defined *text*	Indicates the user-defined format of the Option 82 field.	The value is a string of 1 to 255 characters. For details, see the description in "Usage Guideline."
vlan *vlan-id*	Indicates an outer VLAN ID. If a VLAN ID is specified, only the format of the Option 82 field in the DHCP messages sent from the specified VLAN is configured. If no VLAN is specified, the format of the Option 82 field in all the DHCP messages received by the interface is configured.	The value is an integer that ranges from 1 to 4094.
ce-vlan *ce-vlan-id*	Indicates an inner VLAN ID.	The value is an integer that ranges from 1 to 4094.

Usage Guidelines

Usage Scenario

After the function of inserting the Option 82 field to DHCP messages is enabled, you can use the **dhcp option82 format** command to configure the format of the Option 82 field.

If you run the **dhcp option82 format** command in the system view, the command takes effect for all the DHCP messages on all the interfaces of the device.

You can use the following keywords to define the Option 82 field. The format string can use the hexadecimal notation, ASCII format, or combination of the two formats.

- sysname: indicates the ID of the access point. This keyword is valid only in ASCII format.
- portname: indicates the name of a port, for example, GE0/0/1. This keyword is valid only in ASCII format.

- porttype: indicates the type of a port. This keyword is a character string or in hexadecimal notation. For example, if the value is Ethernet in ASCII format, it is 15 in hexadecimal notation.
- iftype: indicates the type of an interface, which can be eth or trunk. This keyword is valid only in ASCII format.
- mac: indicates the MAC address of a port. In ASCII format, the value is in the format of H-H-H; in hexadecimal notation, the value is a number of six bytes.
- slot: indicates the slot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- subslot: indicates the subslot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- port: indicates the port number. This keyword is valid in ASCII format or in hexadecimal notation.
- svlan: indicates the outer VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- cvlan: specifies the inner VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- length: indicates the total length of the keywords following the keyword length.
- n: indicates the value of the keyword **svlan** or **cvlan** if the SVLAN or CVLAN does not exist. The keyword **n** is on the left of the keyword **svlan** or **cvlan**. If the corresponding VLAN does not exist, the default value of the keyword **svlan** or **cvlan** is 4096 in ASCII format and is all Fs in hexadecimal notation. If the **n** keyword is added to the left of the keyword **svlan** or **cvlan**, the keyword **svlan** or **cvlan** is 0. This keyword is valid in ASCII format or in hexadecimal notation.

NOTE

Delimiters must be added between keywords; otherwise, the device cannot parse the keywords. The delimiters cannot be numbers.

The keyword length can be configured only once.

The symbols used in the format string are as follows:

- The symbol % followed by a keyword indicates the format of the keyword.
- A number to the left of the symbol % indicates the length of the keyword following the symbol %. In an ASCII character string, %05 has the same meaning as %05d in the C language. In a hexadecimal character string, the number indicates the keyword length in bits.
- The symbol [] indicates an optional keyword. Each pair of brackets can contain only one keyword, svlan or cvlan. The keyword in the symbol [] is added to the Option 82 field only if the corresponding VLAN ID exists. To facilitate syntax check, the system does not support nesting of symbols [].
- The symbol \ indicates an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents \.

- The contents in quotation marks (" ") are encapsulated in a character string, and the contents outside the quotation marks are encapsulated in hexadecimal notation.
- Other symbols are processed as common characters. The rules for setting the format string in ASCII format or hexadecimal notation are as follows:
  - An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.
  - A hexadecimal notation string can contain numerals, spaces, and % + keywords.
  - In a hexadecimal notation string, numbers are encapsulated in the Option 82 field in hexadecimal notation. A number from 0 to 255 occupies 1 byte; a number from 256 to 65535 occupies 2 bytes; a number from 65536 to 4294967295 occupies 4 bytes. Numbers larger than 4294967295 are not supported. Multiple numbers must be separated by spaces; otherwise, they are considered as one number.
  - All the spaces in a hexadecimal character string are ignored.
  - By default, the slot ID, subslot ID, port number, and VLAN ID in a hexadecimal character string occupy 2 bytes; the field length occupies 1 byte.
  - If the length of each keyword in a hexadecimal character string is specified, the total length of the hexadecimal character string must be a multiple of 8. If the length of a specified keyword is longer than 32 bits, the first 32 bits of the keyword are the actual keyword value, and other bits are set to 0.
  - A hexadecimal notation string can contain only the keywords whose values are numbers. Other keywords, such as port name, cannot be added to the hexadecimal notation string.
  - If a string is not contained in quotation marks, it is encapsulated in hexadecimal notation. To encapsulate the string in the ASCII format, use a pair of quotation marks to contain the string. For example, the slot ID is 3, and the port number is 4. If the string is in the %slot %port format, the value of the encapsulated string is a hexadecimal number 00030004. If the string is in the "%slot %port" format, the value of the encapsulated string is 3 4.
  - A format string can contain both hexadecimal strings and ASCII strings, for example, %slot %port "%sysname %portname:%svlan.%cvlan."

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

- All Option82 fields configured in the system view or in the same interface view share a length of 1-255 bytes. If their total length exceeds 255 bytes, some Option82 information will be lost.
- There is no limit on the number of Option 82 fields configured on the device. However, a large number of Option 82 fields will occupy a lot of memory and

prolong the device processing time. To ensure device performance, you are advised to configure Option 82 fields based on the service requirements and device memory size.

Example

Configure the default format for the CID in the Option 82 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 circuit-id format default
```

Configure the extended format for the CID and RID in the Option 82 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 format extend
```

Configure the user-defined string for the CID in the Option 82 field and encapsulate the port name, outer VLAN ID, inner VLAN ID, and host name in ASCII format.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 circuit-id format user-defined "%portname:%svlan.%cvlan %sysname"
```

Configure a hexadecimal notation string for the CID of the Option 82 field and encapsulate the CID type (fixed as 0, indicating the hexadecimal notation), length (excluding the lengths of the CID type and the keyword length itself), outer VLAN ID, slot ID (5 bits), subcard ID (3 bits), and port ID (8 bits).

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 circuit-id format user-defined 0 %length %svlan %5slot %3subslot %8port
```

Configure the user-defined string for the RID in the Option 82 field and encapsulate the device MAC address in hexadecimal notation.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 remote-id format user-defined %mac
```

On GE0/0/1, configure the default format for the CID in the Option 82 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 circuit-id format default
```

On GE0/0/1, configure the extended format for the CID and RID in the Option 82 field of DHCP messages from VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 vlan 10 format extend
```

On GE0/0/1, configure a user-defined format for the CID in the Option 82 field and encapsulate the port name, outer VLAN ID, inner VLAN ID, and host name in ASCII format.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 circuit-id format user-defined "%portname:%svlan.
%cvlan %sysname"
```

On GE0/0/1, configure a hexadecimal notation string for the CID of the Option 82 field and encapsulate the CID type (fixed as 0, indicating the hexadecimal notation), length (excluding the lengths of the CID type and the keyword length itself), outer VLAN ID, slot ID (5 bits), subcard ID (3 bits), and port ID (8 bits).

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 circuit-id format user-defined 0 %length %svlan %5slot
%3subslot %8port
```

On GE0/0/1, configure the user-defined format for the RID in the Option 82 field and encapsulate the device MAC address in hexadecimal notation.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 remote-id format user-defined %mac
```

14.8.7 dhcp option82 subscriber-id format

Function

The **dhcp option82 subscriber-id format** command inserts the Sub6 suboption into the DHCP Option 82 field of DHCP messages and configures the format of the Sub6 suboption.

The **undo dhcp option82 subscriber-id format** command cancels the configuration of the Sub6 suboption inserted into the DHCP Option 82 field of DHCP messages.

By default, the Sub6 suboption is not inserted into the DHCP Option 82 field of DHCP messages.

Format

dhcp option82 subscriber-id format { **ascii** *ascii-text* | **hex** *hex-text* }

undo dhcp option82 subscriber-id format

Parameters

Parameter	Description	Value
ascii *ascii-text*	Specifies the ASCII character string in the Sub6 field.	The value is an ASCII character string and contains fewer than 129 characters.
hex *hex-text*	Specifies the HEX character string in the Sub6 field.	The value is in hexadecimal notation. The value can contain only digits 0 to 9, uppercase letters A to F, and lowercase letters a to f. If no space is included, the value length must be an even number smaller than 257.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In an authentication system for wired Ethernet access based on DHCP, DHCP snooping, and Option82, a device can insert suboptions (suboption 1, suboption 2, suboption 6, and suboption 9) into the Option 82 field in DHCP Request messages. These suboptions in DHCP Request messages help locate user devices. Unauthorized users cannot access the network by using static IP addresses or stealing accounts of authorized users. You can run the **dhcp option82 subscriber-id format** command to configure the Sub6 suboption.

Prerequisites

DHCP has been enabled using the **dhcp enable** command.

Example

Configure the Sub6 suboption inserted into the DHCP Option 82 field of DHCP messages on GE0/0/1 and specify the ASCII character string in the Sub6 suboption.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp option82 subscriber-id format ascii hw
```

14.8.8 dhcp option82 vendor-specific format

Function

The **dhcp option82 vendor-specific format** command configures the Sub9 field in the Option 82 field.

The **undo dhcp option82 vendor-specific format** command deletes the configuration of the Sub9 field inserted into the DHCP Option 82 field.

By default, the Sub9 field inserted into the Option 82 field is not configured.

Format

dhcp option82 vendor-specific format vendor-sub-option *sub-option-num* { **ascii** *ascii-text* | **hex** *hex-text* | **ip-address** *ip-address* &<1-8> | **sysname** }

undo dhcp option82 vendor-specific format vendor-sub-option *sub-option-num*

Parameters

Parameter	Description	Value
vendor-sub-option *sub-option-num*	Specifies the vendor-specific suboption in the Sub9 field.	The value is an integer that ranges from 1 to 255.
ascii *ascii-text*	Specifies the ASCII character string in the vendor-specific suboption in the Sub9 field.	The value is an ASCII character string and must be smaller than 129 characters.
hex *hex-text*	Specifies the HEX character string in the vendor-specific suboption in the Sub9 field.	The value is in hexadecimal notation. The value can contain only numerals 0 to 9, lowercase letters a to f, and uppercase letters A to F. If no space is included, the value length must be an even number smaller than 257.
ip-address *ip-address*	Specifies the IP address in the vendor-specific suboption in the Sub9 field.	-
sysname	Specifies the device name in the vendor-specific suboption in the Sub9 field.	-

Views

System view

Usage Guidelines

Usage Scenario

In authentication for wired Ethernet access using DHCP, DHCP snooping, and Option 82, a device can insert suboptions (suboption 1, suboption 2, and suboption 9) to the Option 82 field in DHCP Request messages. These suboptions in DHCP Request messages carry information about user device locations. Unauthorized users cannot access the network by static IP addresses or embezzled accounts of authorized users. The **dhcp option82 vendor-specific format** command configures the suboptions in the Sub9 field.

Prerequisites

DHCP has been enabled using the **dhcp enable** command.

Example

Insert the device name to the vendor-specific suboption 1 in the Sub9 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp option82 vendor-specific format vendor-sub-option 1 sysname
```

14.8.9 dhcp server detect

Function

The **dhcp server detect** command enables DHCP server detection.

The **undo dhcp server detect** command disables DHCP server detection.

By default, DHCP server detection is disabled.

Format

dhcp server detect

undo dhcp server detect

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If bogus DHCP servers exist on the network, they send incorrect information to DHCP clients, such as the incorrect gateway address, incorrect DNS server, and incorrect IP address. As a result, DHCP clients cannot access the network or access incorrect networks.

After DHCP server detection is enabled, a DHCP snooping-capable device checks and logs all the information about DHCP servers in the DHCP Reply messages, such as the addresses and interface numbers of DHCP servers. Based on logs, the network administrator checks for bogus DHCP servers on the network to maintain the network.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

Enable detection of DHCP servers.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp server detect
```

14.8.10 dhcp snooping alarm dhcp-rate enable

Function

The **dhcp snooping alarm dhcp-rate enable** command enables the device to generate an alarm when the number of discarded DHCP messages reaches the threshold.

The **undo dhcp snooping alarm dhcp-rate enable** command disables the device from generating an alarm when the number of discarded DHCP messages reaches the threshold.

By default, the device is disabled from generating an alarm when the number of discarded DHCP messages reaches the threshold.

Format

dhcp snooping alarm dhcp-rate enable [**threshold** *threshold*]

undo dhcp snooping alarm dhcp-rate enable [**threshold**]

Parameters

Parameter	Description	Value
threshold *threshold*	Specifies the alarm threshold. If the number of discarded DHCP messages reaches the threshold, an alarm is generated. For details, see the **dhcp snooping alarm dhcp-rate threshold**.	The value is an integer that ranges from 1 to 1000. The default value is 100.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCP Request messages and Reply messages to the processing unit. If the rate of sending DHCP messages is high, processing efficiency of the processing unit is affected. After the **dhcp snooping check dhcp-rate enable** command is run, the device checks the rate of sending DHCP messages. DHCP messages that are sent in a specified rate are sent to the processing unit and those that exceed the rate are discarded.

If the number of discarded DHCP messages reaches the threshold, an alarm is generated. To set the alarm threshold, run the **dhcp snooping alarm dhcp-rate threshold** command.

If you run the **dhcp snooping alarm dhcp-rate enable** command in the system view, the command takes effect on all the interfaces of the device. If you run the **dhcp snooping alarm dhcp-rate enable** command in the interface view, the command only takes effect on the specified interface.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

In the system view, enable the device to generate an alarm when the number of discarded DHCP messages reaches the threshold.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check dhcp-rate enable
[HUAWEI] dhcp snooping alarm dhcp-rate enable
```

Enable the device to generate an alarm when the number of discarded DHCP messages reaches the threshold on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping check dhcp-rate enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping alarm dhcp-rate enable
```

14.8.11 dhcp snooping alarm dhcpv6-rate enable

Function

The **dhcp snooping alarm dhcpv6-rate enable** command enables a device to generate an alarm when the number of discarded DHCPv6 messages reaches the threshold.

The **undo dhcp snooping alarm dhcpv6-rate enable** command disables a device from generating an alarm when the number of discarded DHCPv6 messages reaches the threshold.

By default, a device is disabled from generating an alarm when the number of discarded DHCPv6 messages reaches the alarm threshold.

Format

dhcp snooping alarm dhcpv6-rate enable

undo dhcp snooping alarm dhcpv6-rate enable

Parameters

None

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCPv6 messages to the processing unit. If the rate of sending DHCPv6 messages is high, processing efficiency of the processing unit is affected. After the device is enabled to check the rate of sending DHCPv6 messages to the processing unit using the **dhcp snooping check dhcpv6-rate enable** command, DHCPv6 messages that are sent in a specified rate are sent to the processing unit and those that exceed the rate are discarded.

If the **dhcp snooping alarm dhcpv6-rate enable** command is run, the device generates an alarm when the number of discarded DHCPv6 messages reaches the threshold. You can configure the alarm threshold using the **dhcp snooping alarm dhcpv6-rate threshold** command.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If the **dhcp snooping alarm dhcpv6-rate enable** command is run in the system view, the configuration takes effect for all the interfaces on the device. If this command is run in the interface view, the configuration takes effect only for the specified interface.

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

In the system view, enable the device to generate an alarm when the number of discarded DHCPv6 messages reaches the alarm threshold.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping alarm dhcpv6-rate enable
```

14.8.12 dhcp snooping alarm dhcp-rate threshold

Function

The **dhcp snooping alarm dhcp-rate threshold** command sets the alarm threshold for the number of discarded DHCP messages.

The **undo dhcp snooping alarm dhcp-rate threshold** command restores the default alarm threshold for the number of discarded DHCP messages.

By default, the global alarm threshold for the number of discarded DHCP messages is 100, and the alarm threshold for the number of discarded DHCP messages on an interface is the same as that configured in the system view.

Format

dhcp snooping alarm dhcp-rate threshold *threshold*

undo dhcp snooping alarm dhcp-rate threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold. If the number of discarded DHCP messages reaches the threshold, an alarm is generated.	The value is an integer that ranges from 1 to 1000. The default value is 100.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **dhcp snooping alarm dhcp-rate enable** command to enable a device to generate an alarm when the number of discarded DHCP messages reaches the threshold, you can set the alarm threshold using the **dhcp snooping alarm dhcp-rate threshold** command. An alarm is generated when the number of discarded DHCP messages reaches the threshold.

If the alarm threshold is set in the system view and interface view, the smaller value takes effect.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

Set the alarm threshold for the number of discarded DHCP messages on GE0/0/1 to 50.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping alarm dhcp-rate threshold 50
```

14.8.13 dhcp snooping alarm dhcpv6-rate threshold

Function

The **dhcp snooping alarm dhcpv6-rate threshold** command sets the alarm threshold for the number of discarded DHCPv6 messages.

The **undo dhcp snooping alarm dhcpv6-rate threshold** command restores the default setting.

By default, the alarm threshold for globally discarded DHCPv6 messages is 100 packets, and the alarm threshold for discarded DHCPv6 messages on an interface is the same as the configured value in the system view.

Format

dhcp snooping alarm dhcpv6-rate threshold *threshold*

undo dhcp snooping alarm dhcpv6-rate threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold. When the number of discarded DHCPv6 messages reaches the threshold, the device generates an alarm.	The value is an integer that ranges from 1 to 1000, in packets.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the device is enabled to generate an alarm when the number of discarded DHCPv6 messages reaches the threshold using the **dhcp snooping alarm dhcpv6-rate enable** command, you can run the **dhcp snooping alarm dhcpv6-rate threshold** *threshold* command to configure the alarm threshold for discarded DHCPv6 messages. The device generates an alarm when the number of discarded DHCPv6 messages reaches the configured alarm threshold.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

- If the **dhcp snooping alarm dhcpv6-rate threshold** command is run in the system view, the configuration takes effect for all the interfaces on the device. If this command is run in the interface view, the configuration takes effect only for the specified interface.
- If an alarm threshold is configured in the system view and interface view simultaneously, the smaller one takes effect.

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

Set the alarm threshold for discarded DHCPv6 messages to 500 packets in the system view.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping alarm dhcpv6-rate threshold 500
```

14.8.14 dhcp snooping alarm enable

Function

The **dhcp snooping alarm enable** command enables the alarm function for DHCP snooping.

The **undo dhcp snooping alarm enable** command disables the alarm function for DHCP snooping.

By default, the alarm function for DHCP snooping is disabled.

Format

dhcp snooping alarm { **dhcp-request** | **dhcp-chaddr** | **dhcp-reply** } **enable** [**threshold** *threshold*]

undo dhcp snooping alarm { **dhcp-request** | **dhcp-chaddr** | **dhcp-reply** } **enable** [**threshold**]

Interface view, port group view, VLAN view

dhcp snooping alarm dhcpv6-request enable

undo dhcp snooping alarm dhcpv6-request enable

Parameters

Parameter	Description	Value
dhcp-request	Generates an alarm when the number of DHCPv4 Request messages discarded because they do not match DHCP snooping binding entries reaches the threshold.	-

Parameter	Description	Value
dhcp-chaddr	Generates an alarm when the number of DHCPv4 Request messages discarded because the CHADDR field in the DHCP message does not match the source MAC address in the Ethernet frame header reaches the threshold.	-
dhcp-reply	Generates an alarm when the number of DHCPv4 Reply messages discarded by untrusted interfaces reaches the threshold.	-
dhcpv6-request	Generates an alarm when the number of DHCPv6 Request messages discarded because they do not match DHCP snooping binding entries reaches the threshold.	-
threshold *threshold*	Specifies an alarm threshold. When the number of discarded DHCPv4 messages reaches the threshold, an alarm is generated.	The value is an integer that ranges from 1 to 1000.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, MultiGE interface view, Eth-Trunk interface view, port group view, bridge domain view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the alarm function is enabled, alarm messages are displayed if DHCP attacks occur and the number of discarded attack messages reaches the threshold. The minimum interval for sending alarms is 1 minute. You can run the **dhcp snooping alarm threshold** command to set the alarm threshold.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

By default, the device does not check the packets received by the client. Therefore:

- Before running the **dhcp snooping alarm** [**dhcp-request** | **dhcpv6-request**] **enable** command, run the **dhcp snooping check dhcp-request enable** command to enable the device to check DHCP messages against the DHCP snooping binding table.

- Before running the **dhcp snooping alarm dhcp-chaddr enable** command, run the **dhcp snooping check dhcp-chaddr enable** command to enable the device to check whether the CHADDR field is the same as the source MAC address in the header of a DHCPv4 Request message.

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

Enable DHCP snooping, dhcp-chaddr check, and the alarm function for packets discarded due to dhcp-chaddr check on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping check dhcp-chaddr enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping alarm dhcp-chaddr enable
```

14.8.15 dhcp snooping alarm threshold

Function

The **dhcp snooping alarm threshold** command sets the alarm threshold for the number of DHCP messages discarded by DHCP snooping.

The **undo dhcp snooping alarm threshold** command restores the default alarm threshold.

By default, an alarm is generated in the system when at least 100 DHCP snooping messages are discarded, and the alarm threshold on an interface is set using the **dhcp snooping alarm threshold** command in the system view.

Format

In the system view:

dhcp snooping alarm threshold *threshold*

undo dhcp snooping alarm threshold

In the interface view, VLAN view and BD view and port group view:

dhcp snooping alarm { **dhcp-request** | **dhcp-chaddr** | **dhcp-reply** } **threshold** *threshold*

undo dhcp snooping alarm { **dhcp-request** | **dhcp-chaddr** | **dhcp-reply** } **threshold**

In the interface view, VLAN view and port group view:

dhcp snooping alarm dhcpv6-request threshold *threshold*

undo dhcp snooping alarm dhcpv6-request threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold for the number of DHCP snooping-discarded messages.	The value is an integer that ranges from 1 to 1000.
dhcp-request	Specifies the alarm threshold for the number of DHCPv4 Request messages discarded because they do not match the DHCP snooping binding entries.	-
dhcp-chaddr	Specifies the alarm threshold for the number of DHCP messages discarded because the CHADDR field in the DHCPv4 request messages does not match the source MAC address in the data frame header.	-
dhcp-reply	Specifies the alarm threshold for the number of DHCPv4 Response messages discarded by untrusted interfaces.	-
dhcpv6-request	Specifies the alarm threshold for the number of DHCPv6 Request messages discarded because they do not match the DHCP snooping binding entries.	-

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After trap for discarded DHCP messages is enabled, run the **dhcp snooping alarm threshold** command to specify the alarm threshold for the number of DHCP messages discarded by DHCP snooping. If the alarm threshold is not set on an interface, the interface uses the global alarm threshold.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

The DHCP snooping alarm function has been enabled using the **dhcp snooping alarm** { **dhcp-request** | **dhcp-chaddr** | **dhcp-reply** | **dhcpv6-request** } **enable** command.

Precautions

If you run the **dhcp snooping alarm threshold** command in the system view, the command takes effect on all the interfaces of the device.

If you specify an alarm threshold for the number of DHCP messages discarded by DHCP snooping in the system view, an alarm is generated when the number of all the discarded DHCP messages reaches the threshold.

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

Set the global alarm threshold for the number of discarded DHCP messages to 200.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping alarm threshold 200
```

On GE0/0/1, enable DHCP snooping, enable the device to check whether the CHADDR field in the DHCP message matches the source MAC address in the Ethernet frame header, and enable alarm for the DHCP messages discarded because the CHADDR field in the DHCP message does not match the source MAC address. Set the alarm threshold to 1000.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping check dhcp-chaddr enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping alarm dhcp-chaddr enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping alarm dhcp-chaddr threshold 1000
```

14.8.16 dhcp snooping check dhcp-giaddr enable

Function

The **dhcp snooping check dhcp-giaddr enable** command enables the device to check whether the GIADDR field in DHCP messages is 0.

The **undo dhcp snooping check dhcp-giaddr enable** command disables the device from checking whether the GIADDR field in DHCP messages is 0.

By default, the device does not check whether the GIADDR field in DHCP messages is 0.

Format

In the system view:

dhcp snooping check dhcp-giaddr enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo dhcp snooping check dhcp-giaddr enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

In the VLAN view and interface view:

dhcp snooping check dhcp-giaddr enable

undo dhcp snooping check dhcp-giaddr enable

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Enables the device to check whether the GIADDR field in DHCP messages sent from a specified VLAN is 0. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*.	The value is an integer that ranges from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure that the device obtains parameters such as MAC addresses for generating a binding table, DHCP snooping needs to be applied to Layer 2 access devices or the first DHCP relay agent from the device. Therefore, the GIADDR field in the DHCP messages received by the DHCP snooping-enabled device is 0. If the GIADDR field is not 0, the message is unauthorized and then discarded. This function is recommended if DHCP snooping is enabled on the DHCP relay agent.

In normal situations, the GIADDR field in DHCP messages sent by user PCs is 0. If the GIADDR field is not 0, the DHCP server cannot correctly allocate IP addresses. To prevent attackers from applying IP addresses with the DHCP messages containing a non-0 GIADDR field, you are advised to configure this function.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcp snooping check dhcp-giaddr enable** command in the VLAN view, the command takes effect on all the DHCP messages from the specified VLAN. If you run the **dhcp snooping check dhcp-giaddr enable** command in the interface view, the command takes effect on all the DHCP messages received by the specified interface.

Example

Enable the device to check whether the GIADDR field in DHCP messages from VLAN10 is 0.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping check dhcp-giaddr enable
```

Enable the device to check whether the GIADDR field in DHCP messages received on GE0/0/1 is 0.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping check dhcp-giaddr enable
```

14.8.17 dhcp snooping check dhcp-rate

Function

The **dhcp snooping check dhcp-rate** command sets the maximum rate of sending DHCP messages to the processing unit.

The **undo dhcp snooping check dhcp-rate** command restores the default maximum rate of sending DHCP messages to the processing unit.

By default, the maximum rate of sending global DHCP messages to the processing unit is 100 pps, which is the same as the maximum rate of sending DHCP messages on interfaces to the processing unit.

Format

In the system view:

dhcp snooping check dhcp-rate *rate* [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo dhcp snooping check dhcp-rate

In the VLAN view and interface view:

dhcp snooping check dhcp-rate *rate*

undo dhcp snooping check dhcp-rate

Parameters

Parameter	Description	Value
rate	Specifies the maximum rate of sending DHCP messages to the processing unit.	The value is an integer that ranges from 1 to 100, in pps.
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Specifies the maximum rate of sending DHCP messages from a specified VLAN to the processing unit. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. If this parameter is not specified, the command takes effect on all the DHCP messages.	The value is an integer that ranges from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCP Request messages and Reply messages to the processing unit. If the rate of sending DHCP messages is high, processing efficiency of the processing unit is affected. After the device is enabled to check the rate of sending DHCP messages to the processing unit, run the **dhcp snooping check dhcp-rate** command to set the maximum rate of sending DHCP messages to the processing unit. DHCP messages that exceed the rate are discarded.

Prerequisites

The device has been enabled to check the rate of sending DHCP messages to the processing unit using the **dhcp snooping check dhcp-rate enable** command.

Precautions

If the maximum rates of sending DHCP messages to the processing unit are set in the system view, VLAN view, and interface view, the smallest value takes effect.

Example

In the system view, set the maximum rate of sending DHCP messages to the processing unit to 50 pps.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check dhcp-rate enable
[HUAWEI] dhcp snooping check dhcp-rate 50
```

14.8.18 dhcp snooping check dhcpv6-rate

Function

The **dhcp snooping check dhcpv6-rate** command sets the maximum rate of sending DHCPv6 messages to the processing unit.

The **undo dhcp snooping check dhcpv6-rate** command restores the default maximum rate of sending DHCPv6 messages to the processing unit.

By default, the maximum rate of DHCPv6 messages sent to the processing unit is 100 pps.

Format

dhcp snooping check dhcpv6-rate *rate*

undo dhcp snooping check dhcpv6-rate

Parameters

Parameter	Description	Value
rate	Specifies the maximum rate of DHCPv6 messages sent to the processing unit.	The value is an integer that ranges from 1 to 400, in pps.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCPv6 messages to the processing unit. If the rate of sending DHCPv6 messages is high, processing efficiency of the processing unit is affected. After the device is enabled to check the rate of sending DHCPv6 messages to the processing unit, DHCPv6 messages that exceed the specified rate are discarded.

Before the maximum rate of DHCP messages sent to the DHCP message processing unit is configured, ensure that the **dhcp snooping check dhcpv6-rate enable** command has been executed to enable the device to check the rate of sending DHCPv6 messages to the processing unit. Otherwise, the configuration does not take effect.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

- If you run the **dhcp snooping check dhcpv6-rate** command in the system view, the configuration takes effect for all the interfaces on the device. If you run this command in the interface view, the configuration takes effect only for the specified interface. If you run this command in the VLAN view, the configuration takes effect for all the interfaces in this VLAN.
- If the maximum rates of sending DHCPv6 messages to the processing unit are set in the system view, VLAN view, and interface view simultaneously, the smallest value takes effect.

Example

In the system view, set the maximum rate of sending DHCPv6 messages to the processing unit to 50 pps.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check dhcpv6-rate 50
```

14.8.19 dhcp snooping check dhcp-rate enable

Function

The **dhcp snooping check dhcp-rate enable** command enables the device to check the rate of sending DHCP messages to the processing unit.

The **undo dhcp snooping check dhcp-rate enable** command disables the device from checking the rate of sending DHCP messages to the processing unit.

By default, the device does not check the rate of sending DHCP messages to the processing unit.

Format

In the system view:

dhcp snooping check dhcp-rate enable [*rate*] [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo dhcp snooping check dhcp-rate enable [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

In the VLAN view and interface view:

dhcp snooping check dhcp-rate enable [*rate*]

undo dhcp snooping check dhcp-rate enable

Parameters

Parameter	Description	Value
rate	Specifies the maximum rate of sending DHCP messages to the processing unit. For the function of *rate*, see the command **dhcp snooping check dhcp-rate**.	The value ranges from 1 to 100, in pps. The default value is 100.
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Enables the device to check the rate of sending DHCP messages from a specified VLAN to the processing unit. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. If this parameter is not specified, the command takes effect on all the DHCP messages.	The value is an integer that ranges from 1 to 4094.

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCP Request messages and Reply messages to the processing unit. If the rate of sending DHCP messages is high, processing efficiency of the processing unit is affected. After the device is enabled to check the rate of sending DHCP messages to the processing unit, DHCP messages that exceed the specified rate are discarded.

The default maximum rate of sending DHCP messages is 100 pps. To set the maximum rate, run the **dhcp snooping check dhcp-rate** command.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

In the system view, enable the device to check the rate of sending DHCP messages to the processing unit.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check dhcp-rate enable
```

In VLAN 10, enable the device to check the rate of sending DHCP messages to the processing unit.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping enable
[HUAWEI-vlan10] dhcp snooping check dhcp-rate enable
```

14.8.20 dhcp snooping check dhcpv6-rate enable

Function

The **dhcp snooping check dhcpv6-rate enable** command enables the device to check the rate of sending DHCPv6 messages to the processing unit.

The **undo dhcp snooping check dhcpv6-rate enable** command disables the device from checking the rate of sending DHCPv6 messages to the processing unit.

By default, the device does not check the rate of DHCPv6 messages sent to the processing unit.

Format

dhcp snooping check dhcpv6-rate enable

undo dhcp snooping check dhcpv6-rate enable

Parameters

None

Views

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the device sends all the received DHCPv6 messages to the processing unit. If the rate of sending DHCPv6 messages is high, processing efficiency of the processing unit is affected. After the device is enabled to check the rate of sending DHCPv6 messages to the processing unit, DHCPv6 messages that exceed the specified rate are discarded.

After the device is enabled to check the rate of sending DHCPv6 messages to the processing unit, the default maximum rate of sending DHCPv6 messages is set to 100 pps. To set the maximum rate, run the **dhcp snooping check dhcpv6-rate** command.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcp snooping check dhcpv6-rate enable** command in the system view, the configuration takes effect for all the interfaces on the device. If you run this command in the interface view, the configuration takes effect only for the specified interface. If you run this command in the VLAN view, the configuration takes effect for all the interfaces in this VLAN.

Example

In the system view, enable the device to check the rate of DHCPv6 messages sent to the processing unit.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check dhcpv6-rate enable
```

14.8.21 dhcp snooping check dhcpv6-request mac

Function

The **dhcp snooping check dhcpv6-request mac** command enables the function of checking the validity of DHCPv6 messages based on MAC addresses.

The **undo dhcp snooping check dhcpv6-request mac** command disables the function of checking the validity of DHCPv6 messages based on MAC addresses.

By default, the function of checking the validity of DHCPv6 messages based on MAC addresses is disabled.

Format

dhcp snooping check dhcpv6-request mac

undo dhcp snooping check dhcpv6-request mac

Parameters

None

Views

System view, VLAN view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After binding entries are generated, the device searches for the binding entries based on the MAC address entry that is used as the key. The device checks whether the Request messages sent by the DHCPv6 client match any binding entry. If they match, the device forwards the messages; otherwise, the device discards the messages. This prevents unauthorized users from sending bogus DHCPv6 messages to extend the IP address lease or release IP addresses.

The rules for checking DHCPv6 Request messages based on binding entries are as follows:

- When receiving a DHCPv6 Request message, the device searches the dynamic binding table based on the user's MAC address. If no corresponding binding entry is found or the binding entry found is a temporary one, the device forwards the message. Otherwise, the device checks whether the VLAN ID, VPN instance, and interface information of the message match the corresponding binding entry. If so, the device forwards the message. If not, the device discards the message.
- When receiving a DHCPv6 Release or Decline message, the device checks whether the VLAN ID, VPN instance, and interface information of the message matches an entry in the dynamic binding table. If a match is found, the device forwards the message. Otherwise, the device discards the message.

Prerequisites

DHCPv6 snooping has been enabled on the device using the **dhcp snooping enable** command.

Follow-up Procedure

Run the **dhcpv6 snooping user-bind mac-conflict detect enable** command to enable DHCPv6 snooping to detect whether a user is online. If a user's DHCPv6 message fails the match check, the device detects whether the user is online. If the user is offline, the device deletes the DHCPv6 snooping entry of the offline user in a timely manner.

Precautions

If you run this command in the VLAN view, the command configuration takes effect only for the DHCPv6 messages from the specified VLAN. If you run this command in the interface view, the command configuration takes effect for all DHCPv6 messages on the specified interface.

This command cannot be used together with **dhcp snooping enable no-user-binding**; otherwise, online users may fail to go offline.

Example

Enable the function of checking the validity of DHCPv6 messages based on MAC addresses in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping check dhcpv6-request mac
```

14.8.22 dhcp snooping check dhcp-chaddr enable

Function

The **dhcp snooping check dhcp-chaddr enable** command enables the device to check whether the CHADDR field matches the source MAC address in the header of DHCP Request messages (DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, DHCP INFORM).

The **undo dhcp snooping check dhcp-chaddr enable** command disables the device from checking whether the CHADDR field matches the source MAC address in the header of

DHCP Request messages (DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, DHCP INFORM).

By default, the device does not check whether the CHADDR field is the same as the source MAC address in the header of DHCP Request messages (DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, DHCP INFORM).

Format

In the system view:

dhcp snooping check dhcp-chaddr enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo dhcp snooping check dhcp-chaddr enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

In the VLAN view, BD view and interface view:

dhcp snooping check dhcp-chaddr enable

undo dhcp snooping check dhcp-chaddr enable

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Enables the device to check whether the CHADDR field matches the source MAC address in the header of a DHCP Request message. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*.	The value is an integer that ranges from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In normal situations, the CHADDR field in DHCP Request messages (DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, DHCP INFORM) matches the MAC address of the DHCP client that sends the message. The DHCP server identifies the client MAC address based on the CHADDR field in the DHCP Request messages (DHCP DISCOVER, DHCP REQUEST, DHCP DECLINE, DHCP RELEASE, DHCP INFORM). If attackers continuously apply for IP addresses by changing the CHADDR field in the DHCP Request message, addresses in the address pool on the DHCP server may be exhausted. As a result, authorized users cannot obtain IP addresses.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcp snooping check dhcp-chaddr enable** command in the VLAN view, the command takes effect on all the DHCP messages in the specified VLAN received by all the interfaces on the device. If you run the **dhcp snooping check dhcp-chaddr enable** command in the interface view, the command takes effect for all the DHCP messages received on the interface.

Example

Enable the device to check whether the CHADDR field in the DHCP message matches the source MAC address on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping check dhcp-chaddr enable
```

14.8.23 dhcp snooping check dhcp-request enable

Function

The **dhcp snooping check dhcp-request enable** command enables the device to check DHCP messages against the DHCP snooping binding table.

The **undo dhcp snooping check dhcp-request enable** command disables the device from checking DHCP messages against the DHCP snooping binding table.

By default, the device does not check DHCP messages against the DHCP snooping binding table.

Format

System view:

dhcp snooping check dhcp-request enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo dhcp snooping check dhcp-request enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

VLAN view, interface view, BD view:

dhcp snooping check dhcp-request enable

undo dhcp snooping check dhcp-request enable

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Enables the device to check DHCP messages from a specified VLAN against the DHCP snooping binding table.	The value is an integer in the range from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a DHCP snooping binding table is generated, the device checks DHCPv4 Request, DHCPv6 Request, or DHCPv4 Release messages against the DHCP snooping binding table. Only DHCP messages that match entries are forwarded, and those that do not match entries are discarded. This prevents unauthorized users from sending bogus DHCP packets to renew or release IP addresses.

The device checks DHCPv4 Request, DHCPv6 Request, or DHCPv4 Release messages against the DHCP snooping binding table based on the following rules:

- For a DHCPv4 Request message:
  a. Checks whether the destination MAC address is all Fs. If so, the device considers the message a broadcast message requesting a lease renewal or a broadcast message a user sends on the first login and directly forwards the message. If not, the device considers the user to have sent the DHCPv4 Request message to renew the IP address lease and checks the message against the DHCP snooping binding table.
  b. Checks whether the CHADDR field in the DHCPv4 Request message matches a DHCP snooping binding entry. If not, the device considers the user to have gone online for the first time and directly forwards the message. If so, the device checks whether the VLAN ID, IP address, and interface number of the message match any DHCP snooping binding entry. If all these fields match a DHCP snooping binding entry, the device forwards the message; otherwise, the device discards the message.
- When receiving a DHCPv4 Release message, the device checks whether the VLAN ID, IP address, MAC address, and interface number of the message match a dynamic DHCP snooping binding entry. If so, the device forwards the message; otherwise, the device discards the message.
- When receiving a DHCPv6 Request message, the device searches the DHCP snooping binding table based on the user's MAC address. If no corresponding binding entry is found or the binding entry found is a temporary one, the device forwards the message. Otherwise, the device considers the message as the one used for requesting a lease renewal and checks whether the VLAN ID, IP address, and interface number of the message match any binding entry. If so, the device forwards the message. If not, the device discards the message.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcp snooping enable** command in the VLAN view, the command takes effect for all the DHCP messages from the specified VLAN. If you run this command in the interface view, the command takes effect for all the DHCP messages received on the specified interface.

After defense against bogus DHCPv6 message attacks is configured using the **dhcp snooping check dhcpv6-request mac** command, the device does not check DHCPv6 messages against the DHCP snooping binding table when the **dhcp snooping check dhcp-request** command is executed.

Example

Enable the device to check DHCP messages against the DHCP snooping binding table in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping enable
[HUAWEI-vlan10] dhcp snooping check dhcp-request enable
```

14.8.24 dhcp snooping check local-reply enable

Function

The **dhcp snooping check local-reply enable** command enables the device to check validity of DHCP reply messages with the CHADDR field being its local MAC address.

The **undo dhcp snooping check local-reply enable** command disables the device from checking validity of DHCP reply messages with the CHADDR field being its local MAC address.

By default, a device does not check validity of DHCP reply messages with the CHADDR field being its local MAC address.

Format

dhcp snooping check local-reply enable

undo dhcp snooping check local-reply enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

There is a possibility that a device, as a DHCP client, obtains an IP address from an untrusted interface even if DHCP snooping is enabled. In this case, IP address validity cannot be ensured. To ensure security, you can enable the device to check validity of the received DHCP reply messages with the CHADDR field being its local MAC address: If the message is received from a trusted interface, the device keeps the message. If the message is received from an untrusted interface, the device discards the message.

Prerequisites

In the system view, run the **dhcp snooping enable** command to enable DHCP snooping.

Example

Enable the device to check whether DHCP reply messages with the CHADDR field being its local MAC address are received from trusted interfaces.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping check local-reply enable
```

14.8.25 dhcp snooping check server-vlan enable

Function

The **dhcp snooping check server-vlan enable** command enables the DHCP snooping-enabled device to check VLAN information in DHCP Reply messages.

The **undo dhcp snooping check server-vlan enable** command disables the DHCP snooping-enabled device from checking VLAN information in DHCP Reply messages.

By default, the DHCP snooping-enabled device does not check VLAN information in DHCP Reply messages.

Format

dhcp snooping check server-vlan enable

undo dhcp snooping check server-vlan enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the DHCP snooping-enabled device identifies devices by checking DHCP reply messages only based on MAC addresses. If devices cannot be identified based on MAC addresses, run the **dhcp snooping check server-vlan enable** command to enable the DHCP snooping-enabled device to identify devices by checking DHCP reply messages based on MAC addresses and VLAN IDs.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

DHCP server detection has been enabled using the **dhcp server detect** command.

Example

Enable the DHCP snooping-enabled device to check VLAN information in DHCP Relay messages.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp server detect
[HUAWEI] dhcp snooping check server-vlan enable
```

14.8.26 dhcp snooping deny enable

Function

The **dhcp snooping deny enable** command enables the function of discarding DHCP messages.

The **undo dhcp snooping deny enable** command disables the function of discarding DHCP messages.

By default, the function of discarding DHCP messages is disabled.

Format

dhcp snooping deny { **dhcp** | **dhcpv6** } **enable**

undo dhcp snooping deny { **dhcp** | **dhcpv6** } **enable**

Parameters

Parameter	Description	Value
dhcp	Indicates that the device processes DHCPv4 messages.	-
dhcpv6	Indicates that the device processes DHCPv6 messages.	-

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling DHCP snooping, you can prevent DHCP messages from being processed by using the **dhcp snooping deny enable** command to discard these messages.

Prerequisites

The **dhcp snooping enable** or **dhcp snooping trusted** command has been run on the specified interface or in the specified VLAN.

Precautions

If you run the **dhcp snooping deny enable** command in the system view, the function of discarding DHCP messages takes effect globally. If you run the **dhcp snooping deny enable** command in the VLAN view, the command takes effect for all DHCP messages in a specified VLAN received by all the interfaces on the device. If you run the **dhcp snooping deny enable** command in the interface view, the command takes effect for all the DHCP messages received on the specified interface.

Example

Enable an interface that has been added to VLAN 10 to discard DHCPv4 messages in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping enable
[HUAWEI-vlan10] dhcp snooping deny dhcp enable
```

14.8.27 dhcp snooping disable

Function

The **dhcp snooping disable** command disables DHCP snooping on an interface.

The **undo dhcp snooping disable** command cancels the configuration.

By default, if the **dhcp snooping enable** command is used on an interface or in a VLAN that an interface belongs to, DHCP snooping is enabled on this interface.

Format

dhcp snooping disable

undo dhcp snooping disable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you run the **dhcp snooping enable** command to enable DHCP snooping in a VLAN, DHCP snooping is enabled on all the interfaces in the VLAN. If you do not run the **dhcp snooping enable** command to enable DHCP snooping on an interface, you cannot run the **undo dhcp snooping enable** command to disable DHCP snooping on the interface. To address this problem, run the **dhcp snooping disable** command to disable DHCP snooping on the interface. Users can properly go online from this interface, but no dynamic binding entry is generated.

Precautions

- The **dhcp snooping disable** command does not only disable DHCP snooping on an interface, but also clears the DHCP snooping configuration and the dynamic binding table. The **undo dhcp snooping enable** command, however, only disables DHCP snooping on the interface and does not clear the configuration or the dynamic binding table.
- The **undo dhcp snooping disable** command enables DHCP snooping on an interface. To enable DHCP snooping, run the **dhcp snooping enable** command.

Example

Disable DHCP snooping on GE0/0/1 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping disable
```

14.8.28 dhcp snooping enable

Function

The **dhcp snooping enable** command enables DHCP snooping.

The **undo dhcp snooping enable** command disables DHCP snooping.

By default, DHCP snooping is disabled on the device.

Format

In the system view:

dhcp snooping enable [**ipv4** | **ipv6** | **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo dhcp snooping enable [**ipv4** | **ipv6** | **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

In the VLAN view, BD view, and interface view:

dhcp snooping enable

undo dhcp snooping enable

Parameters

Parameter	Description	Value
ipv4	Indicates that the device processes only DHCPv4 messages.	-
ipv6	Indicates that the device processes only DHCPv6 messages.	-
vlan { *vlan-id1* [**to** *vlan-id2*] }	Enables DHCP snooping in a specified VLAN. • *vlan-id1* specifies the first VLAN ID. • **to** *vlan-id2* specifies the last VLAN ID. The value of *vlan-id2* must be greater than the value of *vlan-id1*.	The specified VLAN ID must exist.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

NOTE

Only the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S supports the BD view.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

DHCP snooping is a security function to protect DHCP. When you run the **dhcp snooping enable** command to enable DHCP snooping on a device, the device can process both DHCPv4 and DHCPv6 messages. In practice, however, if the DHCP snooping device needs to process only DHCPv4 or DHCPv6 messages, you can run the **dhcp snooping enable ipv4** or **dhcp snooping enable ipv6** command, which improves CPU efficiency.

You must enable DHCP snooping in the system view before enabling DHCP snooping on an interface, in a BD, or in a VLAN.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Follow-up Procedure

After DHCP snooping is enabled on an interface connected to users, in a BD, or in a VLAN, run the **dhcp snooping trusted** command to configure the interface connected to the DHCP server as a trusted interface. Then a DHCP snooping binding table can be generated.

Precautions

The **dhcp snooping enable** command in the system view is the prerequisite for DHCP snooping-related functions. After the **undo dhcp snooping enable** command is run, all DHCP snooping-related configurations of the device are deleted. After DHCP snooping is enabled again using the **dhcp snooping enable** command, all DHCP snooping-related configurations of the device are restored to the default configurations.

If you run the **dhcp snooping enable** command in the VLAN view, the command takes effect for all the DHCP messages from the specified VLAN. If you run this command in the interface view, the command takes effect for all the DHCP messages received on the specified interface.

If both DHCP relay and VRRP are configured on a device, DHCP snooping cannot be enabled.

If the DHCP server is at the subordinate VLAN side and the DHCP client is at the principal VLAN side, DHCP snooping cannot be enabled.

If DHCP snooping is enabled on the device, do not configure 2:2 VLAN mapping. Otherwise, DHCP users cannot go online.

Example

Enable DHCP snooping globally and configure the device to process only IPv4 messages.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable ipv4
```

Enable DHCP snooping on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
```

Enable DHCP snooping in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp snooping enable
```

Enable DHCP snooping in VLANs ranging from VLAN 20 to VLAN 25 in a batch.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan batch 20 to 25
[HUAWEI] dhcp snooping enable vlan 20 to 25
```

14.8.29 dhcp snooping enable no-user-binding

Function

The **dhcp snooping enable no-user-binding** command disables the interfaces from generating DHCP snooping binding entries after DHCP snooping is enabled.

The **undo dhcp snooping enable no-user-binding** command restores the default setting.

By default, an interface generates DHCP snooping binding entries after DHCP snooping is enabled.

Format

System view:

dhcp snooping enable no-user-binding vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo dhcp snooping enable no-user-binding vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

VLAN view and interface view:

dhcp snooping enable no-user-binding

undo dhcp snooping enable no-user-binding

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] }	Disables the interfaces in the specified VLANs from generating DHCP snooping binding entries. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. The value of *vlan-id2* must be greater than the value of *vlan-id1*.	The value is an integer in the range from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled on a device, the device generates DHCP snooping binding entries for users by default. If the number of binding entries on the device reaches the upper limit, new users cannot go online. In certain scenarios, for example, on a trusted DHCP network, if you do not want to limit the number of online users but want to record user location information, run the **dhcp snooping enable no-user-binding** command to disable the device from generating DHCP snooping binding entries.

When the command is executed in an interface view, the command takes effect for all DHCP users connected to the interface. When the command is executed in the VLAN view, the command takes effect for all the DHCP users belonging to this VLAN on all interfaces. When the command is executed in the system view, the command takes effect in the same way as it is executed in the VLAN view, except that multiple VLANs can be specified.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

After this command is executed, the device deletes the binding entries from the corresponding VLAN or interface.

If the DHCP snooping binding entry-dependent function such as IPSG or DAI is configured on the device, the corresponding function does not take effect after this command is run.

This command cannot be used together with **dhcp snooping check dhcp-request enable** and **dhcp snooping check dhcpv6-request mac**. Otherwise, online users may fail to go offline.

Example

In the system view, disable the interfaces in VLAN 10 and VLAN 20 from generating DHCP snooping binding entries.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping enable vlan 10 20
[HUAWEI] dhcp snooping enable no-user-binding vlan 10 20
```

In the VLAN view, disable the interfaces in VLAN 10 from generating DHCP snooping binding entries.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcp snooping enable
[HUAWEI-vlan10] dhcp snooping enable no-user-binding
```

In the interface view, disable GE0/0/1 from generating DHCP snooping binding entries.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable no-user-binding
```

14.8.30 dhcp snooping max-user-number

Function

The **dhcp snooping max-user-number** command sets the maximum number of DHCP snooping binding entries to be learned on an interface.

The **undo dhcp snooping max-user-number** command restores the default maximum number of DHCP snooping binding entries to be learned on an interface.

By default, the maximum number of DHCP snooping binding entries that can be learned on an interface is 512 for S1720GW-E, S1720GWR-E, and 2048 for S5720-LI, S2730S-S, S5735-L1, S300, S5735-L, S5735-L-I, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, , S5735S-H, S5736-S, S6720S-S, and S5720I-SI, and 8192 for other models.

NOTE

The maximum number of DHCP snooping binding entries configured using this command is the sum of DHCPv4 snooping and DHCPv6 snooping binding entries.

Format

In the system view:

dhcp snooping max-user-number *max-user-number* [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo dhcp snooping max-user-number [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

In the VLAN view and interface view:

dhcp snooping max-user-number *max-user-number*

undo dhcp snooping max-user-number

Parameters

Parameter	Description	Value
max-user-number	Specifies the maximum number of DHCP snooping binding entries that can be learned on an interface.	The value is an integer that ranges from 1 to 512 for S1720GW-E, S1720GWR-E, and from 1 to 2048 for S5720-LI, S2730S-S, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, , S5735S-H, S5736-S, S6720S-S, and S5720I-SI, and from 1 to 8192 for other models.

Parameter	Description	Value
		NOTE If the maximum number of DHCP snooping binding entries to be learned by interfaces is N in the system or VLAN view, for a stack, the value in system view and VLAN view ranges from 1 to N * Number of stacked devices. That is, by default, a maximum of N * Number of stacked devices DHCP users are allowed to access the entire device or VLAN. For S5720-LI, S2730S-S, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5720I-SI, S5735S-H, S5736-S, S5731-H, S5731S-H, S5731-S, S5731S-S, S6720-EI, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S, S6735-S, S6720S-EI: A stack of these switches can learn a maximum of 9216 DHCP snooping binding entries. For example, a stack of two S5731-H switches can learn a maximum of 8192 DHCP snooping binding entries globally and in VLANs by default. When three of these switches set up a stack, the stack can learn a maximum of 9216 DHCP snooping binding entries globally and in VLANs by default.
vlan { *vlan-id1* [**to** *vlan-id2*] }	Specifies the maximum number of DHCP snooping binding entries can be learned in a VLAN. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*.	The value is an integer that ranges from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp snooping max-user-number** command sets the maximum number of DHCP snooping binding entries to be learned on an interface. If the number of DHCP snooping binding entries reaches the maximum value, subsequent users cannot access.

When the command is executed in the system view, the value specified in this command is the total number of DHCP snooping binding entries to be learned by all interfaces on the device. If you run the **dhcp snooping max-user-number** command in the VLAN view, the command takes effect on all the interfaces in the VLAN. If you run the **dhcp snooping max-user-number** command in the system view, VLAN view and the interface view, the smallest value takes effect.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

The maximum number of DHCP snooping binding entries to be learned in a stack environment will still be valid if the stack is split. For example, the maximum number of DHCP snooping binding entries to be learned by interfaces is set to N in the system or VLAN view. After the stack splits, run the **display dhcp snooping** command. You will find that the maximum number of entries learned by interfaces in the system or VLAN view is still N (even if N is greater than the maximum number (M) of entries supported by a stand-along device). Pay attention to the following points:

- For the users requiring to go online: The users are allowed to go online when the number of binding entries on the device is smaller than M, and not allowed to go online when the number of binding entries on the device is equivalent to or larger than M.
- For online users: The users are kept online no matter whether the number of binding entries on the device is larger than M. However, if the number of binding entries is larger than M, the users cannot go online again after they go offline.
- Binding entries that have been backed up: After the device restarts, all binding entries on the device can be restored no matter whether the number of binding entries is smaller than M, and the users matching these binding entries can go online.

Example

Set the maximum number of DHCP users to 100 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping max-user-number 100
```

Set the maximum number of DHCP users in VLAN 100 to 100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp snooping enable
[HUAWEI-vlan100] dhcp snooping max-user-number 100
```

14.8.31 dhcp snooping over-vpls enable

Function

The **dhcp snooping over-vpls enable** command enables DHCP snooping on the device on a Virtual Private LAN Service (VPLS) network.

The **undo dhcp snooping over-vpls enable** command disables DHCP snooping on the device on a VPLS network.

By default, DHCP snooping is disabled on the device on a VPLS network.

NOTE

Only the S6730-H, S6730S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S5731S-H, and S5731-H support this command.

Format

dhcp snooping over-vpls enable

undo dhcp snooping over-vpls enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DHCP packets on a VPLS network are different from common DHCP packets. Therefore, DHCP snooping cannot take effect for the device on the VPLS network even if the function is enabled globally using the **dhcp snooping enable** command in the system view. To make DHCP snooping take effect for the device applied to the VPLS network, run the **dhcp snooping over-vpls enable** command to enable the function.

To enable DHCP snooping for the device on the VPLS network, enable it on the device closed to the user side so that the DHCP packets from the user side to the VPLS network can be controlled.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

Precautions

The device management interfaces do not support DHCP snooping on a VPLS network.

When the device is applied to a VPLS network, you only need to run the **dhcp snooping over-vpls enable** command to enable DHCP snooping on the device and other DHCP snooping command have no changes.

Example

Enable DHCP snooping on the device on a VPLS network.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping over-vpls enable
```

14.8.32 dhcp snooping packet-flow log enable

Function

The **dhcp snooping packet-flow log enable** command enables the function of recording logs when DHCP messages are exchanged.

The **undo dhcp snooping packet-flow log enable** command disables the function of recoding logs when DHCP messages are exchanged.

By default, the function of recording logs when DHCP messages are exchanged is disabled.

NOTE

Only the following switch models support this command:

Format

dhcp snooping packet-flow log enable

undo dhcp snooping packet-flow log enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of recording logs when DHCP messages are exchanged is enabled using the **dhcp snooping packet-flow log enable** command, the device records a **DHCP/6/SNP_RCV_MSG** log each time it receives a DHCP message. This log can be used in smart O&M and other scenarios. The network analyzer can perform smart analysis on whether the user obtains an IP address through this log.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

Enable the function of recording logs when DHCP messages are exchanged.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping packet-flow log enable
```

14.8.33 dhcp snooping trusted

Function

The **dhcp snooping trusted** command configures an interface as a trusted interface.

The **undo dhcp snooping trusted** command configures an interface as an untrusted interface.

By default, all interfaces are untrusted interfaces.

Format

In the VLAN view:

dhcp snooping trusted interface *interface-type interface-number*

undo dhcp snooping trusted interface *interface-type interface-number*

In the interface view and BD view:

dhcp snooping trusted

undo dhcp snooping trusted

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface in a VLAN. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable DHCP clients to obtain IP addresses from authorized DHCP servers, DHCP snooping supports the trusted interface and untrusted interfaces. The trusted interface forwards DHCP messages while untrusted interfaces discard received DHCP ACK messages and DHCP Offer messages.

An interface directly or indirectly connected to the DHCP server trusted by the administrator needs to be configured as the trusted interface, and other interfaces are configured as untrusted interfaces. This ensures that DHCP clients obtain IP addresses from authorized DHCP servers.

Prerequisites

In the system view, run the **dhcp snooping enable** command to enable DHCP snooping.

Precautions

If an interface has been configured as a DHCP trusted interface using the **dhcp snooping trusted** command, the device will not consider DHCP packets received by this interface as attack packets or perform attack defense operations on the DHCP packets received by this interface.

If you run the **dhcp snooping trusted** command in the VLAN view, the command takes effect for all the DHCP messages received from the specified VLAN. If you run the **dhcp snooping trusted** command in the interface view, the command takes effect for all the DHCP messages received on the specified interface.

You are advised not to configured more than 15 trusted ports in a VLAN.

After an interface on which the **dhcp snooping trusted** command is run receives a DHCP Request message, it forwards the message to all other trusted interfaces. If there are no other trusted interfaces, it discards the message.

Example

Configure GE0/0/1 in VLAN 100 as the trusted interface.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable

14.8.34 dhcp snooping user-alarm percentage

Function

The **dhcp snooping user-alarm percentage** command configures the alarm thresholds for the percentage of DHCP snooping binding entries.

The **undo dhcp snooping user-alarm percentage** command restores the default alarm thresholds for the percentage of DHCP snooping binding entries.

By default, the lower and upper alarm thresholds for the percentage of DHCP snooping binding entries are 50 and 100, respectively.

Format

dhcp snooping user-alarm percentage *percent-lower-value percent-upper-value*

undo dhcp snooping user-alarm percentage

Parameters

Parameter	Description	Value
percent-lower-value	Specifies the lower alarm threshold for the percentage of DHCP snooping binding entries.	The value is an integer in the range from 1 to 100.
percent-upper-value	Specifies the upper alarm threshold for the percentage of DHCP snooping binding entries.	The value is an integer that ranges from 1 to 100, but must be greater than or equal to the lower alarm threshold.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After you run the **dhcp snooping max-user-number** command to set the maximum number of DHCP snooping binding entries on an interface, you can run the **dhcp snooping user-alarm percentage** command to set the alarm thresholds for the percentage of DHCP snooping binding entries.

When the percentage of learned DHCP snooping binding entries against the maximum number of DHCP snooping entries allowed by the device reaches or exceeds the upper alarm threshold, the device generates an alarm. When the percentage of learned DHCP snooping binding entries against the maximum number of DHCP snooping entries allowed by the device reaches or falls below the lower alarm threshold later, the device generates a clear alarm.

Example

Set the lower alarm threshold for the DHCP user count percentage to 30 and the upper alarm threshold to 80.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping user-alarm percentage 30 80
```

14.8.35 dhcp snooping user-bind autosave

Function

The **dhcp snooping user-bind autosave** command enables local automatic backup of the DHCP snooping binding table.

The **undo dhcp snooping user-bind autosave** command disables local automatic backup of the DHCP snooping binding table.

By default, local automatic backup of the DHCP snooping binding table is disabled.

Format

dhcp snooping user-bind autosave *file-name* [**write-delay** *delay-time*]

undo dhcp snooping user-bind autosave

Parameters

Parameter	Description	Value
file-name	Specifies the path for storing the file that backs up the binding table and the file name. The file path and name supported by the device must be both entered.	The value is a string of 1 to 51 case-insensitive characters without spaces.
write-delay *delay-time*	Specifies the interval for local automatic backup of the DHCP snooping binding table. If this parameter is not specified, the backup interval is the default value.	The value is an integer that ranges from 60 to 4294967295, in seconds. By default, the interval for local automatic backup of the DHCP snooping binding table is 86400 seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp snooping user-bind autosave** command can retain the configured DHCP snooping binding entries after the device restarts. After a DHCP snooping binding table is generated, you can run the **dhcp snooping user-bind autosave** command to enable local automatic backup of the DHCP snooping binding table.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

This prevents data loss in the DHCP snooping binding table. The suffix of the file must be .tbl.

If the system restarts within one day after the system time is changed, immediately run the **dhcp snooping user-bind autosave** command again to back up the latest dynamic binding entries because it is not the time to update the binding table. If you do not run this command, the lease will be inconsistent with the current system time after the dynamic binding table is restored.

If a device where the DHCP snooping binding table is backed up is powered off and then restarted after the lease of DHCP snooping binding table expires, the DHCP snooping entries cannot be restored.

After this function is enabled, if the interface goes down, the DHCP snooping binding table on the interface will be deleted from the backup binding table file.

Example

Configure the device to back up the DHCP snooping binding table to the file **backup.tbl** in the flash every 5000 seconds.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind autosave flash:/backup.tbl write-delay 5000
```

14.8.36 dhcp snooping user-bind cache enable

Function

The **dhcp snooping user-bind cache enable** command enables the device to cache DHCPv4 and DHCPv6 binding entries.

The **undo dhcp snooping user-bind cache enable** command disables the device from caching DHCPv4 and DHCPv6 binding entries.

By default, the function of caching DHCP snooping binding entries is disabled.

Format

dhcp snooping user-bind cache enable

undo dhcp snooping user-bind cache enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device generates DHCP snooping binding entries for DHCP users. To prevent such entries from being lost immediately after the user interface is removed from the VLAN, run the **dhcp snooping user-bind cache enable** command to enable the device to cache the DHCP snooping binding entries.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

Enable the function of caching DHCPv4 and DHCPv6 binding entries.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind cache enable
```

14.8.37 dhcp snooping user-bind ftp

Function

The **dhcp snooping user-bind ftp** command enables the device to automatically back up DHCP snooping binding entries on the remote FTP server.

The **undo dhcp snooping user-bind ftp** command disables the device from automatically backing up DHCP snooping binding entries on the remote FTP server.

By default, the device is not enabled to automatically back up DHCP snooping binding entries on the remote FTP server.

Format

dhcp snooping user-bind ftp remotefilename *filename* **host-ip** *ip-address* [**port** *port-number*] **username** *username* **password** *password* [**write-delay** *delay-time*]

undo dhcp snooping user-bind ftp

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file where DHCP snooping binding entries will be backed up on the remote FTP server.	The value is a string of 1 to 64 case-sensitive characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the remote FTP server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the FTP server.	The value is an integer that ranges from 1 to 65535. By default, the port number is 21.
username *username*	Specifies the user name to connect to the FTP server.	The value is a string of 1 to 64 case-sensitive characters without spaces.

Parameter	Description	Value
password *password*	Specifies the password to connect to the FTP server.	The value is a string of case-sensitive characters without spaces. It can be a cipher-text password of 48 characters or a plain-text password of 1 to 16 characters. **NOTE** To improve security, it is recommended that the password contains at least two types of lower-case letters, upper-case letters, numerals, and special characters, and contains at least 8 characters.
write-delay *delay-time*	Specifies the interval for automatically backing up DHCP snooping binding entries. If this parameter is not used, the default interval is used.	The value is an integer that ranges from 300 to 4294967295, in seconds. By default, the system backs up DHCP snooping binding entries every two days.

2: Configuration level

Usage Guidelines

Usage Scenario

When the device restarts, to prevent loss of generated DHCP snooping binding entries on the device, run the **dhcp snooping user-bind ftp** command to enable the device to automatically back up DHCP snooping binding entries on the remote FTP server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The FTP protocol will bring risk to device security. The SFTP protocol configured using the **dhcp snooping user-bind sftp** command is recommended.

Example

Enable the device to automatically back up DHCP snooping binding entries to the **backup** file on the FTP server at 10.137.12.10 with the FTP user name **test** and password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind ftp remotefilename backup host-ip 10.137.12.10 username test
password YsHsjx_202206
```

14.8.38 dhcp snooping user-bind ftp load

Function

The **dhcp snooping user-bind ftp load** command configures the device to obtain and restore backup DHCP snooping binding entries on the remote FTP server.

Format

dhcp snooping user-bind ftp load remotefilename *filename* **host-ip** *ip-address* [**port** *port-number*] **username** *username* **password** *password*

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file from which the device obtains DHCP snooping binding entries.	The value is a string of 1 to 64 characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the remote FTP server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the FTP server.	The value is an integer that ranges from 1 to 65535. By default, the port number is 21.
username *username*	Specifies the user name to connect to the FTP server.	The value is a string of 1 to 64 characters without spaces.

Parameter	Description	Value
password *password*	Specifies the password to connect to the FTP server.	The value is a string of characters without spaces. It can be a cipher-text password of 48 characters or a plain-text password of 1 to 16 characters. **NOTE** To improve security, it is recommended that the password contains at least two types of lower-case letters, upper-case letters, numerals, and special characters, and contains at least 8 characters.

Parse failures             :     0
```

Table 14-63 Description of the **dhcp snooping user-bind ftp load** command output

Item	Description
Total number of dynamic binding table in remote file	Number of DHCP snooping binding entries stored on the remote server.
m successful, *n* failed	*m* DHCP snooping binding entries are recovered successfully, and *n* DHCP snooping binding entries fail to be recovered.
Binding Collisions	Number of DHCP snooping binding entries that cannot be restored because of collision between local entries and remote entries.
Exceeds max limits	Number of DHCP snooping binding entries that cannot be restored because the number of local entries reaches the upper limit.
Invalid interfaces	Number of DHCP snooping binding entries that cannot be restored because the local interface becomes invalid, for example, Down.
Invalid vlans	Number of DHCP snooping binding entries that cannot be restored because the VLAN on local device becomes invalid, for example, unavailable VLAN.
Invalid snp configurations	Number of DHCP snooping binding entries that cannot be restored because the DHCP snooping function is not enabled.
Expired leases	Number of DHCP snooping binding entries that cannot be restored because the lease of DHCP snooping binding table expires.
Parse failures	Number of DHCP snooping binding entries that cannot be restored because the device fails to parse the binding table file.

14.8.39 dhcp snooping user-bind http https

Function

The **dhcp snooping user-bind http https** command enables the device to automatically back up DHCP snooping binding entries on the remote HTTP or HTTPS server.

The **undo dhcp snooping user-bind http https** command disables the device from automatically backing up DHCP snooping binding entries on the remote HTTP or HTTPS server.

By default, the device is not enabled to automatically back up DHCP snooping binding entries on the remote HTTP or HTTPS server.

Format

dhcp snooping user-bind http { **remotefilename** *filename* **host-ip** *ip-address* [**port** *port-number*] | **url** *url-string* } [**username** *username* **password** *password*] [**write-delay** *delay-time*]

dhcp snooping user-bind https ssl-policy *ssl-policy-name* { **remotefilename** *filename* **host-ip** *ip-address* [**port** *port-number*] | **url** *url-string* } [**username** *username* **password** *password*] [**write-delay** *delay-time*]

undo dhcp snooping user-bind { **http** | **https** }

Parameters

Parameter	Description	Value
ssl-policy *ssl-policy-name*	Specifies the name of the SSL policy used by the HTTPS protocol.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).
remotefilename *filename*	Specifies the name of the file where DHCP snooping binding entries will be backed up on the HTTP or HTTPS server.	The value is a string of 1 to 64 case-sensitive characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the HTTP or HTTPS server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the HTTP or HTTPS server.	The value is an integer that ranges from 1 to 65535.

Parameter	Description	Value
url *url-string*	Specifies the URL of the HTTP or HTTPS server, in the format http://*server_location*/*file_location*, for example, http://10.1.1.1:70/32768snp.txt.	The value is a string of 1 to 200 case-sensitive characters without spaces.
username *username*	Specifies the user name to connect to the HTTP or HTTPS server.	The value is a string of 1 to 64 case-sensitive characters without spaces.
password *password*	Specifies the password to connect to the HTTP or HTTPS server.	The value is a string of case-sensitive characters without spaces. It can be a ciphertext password of 48 characters or a plaintext password of 1 to 16 characters. **NOTE** For security purposes, it is recommended that the password contains at least two types of lowercase letters, uppercase letters, numerals, and special characters, and contains at least 8 characters.
write-delay *delay-time*	Specifies the interval for automatically backing up DHCP snooping binding entries. If this parameter is not used, the default interval is used.	The value is an integer that ranges from 300 to 4294967295, in seconds. By default, the system backs up DHCP snooping binding entries every two days.

Usage Guidelines

Usage Scenario

When the device restarts, to prevent loss of generated DHCP snooping binding entries on the device, run the **dhcp snooping user-bind http https** command to enable the device to automatically back up DHCP snooping binding entries on the remote HTTP or HTTPS server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The HTTP protocol will bring risk to device security. The HTTPS protocol is recommended for file operations.

Example

Configure the device to automatically back up DHCP snooping binding entries to the **backup** file on the HTTP server at 10.1.1.1 with the HTTP user name **test** and password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind http remotefilename backup host-ip 10.1.1.1 username test
password YsHsjx_202206
```

Configure the device to back up DHCP snooping binding entries to the HTTPS server at 10.1.1.1 and specify the SSL policy name as **s1**, backup file name as **backup**, HTTPS user name as **test**, and HTTPS password as **test@123**.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind https ssl-policy s1 remotefilename backup host-ip 10.1.1.1
username test password test@123
```

14.8.40 dhcp snooping user-bind http https load

Function

The **dhcp snooping user-bind http https load** command configures the device to obtain and restore backup DHCP snooping binding entries on the remote HTTP or HTTPS server.

Format

dhcp snooping user-bind http load { **remotefilename** *filename* **host-ip** *ip-address* [**port** *port-number*] | **url** *url-string* } [**username** *username* **password** *password*]

dhcp snooping user-bind https ssl-policy *ssl-policy-name* **load** { **remotefilename** *filename* **host-ip** *ip-address* [**port** *port-number*] | **url** *url-string* } [**username** *username* **password** *password*]

Parameters

Parameter	Description	Value
ssl-policy *ssl-policy-name*	Specifies the name of the SSL policy used by the HTTPS protocol.	The value is a string of 1 to 23 case-insensitive characters without spaces. The value can contain digits, letters, and underscores (_).
remotefilename *filename*	Specifies the name of the file from which the device obtains DHCP snooping binding entries.	The value is a string of 1 to 64 characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the HTTP or HTTPS server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the HTTP or HTTPS server.	The value is an integer that ranges from 1 to 65535.
url *url-string*	Specifies the URL of the HTTP or HTTPS server, in the format http://*server_location*/*file_location*, for example, http://10.1.1.1:70/32768snp.txt.	The value is a string of 1 to 200 case-sensitive characters without spaces.
username *username*	Specifies the user name to connect to the HTTP or HTTPS server.	The value is a string of 1 to 64 characters without spaces.
password *password*	Specifies the password to connect to the HTTP or HTTPS server.	The value is a string of characters without spaces. It can be a ciphertext password of 48 characters or a plaintext password of 1 to 16 characters. **NOTE** For security purposes, it is recommended that the password contains at least two types of lowercase letters, uppercase letters, numerals, and special characters, and contains at least 8 characters.

 Snooping not enable   :     0     Lease expired         :     0
 Parse failures        :     0
```

Table 14-64 Description of the **dhcp snooping user-bind http https load** command output

Item	Description
Total number of dynamic binding table in remote file	Number of DHCP snooping binding entries stored on the remote server.
m successful, *n* failed	*m* DHCP snooping binding entries are recovered successfully, and *n* DHCP snooping binding entries fail to be recovered.
Binding Collisions	Number of DHCP snooping binding entries that cannot be restored because of collision between local entries and remote entries.
Exceeds max limit	Number of DHCP snooping binding entries that cannot be restored because the number of local entries reaches the upper limit.
Invalid interfaces	Number of DHCP snooping binding entries that cannot be restored because the local interface becomes invalid, for example, Down.
Invalid vlan	Number of DHCP snooping binding entries that cannot be restored because the VLAN on local device becomes invalid, for example, unavailable VLAN.
Snooping not enable	Number of DHCP snooping binding entries that cannot be restored because the DHCP snooping function is not enabled.
Lease expired	Number of DHCP snooping binding entries that cannot be restored because the lease of DHCP snooping binding table expires.
Parse failures	Number of DHCP snooping binding entries that cannot be restored because the device fails to parse the binding table file.

14.8.41 dhcp snooping user-bind sftp

Function

The **dhcp snooping user-bind sftp** command enables the device to automatically back up DHCP snooping binding entries on the remote SFTP server.

The **undo dhcp snooping user-bind sftp** command disables the device from automatically backing up DHCP snooping binding entries on the remote SFTP server.

By default, the device is not enabled to automatically back up DHCP snooping binding entries on the remote SFTP server.

Format

dhcp snooping user-bind sftp remotefilename *filename* **host-ip** *ip-address* [**port** *port-number*] **username** *username* **password** *password* [**write-delay** *delay-time*]

undo dhcp snooping user-bind sftp

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file where DHCP snooping binding entries will be backed up on the remote SFTP server.	The value is a string of 1 to 64 characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the remote SFTP server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the SFTP server.	The value is an integer that ranges from 1 to 65535. By default, the port number is 22.
username *username*	Specifies the user name to connect to the SFTP server.	The value is a string of 1 to 64 case-sensitive characters without spaces.

Parameter	Description	Value
password *password*	Specifies the password to connect to the SFTP server.	The value is a string of case-sensitive characters without spaces. It can be a cipher-text password of 48 characters or a plain-text password of 1 to 16 characters. **NOTE** To improve security, it is recommended that the password contains at least two types of lower-case letters, upper-case letters, numerals, and special characters, and contains at least 8 characters.
write-delay *delay-time*	Specifies the interval for automatically backing up DHCP snooping binding entries. If this parameter is not used, the default interval is used.	The value is an integer that ranges from 300 to 4294967295, in seconds. By default, the system backs up DHCP snooping binding entries every two days.

When the device restarts, to prevent loss of generated DHCP snooping binding entries on the device, run the **dhcp snooping user-bind sftp** command to enable the device to automatically back up DHCP snooping binding entries on the remote SFTP server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The suffix of the file must be .tbl.

Example

Enable the device to automatically back up DHCP snooping binding entries to the **backup** file on the SFTP server at 10.137.12.10 with the SFTP user name **test** and password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind sftp remotefilename backup host-ip 10.137.12.10 username test
password YsHsjx_202206
```

14.8.42 dhcp snooping user-bind sftp load

Function

The **dhcp snooping user-bind sftp load** command configures the device to obtain and restore backup DHCP snooping binding entries on the remote SFTP server.

Format

dhcp snooping user-bind sftp load remotefilename *filename* **host-ip** *ip-address* [**port** *port-number*] **username** *username* **password** *password*

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file from which the device obtains DHCP snooping binding entries.	The value is a string of 1 to 64 characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the remote SFTP server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the SFTP server.	The value is an integer that ranges from 1 to 65535. By default, the port number is 22.
username *username*	Specifies the user name to connect to the SFTP server.	The value is a string of 1 to 64 characters without spaces.
password *password*	Specifies the password to connect to the SFTP server.	The value is a string of characters without spaces. It can be a cipher-text password of 48 characters or a plain-text password of 1 to 16 characters. **NOTE** To improve security, it is recommended that the password contains at least two types of lower-case letters, upper-case letters, numerals, and special characters, and contains at least 8 characters.

Usage Scenario

After running the **dhcp snooping user-bind sftp** command to enable the device to automatically back up DHCP snooping binding entries on the remote SFTP server, you can run the **dhcp snooping user-bind sftp load** command to configure the device to obtain and restore backup DHCP snooping binding entries on the remote SFTP server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Example

Configure the device to obtain and restore backup DHCP snooping binding entries from the **backup** file on the remote SFTP server at 10.137.12.10 with the SFTP user name **test** and password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind sftp load remotefilename backup host-ip 10.137.12.10 username
test password YsHsjx_202206
Info: Downloading the file from the remote SFTP server. Please wait...done.
 Total number of dynamic binding table in remote file: 30
 Recovering dynamic binding table, please wait for a moment....
 10 successful, 20 failed.
 Binding Collisions         :   20    Exceeds max limits    :    0
 Invalid interfaces         :    0    Invalid vlans         :    0
 Invalid snp configurations :    0    Expired leases        :    0
 Parse failures             :    0
```

Table 14-65 Description of the **dhcp snooping user-bind sftp load** command output

Item	Description
Total number of dynamic binding table in remote file	Number of DHCP snooping binding entries stored on the remote server.
m successful, *n* failed	*m* DHCP snooping binding entries are recovered successfully, and *n* DHCP snooping binding entries fail to be recovered.
Binding Collisions	Number of DHCP snooping binding entries that cannot be restored because of collision between local entries and remote entries.

Item	Description
Exceeds max limits	Number of DHCP snooping binding entries that cannot be restored because the number of local entries reaches the upper limit.
Invalid interfaces	Number of DHCP snooping binding entries that cannot be restored because the local interface becomes invalid, for example, Down.
Invalid vlans	Number of DHCP snooping binding entries that cannot be restored because the VLAN on local device becomes invalid, for example, unavailable VLAN.
Invalid snp configurations	Number of DHCP snooping binding entries that cannot be restored because the DHCP snooping function is not enabled.
Expired leases	Number of DHCP snooping binding entries that cannot be restored because the lease of DHCP snooping binding table expires.
Parse failures	Number of DHCP snooping binding entries that cannot be restored because the device fails to parse the binding table file.

14.8.43 dhcp snooping user-bind tftp

Function

The **dhcp snooping user-bind tftp** command enables the device to automatically back up DHCP snooping binding entries on the remote TFTP server.

The **undo dhcp snooping user-bind tftp** command disables the device from automatically backing up DHCP snooping binding entries on the remote TFTP server.

By default, the device is not enabled to automatically back up DHCP snooping binding entries on the remote TFTP server.

Format

dhcp snooping user-bind tftp remotefilename *filename* **host-ip** *ip-address* [**write-delay** *delay-time*]

undo dhcp snooping user-bind tftp

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file where DHCP snooping binding entries will be backed up on the remote TFTP server.	The value is a string of 1 to 64 case-sensitive characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the TFTP server.	The value is in dotted decimal notation.
write-delay *delay-time*	Specifies the interval for automatically backing up DHCP snooping binding entries. If this parameter is not used, the default interval is used.	The value is an integer that ranges from 300 to 4294967295, in seconds. By default, the interval for local automatic backup of the DHCP snooping binding table is 86400 seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device restarts, to prevent loss of generated DHCP snooping binding entries on the device, run the **dhcp snooping user-bind tftp** command to enable the device to automatically back up DHCP snooping binding entries on the remote TFTP server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The TFTP protocol will bring risk to device security. The SFTP protocol configured using the **dhcp snooping user-bind sftp** command is recommended.

Example

Enable the device to automatically back up DHCP snooping binding entries to the **backup** file on the TFTP server at 10.137.12.10 at intervals of 5000s.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind tftp remotefilename backup host-ip 10.137.12.10 write-delay 5000
```

14.8.44 dhcp snooping user-bind tftp load

Function

The **dhcp snooping user-bind tftp load** command configures the device to obtain and restore backup DHCP snooping binding entries on the remote TFTP server.

Format

dhcp snooping user-bind tftp load remotefilename *filename* **host-ip** *ip-address*

Parameters

Parameter	Description	Value
remotefilename *filename*	Specifies the name of the file from which the device obtains DHCP snooping binding entries.	The value is a string of 1 to 64 characters without spaces. The string cannot contain the following characters: ~ * \ | : " ? < >.
host-ip *ip-address*	Specifies the IP address of the remote TFTP server.	The value is in dotted decimal notation.

2: Configuration level

Usage Guidelines

Usage Scenario

After running the **dhcp snooping user-bind tftp** command to enable the device to automatically back up DHCP snooping binding entries on the remote TFTP server, you can run the **dhcp snooping user-bind tftp load** command to configure the device to obtain and restore backup DHCP snooping binding entries on the remote TFTP server.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The TFTP protocol will bring risk to device security. The SFTP protocol configured using the **dhcp snooping user-bind sftp load** command is recommended.

Example

Configure the device to obtain and restore backup DHCP snooping binding entries from the **backup** file on the remote TFTP server at 10.137.12.10.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind tftp load remotefilename backup host-ip 10.137.12.10
Info: Transfer file in binary mode.
Downloading the file from the remote TFTP server. Please wait...
100%
TFTP: Downloading the file successfully.
656 byte(s) received in 1 second(s).
 Total number of dynamic binding table in remote file: 20
 Recovering dynamic binding table, please wait for a moment....
 10 successful, 10 failed.
 Binding Collisions         :    10     Exceeds max limit    :     0
 Invalid interfaces         :     0     Invalid vlan         :     0
 Invalid snp configurations :     0     Expired leases       :     0
 Parse failures             :     0
```

Table 14-66 Description of the dhcp snooping user-bind tftp load command output

Item	Description
Total number of dynamic binding table in remote file	Number of DHCP snooping binding entries stored on the remote server.
Binding Collisions	Number of DHCP snooping binding entries that cannot be restored because of collision between local entries and remote entries.
Exceeds max limit	Number of DHCP snooping binding entries that cannot be restored because the number of local entries reaches the upper limit.
Invalid interfaces	Number of DHCP snooping binding entries that cannot be restored because the local interface becomes invalid, for example, Down.
Invalid vlan	Number of DHCP snooping binding entries that cannot be restored because the VLAN on local device becomes invalid, for example, unavailable VLAN.
Invalid snp configurations	Number of DHCP snooping binding entries that cannot be restored because the DHCP snooping function is not enabled.
Expired leases	Number of DHCP snooping binding entries that cannot be restored because the lease of DHCP snooping binding table expires.

Item	Description
Parse failures	Number of DHCP snooping binding entries that cannot be restored because the device fails to parse the binding table file.

14.8.45 dhcp snooping user-offline remove mac-address

Function

The **dhcp snooping user-offline remove mac-address** command enables the device to delete the MAC address entry of a user whose DHCP snooping binding entry is deleted.

The **undo dhcp snooping user-offline remove mac-address** command disables the device from deleting the MAC address entry of a user whose binding entry is deleted.

By default, the device does not delete the MAC address entry of a user whose DHCP snooping binding entry is deleted.

Format

dhcp snooping user-offline remove mac-address

undo dhcp snooping user-offline remove mac-address

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a user goes offline but its MAC address entry is not aged, the device forwards the packet whose destination address is the IP address of the user based on the dynamic MAC address entry. After the **dhcp snooping user-offline remove mac-address** command is executed, the user MAC address entry is deleted when the DHCP snooping binding entry is deleted. With the function of discarding unknown unicast packets on the network-side interface, the device discards packets destined to offline users.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

Enable the device to delete the MAC address entry of a user whose DHCP snooping binding entry is deleted.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-offline remove mac-address
```

14.8.46 dhcp snooping user-bind upload format ascii

Function

The **dhcp snooping user-bind upload format ascii** command configures DHCP snooping binding entries to be backed up in both ASCII and binary formats.

The **undo dhcp snooping user-bind upload format ascii** command restores the default configuration.

By default, DHCP snooping binding entries are backed up only in binary format when the automatic backup of DHCP snooping binding entries on the remote server is enabled.

Format

dhcp snooping user-bind upload format ascii

undo dhcp snooping user-bind upload format ascii

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, DHCP snooping binding entries are backed up only in binary format when the automatic backup of DHCP snooping binding entries on the remote server is enabled. Huawei switches can restore DHCP snooping binding entries in binary format. However, customers cannot read backup DHCP snooping binding entries in binary format. To resolve this problem, run the **dhcp snooping user-**

bind upload format ascii command to configure the device to back up DHCP snooping binding entries in ASCII and binary formats. Customers then can read DHCP snooping binding entries in ASCII format and store the entries to the local database.

Prerequisites

Backup of DHCP snooping binding entries must be enabled for the remote FTP, HTTP, HTTPS, SFTP, and TFTP servers. Otherwise, the configuration of the **dhcp snooping user-bind upload format ascii** command does not take effect.

Example

Enable the device to back up DHCP snooping binding entries to the file named **backup** on the FTP server at 10.137.12.10 with the FTP user name **test** and password YsHsjx_202206. DHCP snooping binding entries can be backed up in both ASCII and binary formats.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] dhcp snooping user-bind ftp remotefilename backup host-ip 10.137.12.10 username test
password YsHsjx_202206
[HUAWEI] dhcp snooping user-bind upload format ascii
```

14.8.47 dhcp snooping user-transfer enable

Function

The **dhcp snooping user-transfer enable** command enables location transition for DHCP snooping users.

The **undo dhcp snooping user-transfer enable** command disables location transition for DHCP snooping users.

By default, location transition is enabled for DHCP snooping users.

Format

dhcp snooping user-transfer enable

undo dhcp snooping user-transfer enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a mobile user goes online through interface A, goes offline, and then goes online through interface B, the user sends a DHCP Discover message to apply an IP address. By default, if DHCP snooping is enabled on the device, the device allows the user to go online and updates the DHCP snooping binding entries. However, this may bring security risks. For example, if an attacker pretends an authorized user to send a DHCP Discover message, the authorized user cannot access the network after the DHCP snooping binding table is updated. To prevent such attacks, you can disable the DHCP snooping location transition function. After this function is disabled, the device discards the DHCP Discover messages sent by a user who has an entry in the DHCP snooping binding table (user's MAC address exists in the DHCP snooping binding table) through another interface.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Example

Disable location transition for DHCP snooping users.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] undo dhcp snooping user-transfer enable
```

14.8.48 dhcpv6 interface-id format

Function

The **dhcpv6 interface-id format** command configures the Interface-ID format in DHCPv6 packets.

The **undo dhcpv6 interface-id format** command restores the default Interface-ID format in DHCPv6 packets.

By default, the Interface-ID format in DHCPv6 packets is **default**.

Format

dhcpv6 interface-id format { **default** | **user-defined** *text* }

undo dhcpv6 interface-id format

Parameters

Parameter	Description	Value
default	Specifies the default Interface-ID format. The default Interface-ID format is %04svlan.%04cvlan.%mac:%portname. The values of the S-VLAN and C-VLAN are integers containing four characters. If the length is fewer than four characters, the value is prefixed with 0s. For example, if the outer VLAN value in the DHCPv6 packets received by the device is 11, the inner VLAN value is 22, the inbound interface is VLANIF100, and the device MAC address is 00e0-fc12-3456, the Interface-ID generated during the system parsing process is 0011.0022.00e0fc123456:vlanif100.	-
user-defined *text*	Specifies a user-defined format as the Interface-ID format. A user-defined format can be: ● Format defined by keywords: The Interface-ID is defined based on the keywords supported by the user-defined format. For example, if the name of the device to which the users are connected and the outer VLAN to which the users belong need to be recorded, the user-defined format can be %sysname %svlan. If the device name is HUAWEI and the S-VLAN is 100, the user location information recorded by the Interface-ID is HUAWEI 100. For description of the keywords supported by the user-defined format, see **Table 14-67**. ● Format defined by common character strings: The Interface-ID is directly defined as a character string. For example, if all users on an interface are located in the office building named N8, the Interface-ID can be directly defined as N8. ● Mixed format: The Interface-ID is defined by both the keywords and common character strings. For example, the Interface-ID can be defined as %sysname N8.	The value is a string of case-sensitive characters without spaces. The character string contains 1 to 251 characters, excluding the quotation marks.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Interface-ID records user access information such as the inbound interfaces of the DHCPv6 packets sent from the clients to the device. The device functions as a DHCPv6 relay or lightweight DHCPv6 relay agent (LDRA). When receiving the request packets sent from the DHCPv6 clients and forwarding the packets to the DHCPv6 server, the device can insert the Interface-ID to the packets to identify the DHCPv6 client location information. The location information can be used by the DHCPv6 server to assign IPv6 addresses and network parameters. You can run the **dhcpv6 interface-id format** command to configure the format of the Interface-ID inserted into DHCPv6 packets.

Table 14-67 Description of the keywords supported by the user-defined format

Keyword	Description
duid	Specifies the client ID, including information such as the client MAC address.
sysname	Specifies the device name of the client.
portname	Specifies the name of the inbound interface that receives the DHCPv6 packets sent from the client to the device.
porttype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is specified when the NAS interface is configured in certain scenarios.
iftype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is usually GE.
mac	Specifies the device MAC address.
slot	Specifies the slot number of the DHCPv6 packet sent from the client to the device.
subslot	Specifies the sub-slot number of the DHCPv6 packet sent from the client to the device.
port	Specifies the port number of the DHCPv6 packet sent from the client to the device.
svlan	Specifies the outer VLAN of the DHCPv6 packet sent by the client.
cvlan	Specifies the inner VLAN of the DHCPv6 packet sent by the client.

Keyword	Description
length	Specifies the total length of the keywords following the length keyword. The length of the length keyword is excluded.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

- The user-defined format content must be specified between the double quotation marks (""). For example, to configure the user-defined format content as **mac**, run the **dhcpv6 interface-id format user-defined "%mac"** command.
- Separators that cannot be digits must be added between the keywords in the user-defined format. Otherwise, the keywords cannot be parsed.
- The symbol % must be prefixed to the keywords in the user-defined format to differentiate them from common character strings. If a digit exists before the symbol % and keyword, the digit refers to the number of characters in the keyword.
- The self-defined content is encapsulated in ASCII format. In addition to the preceding precautions, note the following rules:
  - The symbol \ is an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents the character \.
  - An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.

Example

Configure a user-defined format as the format of the Interface-ID in DHCPv6 packets and the device MAC address as the encapsulated content.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 interface-id format user-defined "%mac"
```

14.8.49 dhcpv6 option18 format

Function

The **dhcpv6 option18 format** command configures the format of the Option 18 field in a DHCPv6 message.

The **undo dhcpv6 option18 format** command restores the default format of the Option 18 field in a DHCPv6 message.

By default, the format of the Option 18 field is not configured in a DHCPv6 message. If the function of adding the Option 18 field to DHCPv6 messages is enabled, DHCPv6 messages are encapsulated in the default format %portname:%svlan.%cvlan %sysname/0/%cssid/%slot/%subslot/%port.

Format

dhcpv6 option18 [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] **format user-defined** *text*

undo dhcpv6 option18 { [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] **format** | **format all** }

Parameters

Parameter	Description	Value
user-defined *text*	Indicates the user-defined format of the Option 18 field.	The value is a string of 1 to 251 characters. The details about the user-defined format string are provided in the Usage Guidelines.
vlan *vlan-id*	Specifies the outer VLAN ID. **NOTE** ● If a VLAN is specified, only the format of the Option 18 field in DHCPv6 messages that belong to this VLAN is configured. If no VLAN is specified, the format of the Option 18 field in all DHCPv6 messages received by the interface is configured. ● If the format of the Option 18 field is configured on an interface and the VLAN to which it belongs, the configuration on the interface takes effect. ● This parameter is not supported in the VLAN view.	The value is an integer in the range from 1 to 4094.
ce-vlan *ce-vlan-id*	Specifies the inner VLAN ID. **NOTE** This parameter is not supported in the VLAN view.	The value is an integer in the range from 1 to 4094.
all	Deletes all formats of the Option 18 field.	-

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **dhcpv6 option18** { **insert** | **rebuild** } **enable** command is executed to enable the device to insert the Option 18 field to a DHCPv6 message, you can run the **dhcpv6 option18 format** command to configure the format of the Option 18 field in a DHCPv6 message.

You can use the following keywords to define the Option 18 field. The format string can use the hexadecimal notation, ASCII format, or combination of the two formats.

- duid: indicates the ID of the client. This keyword is valid only in the string format.
- sysname: indicates the ID of the access point. This keyword is valid only in ASCII format.
- portname: indicates the name of a port, for example, GE0/0/1. This keyword is valid only in ASCII format.
- porttype: indicates the type of a port. This keyword is a character string or in hexadecimal notation. For example, if the value is Ethernet in ASCII format, it is 15 in hexadecimal notation.
- iftype: indicates the type of a port, including eth and trunk. This keyword is valid only in ASCII format.
- mac: indicates the MAC address of a port. In ASCII format, the value is in the format of H-H-H; in hexadecimal notation, the value is a number of six bytes.
- slot: indicates the slot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- subslot: indicates the subslot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- port: indicates the port number. This keyword is valid in ASCII format or in hexadecimal notation.
- svlan: specifies the outer VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- cvlan: specifies the inner VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- length: indicates the total length of the keywords following the keyword length.
- n: indicates the value of the keyword **svlan** or **cvlan** if the SVLAN or CVLAN does not exist. The keyword **n** is on the left of the keyword **svlan** or **cvlan**. If the corresponding VLAN does not exist, the default value of the keyword **svlan** or **cvlan** is 4096 in ASCII format and is all Fs in hexadecimal notation. If the **n** keyword is added to the left of the keyword **svlan** or **cvlan**, the keyword **svlan** or **cvlan** is 0. This keyword is valid in ASCII format or in hexadecimal notation.

If the Option 18 format is not customized, the following keywords are used for encapsulation by default:

- portname: indicates the name of a port, for example, GE0/0/1. This keyword is valid only in ASCII format.
- svlan: specifies the outer VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- cvlan: specifies the inner VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- sysname: indicates the ID of the access point. This keyword is valid only in ASCII format.
- cssid: indicates the cluster ID. The value is 0 in non-cluster scenarios.
- slot: indicates the slot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- subslot: indicates the subslot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- port: indicates the port number. This keyword is valid in ASCII format or in hexadecimal notation.

NOTE

Delimiters must be added between keywords; otherwise, the device cannot parse the keywords. The delimiters cannot be numbers.

The symbols used in the format string are as follows:

- The symbol % followed by a keyword indicates the format of the keyword.
- A number to the left of the symbol % indicates the length of the keyword following the symbol %. In an ASCII character string, %05 has the same meaning as %05d in the C language. In a hexadecimal character string, the number indicates the keyword length in bits.
- The symbol [] indicates an optional keyword. Each pair of brackets can contain only one keyword, svlan or cvlan. The keyword in the symbol [] is added to the Option 18 field only if the corresponding VLAN ID exists. To facilitate syntax check, the system does not support nesting of symbols [].
- The symbol \ indicates an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents \.
- "" indicates that the contents in the double quotation marks are encapsulated in ASCII format. Contents that are not enclosed in double quotation marks are encapsulated in hexadecimal notation.
- Other symbols are processed as common characters. The rules for setting the format string in ASCII format or hexadecimal notation are as follows:
  - An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.

- A hexadecimal notation string can contain numerals, spaces, and % + keywords.
- In a hexadecimal notation string, numbers are encapsulated in the Option 18 field in hexadecimal notation. A number from 0 to 255 occupies 1 byte; a number from 256 to 65535 occupies 2 bytes; a number from 65536 to 4294967295 occupies 4 bytes. Numbers larger than 4294967295 are not supported. Multiple numbers must be separated by spaces; otherwise, they are considered as one number.
- All the spaces in a hexadecimal character string are ignored.
- By default, the slot ID, subslot ID, port number, and VLAN ID in a hexadecimal character string occupy 2 bytes; the field length occupies 1 byte.
- If the length of each keyword in a hexadecimal character string is specified, the total length of the hexadecimal character string must be a multiple of 8. If the length of a specified keyword is longer than 32 bits, the first 32 bits of the keyword are the actual keyword value, and other bits are set to 0.
- A hexadecimal notation string can contain only the keywords whose values are numbers. Other keywords, such as port name, cannot be added to the hexadecimal notation string.
- If a string is not contained in quotation marks, it is encapsulated in hexadecimal notation. To encapsulate the string in the ASCII format, use a pair of quotation marks to contain the string. For example, the slot ID is 3, and the port number is 4. If the string is in the %slot %port format, the value of the encapsulated string is a hexadecimal number 00030004. If the string is in the "%slot %port" format, the value of the encapsulated string is 3 4.
- A format string can contain both hexadecimal strings and ASCII strings, for example, %slot %port "%sysname %portname:%svlan.%cvlan."

Precautions

After the **dhcpv6 snooping relay-information enable** command is run in the VLAN view, the **dhcpv6 option18 format** command does not take effect in the VLAN.

Example

Configure the format of the Option 18 field in a DHCPv6 message in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcpv6 option18 format user-defined "%length %svlan %5slot %3subslot %8port"
```

Configure the format of the Option 18 field in a DHCPv6 message on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 option18 format user-defined "%length %svlan %5slot
%3subslot %8port"
```

14.8.50 dhcpv6 option37 format

Function

The **dhcpv6 option37 format** command configures the format of the Option 37 field in a DHCPv6 message.

The **undo dhcpv6 option37 format** command restores the default format of the Option 37 field in a DHCPv6 message.

By default, the format of the Option 37 field is not configured in a DHCPv6 message. If the function of adding Option 37 to DHCPv6 messages is enabled, DHCPv6 messages are encapsulated in the default format: enterprise-id:%sysmac.

Format

dhcpv6 option37 [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] **format user-defined** *text*

undo dhcpv6 option37 { [**vlan** *vlan-id*] [**ce-vlan** *ce-vlan-id*] **format** | **format all** }

Parameters

Parameter	Description	Value
user-defined *text*	Indicates the user-defined format of the Option 37 field.	The value is a string of 1 to 247 characters. The details about the user-defined format string are provided in the Usage Guidelines.
vlan *vlan-id*	Specifies the outer VLAN ID. **NOTE** • If a VLAN is specified, only the format of the Option 37 field in DHCPv6 messages that belong to this VLAN is configured. If no VLAN is specified, the format of the Option 37 field in all DHCPv6 messages received by the interface is configured. • If the format of the Option 37 field is configured on an interface and the VLAN to which it belongs, the configuration on the interface takes effect. • This parameter is not supported in the VLAN view.	The value is an integer in the range from 1 to 4094.
ce-vlan *ce-vlan-id*	Specifies the inner VLAN ID. **NOTE** This parameter is not supported in the VLAN view.	The value is an integer in the range from 1 to 4094.

Parameter	Description	Value
all	Deletes all formats of the Option 37 field.	-

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

After the **dhcpv6 option37** { **insert** | **rebuild** } **enable** command is executed to enable the device to insert the Option 37 field to a DHCPv6 message, you can run the **dhcpv6 option37 format** command to configure the format of the Option 37 field in a DHCPv6 message.

You can use the following keywords to define the Option 37 field. The format string can use the hexadecimal notation, ASCII format, or combination of the two formats.

- duid: indicates the ID of the client. This keyword is valid only in the string format.
- sysname: indicates the ID of the access point. This keyword is valid only in ASCII format.
- portname: indicates the name of a port, for example, GE0/0/1. This keyword is valid only in ASCII format.
- porttype: indicates the type of a port. This keyword is a character string or in hexadecimal notation. For example, if the value is Ethernet in ASCII format, it is 15 in hexadecimal notation.
- iftype: indicates the type of a port, including eth and trunk. This keyword is valid only in ASCII format.
- mac: indicates the MAC address of a port. In ASCII format, the value is in the format of H-H-H; in hexadecimal notation, the value is a number of six bytes.
- slot: indicates the slot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- subslot: indicates the subslot ID. This keyword is valid in ASCII format or in hexadecimal notation.
- port: indicates the port number. This keyword is valid in ASCII format or in hexadecimal notation.
- svlan: specifies the outer VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.

- cvlan: specifies the inner VLAN ID. The value ranges from 1 to 4094. If this field is not required, this field is 0. This keyword is valid in ASCII format or in hexadecimal notation.
- length: indicates the total length of the keywords following the keyword length.
- n: indicates the value of the keyword **svlan** or **cvlan** if the SVLAN or CVLAN does not exist. The keyword **n** is on the left of the keyword **svlan** or **cvlan**. If the corresponding VLAN does not exist, the default value of the keyword **svlan** or **cvlan** is 4096 in ASCII format and is all Fs in hexadecimal notation. If the **n** keyword is added to the left of the keyword **svlan** or **cvlan**, the keyword **svlan** or **cvlan** is 0. This keyword is valid in ASCII format or in hexadecimal notation.

If the Option 37 format is not customized, the following keywords are used for encapsulation by default:

- enterprise-id: indicates the enterprise code. The value is fixed at 2011: Huawei proprietary message.
- sysmac: indicates the system MAC address of the device.

NOTE

Delimiters must be added between keywords; otherwise, the device cannot parse the keywords. The delimiters cannot be numbers.

The symbols used in the format string are as follows:

- The symbol % followed by a keyword indicates the format of the keyword.
- A number to the left of the symbol % indicates the length of the keyword following the symbol %. In an ASCII character string, %05 has the same meaning as %05d in the C language. In a hexadecimal character string, the number indicates the keyword length in bits.
- The symbol [] indicates an optional keyword. Each pair of brackets can contain only one keyword, svlan or cvlan. The keyword in the symbol [] is added to the Option 37 field only if the corresponding VLAN ID exists. To facilitate syntax check, the system does not support nesting of symbols [].
- The symbol \ indicates an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents \.
- "" indicates that the contents in the double quotation marks are encapsulated in ASCII format. Contents that are not enclosed in double quotation marks are encapsulated in hexadecimal notation.
- Other symbols are processed as common characters. The rules for setting the format string in ASCII format or hexadecimal notation are as follows:
  - An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.
  - A hexadecimal notation string can contain numerals, spaces, and % + keywords.
  - In a hexadecimal notation string, numbers are encapsulated in the Option 37 field in hexadecimal notation. A number from 0 to 255

occupies 1 byte; a number from 256 to 65535 occupies 2 bytes; a number from 65536 to 4294967295 occupies 4 bytes. Numbers larger than 4294967295 are not supported. Multiple numbers must be separated by spaces; otherwise, they are considered as one number.

- All the spaces in a hexadecimal character string are ignored.
- By default, the slot ID, subslot ID, port number, and VLAN ID in a hexadecimal character string occupy 2 bytes; the field length occupies 1 byte.
- If the length of each keyword in a hexadecimal character string is specified, the total length of the hexadecimal character string must be a multiple of 8. If the length of a specified keyword is longer than 32 bits, the first 32 bits of the keyword are the actual keyword value, and other bits are set to 0.
- A hexadecimal notation string can contain only the keywords whose values are numbers. Other keywords, such as port name, cannot be added to the hexadecimal notation string.
- If a string is not contained in quotation marks, it is encapsulated in hexadecimal notation. To encapsulate the string in the ASCII format, use a pair of quotation marks to contain the string. For example, the slot ID is 3, and the port number is 4. If the string is in the %slot %port format, the value of the encapsulated string is a hexadecimal number 00030004. If the string is in the "%slot %port" format, the value of the encapsulated string is 3 4.
- A format string can contain both hexadecimal strings and ASCII strings, for example, %slot %port "%sysname %portname:%svlan.%cvlan."

Precautions

After the **dhcpv6 snooping relay-information enable** command is run in the VLAN view, the **dhcpv6 option37 format** command does not take effect in the VLAN.

Example

Configure the format of the Option 37 field in a DHCPv6 message in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcpv6 option37 format user-defined "%length %svlan %5slot %3subslot %8port"
```

Configure the format of the Option 37 field in a DHCPv6 message on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 option37 format user-defined "%length %svlan %5slot
%3subslot %8port"
```

14.8.51 dhcpv6 { option18 | option37 } enable

Function

The **dhcpv6** { **option18** | **option37** } **enable** command enables the device to insert the Option 18 or Option 37 field to a DHCPv6 message.

The **undo dhcpv6** { **option18** | **option37** } **enable** command disables the device from adding the Option 18 or Option 37 field to a DHCPv6 message.

By default, the device does not insert the Option 18 or Option 37 field to a DHCPv6 message.

Format

dhcpv6 { **option18** | **option37** } { **insert** | **rebuild** } **enable**

undo dhcpv6 { **option18** | **option37** } { **insert** | **rebuild** } **enable**

Parameters

Parameter	Description	Value
insert	Enables the device to insert the Option 18 or Option 37 field to a DHCPv6 message.	-
rebuild	Enables the device to modify the Option 18 or Option 37 field in a DHCPv6 message that carries either option; enables the device to forcibly insert the Option 18 or Option 37 field to a DHCPv6 message that does not carry either option.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The function of Option 18 or Option 37 is similar to that of Option 82 (see the **dhcp option82 enable** command). The Option 18 field contains the port number of a client and the Option 37 field contains the MAC address of a client. The device inserts the Option 18 or Option 37 field to a DHCPv6 Request message to notify the DHCP server of the DHCPv6 client location. As such, the DHCP server can properly assign an IP address and other configurations to the DHCPv6 client, ensuring DHCP client security.

Prerequisites

DHCP snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcpv6** { **option18** | **option37** } **enable** command in the VLAN view, the command takes effect for all the DHCPv6 messages received from the specified VLAN. If you run this command in the interface view, the command takes effect for all the DHCPv6 messages received on the specified interface.

After the **dhcpv6 snooping relay-information enable** command is run in the VLAN view, the **dhcpv6 { option18 | option37 } enable** command does not take effect in the VLAN.

Example

Insert the Option 37 field into DHCPv6 Request messages sent by GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 option37 insert enable
```

14.8.52 dhcpv6 remote-id format

Function

The **dhcpv6 remote-id format** command sets the format of the Remote-ID in DHCPv6 messages.

The **undo dhcpv6 remote-id format** command restores the default format of the Remote-ID in DHCPv6 messages.

By default, the default format of the Remote-ID in DHCPv6 messages is used.

Format

dhcpv6 remote-id format { **default** | **user-defined** *text* }

undo dhcpv6 remote-id format

Parameters

Parameter	Description	Value
default	Indicates to adopt the default format of the remote ID. The default format of the remote ID is %duid %portname:%04svlan.%04cvlan, where the values of the outer VLAN ID and inner VLAN ID are integers and composed of four characters. If the length is shorter than four characters, 0s are prefixed to the value. For example, if the outer VLAN value in the DHCPv6 packets received by the device is 11, the inner VLAN value is 22, the inbound interface is GE0/0/1, and the client DUID is 0003000180FB063545B3, the Remote-ID option generated during the system parsing process is 0003000180FB063545B3 GigabitEthernet 0/0/1:0011.0022.	-

Parameter	Description	Value
user-defined *text*	Specifies a user-defined format as the Remote-ID format. A user-defined format can be: - Format defined by keywords: The Remote-ID is defined based on the keywords supported by the user-defined format. For example, if the name of the device to which the users are connected and the outer VLAN to which the users belong need to be recorded, the user-defined format can be %sysname %svlan. If the device name is HUAWEI and the S-VLAN is 100, the user location information recorded by the Remote-ID is HUAWEI 100. For description of the keywords supported by the user-defined format, see **Table 14-68**. - Format defined by common character strings: The Remote-ID is directly defined as a character string. For example, if all users on an interface are located in the office building named N8, the Remote-ID can be directly defined as N8. - Mixed format: The Remote-ID is defined by both the keywords and common character strings. For	The value is a string of 3 to 247 case-sensitive characters with spaces.

Parameter	Description	Value
	example, the Remote-ID can be defined as %sysname N8.	

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The Remote-ID records user access information such as the DUID of the DHCPv6 packets sent from the clients to the device. The device functions as a DHCPv6 relay or lightweight DHCPv6 relay agent (LDRA). When receiving the request packets sent from the DHCPv6 clients and forwarding the packets to the DHCPv6 server, the device can insert the Remote-ID to the packets to identify the DHCPv6 client location information. The location information can be used by the DHCPv6 server to assign IPv6 addresses and network parameters. You can run the **dhcpv6 remote-id format** command to configure the format of the Remote-ID inserted into DHCPv6 packets.

Table 14-68 Description of the keywords supported by the user-defined format

Keyword	Description
duid	Specifies the client ID, including information such as the client MAC address.
sysname	Specifies the device name of the client.
portname	Specifies the name of the inbound interface that receives the DHCPv6 packets sent from the client to the device.
porttype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is specified when the NAS interface is configured in certain scenarios.
iftype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is usually GE.

Keyword	Description
mac	Specifies the device MAC address.
slot	Specifies the slot number of the DHCPv6 packet sent from the client to the device.
subslot	Specifies the sub-slot number of the DHCPv6 packet sent from the client to the device.
port	Specifies the port number of the DHCPv6 packet sent from the client to the device.
svlan	Specifies the outer VLAN of the DHCPv6 packet sent by the client.
cvlan	Specifies the inner VLAN of the DHCPv6 packet sent by the client.
length	Specifies the total length of the keywords following the length keyword. The length of the length keyword is excluded.

Prerequisites

The DHCP function has been enabled using the **dhcp enable** command in the system view.

Follow-up Procedure

When the device functions as a DHCPv6 relay, you must run the **dhcpv6 remote-id insert enable** or **dhcpv6 remote-id rebuild enable** command to enable the function of inserting the Remote-ID into DHCPv6 relay packets after running the **dhcpv6 remote-id format** command to configure the Remote-ID format in DHCPv6 packets.

NOTE

When the device functions as an LDRA, the Remote-ID is inserted into DHCPv6 relay packets by default and the function does not need to be enabled.

Precautions

- The user-defined format content must be specified between the double quotation marks (""). For example, to configure the user-defined format content as **mac**, run the **dhcpv6 interface-id format user-defined "%mac"** command.
- Separators that cannot be digits must be added between the keywords in the user-defined format. Otherwise, the keywords cannot be parsed.
- The symbol % must be prefixed to the keywords in the user-defined format to differentiate them from common character strings. If a digit exists before the symbol % and keyword, the digit refers to the number of characters in the keyword.
- The self-defined content is encapsulated in ASCII format. In addition to the preceding precautions, note the following rules:

- The symbol \ is an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents the character \.
- An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
- By default, the length of each keyword in an ASCII character string is the actual length of the keyword.

Example

Set the customized format for the remote ID carried in DHCPv6 messages and encapsulate the MAC address of the device into the remote ID.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 remote-id format user-defined "%mac"
```

14.8.53 dhcpv6 snooping check relay-forward enable

Function

The **dhcpv6 snooping check relay-forward enable** command enables the function of discarding DHCPv6 Relay-Forward messages.

The **undo dhcpv6 snooping check relay-forward enable** command disables the function of discarding DHCPv6 Relay-Forward messages.

By default, the function of discarding DHCPv6 Relay-Forward messages is disabled.

Format

In the system view:

dhcpv6 snooping check relay-forward enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo dhcpv6 snooping check relay-forward enable vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

In the VLAN view or interface view:

dhcpv6 snooping check relay-forward enable

undo dhcpv6 snooping check relay-forward enable

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Discards DHCPv6 Relay-Forward messages received in specified VLANs. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. The value of *vlan-id2* must be greater than the value of *vlan-id1*.	The value is an integer in the range from 1 to 4094.

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

DHCPv6 snooping needs to be deployed on access devices on a Layer 2 network or the first DHCPv6 relay agent. Therefore, the device that has DHCPv6 snooping configured should not receive the DHCPv6 Relay-Forward messages forwarded by the relay agent. If the device receives the DHCPv6 Relay-Forward messages, it considers the messages invalid and discards them.

Prerequisites

DHCPv6 snooping has been enabled on the device using the **dhcp snooping enable** command.

Precautions

If you run the **dhcp snooping enable** command in the VLAN view, the command configuration takes effect only for the DHCP messages from the specified VLAN. If you run this command in the interface view, the command configuration takes effect for all DHCP messages on the specified interface.

Example

Enable the function of discarding DHCPv6 Relay-Forward messages in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcpv6 snooping check relay-forward enable
```

Enable the function of discarding DHCPv6 Relay-Forward messages on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcp snooping enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 snooping check relay-forward enable
```

14.8.54 dhcpv6 snooping relay-information enable

Function

The **dhcpv6 snooping relay-information enable** command enables Lightweight DHCPv6 Relay Agent (LDRA) for DHCPv6 snooping.

The **undo dhcpv6 snooping relay-information enable** command disables LDRA.

By default, LDRA for DHCPv6 snooping is disabled.

Format

dhcpv6 snooping relay-information enable [**trust**]

undo dhcpv6 snooping relay-information enable [**trust**]

Parameters

Parameter	Description	Value
trust	Configures the device to trust the received Relay-Forward messages. If this parameter is not specified, the device does not trust the received Relay-Forward messages.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

In some scenarios, for example, interfaces in the same VLAN have different network access rights and QoS requirements, the DHCPv6 server must be able to detect user access locations, and assign corresponding access control and QoS policies. The DHCPv6 relay agent is usually configured on the gateway. The relay agent can record user access locations; however, if access devices are located between the relay agent and users, the relay agent cannot detect the access locations of users.

LDRA can meet the requirements of these scenarios. LDRA is configured on the user-side access device. The LDRA-enabled device can forward user access locations (such as the network-side interfaces on clients) to the DHCPv6 server. The DHCPv6 server delivers policies to users accordingly.

This command enables LDRA for DHCPv6 snooping and configures the handling methods for received Relay-Forward messages:

- Trust: The device forwards the received Relay-Forward messages to the DHCPv6 server. This method is usually used when multiple LDRA-enabled devices are directly connected. If the downstream LDRA-enabled device trusts the Relay-Forward messages from the upstream LDRA-enabled device, this method can be used.
- Untrust: The device discards the received Relay-Forward messages. This method is usually used when an LDRA-enabled device directly connects to users, and the users may send invalid Relay-Forward messages.

Prerequisites

DHCP snooping has been enabled using the **dhcp snooping enable** command.

Precautions

The LDRA function only records the client location information and forwards the information to the DHCPv6 server. The differentiated policies for IP address allocation, accounting, access control, and QoS are configured on the DHCPv6 server.

Example

Enable LDRA for DHCPv6 snooping in VLAN10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] dhcpv6 snooping relay-information enable
```

14.8.55 dhcpv6 snooping user-bind detect confirm-client enable

Function

The **dhcpv6 snooping user-bind detect confirm-client enable** command enables the confirm-client probing function of DHCPv6 snooping.

The **undo dhcpv6 snooping user-bind detect confirm-client enable** command disables the confirm-client probing function of DHCPv6 snooping.

By default, the confirm-client probing function is enabled.

Format

dhcpv6 snooping user-bind detect confirm-client enable

undo dhcpv6 snooping user-bind detect confirm-client enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a binding entry is generated for a client using the DHCPv6 Confirm packet, this client is a confirm-client. When the client goes online again, it sends a DHCPv6 Confirm packet.

When a user-side interface receives the DHCPv6 Confirm packet, a DHCPv6 snooping binding entry is generated for the client. Because the DHCPv6 Confirm packet does not contain lease information, the binding entry of the client cannot be deleted immediately when the client goes offline. This occupies binding table space and new users may fail to go online.

After the confirm-client probing function is enabled, DHCPv6 snooping periodically sends DAD NS packets to detect whether the confirm-client is online. The DHCPv6 snooping entries are promptly deleted when the confirm-clients go offline.

Prerequisites

The **dhcp snooping enable ipv6** command has been executed to enable DHCPv6 snooping.

Example

Enable confirm-client probing of DHCPv6 snooping.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable ipv6
[HUAWEI] dhcpv6 snooping user-bind detect confirm-client enable
```

14.8.56 dhcpv6 snooping user-bind detect retransmit

Function

The **dhcpv6 snooping user-bind detect retransmit** command sets the number of times and interval at which the DAD NS packets are sent for DHCPv6 snooping.

The **undo dhcpv6 snooping user-bind detect retransmit** command restores the default number of times and interval at which the DAD NS packets are sent for DHCPv6 snooping.

By default, a DAD NS packet is sent up to three times at the interval of 180 seconds.

Format

dhcpv6 snooping user-bind detect retransmit *times* **interval** *interval*

undo dhcpv6 snooping user-bind detect retransmit

Parameters

Parameter	Description	Value
times	Specifies the number of times a DAD NS packet is sent.	The value is an integer that ranges from 1 to 10.
interval *interval*	Specifies the interval for sending DAD NS packets.	The value is an integer that ranges from 60 to 86400, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the function of enabling DHCPv6 snooping to detect whether the confirm-client is online is enabled using the **dhcpv6 snooping user-bind detect confirm-client enable** command, the DHCPv6 snooping-enabled device will periodically send DAD NS packets to detect whether the confirm-client is online and delete the DHCPv6 snooping entry of the offline confirm-client. You can change the number of times and interval at which the DHCPv6 snooping-enabled device sends DAD NS packets as required.

Prerequisites

The **dhcp snooping enable ipv6** command has been executed to enable DHCPv6 snooping.

Example

Set the number of times and interval at which the DAD NS packets are sent to 2 and 60 seconds, respectively.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable ipv6
[HUAWEI] dhcpv6 snooping user-bind detect retransmit 2 interval 60
```

14.8.57 dhcpv6 snooping user-bind mac-conflict detect enable

Function

The **dhcpv6 snooping user-bind mac-conflict detect enable** command enables DHCPv6 snooping for detecting whether a user is online.

The **undo dhcpv6 snooping user-bind mac-conflict detect enable** command disables DHCPv6 snooping from detecting whether a user is online.

By default, DHCPv6 snooping is disabled from detecting whether a user is online.

Format

dhcpv6 snooping user-bind mac-conflict detect enable

undo dhcpv6 snooping user-bind mac-conflict detect enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After binding entries are generated, you can run the **dhcp snooping check dhcpv6-request mac** command to enable the function of checking the validity of DHCPv6 messages based on MAC addresses. Then the device searches for the binding entries based on the MAC address entry that is used as the key. The device checks whether the Request messages sent by the DHCPv6 client match any binding entry. If they match, the device forwards the messages; otherwise, the device discards the messages. This prevents unauthorized users from sending bogus DHCPv6 messages to extend the IP address lease or release IP addresses. When determining that a DHCPv6 message is invalid, the device discards it. In this case, you can enable the function of detecting whether DHCPv6 users are online. DHCPv6 snooping then sends DAD NS packets at an interval of 3 seconds for three times to detect whether a DHCPv6 user is online. If no response packet is received from the DHCPv6 user within the timeout period, the device considers that the user is offline and deletes the DHCPv6 snooping entry of the offline user.

Prerequisites

1. The **dhcp snooping enable ipv6** command has been run to enable DHCPv6 snooping globally.
2. The **dhcp snooping check dhcpv6-request mac** command has been run to enable the function of checking the validity of DHCPv6 messages based on MAC addresses.

Example

Enable DHCPv6 snooping for detecting whether a user is online.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
```

```
[HUAWEI] dhcp snooping enable ipv6
[HUAWEI] dhcpv6 snooping user-bind mac-conflict detect enable
```

14.8.58 display dhcp option82 configuration

Function

The **display dhcp option82 configuration** command displays the DHCP Option 82 configuration.

Format

display dhcp option82 configuration [**vlan** *vlan-id* | **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the DHCP Option 82 configuration in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Displays the DHCP Option 82 configuration on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The Option 82 field records the location of a DHCP client. A device inserts the Option 82 field to a DHCP Request message to notify the DHCP server of the DHCP client location. The DHCP server can properly assign an IP address and other configurations to the DHCP client, ensuring DHCP client security.

After the Option 82 field is inserted to a DHCP message, run the **display dhcp option82 configuration** command to display the DHCP Option 82 configuration.

Example

Display all the DHCP Option82 configurations.

```
<HUAWEI> display dhcp option82 configuration
#
dhcp option82 vendor-specific format vendor-sub-option 1 ascii 22
#
interface GigabitEthernet0/0/1
 dhcp option82 subscriber-id format ascii 222
 dhcp option82 insert enable
 dhcp option82 encapsulation circuit-id
 dhcp option82 append vendor-specific
 dhcp option82 circuit-id format common
#
```

Table 14-69 Description of the **display dhcp option82 configuration** command output

Item	Description
interface *ifn*	Option 82 configuration on interface *ifn*.
dhcp option82 vendor-specific format vendor-sub-option *i* ascii *text1*	The Sub9 of the old format is inserted into the Option 82 field of DHCP messages. To specify the parameter, run the **dhcp option82 vendor-specific format** command.
dhcp option82 subscriber-id format ascii *text2*	The Sub6 suboption is inserted into the Option 82 field of DHCP messages. To specify the parameter, run the **dhcp option82 subscriber-id format** command.
dhcp option82 insert enable	The function of inserting Option 82 to DHCP messages is enabled and the insertion method is configured: ● dhcp option82 rebuild enable: Rebuild mode ● dhcp option82 insert enable: Insert mode To specify the parameter, run the **dhcp option82 enable** command.
dhcp option82 encapsulation circuit-id	The suboption inserted into the Option 82 field of DHCP messages is configured. To specify the parameter, run the **dhcp option82 encapsulation** command.
dhcp option82 append vendor-specific	The Sub9 of the new format is inserted into the Option 82 field of DHCP messages. To specify the parameter, run the **dhcp option82 append vendor-specific** command.

Item	Description
dhcp option82 circuit-id format common	Format of the circuit-id suboption. To specify the parameter, run the **dhcp option82 format** command.

14.8.59 display dhcp snooping

Function

The **display dhcp snooping** command displays DHCP snooping running information.

Format

display dhcp snooping [**interface** *interface-type interface-number* | **vlan** *vlan-id* | **bridge-domain** *bd-id*]

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays DHCP snooping running information on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
vlan *vlan-id*	Displays DHCP snooping running information in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
bridge-domain *bd-id*	Displays DHCP snooping running information in a specified BD.	The BD ID must already exist.

Default Level

1: Monitoring level

Usage Guidelines

The **display dhcp snooping** command displays DHCP snooping running information. If no interface or VLAN is specified, global DHCP snooping running information is displayed. If an interface or a VLAN ID is specified, DHCP snooping running information of the interface or VLAN is displayed.

Example

Display global DHCP snooping running information.

```
<HUAWEI> display dhcp snooping
 DHCP snooping global running information   :
 DHCPv4 snooping                           : Enable
 DHCPv6 snooping                           : Enable
 Static user max number                    : 1024
 Current static user number                : 1
 Dhcp user(dhcpv4/dhcpv6/nd) max number     : 4096
 Dhcp user(dhcpv4/dhcpv6) max number        : 3000
 Nd user max number                        : 1000
 Current dhcpv4 user number                 : 0
 Current dhcpv6 user number                 : 0
 Current nd user number                    : 0
 Arp dhcp-snooping detect                  : Disable  (default)
 Alarm threshold                           : 100      (default)
 Check dhcp-rate                           : Disable  (default)
 Dhcp-rate limit(pps)                      : 100      (default)
 Alarm dhcp-rate                           : Disable  (default)
 Alarm dhcp-rate threshold                 : 100      (default)
 Discarded dhcp packets for rate limit      : 0
 Bind-table autosave                       : Disable  (default)
 Client position transfer allowed          : Enable   (default)
 DHCPv6 confirm-client online detection     : Enable   (default)
 DHCPv6 client online detection times       : 3        (default)
 DHCPv6 client online detection interval    : 180      (default)
 Check dhcpv6-rate                         : Disable  (default)
 Dhcpv6-rate limit(pps)                    : 100      (default)
 Alarm dhcpv6-rate                         : Enable
 Alarm dhcpv6-rate threshold               : 10
 Discarded dhcpv6 packets for rate limit    : 0
 DHCP snooping packet-flow log             : Disable  (default)

 DHCP snooping running information for interface GigabitEthernet0/0/1   :
 DHCP snooping                             : Enable
 Trusted interface                         : No
 Dhcp user(dhcpv4/dhcpv6/nd) max number     : 4096
 Current dhcpv4 user number                 : 0
 Current dhcpv6 user number                 : 0
 Current nd user number                    : 0
 Check dhcp-giaddr                         : Enable
 Check dhcp-chaddr                         : Disable  (default)
 Alarm dhcp-chaddr                         : Disable  (default)
 Check dhcp-request                        : Disable  (default)
 Alarm dhcp-request                        : Disable  (default)
 Check dhcp-rate                           : Enable
 Dhcp-rate limit(pps)                      : 100
 Alarm dhcp-rate                           : Enable
 Alarm dhcp-rate threshold                 : 100
 Discarded dhcp packets for rate limit      : 0
 Alarm dhcp-reply                          : Disable  (default)
 Check dhcpv6-rate                         : Enable
 Dhcpv6-rate limit(pps)                    : 100
 Alarm dhcpv6-rate                         : Enable
 Alarm dhcpv6-rate threshold               : 10
 Discarded dhcpv6 packets for rate limit    : 0
 Alarm dhcpv6-request                      : Enable
 Alarm dhcpv6-request threshold            : 100
```

```
Discarded dhcpv6 packets for check request : 0
DHCPv6 snooping check relay-forward        : Enable
Check dhcpv6-request                       : Disable  (default)
```

Table 14-70 Description of the **display dhcp snooping** command output

Item	Description
DHCPv4 snooping	Whether DHCPv4 snooping is enabled globally. To enable DHCP snooping, run the **dhcp snooping enable** command.
DHCPv6 snooping	Whether DHCPv6 snooping is enabled globally. To enable DHCP snooping, run the **dhcp snooping enable** command.
DHCP snooping	Whether DHCP snooping is enabled on an interface or in a VLAN. To enable DHCP snooping, run the **dhcp snooping enable** command.
Static user max number	Maximum number of static users.
Current static user number	Number of current static users.
Dhcp user(dhcpv4/dhcpv6/nd) max number	Shared specifications of the DHCPv4 snooping, ND snooping, and DHCPv6 snooping binding tables.
Dhcp user(dhcpv4/dhcpv6) max number	Maximum number of DHCPv4 snooping and DHCPv6 snooping users that can be set using a command. To configure this item, run the **dhcp snooping max-user-number** command. If this command is not configured, the item is not displayed.
Nd user max number	Maximum number of ND snooping users that can be set using a command. To configure this item, run the **nd snooping max-user-number** command. If this command is not configured, the item is not displayed.
Current dhcpv4 user number	Number of currently online DHCPv4 users.
Current dhcpv6 user number	Number of currently online DHCPv6 users.
Current nd user number	Number of currently online ND users.

Item	Description
Arp dhcp-snooping detect	Whether association between ARP and DHCP snooping is enabled. To enable association between ARP and DHCP snooping, run the **arp dhcp-snooping-detect enable** command.
Alarm threshold	Global alarm threshold for the number of discarded DHCP snooping messages. To set the global alarm threshold for the number of discarded DHCP snooping messages, run the **dhcp snooping alarm threshold** command.
Check dhcp-rate	Whether a device is enabled to check the rate of sending DHCP messages. To enable the device to check the rate of sending DHCP messages, run the **dhcp snooping check dhcp-rate enable** command.
Dhcp-rate limit(pps)	Rate limit of DHCP messages, in pps. To set the rate limit of DHCP messages, run the **dhcp snooping check dhcp-rate** command.
Alarm dhcp-rate	Whether trap for checking the rate of sending DHCP messages to the processing unit is enabled. To enable trap for checking the rate of sending DHCP messages to the processing unit, run the **dhcp snooping alarm dhcp-rate enable** command.
Alarm dhcp-rate threshold	Alarm threshold for the number of discarded DHCP messages. An alarm is generated if the number of discarded DHCP messages reaches the alarm threshold. To set the alarm threshold for the number of discarded DHCP messages, run the **dhcp snooping alarm dhcp-rate threshold** command.
Discarded dhcp packets for rate limit	Number of discarded DHCP messages whose rate exceeds the rate limit.

Item	Description
Bind-table autosave	Whether a device is enabled to save the DHCP snooping binding table. To enable the device to save the binding table, run the **dhcp snooping user-bind autosave** command.
Client position transfer allowed	Whether location transition is enabled for DHCP snooping users. To enable location transition for DHCP snooping users, run the **dhcp snooping user-transfer enable** command.
DHCPv6 confirm-client online detection	Whether the confirm-client probing function of DHCPv6 snooping is enabled. To configure the confirm-client probing function of DHCPv6 snooping, run the **dhcpv6 snooping user-bind detect confirm-client enable** command.
DHCPv6 client online detection times	Number of times that the DAD NS messages are sent for DHCPv6 snooping to detect whether the user is online. To configure the number of times that the DAD NS messages are sent for DHCPv6 snooping to detect whether the user is online, run the **dhcpv6 snooping user-bind detect retransmit** command.
DHCPv6 client online detection interval	Interval at which the DAD NS messages are sent for DHCPv6 snooping to detect whether the user is online. To configure the number of times that the DAD NS messages are sent for DHCPv6 snooping to detect whether the user is online, run the **dhcpv6 snooping user-bind detect retransmit** command.
Check dhcpv6-rate	Whether a device is enabled to check the rate of sending DHCPv6 messages. To enable a device to check the rate of sending DHCPv6 messages, run the **dhcp snooping check dhcpv6-rate enable** command.

Item	Description
Dhcpv6-rate limit(pps)	Rate limit of DHCPv6 messages, in pps. To configure the rate limit of DHCPv6 messages, run the **dhcp snooping check dhcpv6-rate** command.
Alarm dhcpv6-rate	Whether a device is enabled to generate an alarm when the rate of sending DHCPv6 messages to the processing unit exceeds the alarm threshold. To enable the device to generate an alarm when the rate of sending DHCPv6 messages to the processing unit exceeds the alarm threshold, run the **dhcp snooping alarm dhcpv6-rate enable** command.
Alarm dhcpv6-rate threshold	Alarm threshold for the number of discarded DHCPv6 messages. An alarm is generated if the number of discarded DHCPv6 messages reaches the alarm threshold. To configure the alarm threshold for the number of discarded DHCPv6 messages, run the **dhcp snooping alarm dhcpv6-rate threshold** command.
Discarded dhcpv6 packets for rate limit	Number of discarded DHCPv6 messages whose rate exceeds the rate limit.
DHCP snooping packet-flow log	Whether the log function is enabled for DHCP message exchange: ● Enable: The function is enabled. ● Disable: The function is disabled. To configure this function, run the **dhcp snooping packet-flow log enable** command.
Trusted interface	Whether an interface is a trusted interface. To configure an interface as a trusted interface, run the **dhcp snooping trusted** command.

Item	Description
Check dhcp-giaddr	Whether a device is enabled to check the GIADDR field in a DHCP Request message. To enable the device to check the GIADDR field in a DHCP Request message, run the **dhcp snooping check dhcp-giaddr enable** command.
Check dhcp-chaddr	Whether a device is enabled to check whether the CHADDR field in a DHCP Request message matches the source MAC address in the Ethernet frame header. To enable the device to check whether the CHADDR field in a DHCP Request message matches the source MAC address in the Ethernet frame header, run the **dhcp snooping check dhcp-chaddr enable** command.
Alarm dhcp-chaddr	Whether a device is enabled to generate an alarm when the number of discarded DHCP Request messages with the CHADDR field different from the source MAC address in the Ethernet frame header exceeds the alarm threshold. To enable the device to generate an alarm when the number of discarded DHCP Request messages with the CHADDR field different from the source MAC address in the Ethernet frame header exceeds the alarm threshold, run the **dhcp snooping alarm enable** command.
Check dhcp-request	Whether an interface is enabled to check DHCP Request messages. To enable the interface to check DHCP Request messages, run the **dhcp snooping check dhcp-request enable** command.

Item	Description
Alarm dhcp-request	Whether a device is enabled to generate an alarm when the number of DHCP Request messages discarded within a specified period reaches the alarm threshold. To enable the device to generate an alarm when the number of DHCP Request messages discarded within a specified period reaches the alarm threshold, run the **dhcp snooping alarm enable** command.
Alarm dhcp-reply	Whether a device is enabled to generate an alarm when an interface discards a DHCP Reply message from an untrusted interface. To enable the device to generate an alarm when an interface discards a DHCP Reply message from an untrusted interface, run the **dhcp snooping alarm enable** command.
Alarm dhcpv6-request	Whether a device is enabled to generate an alarm when an interface discards a DHCPv6 Request message from an untrusted interface. To enable the device to generate an alarm when an interface discards a DHCPv6 Request message from an untrusted interface, run the **dhcp snooping alarm enable** command.
Alarm dhcpv6-request threshold	Alarm threshold for the number of discarded DHCPv6 Request messages that are received from untrusted interfaces. To configure the alarm threshold, run the **dhcp snooping alarm threshold** command.
Discarded dhcpv6 packets for check request	Number of discarded DHCPv6 messages whose rate exceeds the rate limit.
DHCPv6 snooping check relay-forward	Whether the function of discarding DHCPv6 Relay-Forward messages is enabled. To configure this function, run the **dhcpv6 snooping check relay-forward enable** command.

Item	Description
Check dhcpv6-request	Whether the function of checking the validity of DHCPv6 messages based on MAC addresses is enabled. To configure this function, run the **dhcp snooping check dhcpv6-request mac** command.

14.8.60 display dhcp snooping configuration

Function

The **display dhcp snooping configuration** command displays the DHCP snooping configuration.

Format

display dhcp snooping configuration [**vlan** *vlan-id* | **interface** *interface-type interface-number* | **bridge-domain** *bd-id*]

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the DHCP snooping configuration in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Displays the DHCP snooping configuration on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
bridge-domain *bd-id*	Displays DHCP snooping running information in a specified BD.	The BD ID must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After DHCP snooping configuration is complete, run the **display dhcp snooping configuration** command to view the DHCP snooping configuration. If no VLAN or interface is specified, all the DHCP snooping configurations are displayed. If a VLAN or an interface is specified, only the DHCP snooping configuration in the VLAN or on the interface is displayed.

Example

Display all the DHCP snooping configurations.

```
<HUAWEI> display dhcp snooping configuration
#
dhcp snooping enable
#
vlan 3
 dhcp snooping enable
 dhcp snooping check dhcp-giaddr enable
#
interface GigabitEthernet0/0/1
 dhcp snooping enable
#
```

14.8.61 display dhcp snooping statistics

Function

The **display dhcp snooping statistics** command displays statistics about received DHCP messages.

Format

display dhcp snooping statistics { **bridge-domain** *bd-id* | **global** | **interface** *interface-type interface-number* [**vlan** *vlan-id*] | **vlan** *vlan-id* [**interface** *interface-type interface-number*] }

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
bridge-domain *bd-id*	Displays DHCP snooping statistics in a specified BD.	The value is an integer that ranges from 1 to 16777215.
global	Displays all DHCP snooping statistics on the device.	-
vlan *vlan-id*	Displays DHCP snooping statistics in a specified VLAN.	The value is an integer in the range from 1 to 4094.
interface *interface-type interface-number*	Displays DHCP snooping statistics on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view statistics about the received DHCP messages of all types, run the **display dhcp snooping statistics** command.

Example

Display DHCP snooping statistics on a specified interface.

```
<HUAWEI> display dhcp snooping statistics interface gigabitethernet 0/0/1
 DHCP Snooping Statistics:
 Dropped by mac-address check:   0
 Dropped by untrust reply:       0
 Dropped by request check:       0
 Dropped by requestv6 check:     0
 Dropped by no trust port:       0
 Dropped by deny dhcp:           0
```

Display DHCP snooping statistics in a specified BD.

```
<HUAWEI> display dhcp snooping statistics bridge-domain 300
 DHCP Snooping Statistics:
```

```
  Dropped by mac-address check:   0
  Dropped by untrust reply:       0
  Dropped by request check:       0
  Dropped by requestv6 check:     0
  Dropped by no trust port:       0
 Dropped by deny dhcp:            0
```

Display all DHCP snooping statistics on the device.

```
<HUAWEI> display dhcp snooping statistics global
 DHCP Snooping Statistics:

 Client Request:
  Dhcp Discover:                  0
  Dhcp Request:                   0
  Dhcp Decline:                   0
  Dhcp Release:                   0
  Dhcp Inform:                    0
 Server Reply:
  Dhcp Offer:                     0
  Dhcp Ack:                       0
  Dhcp Nak:                       0
 Drop Packet:
  Dropped by mac-address check:   0
  Dropped by untrust reply:       0
  Dropped by request conflict:    0
  Dropped by no trust port:       0
  Dropped by deny dhcp:           0
 Delete DHCP snooping table:
  Receive release packet:         0
  Receive decline packet:         0
  Lease expired:                  0
  User command:                   0
  Client transfers:               0
  Interface down:                 0
  Arp detect:                     0
  Ucm notify:                     0
 Terminal Identity:
  Single upload count:            0
  Batch get count:                0
  Batch upload count:             0
```

Table 14-71 Description of the **display dhcp snooping statistics** command output

Item	Description
DHCP Snooping Statistics	DHCP snooping statistics.
Client Request	Number of messages sent by DHCP clients: - DHCP Discover messages - DHCP Request messages - DHCP Decline messages - DHCP Release messages - DHCP Inform messages

Item	Description
Server Reply	Number of messages sent by the DHCP server: - DHCP Offer messages - DHCP ACK messages - DHCP NAK messages
Drop Packet	Number of discarded messages.
Dropped by mac-address check	Number of discarded DHCP messages whose MAC address is different from the CHADDR field.
Dropped by untrust reply	Number of untrusted reply messages that are discarded.
Dropped by request check	Number of DHCP Request messages discarded on an interface due to mismatch of any DHCP snooping binding entry.
Dropped by requestv6 check	Number of DHCPv6 Request messages discarded on an interface due to mismatch of any DHCPv6 snooping binding entry.
Dropped by request conflict	Number of packets that are discarded because the client and server MAC addresses conflict.
Dropped by untrust relay-forw	Number of untrusted Relay-Forward messages that are discarded.
Dropped by no trust port	Number of messages discarded because no trusted interface is configured.
Dropped by deny dhcp	Number of DHCP messages discarded because the function of discarding DHCP messages is enabled.
Dropped by relay-forward check	Number of discarded DHCPv6 Relay-Forward messages.
Delete DHCP snooping table	Number of DHCP snooping binding entries deleted by the device.
Receive release packet	Number of DHCP snooping binding entries deleted by the device after the device receives DHCP Release messages.
Receive decline packet	Number of DHCP snooping binding entries deleted by the device after the device receives DHCP Decline messages.
Lease expired	Number of DHCP snooping binding entries deleted by the device because of lease expiry.

Item	Description
User command	Number of DHCP snooping binding entries deleted using commands.
Client transfers	Number of DHCP snooping binding entries deleted because the client connects to another interface on the device.
Interface down	Number of DHCP snooping binding entries deleted because the port is shut down.
Arp detect	Number of DHCP snooping binding entries deleted due to ARP probe.
Ucm notify	Number of times the UCM module requests DHCP snooping to delete user binding entries.
Terminal Identity	Terminal identity.
Single upload count	Number of times that the DHCP snooping module reports a single user entry.
Batch get count	Number of times that the device requests to obtain entry information in a batch from the DHCP snooping module.
Batch upload count	Number of times that the DHCP snooping module reports entry information in a batch.

14.8.62 display dhcp snooping user-bind

Function

The **display dhcp snooping user-bind** command displays information about the DHCP snooping dynamic binding table.

Format

display dhcp snooping user-bind { { **interface** *interface-type interface-number* | **ip-address** *ip-address* | **mac-address** *mac-address* | **vlan** *vlan-id* | **bridge-domain** *bd-id* } * | **all** } [**verbose**]

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays binding entries mapping a specified interface. In the preceding information: - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
ip-address *ip-address*	Displays binding entries mapping a specified IP address.	The value is in dotted decimal notation.
mac-address *mac-address*	Displays binding entries mapping a specified MAC address.	The value is in H-H-H format. Each H is a hexadecimal number of 4 digits.
vlan *vlan-id*	Displays binding entries mapping a specified VLAN ID.	The value is an integer in the range from 1 to 4094.
bridge-domain *bd-id*	Displays DHCP snooping running information in a specified BD.	The BD ID must already exist.
all	Displays all entries in the binding table.	-
verbose	Displays detailed information about the binding table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After DHCP snooping is enabled, the device generates a DHCP snooping binding table. A binding entry contains the MAC address, IP address, interface connecting to the DHCP client, and ID of the VLAN to which the interface belongs. You can run the **display dhcp snooping user-bind** command to view the DHCP snooping binding table.

Example

Display information about the DHCP snooping binding table.

- Display information about all binding entries.

```
<HUAWEI> display dhcp snooping user-bind all
DHCP Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
IP Address       MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Interface      Lease
--------------------------------------------------------------------------------
10.1.28.141      00e0-fc12-3456  10                        GE0/0/1        2008.10.17-07:31
--------------------------------------------------------------------------------
Print count:           1          Total count:           1
```

- Display detailed information about the DHCP snooping binding table by specifying the **verbose** parameter.

```
<HUAWEI> display dhcp snooping user-bind all verbose
DHCP Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
--------------------------------------------------------------------------------
 IP Address     : 10.10.21.254
 MAC Address    : 00e0-fc12-3456
 Bridge-domain : 1
 VSI            : --
 VLAN(O/I/P)    : 10  /--  /--
 Interface      : GE0/0/1
 Renew time     : 2020.08.26-11:58
 Expire time    : 2019.08.27-11:58
 Cache time     : 2022.10.27-23:32
 Gateway        : 10.10.21.1
 Server-ip      : 10.10.21.1

Table 14-72 Description of the **display dhcp snooping user-bind** command output

Item	Description
DHCP Dynamic Bind-table	DHCP snooping dynamic binding table.
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping	O indicates the outer VLAN ID; I indicates the inner VLAN ID; P indicates the mapped VLAN ID.
IP Address	User IP address.
MAC Address	User MAC address.

Item	Description
VSI	Name of the VPN instance that the online user belongs to. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
VLAN (O/I/P)	Outer VLAN ID, inner VLAN ID, or mapped VLAN ID of the online user. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
(BD-VLAN)	BD and the VLAN to which the BD is bound. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
Bridge-domain	Broadcast domain.
Interface	Interface through which a user goes online.
Renew time	Entry update time.
Expire time	Aging time of entries.
Cache time	Cache time of entries.
IPSG Status	IPv4 effective indicates that IPv4 packet check takes effect. slot: <3> indicates that the slot ID is 3.
Lease	Time when the lease of the IP address used by a user expires.
Gateway	Gateway IP address.
Server-ip	IP addresses of the DHCP server.
Discover time	Time when the access device receives a DHCP request message.
Ack time	Time when the access device receives a DHCP ACK message.
Option12	DHCP Option 12 information carried by a user packet. This field is displayed only when a user packet carries this attribute.
Option55	DHCP Option 55 information carried by a user packet. This field is displayed only when a user packet carries this attribute.
Option60	DHCP Option 60 information carried by a user packet. This field is displayed only when a user packet carries this attribute.

Item	Description
OptionList	DHCP Option information carried by a user packet. This field is displayed only when a user packet carries this attribute.

14.8.63 display dhcpv6 snooping statistics

Function

The **display dhcpv6 snooping statistics** command displays DHCPv6 snooping statistics.

Format

display dhcpv6 snooping statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

None

Example

Display DHCPv6 snooping statistics.

```
<HUAWEI> display dhcpv6 snooping statistics
DHCPV6 Snooping Statistics:
--------------------------------------------------------------------------------
 DHCPV6 packets received from clients:
   Solicit                 : 3
   Request                 : 3
   Renew                   : 36
   Rebind                  : 0
   Inform                  : 0
   Release                 : 2
   Confirm                 : 394213
   Decline                 : 0
   Relay-forward           : 0
 DHCPV6 packets received from servers:
   Advertise               : 3
   Reply                   : 43
   Relay-reply             : 0
 DHCPV6 Packets Dropped:
```

```
  LDRA distrust relay-forward    : 0
  Src mac conflict with server   : 0
  Not allow client transfer      : 0
  Fake server                    : 0
  Reach savi user max number     : 0
  Reach dhcp user max number     : 0
  untrust relay-forw             : 0
  relay-forward check            : 0
  Check dhcpv6-request mac       : 0
  Deny dhcpv6                    : 0
 DHCPV6 snooping user-bind table deleted:
  Receive release packet         : 2
  Receive decline packet         : 0
  Exceed lifetime                : 0
  User command                   : 0
  Client transfer                : 0
  Interface down                 : 1
  Confirm-reply with error code  : 0
  Confirm-client offline         : 2
  Check mac client offline       : 0
 DAD NS packets sent to clients   : 16
 NA packets received from clients : 0
-------------------------------------------------------------------------------
```

Table 14-73 Description of the **display dhcpv6 snooping statistics** command output

Item	Description
DHCPV6 Snooping Statistics	DHCPv6 snooping statistics.
DHCPV6 packets received from clients	Number of DHCPv6 packets received from clients.
Solicit	Number of received Solicit packets.
Request	Number of received Request packets.
Renew	Number of received Renew packets.
Rebind	Number of received Rebind packets.
Inform	Number of received Inform packets.
Release	Number of received Release packets.
Confirm	Number of received Confirm packets.
Decline	Number of received Decline packets.
Relay-forward	Number of received Relay-Forward packets.
DHCPV6 packets received from servers	Number of DHCPv6 packets received from servers.
Advertise	Number of received Advertise packets.
Reply	Number of received Reply packets.
Relay-reply	Number of received Relay-reply packets.
DHCPV6 Packets Dropped	Number of discarded DHCPv6 packets.

Item	Description
LDRA distrust relay-forward	Number of Relay-Forward packets discarded by the LDRA untrusted port from the upstream LDRA.
Src mac conflict with server	When the source MAC address of a DHCPv6 packet from a client conflicts with the DHCPv6 server's MAC address, the DHCPv6 packet is discarded. The field indicates the number of DHCPv6 packets discarded for this reason.
Not allow client transfer	After clients are not allowed to change access interfaces, if a DHCPv6 snooping binding entry of a client exists on the original interface and the client attempts to change the access interface, the DHCPv6 packets from this client are discarded. The field indicates the number of DHCPv6 packets discarded for this reason. To configure this item, run the **undo dhcp snooping user-transfer enable** command.
Fake server	Number of packets discarded by the DHCP snooping-enabled interface from the DHCPv6 server. To configure this item, run the **dhcp snooping enable** command.
Reach savi user max number	Number of packets from clients discarded because the maximum number of SAVI binding entries that can be learned by the interface is reached.
Reach dhcp user max number	Number of packets from clients discarded because the maximum number of DHCP snooping binding entries that can be learned by the interface is reached.
untrust relay-forw	Number of Relay-Forward packets discarded by an LDRA untrusted interface.
relay-forward check	Number of discarded DHCPv6 Relay-Forward packets after the **dhcpv6 snooping check relay-forward enable** command is executed.
Check dhcpv6-request mac	Number of DHCPv6 packets that are discarded after the function of checking the validity of DHCPv6 packets based on MAC addresses is enabled.

Item	Description
Deny dhcpv6	Number of DHCPv6 messages discarded because the function of discarding DHCPv6 messages is enabled.
DHCPV6 snooping user-bind table deleted	Number of deleted DHCPv6 snooping binding entries.
Receive release packet	Number of binding entries deleted after receiving Release packets.
Receive decline packet	Number of binding entries deleted after receiving Decline packets.
Exceed lifetime	Number of binding entries that are aged out (the lease time is the same as that on client).
User command	Number of binding entries deleted using the **reset dhcp snooping user-bind** command.
Client transfer	After a client disconnects from one interface and connects to another one, the binding entry of the client on the original interface is deleted. The field indicates the number of binding entries deleted on original interfaces.
Interface down	Number of binding entries deleted because the interface physical status becomes Down.
Confirm-reply with error code	After a Confirm packet is received, a binding entry is generated. If a Reply packet in which the status code is not 0 is received within the timeout period (10 seconds), the generated binding entry is deleted. The field indicates the number of binding entries deleted for this reason.
Confirm-client offline	After the confirm-client probing function is enabled, an NA packet is returned for every DAD NS packet. If no NA packet is received when the maximum number of retransmission times of a DAD NS packet is reached, the binding entry is deleted. The field indicates the number of binding entries deleted for this reason.

Item	Description
Check mac client offline	Number of binding entries deleted because the device detects that users have gone offline after DHCPv6 snooping is enabled for detecting whether users are online.
DAD NS packets sent to clients	Number of DAD NS packets sent for confirm-client probing.
NA packets received from clients	Number of NA packets received from confirm-client probing.

14.8.64 display dhcpv6 snooping user-bind

Function

The **display dhcpv6 snooping user-bind** command displays the DHCPv6 snooping binding table.

Format

display dhcpv6 snooping user-bind { { **interface** *interface-type interface-number* | **ipv6-address** { *ipv6-address* | **all** } | **mac-address** *mac-address* | **vlan** *vlan-id* } * | **confirm-client** | **all** } [**verbose**]

display dhcpv6 snooping user-bind ipv6-prefix { *prefix/prefix-length* | **all** } [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the binding entry mapping a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
ipv6-address *ipv6-address*	Displays the binding entry mapping a specified IPv6 address.	The address is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
mac-address *mac-address*	Displays the binding entry mapping a specified MAC address.	The value is in hexadecimal notation.
vlan *vlan-id*	Displays the binding entry mapping a specified VLAN ID.	The value is an integer in the range from 1 to 4094.
ipv6-prefix	Displays an IPv6 suffix binding entry.	-
prefix/*prefix-length*	Displays the binding entry mapping a specified IPv6 prefix.	*prefix* is a 32-digit hexadecimal number, in the format of X:X::X:X. *prefix-length* is an integer that ranges from 1 to 128.
confirm-client	Displays the DHCPv6 snooping binding entries generated using DHCPv6 Confirm packets.	-
all	Displays all entries in the binding table.	-
verbose	Displays detailed information about the binding table. If the parameter is not specified, brief information about the binding table is displayed.	-

All views

Default Level

1: Monitoring level

Usage Guidelines

After DHCP snooping is enabled, the device generates a DHCP snooping binding table. A binding entry contains the MAC address, IP address, interface connecting to the DHCP client, and ID of the VLAN to which the interface belongs. You can run the **display dhcpv6 snooping user-bind** command to view the DHCPv6 snooping binding table.

If prefix delegation (PD) users exist on the network, the device generates an IPv6 prefix binding entry. The **display dhcpv6 snooping user-bind ipv6-prefix** command displays IPv6 prefix binding entries.

If a DHCPv6 snooping user is going online, running the **display dhcpv6 snooping user-bind** command generates a binding entry with an empty address. If the user goes online successfully, the binding entry is updated. If the user fails to go online, the binding entry ages and disappears.

Example

Display the DHCPv6 binding table.

- Display all binding entries.

```
<HUAWEI> display dhcpv6 snooping user-bind all
DHCPV6 Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
IP Address                    MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Lease
--------------------------------------------------------------------------------
FC00:1::1                    00e0-fc12-3456  500 /--  /--    2008.10.01-00:26
--------------------------------------------------------------------------------
print count:           1          total count:           1
```

- Display detailed information about the DHCPv6 binding table.

```
<HUAWEI> display dhcpv6 snooping user-bind all verbose
DHCPV6 Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
--------------------------------------------------------------------------------
 IP Address  : FC00:1::1
 MAC Address : 00e0-fc12-3456
 VSI         : --
 VLAN(O/I/P) : 500 /--  /--
 Interface   : GE0/0/1
 Renew time  : 2008.10.01-00:27
 Expire time : 2008.10.03-00:27
 Cache time  : 2022.10.03-00:27
 IPSG Status : ineffective
 DadTimerId  : --
 DadPktNum   : --
 User State  : BOUND
--------------------------------------------------------------------------------
print count:           1          total count:           1
```

Display the IPv6 prefix binding table.

- Display all binding entries.

```
<HUAWEI> display dhcpv6 snooping user-bind ipv6-prefix all
PD Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
IPv6 Prefix                   MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Lease
--------------------------------------------------------------------------------
FC00:2::/36                   00e0-fc12-3456  500 /--  /--    2008.10.03-00:30
--------------------------------------------------------------------------------
print count:           1          total count:           1
```

- Display detailed information about the IPv6 prefix binding table by specifying the **verbose** parameter.

```
<HUAWEI> display dhcpv6 snooping user-bind ipv6-prefix all verbose
PD Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
--------------------------------------------------------------------------------
 IP Address  : FC00:2::/36
 MAC Address : 00e0-fc12-3456
 VSI         : --
 VLAN(O/I/P) : 500 /--  /--
 Interface   : GE0/0/1
```

```
 Lease       : 2008.10.03-00:30
 User State  : BOUND
--------------------------------------------------------------------------------
print count:           1          total count:           1
```

Table 14-74 Description of the **display dhcpv6 snooping user-bind** command output

Item	Description
DHCPV6 Dynamic Bind-table	DHCPv6 snooping dynamic binding table.
PD Dynamic Bind-table	IPv6 prefix binding table.
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping	VLAN ID. ● O: Outer VLAN ● I: Inner VLAN ● P: VLAN mapping
IP Address	User IPv6 address.
IPv6 Prefix	User IPv6 prefix.
MAC Address	User MAC address.
VSI	Name of the VPN instance that the online user belongs to. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
VLAN(O/I/P)	Outer VLAN ID, inner VLAN ID, or mapped VLAN ID of the online user. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
(BD-VLAN)	BD and the VLAN to which the BD is bound. **NOTE** If **verbose** is not specified, only one of VSI, (BD-VLAN), and VLAN (O/I/P) is displayed.
Interface	Interface through which a user goes online.
Lease	Time when the lease of the IP address used by a user expires.
IPSG Status	Whether the binding table is effective for IP packet check that has been enabled. ● IPv6 effective slot: <0> indicates that the binding table is effective for IPv6 packet checking in slot 0. ● ineffective This field is invalid if IP packet check is disabled.
Renew time	Entry update time.

Item	Description
Expire time	Entry expiration time.
Cache time	Cache time of entries.
DadTimerId	Client probing timer ID.
DadPktNum	Remaining number of times a DAD NS packet can be transmitted.
User State	Status of a DHCPv6 snooping binding entry is as follows: ● START ● DETECTION ● BOUND ● LIVE ● DELETE ● CONFIRM ● TESTING_VP

14.8.65 reset dhcp snooping statistics

Function

The **reset dhcp snooping statistics** command clears DHCP snooping statistics.

Format

reset dhcp snooping statistics { **bridge-domain** *bd-id* | **global** | **interface** *interface-type interface-number* [**vlan** *vlan-id*] | **vlan** *vlan-id* [**interface** *interface-type interface-number*] }

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
bridge-domain *bd-id*	Clears DHCP snooping statistics in a specified BD.	The value is an integer that ranges from 1 to 16777215.
global	Clears global DHCP snooping statistics.	-

Parameter	Description	Value
interface *interface-type interface-number*	Clears DHCP snooping statistics on the specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vlan *vlan-id*	Clears DHCP snooping statistics in the specified VLAN. *vlan-id* specifies a VLAN ID.	*vlan-id* is an integer that ranges from 1 to 4094.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If statistics are collected after DHCP snooping is enabled, you can run the **reset dhcp snooping statistics** command to clear the statistics.

Precautions

If both **interface** and **vlan** are specified, the specified interface must have been added to the specified VLAN. The **reset dhcp snooping statistics** command is used to clear DHCP snooping statistics in the VLAN to which the specified interface is added.

Example

Clear DHCP snooping statistics on GE0/0/1.

```
<HUAWEI> reset dhcp snooping statistics interface gigabitethernet 0/0/1
```

14.8.66 reset dhcp snooping user-bind

Function

The **reset dhcp snooping user-bind** command clears DHCP snooping binding entries.

Format

reset dhcp snooping user-bind [**vlan** *vlan-id* | **interface** *interface-type interface-number*] * [**ipv4** | **ipv6**]

reset dhcp snooping user-bind [**ip-address** [*ip-address*] | **ipv6-address** [*ipv6-address*] | **vpls** *vpls-name*]

reset dhcp snooping user-bind bridge-domain *bd-id*

reset dhcp snooping user-bind [**ipv6-prefix** [*prefix/prefix-length*]]

NOTE

Only the , S5731-H, S5731S-H, S5732-H, S6730-H, S6730S-H support **vpls** parameter.

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
vlan *vlan-id*	Clears DHCP snooping binding entries mapping a specified VLAN ID.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Clears DHCP snooping binding entries mapping a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
bridge-domain *bd-id*	Clears DHCP snooping binding entries in a specified BD.	The BD ID must already exist.
ipv4 or **ip-address**	Clears DHCP snooping binding entries mapping IPv4 addresses.	-
ipv6-address, **ipv6** or **ipv6-prefix**	Clears DHCP snooping binding entries mapping IPv6 addresses or IPv6 prefixes. ● **ipv6** indicates that DHCP snooping binding entries mapping IPv6 addresses or IPv6 prefixes are cleared. ● **ipv6-address** indicates that DHCP snooping binding entries mapping IPv6 addresses are cleared. ● **ipv6-prefix** indicates that DHCP snooping binding entries mapping IPv6 prefixes are cleared.	-

Parameter	Description	Value
ip-address	Clears DHCP snooping binding entries mapping a specified IPv4 address.	The value is in dotted decimal notation.
ipv6-address	Clears DHCP snooping binding entries mapping a specified IPv6 address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
prefix/*prefix-length*	Clears DHCP snooping binding entries mapping a specified IPv6 prefix. - *prefix* specifies the IPv6 prefix. - *prefix-length* specifies the IPv6 prefix length.	*prefix* is a 32-digit hexadecimal characters in the format of X:X::X:X. *prefix-length* is an integer that ranges from 1 to 128.
vpls *vpls-name*	Clears DHCP snooping binding entries mapping a specified VPLS name.	The value must be an existing VPLS name.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After DHCP snooping is enabled, the mapping DHCP snooping binding entries are generated after DHCP users log in. The **reset dhcp snooping user-bind** command clears binding entries mapping a specified parameter. If no parameter is specified, all the binding entries are cleared.

Precautions

If both **interface** *interface-type interface-number* and **vlan** *vlan-id* are configured, the interface specified by **interface** *interface-type interface-number* must have been added to the VLAN specified by **vlan** *vlan-id*. In this case, the command clears the DHCP snooping binding entries on a specified interface belonging to a certain VLAN.

Example

Clear DHCP snooping binding entries in VLAN 100.

```
<HUAWEI> reset dhcp snooping user-bind vlan 100
```

14.8.67 reset dhcpv6 snooping statistics

Function

The **reset dhcpv6 snooping statistics** command deletes DHCPv6 snooping statistics.

Format

reset dhcpv6 snooping statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

When you locate faults in DHCPv6 services, you need to collect statistics on DHCPv6 snooping packets and deleted entries within a certain period of time. Before collecting statistics using the **display dhcpv6 snooping statistics** command, run the **reset dhcpv6 snooping statistics** command to delete historical statistics.

Example

Delete DHCPv6 snooping statistics.

```
<HUAWEI> reset dhcpv6 snooping statistics
```

14.9 ND Snooping Configuration Commands

14.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.9.2 display nd snooping configuration

Function

The **display nd snooping configuration** command displays the ND snooping configuration.

Format

display nd snooping configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

ND snooping configuration includes whether ND snooping is enabled or disabled and information about ND snooping trusted interfaces.

To view ND snooping configuration, run the **display nd snooping configuration** command.

Example

Display ND snooping configuration.

```
<HUAWEI> display nd snooping configuration
#
nd snooping enable
#
interface GigabitEthernet0/0/1
 nd snooping trusted
#
```

14.9.3 display nd snooping prefix

Function

The **display nd snooping prefix** command displays prefix management entries of users.

Format

display nd snooping [**static** | **dynamic**] **prefix** [**verbose**]

Parameters

Parameter	Description	Value
static	Displays statically configured prefix management entries.	-
dynamic	Displays dynamically generated prefix management entries.	-
verbose	Displays details about prefix management entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A device can establish a prefix management table which can be used to implement duplicate address detection for users with IPv6 addresses and establish a dynamic ND snooping binding table. A prefix management entry can be statically configured or dynamically generated.

- Dynamic generation: The device obtains an RA packet received from an ND snooping trusted interface and automatically generates a prefix management entry based on the RA packet.
- Static configuration: When a gateway device does not send RA packets, you can run the **nd snooping static-prefix** command to configure a static prefix management entry.

You can run the **display nd snooping prefix** command to check prefix management entries.

Example

Display prefix management entries of users.

```
<HUAWEI> display nd snooping prefix
prefix-table:
Prefix                       Length     Valid-Time    Vlan(O/I)/BD     Prefix-
Type
--------------------------------------------------------------------------------
FC00:1::                      64       -        10  /24/-      static
FC00:2::                      64       2592000      1   /-/-      dynamic
--------------------------------------------------------------------------------
Prefix table total count:       2        Print count:         2
```

Table 14-75 Description of the **display nd snooping prefix** command output

Item	Description
prefix-table	Prefix management table of users.
Prefix	Prefix. The value is a 32-digit hexadecimal number, in the X:X:X:X:X:X:X:X format.
Length	Prefix length. The value is an integer that ranges from 1 to 128.
Valid-Time	Valid lifetime of a prefix. The value ranges from 0 to 4294967295, in seconds.
Vlan(O/I)/BD	VLAN or BD information in a prefix management entry.
Prefix-Type	Type of a prefix management entry. The value can be: ● static: The prefix management entry is statically configured. ● dynamic: The prefix management entry is dynamically generated.
Prefix table total count	Total number of entries in the prefix management table.
Print count	Number of displayed prefix management entries.

Display prefix management entries of users.

```
<HUAWEI> display nd snooping prefix verbose
prefix-table:
-------------------------------------------------------------------------------

 VLAN ID(Outer/Inner)    : 1/-
 Prefix Type             : dynamic
-------------------------------------------------------------------------------
Prefix table total count:      2          Print count:         2
```

Table 14-76 Description of the **display nd snooping prefix verbose** command output

Item	Description
prefix-table	Prefix management table of users.
Prefix	Prefix. The value is a 32-digit hexadecimal number, in the X:X:X:X:X:X:X:X format.
Prefix Length	Prefix length. The value is an integer that ranges from 1 to 128.
Valid Lifetime(sec)	Valid lifetime of a prefix. The value ranges from 0 to 4294967295, in seconds.
Preferred Lifetime(sec)	Preferred lifetime of a prefix. The value ranges from 0 to 4294967295, in seconds.
Interface	Interface information in a prefix management entry.
VLAN ID(Outer/Inner)	VLAN information in a prefix management entry.
Prefix-Type	Type of a prefix management entry. The value can be: ● static: The prefix management entry is statically configured. ● dynamic: The prefix management entry is dynamically generated.
Prefix table total count	Total number of entries in the prefix management table.
Print count	Number of printed entries.

14.9.4 display nd snooping statistics

Function

The **display nd snooping statistics** command displays statistics about the ND snooping packets received, sent, and discarded by the device.

Format

display nd snooping statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After ND snooping is enabled, the device records statistics on the received, sent, and discarded ND snooping packets to facilitate maintenance.

Example

Display statistics on the ND snooping packets received, sent, and discarded on the device.

```
<HUAWEI> display nd snooping statistics
Input: total 203 packets, discarded 14 packets
  ns                                        :       178
  na                                        :        21
  rs                                        :         4
  ra                                        :         0
  other                                     :         0
Drop Packet:
  The local link address is incorrect           :         7
  It does not match the binding table            :         1
  The destination IP address is incorrect        :         6
Output: total 50 packets
  ns                                        :         50
```

Table 14-77 Description of the **display nd snooping statistics** command output

Item	Description
Input: total *n* packets, discarded *m* packets	Number (*n*) of ND packets received by the device and number (*m*) of discarded ND packets.
ns	Number of sent or received NS packets on a device.
na	Number of received NA packets.
rs	Number of received RS packets.
ra	Number of received RA packets.
other	Number of received other packets.
Drop Packet	Number of dropped packets. The displayed information varies according to the packet drop reasons.
The local link address is incorrect	Number of packets dropped due to incorrect link-local address.

Item	Description
It does not match the binding table	Number of packets dropped because the packets do not match the binding entries.
The destination IP address is incorrect	Number of packets dropped due to incorrect destination IP addresses.
Output: total *x* packets	Number (*x*) of ND packets sent by a device.

14.9.5 display nd snooping user-bind

Function

The **display nd snooping user-bind** command displays the ND snooping dynamic binding table.

Format

display nd snooping user-bind all [**verbose**]

display nd snooping user-bind { **ipv6-address** *ipv6-address* | **mac-address** *mac-address* | **interface** *interface-type interface-number* | **vlan** *vlan-id* | **bridge-domain** *bd-id* } * [**verbose**]

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
all	Displays all ND snooping dynamic binding entries.	-
verbose	Displays detailed information about ND snooping dynamic binding entries.	-
ipv6-address *ipv6-address*	Displays information about the IPv6 address in the ND snooping dynamic binding table.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
mac-address *mac-address*	Displays information about the MAC address in the ND snooping dynamic binding table.	The value is in the format of H-H-H. An H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
vlan *vlan-id*	Displays information about the VLAN in the ND snooping dynamic binding table.	The value is an integer ranging from 1 to 4094.
interface *interface-type interface-number*	Displays interface information in the ND snooping dynamic binding table. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
bridge-domain *bd-id*	Displays information about the BD in the ND snooping dynamic binding table.	The value is an integer ranging from 1 to 16777215.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An ND snooping dynamic binding entry includes the source IPv6 address and source MAC address of a user, and the VLAN that a user belongs to. You can run the **display nd snooping user-bind** command to view details in the ND snooping dynamic binding table.

Example

Display all ND snooping dynamic binding entries.

```
<HUAWEI> display nd snooping user-bind all
ND Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
IP Address                    MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Lease
-----------------------------------------------------------------------------------------
FC00:1::2                    00e0-fc12-3456  10  /--  /--            2011.05.06-20:09
-----------------------------------------------------------------------------------------
Print count:           1          Total count:           1
```

Display detailed information about ND snooping dynamic binding entries.

```
<HUAWEI> display nd snooping user-bind all verbose
ND Dynamic Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
------------------------------------------------------------------------------------------
 IP Address     : FE80::6BD:70FF:FEE0:733
```

```
 MAC Address   : 00e0-fc12-3456
 Bridge-domain : 50
 VSI           : --
 VLAN(O/I/P)   : 200 /--  /--
 Interface     : GE0/0/1
 Renew time    : 2019.10.28-15:02
 Expire time   : 2019.10.28-16:02
 DadTimerId    : --
 DadPktNum     : --
 User State    : BOUND
--------------------------------------------------------------------------------
Print count:          1          Total count:          1
```

Table 14-78 Description of the **display nd snooping user-bind** command output

Item	Description
ND Dynamic Bind-table	ND snooping dynamic binding table.
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping	O indicates the outer VLAN ID; I indicates the inner VLAN ID; P indicates the mapped VLAN ID.
IP Address	IPv6 address of a user.
MAC Address	MAC address of a user.
Bridge-domain	Broadcast domain.
VSI	VPN instance that a user belongs to.
VLAN(O/I/P)	Inner VLAN ID, outer VLAN ID, or VLAN mapping information of the online user. **NOTE** The ND snooping binding table does not contain VLAN mapping information. Therefore, no value is displayed in the P field.
Interface	User access interface.
User State	Status of an ND snooping dynamic binding entry is as follows: ● START: The binding entry is being created and is in the initialization state. ● DETECTION: The system is performing detection for the binding entry to check whether the user is online. ● BOUND: The binding entry has been successfully created.

14.9.6 nd snooping alarm binding-table check enable

Function

The **nd snooping alarm binding-table check enable** command enables the alarm function for checking packets against the ND snooping binding table.

The **undo nd snooping alarm binding-table check enable** command disables the alarm function for checking packets against the ND snooping binding table.

By default, the alarm function for checking packets against the ND snooping binding table is disabled.

Format

nd snooping alarm binding-table check enable

undo nd snooping alarm binding-table check enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After ND protocol packet validity check is enabled using the **nd snooping check enable** command, the device checks the NA, NS, and RS packets received from untrusted interfaces against the ND snooping binding table and discards the packets that do not match the binding table. If the number of discarded packets exceeds the threshold, the corresponding alarm is generated. The minimum interval for sending alarm messages is 1 minute. You can run the **nd snooping alarm binding-table check threshold** command to set the alarm threshold.

Prerequisites

ND snooping has been enabled on the device using the **nd snooping enable** command.

Precautions

To ensure that alarms can be properly reported, you need to run the **snmp-agent trap enable feature-name dhcp** command to enable the DHCP module to report the corresponding alarm. You can check whether the DHCP module is enabled to report the corresponding alarm using the **display snmp-agent trap feature-name dhcp all** command.

Example

Enable the alarm function for checking packets against the ND snooping binding table on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping alarm binding-table check enable
```

14.9.7 nd snooping alarm binding-table check threshold

Function

The **nd snooping alarm binding-table check threshold** command configures the alarm threshold for the number of ND snooping-discarded packets.

The **undo nd snooping alarm binding-table check threshold** command restores the default alarm threshold.

By default, the global alarm threshold for the number of ND snooping-discarded packets is 100, and the alarm threshold for the number of ND snooping-discarded packets on an interface is the value configured in the system view.

Format

nd snooping alarm binding-table check threshold *threshold*

undo nd snooping alarm binding-table check threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold for the number of ND snooping-discarded packets.	The value is an integer that ranges from 1 to 1000.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the alarm function for checking packets against the ND snooping binding table is enabled using the **nd snooping alarm binding-table check enable** command, you can run the **nd snooping alarm binding-table check threshold** command to configure the alarm threshold for the number of ND snooping-discarded packets.

Prerequisites

ND snooping has been enabled on the device using the **nd snooping enable** command.

Precautions

If this command is run in the system view, it takes effect on all the interfaces of the device.

Example

Set the alarm threshold for the number of ND snooping-discarded packets on GE0/0/1 to 1000.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping alarm binding-table check threshold 1000
```

14.9.8 nd snooping check enable

Function

The **nd snooping check enable** command enables ND protocol packet validity check.

The **undo nd snooping check enable** command disables ND protocol packet validity check.

By default, ND protocol packet validity check is disabled.

Format

nd snooping check { **na** | **ns** | **rs** } **enable**

undo nd snooping check { **na** | **ns** | **rs** } **enable**

Parameters

Parameter	Description	Value
na	Enables validity check for Neighbor Advertisement (NA) packets.	-
ns	Enables validity check for Neighbor Solicitation (NS) packets.	-
rs	Enables validity check for Router Solicitation (RS) packets.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

ND packet validity check prevents forged NA/NS/RS packets.

After ND packet validity check is enabled, the device verifies the NA/NS/RS packets received by untrusted interfaces against the ND snooping binding table, to determine whether the NA/NS/RS packets are sent from valid users in the VLAN on the interface. The device forwards the ND packets from valid users and drops invalid ND packets.

Prerequisites

ND snooping has been enabled globally using the **nd snooping enable** command.

Example

Enable NA packet validity check on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping check na enable
```

14.9.9 nd snooping check dad-ns retransmit-rate rate

Function

The **nd snooping check dad-ns retransmit-rate rate** command configures the maximum retransmission rate of DAD NS packets.

The **undo nd snooping check dad-ns retransmit-rate rate** command restores the default retransmission rate of DAD NS packets.

By default, the maximum retransmission rate of DAD NS packets is 50 packets per second.

Format

nd snooping check dad-ns retransmit-rate rate *rate-value*

undo nd snooping check dad-ns retransmit-rate rate

Parameters

Parameter	Description	Value
rate-value	Specifies the maximum retransmission rate of DAD NS packets.	The value is an integer that ranges from 1 to 100, in packet per second. The default value is 50.

Views

System view, VLAN view, Eth-Trunk view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the ND snooping binding entry is not established, an untrusted interface on a device forwards a DAD NS packet after receiving it. After the **nd snooping check dad-ns retransmit-rate enable** command is configured, the device checks the retransmission rate of DAD NS packets. You can run the **nd snooping check dad-ns retransmit-rate rate** *rate-value* command to configure the retransmission rate of DAD NS packets. If the number of DAD NS packets retransmitted per second exceeds the value of the *rate-value* parameter, the device directly discards excessive packets instead of forwarding these packets.

Prerequisites

ND snooping has been enabled using the **nd snooping enable** command in the system view.

Example

Set the retransmission rate of DAD NS packets to 60 packets per second in the system view.

```
<HUAWEI> system-view
[HUAWEI] nd snooping check dad-ns retransmit-rate rate 60
```

14.9.10 nd snooping check dad-ns retransmit-rate enable

Function

The **nd snooping check dad-ns retransmit-rate enable** command enables the function of checking the retransmission rate of DAD NS packets.

The **undo nd snooping check dad-ns retransmit-rate enable** command disables the function of checking the retransmission rate of DAD NS packets.

By default, the function of checking the retransmission rate of DAD NS packets is disabled.

Format

nd snooping check dad-ns retransmit-rate enable

undo nd snooping check dad-ns retransmit-rate enable

Parameters

None

Views

System view, VLAN view, Eth-Trunk view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an untrusted interface on a device receives a DAD NS packet, the interface forwards the packet for the duplicate address detection and bogus user check. To avoid the situation that the remote interface cannot receive packets forwarded by the local device because of packet loss when the ND snooping binding entry is not established, configure the untrusted interface on the local device to forward a DAD NS packet after receiving it. By default, a device does not control the retransmission rate of DAD NS packets. When excessive packets are received, packet retransmission may affect normal operation of network services. To solve this problem, you can run the **nd snooping check dad-ns retransmit-rate enable** command to enable the function of checking the retransmission rate of DAD NS packets. After this function is enabled, the device limits the retransmission rate of DAD NS packets.

You can run the **nd snooping check dad-ns retransmit-rate rate** *rate-value* command to configure the retransmission rate of DAD NS packets. If the number of DAD NS packets retransmitted per second exceeds the value of the *rate-value* parameter, the device directly discards excessive packets instead of forwarding these packets.

Prerequisites

ND snooping has been enabled using the **nd snooping enable** command in the system view.

Example

Enable the function of checking the retransmission rate of DAD NS packets in the system view.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] nd snooping check dad-ns retransmit-rate enable
```

14.9.11 nd snooping disable

Function

The **nd snooping disable** command disables ND snooping on an interface.

The **undo nd snooping disable** command restores the default configuration.

By default, ND snooping is disabled on an interface.

Format

nd snooping disable

undo nd snooping disable

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6735-S, S6730-S, and S6730S-S support this command.

Parameters

None.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If ND snooping is enabled in a specific VLAN using the **nd snooping enable** command, ND snooping is enabled on all the interfaces in this VLAN. The **nd snooping enable** command is configured in the VLAN, and interfaces in the VLAN do not have the command configuration. Therefore, the **undo nd snooping enable** command cannot disable ND snooping on a specific interface in this VLAN. To solve this problem, run the **nd snooping disable** command on this interface to disable ND snooping on it.

Precautions

- Running the **nd snooping disable** command will disable ND snooping on an interface and clear the ND snooping configuration and the dynamic ND snooping binding table. Running the **undo nd snooping enable** command will disable ND snooping on an interface will the dynamic ND snooping binding table, but will not clear the ND snooping configuration.
- Running the **undo nd snooping disable** command on an interface will disable ND snooping on the interface. To enable ND snooping on the interface, run the **nd snooping enable** command.

Example

Disable ND snooping on GE0/0/1 that has been added to VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] nd snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping disable
```

14.9.12 nd snooping enable

Function

The **nd snooping enable** command enables ND snooping.

The **undo nd snooping enable** command disables ND snooping.

By default, ND snooping is disabled.

Format

nd snooping enable

undo nd snooping enable

Parameters

None

Views

System view, VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

ND provides powerful functions but has no security mechanism. Attackers often use ND to attack network devices. Common ND attacks are as follows:

- An attacker uses the IP address of host A to send NS, NA, or RS packets to host B or the gateway. Host B or the gateway then modifies their ND entries. As a result, all packets sent from host B or the gateway to host A are sent to the attacker.
- An attacker uses the gateway IP address to send RA packets to hosts. Then the hosts incorrectly set IPv6 parameters and modify their ND entries.

To prevent ND attacks, enable ND snooping on the device. The device detects NS packets in the DAD process to establish an ND snooping dynamic binding table that includes source IPv6 addresses, source MAC addresses, VLANs, and inbound ports. When receiving ND packets, the device checks the validity of ND packets based on the ND snooping binding table and checks whether the user is an authorized user in the VLAN that the port receiving ND packets belongs to. The device forwards valid ND packets and discards invalid ND packets to defend against ND attacks from bogus hosts or gateways.

NOTE

By default, the system reports a port-Up event 2 seconds after a user-side interface transits from Down to Up state. If ND snooping is enabled before the port-Up event is reported, the system cannot generate the ND snooping entry of the user connected to this interface. To avoid this problem, run the **carrier up-hold-time** *interval* command to change the delay in reporting the port-Up event to 0.

Example

Enable ND snooping globally and on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping enable
```

14.9.13 nd snooping enable dhcpv6 only

Function

The **nd snooping enable dhcpv6 only** command enables ND snooping in the DHCPv6 Only scenario.

The **undo nd snooping enable** command disables ND snooping in the DHCPv6 Only scenario.

By default, ND snooping is disabled in the DHCPv6 Only scenario.

Format

nd snooping enable dhcpv6 only

undo nd snooping enable

Parameters

None

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device checks the validity of ND protocol packets against the IPv6 static binding table, DHCPv6 dynamic binding table, and ND snooping binding table. The IPv6 static binding table is manually configured by the administrator, the DHCPv6 dynamic binding table is automatically generated by extracting information from DHCPv6 Reply packets, and the ND snooping binding table is automatically generated by extracting information from DAD NS packets. At the same time, the ND protocol packet validity check function depends on the ND snooping function (including enabling ND snooping and configuring ND snooping trusted interfaces). In the DHCPv6 Only scenario, users are only allowed to obtain IPv6 addresses using DHCPv6 and IPv6 addresses that are privately configured by users and automatically generated using the PD address prefix are considered as invalid addresses. In this scenario, ND snooping is disabled to prevent ND snooping binding entries from being generated for such invalid addresses. In this case, the ND protocol packet validity check function cannot be performed, so that address spoofing attacks may exist on the network.

To resolve this problem, you can run the **nd snooping enable dhcpv6 only** and **nd snooping trusted dhcpv6 only** commands to enable the ND snooping function in the DHCPv6 Only scenario. After the **nd snooping enable dhcpv6 only** command is configured, no ND snooping binding entry is generated for the IPv6 global unicast addresses that are manually configured by users and automatically generated using the PD address prefixes. The device checks the validity of ND protocol packets against the IPv6 static binding table and DHCPv6 dynamic binding table.

Prerequisites

ND snooping has been enabled globally using the **nd snooping enable** command.

Precautions

- In the DHCPv6 Only scenario, ND snooping binding entries are generated for the IPv6 link-local addresses that are manually configured by users and automatically generated. To be specific, only records corresponding to the IPv6 link-local addresses exist in the ND snooping binding table in the DHCPv6 Only scenario.
- IPv6 addresses obtained using DHCPv6 PD also apply to the DHCPv6 Only scenario.

Example

Enable ND snooping globally and on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping enable dhcpv6 only
```

14.9.14 nd snooping max-user-number

Function

The **nd snooping max-user-number** command sets the maximum number of ND snooping dynamic binding entries to be learned by an interface.

The **undo nd snooping max-user-number** command restores the default maximum number of ND snooping dynamic binding entries to be learned by an interface.

By default, the maximum number of ND snooping binding entries that can be learned on an interface is 512 for S200, S1720GW-E, S1720GWR-E, and 2048 for S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5720I-SI, S5735S-H, S5736-S, S6735-S, and 8192 for other models.

Format

nd snooping max-user-number *max-user-number*

undo nd snooping max-user-number

Parameters

Parameter	Description	Value
max-user-number	Specifies the maximum number of ND snooping dynamic binding entries to be learned by an interface.	The value is an integer that ranges from 1 to 512 for S1720GW-E, S1720GWR-E, and from 1 to 2048 for S5720-LI, S2730S-S, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, , S5735S-H, S5736-S, S6720S-S, and S5720I-SI, and from 1 to 8192 for other models.

Views

System view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a lot of users go online through an interface, the device consumes many ND snooping dynamic binding entries to process the NS packets. To prevent this problem, you can set the maximum number of ND snooping dynamic binding entries to be learned by an interface. If the number of the ND snooping dynamic binding entries learned by an interface reaches the maximum number, no entry can be added.

You can set the maximum number ND snooping entries in the system view or interface view. The configuration in the system view is valid for all interfaces. The settings in the interface view only take effect on the specified interface. If the settings are performed in both the interface view and system view, the smaller value is adopted.

Prerequisites

Before setting the maximum number of ND snooping dynamic binding entries to be learned by an interface, ensure that ND snooping has been enabled in the system view using the **nd snooping enable** command.

Example

Set the maximum number of ND snooping binding entries to 200 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping max-user-number 200
```

14.9.15 nd snooping static-prefix

Function

The **nd snooping static-prefix** command configures a static prefix management entry.

The **undo nd snooping static-prefix** command deletes a configured static prefix management entry.

By default, no static prefix management entry is configured on a device.

Format

nd snooping static-prefix *ipv6-address/prefix-length* [**vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*]]

undo nd snooping static-prefix *ipv6-address/prefix-length* [**vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*]]

Parameters

Parameter	Description	Value
ipv6-address/prefix-length	Specifies the IPv6 address prefix. Descriptions of each part in this parameter are as follows: - *ipv6-address*: Specifies an IPv6 address. - *prefix-length*: Specifies the IPv6 address prefix length.	- *ipv6-address*: The total length of the value is 128 bits. The string is divided into eight groups, each of which consists of four hexadecimal digits. The address is in the X:X:X:X:X:X:X:X format. - *prefix-length*: The value is an integer that ranges from 1 to 128.
vlan *vlan-id*	Specifies the outer VLAN ID. **NOTE** By default, the outer VLAN ID is 1 and no inner VLAN is configured.	The value is an integer that ranges from 1 to 4094.
ce-vlan *ce-vlan-id*	Specifies the inner VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After receiving an NS packet from a user, a device can generate a dynamic ND snooping binding entry only after the value of the **Target Address** field in the packet matches the user's prefix management entry. The device obtains an RA packet received from an ND snooping trusted interface and automatically generates a prefix management entry based on the RA packet. However, if a gateway device does not send RA packets, the device cannot automatically generate a prefix management entry and then cannot establish a corresponding dynamic ND snooping binding entry, affecting services. In this case, you can run the **nd snooping static-prefix** *ipv6-address/prefix-length* [**vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*]] command to manually configure a prefix management entry.

Prerequisites

ND snooping has been enabled using the **nd snooping enable** command in the system view.

Precautions

The total number of statically configured and dynamically generated prefix management entries cannot exceed the maximum number of entries allowed on a device. Otherwise, no prefix management entry can be further statically configured or dynamically generated.

Example

Configure a static prefix management entry with the IPv6 address prefix FC00:1::/64.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] nd snooping static-prefix fc00:1::/64
```

14.9.16 nd snooping trusted

Function

The **nd snooping trusted** command configures the trusted interface.

The **undo nd snooping trusted** command restores the trusted interface to an untrusted interface.

Format

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

nd snooping trusted

undo nd snooping trusted

VLAN view

nd snooping trusted interface *interface-type interface-number*

undo nd snooping trusted interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the trusted interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

ND snooping classifies interfaces connected to IPv6 nodes into trusted and untrusted interfaces. The trusted interfaces connect to trusted IPv6 nodes and untrusted interfaces connect to untrusted IPv6 nodes. By default, all interfaces are untrusted.

- You must configure the interface connected to a trusted IPv6 node as a trusted interface so that the device can forward the ND packets received by this interface. In addition, the device creates a prefix management table according to the received RA packet to help network administrators manage IPv6 addresses.
- The interface connected to an untrusted IPv6 node must be configured as an untrusted interface. The device discards the RA packets received by the untrusted interface to prevent RA attacks.

NOTE

Generally, the interface connecting to the gateway is configured as the trusted interface, and other interfaces are all untrusted interfaces.

Prerequisites

ND snooping has been enabled using the **nd snooping enable** command in the system view.

Precautions

After the **nd snooping trusted** command is executed, ND snooping is enabled on the interface.

When you run the **nd snooping trusted** command in the VLAN view, the specified interface must belong to the VLAN.

Example

Configure GE0/0/1 as a trusted interface.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping trusted
```

Configure GE0/0/1 in VLAN 10 as a trusted interface.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] nd snooping trusted interface gigabitethernet 0/0/1
```

14.9.17 nd snooping trusted dhcpv6 only

Function

The **nd snooping trusted dhcpv6 only** command configures the interfaces in the DHCPv6 Only scenario as ND snooping trusted interfaces.

The **undo nd snooping trusted** command restores the interfaces to untrusted.

By default, all interfaces are untrusted.

Format

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

nd snooping trusted dhcpv6 only

undo nd snooping trusted

VLAN view

nd snooping trusted interface *interface-type interface-number* **dhcpv6 only**

undo nd snooping trusted interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the interface that will be configured as an ND snooping trusted interface in the DHCPv6 Only scenario. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view, BD view

Default Level

2: Configuration level

Usage Guidelines

The device checks the validity of ND protocol packets against the IPv6 static binding table, DHCPv6 dynamic binding table, and ND snooping binding table. The IPv6 static binding table is manually configured by the administrator, the DHCPv6 dynamic binding table is automatically generated by extracting information from DHCPv6 Reply packets, and the ND snooping binding table is automatically generated by extracting information from DAD NS packets. At the same time, the ND protocol packet validity check function depends on the ND snooping function (including enabling ND snooping and configuring ND snooping trusted interfaces). In the DHCPv6 Only scenario, users are only allowed to obtain IPv6 addresses using DHCPv6 and IPv6 addresses that are privately configured by users and automatically generated using the PD address prefix are considered as invalid addresses. In this scenario, ND snooping is disabled to prevent ND snooping binding entries from being generated for such invalid addresses. In this case, the ND protocol packet validity check function cannot be performed, so that address spoofing attacks may exist on the network.

To resolve this problem, you can run the **nd snooping enable dhcpv6 only** and **nd snooping trusted dhcpv6 only** commands to enable the ND snooping function in the DHCPv6 Only scenario. After the **nd snooping trusted dhcpv6 only** command is configured, no prefix management entry is generated when the trusted interface receives an RA packet, which is different from the **nd snooping trusted** command. This is because the prefix management entries need to be matched before the corresponding ND snooping binding entries are generated for the IPv6 addresses excluding the IPv6 link-local addresses. However, only records corresponding to the IPv6 link-local addresses exist in the ND snooping binding table in the DHCPv6 Only scenario. Therefore, the prefix management entries do not need to be generated.

Example

Configure GE0/0/1 as an ND snooping trusted interface.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd snooping trusted dhcpv6 only
```

Configure GE0/0/1 as an ND snooping trusted interface in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] nd snooping trusted interface gigabitethernet 0/0/1 dhcpv6 only
```

14.9.18 nd snooping user-alarm percentage

Function

The **nd snooping user-alarm percentage** command configures the alarm thresholds for the percentage of ND snooping dynamic binding entries.

The **undo nd snooping user-alarm percentage** command restores the default alarm thresholds for the percentage of ND snooping dynamic binding entries.

By default, the lower alarm threshold for the percentage of ND snooping dynamic binding entries is 50, and the upper alarm threshold for the percentage of ND snooping dynamic binding entries is 100.

Format

nd snooping user-alarm percentage *percent-lower-value percent-upper-value*

undo nd snooping user-alarm percentage

Parameters

Parameter	Description	Value
percent-lower-value	Specifies the lower alarm threshold for the percentage of ND snooping dynamic binding entries.	The value is an integer that ranges from 1 to 100.
percent-upper-value	Specifies the upper alarm threshold for the percentage of ND snooping dynamic binding entries.	The value is an integer that ranges from 1 to 100, but must be greater than or equal to the lower alarm threshold.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After you run the **nd snooping max-user-number** command to set the maximum number of ND snooping dynamic binding entries on an interface, you can run the **nd snooping user-alarm percentage** command to set the alarm thresholds for the percentage of ND snooping dynamic binding entries.

When the percentage of learned ND snooping dynamic binding entries against the maximum number of ND snooping dynamic entries allowed by the device reaches or exceeds the upper alarm threshold, the device generates an alarm. When the percentage of learned ND snooping dynamic binding entries against the maximum number of ND snooping dynamic entries allowed by the device reaches or falls below the lower alarm threshold later, the device generates a clear alarm. The alarm information helps network administrators monitor the status of ND snooping binding table in real time.

Example

Set the lower alarm threshold for the percentage of ND snooping dynamic binding entries to 30 and the upper alarm threshold to 80.

```
<HUAWEI> system-view
[HUAWEI] nd snooping user-alarm percentage 30 80
```

14.9.19 nd snooping wait-time life-time

Function

The **nd snooping wait-time life-time** command configures the wait time for a device to send an NS packet to detect the user status and the lifetime of an ND snooping binding entry when a device detects the user status.

The **undo nd snooping wait-time life-time** command restores the default settings.

By default, the wait time for a device to send an NS packet to detect the user status is 250 milliseconds and the lifetime of an ND snooping binding entry when a device detects the user status is 500 milliseconds.

Format

nd snooping wait-time *wait-time* **life-time** *life-time*

undo nd snooping wait-time life-time

Parameters

Parameter	Description	Value
wait-time	Specifies the wait time for a device to send an NS packet to detect the user status.	The value is an integer that ranges from 1 to 5000, in milliseconds. The default value is 250 milliseconds.
life-time	Specifies the lifetime of an ND snooping binding entry when a device detects the user status.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 500 milliseconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device updates the ND snooping binding table by detecting the received NA packets. If an ND snooping binding entry exists and the device receives an NA packet with the IP address the same as that in the corresponding entry and inbound port number different from that in the entry, the NA packet conflicts with the entry. The device is then triggered to send an NS packet to detect whether the user corresponding to the entry is online. You can run the **nd snooping wait-time** *wait-time* **life-time** *life-time* command to configure the wait time for a device to send an NS packet to detect the user status and the lifetime of an ND snooping binding entry when a device detects the user status.

- If the entry is within the lifetime and the device receives an NA packet from the port corresponding to the entry, the user corresponding to the entry is still online and the device updates the IP address lease in the corresponding entry.
- If the entry is within the lifetime and the device does not receive an NA packet from the port corresponding to the entry, the user corresponding to the entry is offline and the device updates the user's IP address lease time in the entry and updates the port number in the entry to that in the previously received NA packet.

Prerequisites

ND snooping has been enabled using the **nd snooping enable** command in the system view.

Precautions

After the device receives an NA packet conflicting with an ND snooping binding entry and user status detection is enabled, periodic user status detection is suspended.

Example

Set the wait time for a device to send an NS packet to detect the user status to 300 milliseconds and the lifetime of an ND snooping binding entry when a device detects the user status to 2000 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] nd snooping enable
[HUAWEI] nd snooping wait-time 300 life-time 2000
```

14.9.20 nd user-bind detect

Function

The **nd user-bind detect** command configures the number of times and interval for sending NS packets to detect the user status.

The **undo nd user-bind detect** command restores the default setting.

After automatic user status detection is enabled for users mapping ND snooping dynamic binding entries, the default number of detection times is 2, and the default detection interval is 1000 milliseconds.

Format

nd user-bind detect retransmit *retransmit-times* **interval** *retransmit-interval*

undo nd user-bind detect retransmit interval

Parameters

Parameter	Description	Value
retransmit *retransmit-times*	Specifies the number of times for sending NS packets to detect the user status.	The value is an integer ranging from 1 to 10. The default value is 2.
interval *retransmit-interval*	Specifies the interval for sending NS packets to detect the user status.	The value is an integer ranging from 1 to 10000, in milliseconds. The default value is 1000 milliseconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After automatic user status detection for users mapping ND snooping dynamic binding entries is enabled, the device sends NS packets to users based on the configured detection times and interval. If no NA packet is returned from a user after NS packets are sent for configured times, the device considers the user to be offline and deletes the mapping ND snooping dynamic binding entry.

You can run the **nd user-bind detect** command to change the number of times and interval for sending NS packets to detect the user status. On a small network with good network quality, the user returns an NA packet quickly. In this scenario, you can set the interval for sending NS packets to a small value. On a large network with poor network quality, the user returns an NA packet slowly. You can set the interval to a large value to prevent the device from sending the next NS packet before receiving the NA packet. You can change the interval based on the actual network environment.

Prerequisites

Automatic user status detection for users mapping ND snooping dynamic binding entries has been enabled using the **nd user-bind detect enable** command.

Precautions

After you run the **nd user-bind detect enable** command, the device sends an NS packet after a period of time. The maximum value of this period is 20 seconds.

Example

Set the number of times for sending NS packets to 10, and the interval for sending NS packets to 1000 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] nd user-bind detect enable
[HUAWEI] nd user-bind detect retransmit 10 interval 1000
```

14.9.21 nd user-bind detect enable

Function

The **nd user-bind detect enable** command enables the function for automatically detecting status of users mapping ND snooping dynamic binding entries.

The **undo nd user-bind detect enable** command disables the function for automatically detecting status of users mapping ND snooping dynamic binding entries.

By default, the function for automatically detecting status of users mapping ND snooping dynamic binding entries is disabled.

Format

nd user-bind detect enable

undo nd user-bind detect enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After ND snooping is enabled, the device snoops NS packets in the DAD process to establish ND dynamic binding entries. The aging time of an ND snooping dynamic binding table depends on the IPv6 address lease. If the address lease does not expire but the user is offline, the ND snooping dynamic entry mapping the user cannot be deleted, which occupies binding entry resources on the device.

To prevent this problem, you can enable the automatic user status detection for users mapping ND snooping dynamic binding entries on the device. After this function is enabled, the device sends NS packets to the user according to the detection times (n) specified in **nd user-bind detect** and detection interval. If the device receives no NA packet from the user after sending the NS packets n times, the device considers the user to be offline and deletes the dynamic ND snooping binding entry matching the user.

Precautions

After you run the **nd user-bind detect enable** command, the device sends an NS packet after a period of time. The maximum value of this period is 20 seconds.

Example

Enable the function for automatically detecting status of users mapping ND snooping dynamic binding entries.

```
<HUAWEI> system-view
[HUAWEI] nd user-bind detect enable
```

14.9.22 reset nd snooping prefix

Function

The **reset nd snooping prefix** command clears prefix management entries of users.

Format

reset nd snooping prefix [*ipv6-address*/*prefix-length*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies an IPv6 address.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
prefix-length	Specifies the prefix length.	The value is an integer ranging from 1 to 128. If the global unicast address needs to be set in EUI-64 format, the value of *prefix-length* ranges from 1 to 64.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The ND server that functions as the gateway router sends RA packets periodically to instruct users to update prefixes. The switch that functions as the access device establishes prefix management entries based on RA packets to maintain and manage user prefixes.

Generally, do not delete prefix management entries of users manually. Run the **reset nd snooping prefix** command to delete prefix management entries of users if the following requirements are met:

- The user lease does not expire and the prefix management table cannot age automatically.
- The user is no longer connected to the network.

Precautions

After a prefix management entry is deleted, the switch cannot establish the ND snooping dynamic binding table for new users with the prefix management entry.

Example

Delete the prefix management entry with the prefix address being fc00:1::1 and the prefix length being 64.

```
<HUAWEI> reset nd snooping prefix fc00:1::1/64
```

14.9.23 reset nd snooping statistics

Function

The **reset nd snooping statistics** command deletes statistics on ND snooping packets.

Format

reset nd snooping statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Use Scenario

After ND snooping is enabled, the device records statistics on the sent and received ND packets. This command deletes the statistics on ND packets.

Precautions

Deleted statistics cannot be restored. Exercise caution.

Example

Delete statistics on ND snooping packets.

```
<HUAWEI> reset nd snooping statistics
```

14.9.24 reset nd snooping user-bind

Function

The **reset nd snooping user-bind** command clears ND snooping dynamic binding entries on the device.

Format

reset nd snooping user-bind [**interface** *interface-type interface-number* | **ipv6-address** *ipv6-address* | **mac-address** *mac-address* | **vlan** *vlan-id* | **bridge-domain** *bd-id*]

NOTE

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6720-EI, S6735-S, S6720S-EI support the **bridge-domain** parameter.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the interface in the ND snooping dynamic binding entry to be cleared. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
ipv6-address *ipv6-address*	Specifies the IPv6 address in the ND snooping dynamic binding entry to be cleared.	The value is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format.
mac-address *mac-address*	Specifies the MAC address in the ND snooping dynamic binding entry to be cleared.	The value is in the format of H-H-H. An H is a hexadecimal number of 1 to 4 digits.
vlan *vlan-id*	Specifies the VLAN ID in the ND snooping dynamic binding entry to be cleared.	The value is an integer ranging from 1 to 4094.
bridge-domain *bd-id*	Specifies the BD ID in the ND snooping dynamic binding entry to be cleared.	The value is an integer ranging from 1 to 16777215.

Views

User view

Default Level

3: Management level

Usage Guidelines

You need to manually delete ND snooping dynamic binding entries if the following requirements are met:

- The ND snooping dynamic binding entry does not reach the aging time, so the entry cannot age automatically.
- The user is no longer connected to the network.
- The user VLAN or interface information changes.

The networking environment change may lead to the change in the VLAN or interface information, while the ND snooping dynamic binding entry mapping a user does not age out and cannot update in real time. As a result, the device discards valid ND packets that do not match the old ND snooping dynamic binding entries. Before changing the networking environment, clear all ND snooping dynamic binding entries manually so that a device generates a new ND snooping dynamic binding table based on the new networking environment.

Example

Delete the ND snooping dynamic binding entry that contains the IPv6 address being fc00:1::1.

```
<HUAWEI> reset nd snooping user-bind ipv6-address fc00:1::1
```

Delete the ND snooping dynamic binding entry that contains the MAC address being 00e0-fc11-2222.

```
<HUAWEI> reset nd snooping user-bind mac-address 00e0-fc11-2222
```

14.10 IPv6 RA Guard Configuration Command

14.10.1 Command Support

All models of S300, S500, S2700, S5700, and S6700 series switches (except the S5731-L and S5731S-L) support IPv6 RA Guard.

14.10.2 display nd raguard policy

Function

The **display nd raguard policy** command displays the configuration of an IPv6 RA guard policy.

Format

display nd raguard policy [*policy-name*]

Parameters

Parameter	Description	Value
policy-name	Displays the configuration of the IPv6 RA guard policy with the specified name.	The value must be the name of an existing IPv6 RA guard policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the matching rules configured in a specified IPv6 RA guard policy, run the **display nd raguard policy** command. RA messages can be forwarded only when they match all rules.

Example

Display the IPv6 RA guard policy configured on the device.

```
<HUAWEI> display nd raguard policy
-----------------------------------------------
   ID        nd-raguard-policy name
    0        p1
    1        p2
    2        p3
-----------------------------------------------
   Total 3, printed 3
```

Table 14-79 Description of the **display nd raguard policy** command output

Item	Description
ID	ID.
nd-raguard-policy name	Name of an IPv6 RA guard policy.
Total *m*, printed *n*	There are a total of *m* entries and *n* entries are printed.

Display the configuration of the IPv6 RA guard policy named **p1**.

```
<HUAWEI> display nd raguard policy p1
ND raguard policy: p1
  if-match source-mac-address acl 4000
  if-match ipv6-source-address acl 2000
  if-match ra-prefix acl 2000
  hop-limit minimum 10
  hop-limit maximum 20
```

```
router-preference maximum medium
managed-address-flag on
other-config-flag on
```

Table 14-80 Description of the **display nd raguard policy** *policy-name* command output

Item	Description
ND raguard policy	Name of an IPv6 RA guard policy. To set the value, run the **nd raguard policy** command.
if-match source-mac-address acl	Number of the Layer 2 ACL that is used to match the source MAC address of RA messages. To set the value, run the **if-match source-mac-address** command.
if-match ipv6-source-address acl	Number of the basic ACL6 that is used to match the source IPv6 address of RA messages. To set the value, run the **if-match ipv6-source-address** command.
if-match ra-prefix acl	Number of the basic ACL6 that is used to match the IPv6 prefix of RA messages. To set the value, run the **if-match prefix** command.
hop-limit minimum	Minimum hop limit used to match RA messages. To set the value, run the **hop-limit minimum** command.
hop-limit maximum	Maximum hop limit used to match RA messages. To set the value, run the **hop-limit maximum** command.
router-preference maximum	Highest route preference used to match RA messages: ● high: high preference ● medium: medium preference ● low: low preference To set the value, run the **router-preference maximum** command.

Item	Description
managed-address-flag	M flag used to match RA messages: - on: The M flag is set to 1. - off: The M flag bit is set to 0. To set the value, run the **managed-address-flag** command.
other-config-flag	O flag used to match RA messages: - on: The O flag is set to 1. - off: The O flag bit is set to 0. To set the value, run the **other-config-flag** command.

14.10.3 display nd raguard statistic

Function

The **display nd raguard statistic** command displays statistics about RA messages discarded by interfaces.

Format

display nd raguard statistic [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays statistics about RA messages discarded by a specified interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the interface role of an interface is a host interface or when an IPv6 RA guard policy is applied to an interface and RA messages received on the interface do not match the rules configured in the policy, the interface discards RA messages. The device supports the display of discarded RA message statistics based on interfaces.

Example

Display statistics about RA messages discarded by a specified interface.

```
<HUAWEI> display nd raguard statistic
RA messages dropped by RA guard:
Interface              Dropped
Eth-trunk10              1221
```

Table 14-81 Description of the **display nd raguard statistic** command output

Item	Description
Interface	Interface that discards RA messages.
Dropped	Number of discarded RA messages.

14.10.4 hop-limit

Function

The **hop-limit** command configures a rule to match RA messages against the maximum and minimum hop limits in RA messages.

The **undo hop-limit** command restores the default hop limits.

By default, the maximum and minimum hop limits in an RA message are 255 and 1 respectively.

Format

hop-limit { **maximum** *max-value* | **minimum** *min-value* }

undo hop-limit { **maximum** | **minimum** }

Parameters

Parameter	Description	Value
maximum *max-value*	Specifies the maximum hop limit used to match RA messages.	The value is an integer in the range from 1 to 255.
minimum *min-value*	Specifies the minimum hop limit used to match RA messages.	The value is an integer in the range from 1 to 255.

NOTE

In the same IPv6 RA guard policy, if both *max-value* and *min-value* are configured, *min-value* must be less than or equal to *max-value*.

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

The **Hop Limit** field in an RA message indicates the maximum number of hops that the message can pass through. The value is decremented by 1 each time the message passes through a device. The message is discarded when the field value is 0. After the maximum or minimum hop limit is configured in the IPv6 RA guard policy view, the interface to which the policy is applied forwards only the RA messages whose hop limit is within the configured range and discards those whose hop limit is outside the configured range.

Example

In the IPv6 RA guard policy **p1**, set the maximum and minimum hop limits in RA messages to 10 and 5 respectively.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] hop-limit maximum 10
[HUAWEI-nd-raguard-policy-p1] hop-limit minimum 5
```

14.10.5 if-match source-mac-address

Function

The **if-match source-mac-address** command configures an ACL to match RA messages against the source MAC address in RA messages.

The **undo if-match source-mac-address** command deletes the ACL used to match RA messages against the source MAC address in RA messages.

By default, no ACL is configured to match RA messages against the source MAC address in RA messages.

Format

if-match source-mac-address acl *acl-number*

undo if-match source-mac-address acl

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of a Layer 2 ACL.	The value is an integer in the range from 4000 to 4999.

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an ACL is configured in an IPv6 RA guard policy to match RA messages against the source MAC address in RA messages, the interface to which the policy is applied checks the source MAC address of the received RA messages and forwards only the RA messages that match the ACL.

Precautions

- If the ACL specified as a matching rule is not created, no rule is configured in the ACL, or the rule configured in the ACL is not a source MAC address, RA messages will not match against the ACL.
- In the matching process, the permit and deny actions configured in the ACL are ignored, and the focus is only on the rule configured in the ACL. That is, RA messages are forwarded as long as they match the rule.

Example

In the IPv6 RA guard policy **p1**, configure the switch to forward RA messages with the source MAC address 0001-0001-0001 or 0022-0022-0022.

```
<HUAWEI> system-view
[HUAWEI] acl 4001
[HUAWEI-acl-L2-4001] rule 1 permit source-mac 0001-0001-0001
[HUAWEI-acl-L2-4001] rule 2 permit source-mac 0022-0022-0022
[HUAWEI-acl-L2-4001] quit
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] if-match source-mac-address acl 4001
```

14.10.6 if-match ipv6-source-address

Function

The **if-match ipv6-source-address** command configures an ACL to match RA messages against the source IPv6 address in RA messages.

The **undo if-match ipv6-source-address** command deletes the ACL used to match RA messages against the source IPv6 address in RA messages.

By default, no ACL is configured to match RA messages against the source IPv6 address in RA messages.

Format

if-match ipv6-source-address acl *acl-number*

undo if-match ipv6-source-address acl

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of a basic ACL6.	The value is an integer in the range from 2000 to 2999.

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an ACL is configured in an IPv6 RA guard policy to match RA messages against the source IPv6 address in RA messages, the interface to which the policy is applied checks whether the source IPv6 address of the received RA messages is within the network segment configured in the ACL and forwards only the RA messages that match the ACL.

Precautions

- If the ACL specified as a matching rule is not created, no rule is configured in the ACL, or the rule configured in the ACL is not a source IP address or prefix, RA messages will not match against the ACL.
- In the matching process, the permit and deny actions configured in the ACL are ignored, and the focus is only on the rule configured in the ACL. That is, RA messages are forwarded as long as they match the rule.

Example

In the IPv6 RA guard policy **p1**, configure the switch to forward RA messages with the source IPv6 address FC00:1::10/64.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2000
[HUAWEI-acl6-basic-2000] rule 1 permit source fc00:1::/64
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] if-match ipv6-source-address acl 2000
```

14.10.7 if-match prefix

Function

The **if-match prefix** command configures an ACL to match RA messages against the IPv6 prefix in RA messages.

The **undo if-match prefix** command deletes the ACL used to match RA messages against the IPv6 prefix in RA messages.

By default, no ACL is configured to match RA messages against the IPv6 prefix in RA messages.

Format

if-match prefix acl *acl-number*

undo if-match prefix acl

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of a basic ACL6.	The value is an integer in the range from 2000 to 2999.

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an ACL is configured in an IPv6 RA guard policy to match RA messages against the IPv6 prefix in RA messages, the interface to which the policy is applied checks whether the IPv6 prefix of the received RA messages is within the network segment configured in the ACL and forwards the RA messages only when the messages match the ACL. Otherwise, the interface discards the messages.

Precautions

- If the ACL specified as a matching rule is not created, no rule is configured in the ACL, or the rule configured in the ACL is not a source IP address or prefix, RA messages will not match against the ACL.
- In the matching process, the permit and deny actions configured in the ACL are ignored, and the focus is only on the rule configured in the ACL. That is, RA messages are forwarded as long as they match the rule.

Example

In the IPv6 RA guard policy **p1**, configure the switch to forward RA messages with the IPv6 prefix FC00:1::/64.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 2000
[HUAWEI-acl6-basic-2000] rule 1 permit source fc00:1::/64
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] if-match prefix acl 2000
```

14.10.8 managed-address-flag

Function

The **managed-address-flag** command configures a rule to match RA messages against the M flag in RA messages.

The **undo managed-address-flag** command deletes the rule used to match RA messages against the M flag in RA messages.

By default, no rule is configured to match RA messages against the M flag in RA messages.

Format

managed-address-flag { **on** | **off** }

undo managed-address-flag

Parameters

Parameter	Description	Value
on	Indicates that the M flag is set to 1.	-
off	Indicates that the M flag is set to 0.	-

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

The M flag in an RA message determines whether users use stateful autoconfiguration to obtain IPv6 addresses. When the M flag is set to 1, a user obtains an IPv6 address using stateful autoconfiguration (for example, a DHCPv6 server). When the M flag is set to 0, a user obtains an IPv6 address using stateless autoconfiguration. That is, an IPv6 address is generated for the user according to the prefix information advertised by the router and the link-layer address of the user.

After a rule is configured to match RA messages against the M flag in RA messages in the IPv6 RA guard policy view, the interface to which the policy is applied checks the M flag in the received RA messages and forwards the messages only when the messages match the rule. Otherwise, the interface discards the messages.

Example

In the IPv6 RA guard policy **p1**, set the matching rule of the M flag to **on**. That is, users obtain IPv6 addresses using stateful autoconfiguration.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] managed-address-flag on
```

14.10.9 nd raguard role

Function

The **nd raguard role** command configures an interface role for IPv6 RA guard.

The **undo nd raguard role** command deletes the interface role configured for IPv6 RA guard.

By default, no interface role is configured for IPv6 RA guard.

Format

nd raguard role { **host** | **router** }

undo nd raguard role

Parameters

Parameter	Description	Value
host	Specifies the interface role as a host interface.	-
router	Specifies the interface role as a router interface.	-

Views

Layer 2 Ethernet interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Administrators can configure an interface role based on the network location of interfaces. If an interface is connected to a user host, administrators can configure the interface role of the interface as a host interface. If the interface is connected to a router, administrators can configure the interface role of the interface as a router interface.

- If the interface role of the interface is a router interface, the system forwards the RA messages received by the interface.
- If the interface role of the interface is a host interface, the system discards the RA messages.

Example

On GE0/0/1, configure the interface role as a router interface for IPv6 RA guard.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd raguard role router
```

14.10.10 nd raguard policy

Function

The **nd raguard policy** command creates an IPv6 RA guard policy and displays the IPv6 RA guard policy view.

The **undo nd raguard policy** command deletes a created IPv6 RA guard policy.

By default, no IPv6 RA guard policy is created.

Format

nd raguard policy *policy-name*

undo nd raguard policy *policy-name*

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an IPv6 RA guard policy.	The value is a string of 1 to 31 case-insensitive characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure an IPv6 RA guard policy for an interface to filter RA messages in the following situations:

- The type of the device or terminal connected to the interface cannot be determined. That is, no interface role can be configured for the interface to help determine whether to discard or forward RA messages.
- The interface is connected to a router and needs to filter RA messages based on specific conditions instead of forwarding RA messages immediately.

Follow-up Procedure

Configure a matching rule in the IPv6 RA guard policy view and run the **nd raguard attach-policy** command to apply the IPv6 RA guard policy to an interface.

Example

Create an IPv6 RA guard policy named **p1**.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
```

14.10.11 nd raguard attach-policy

Function

The **nd raguard attach-policy** command binds an IPv6 RA guard policy to an interface.

The **nd raguard attach-policy** command unbinds an IPv6 RA guard policy from an interface.

By default, no IPv6 RA guard policy is applied to an interface.

Format

nd raguard attach-policy *policy-name*

undo nd raguard attach-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of an IPv6 RA guard policy.	The value must be the name of an existing IPv6 RA guard policy.

Views

Layer 2 Ethernet interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

After an IPv6 RA guard policy is bound to an interface, the interface filters received RA messages based on the matching rules configured in the policy.

Example

Bind the IPv6 RA guard policy **p1** to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
```

```
[HUAWEI-nd-raguard-policy-p1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] nd raguard attach-policy p1
```

14.10.12 nd raguard log enable

Function

The **nd raguard log enable** command enables the IPv6 RA guard log function.

The **nd raguard log enable** command disables the IPv6 RA guard log function.

By default, the IPv6 RA guard log function is disabled.

Format

nd raguard log enable

undo nd raguard log enable

Parameters

None.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The IPv6 RA guard log function records RA message processing information to meet the audit requirements of administrators. After this function is enabled, the device generates the ND_RAGUARD/3/ND_RAGUARD_DROP log when detecting invalid RA messages. The log content includes the name of the attacked interface, source IP address and source MAC address of RA messages, and total number of RA messages discarded on the interface.

The IPv6 RA guard logs generated by the device are sent to the information center module for processing. The configuration of the information center module determines the output rules and output directions of the logs. For details about the information center, see Information Center Configuration in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - Device Management*.

Example

Enable the IPv6 RA guard log function.

```
<HUAWEI> system-view
[HUAWEI] nd raguard log enable
```

14.10.13 other-config-flag

Function

The **other-config-flag** command configures a rule to match RA messages against the O flag in RA messages.

The **undo other-config-flag** command deletes the rule used to match RA messages against the O flag in RA messages.

By default, no rule is configured to match RA messages against the O flag in RA messages.

Format

other-config-flag { **on** | **off** }

undo other-config-flag

Parameters

Parameter	Description	Value
on	Indicates that the O flag is set to 1.	-
off	Indicates that the O flag is set to 0	-

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

The O flag in an RA message determines whether users use stateful autoconfiguration to obtain information other than IPv6 addresses. When the O flag is set to 1, a user obtains information other than an IPv6 address using stateful autoconfiguration (for example, a DHCPv6 server). When the O flag is set to 0, a user obtains information other than an IPv6 address using stateless autoconfiguration.

After a rule is configured to match RA messages against the O flag in RA messages in the IPv6 RA guard policy view, the interface to which the policy is applied checks the O flag in the received RA messages and forwards the messages only when the messages match the rule. Otherwise, the interface discards the messages.

Example

In the IPv6 RA guard policy **p1**, set the matching rule of the O flag to **on**. That is, users obtain information other than IPv6 addresses using stateful autoconfiguration.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] other-config-flag on
```

14.10.14 router-preference maximum

Function

The **router-preference maximum** command configures a rule to match RA messages against the highest route preference in RA messages.

The **undo router-preference maximum** command deletes the rule used to match RA messages against the highest route preference in RA messages.

By default, no rule is configured to match RA messages against the highest route preference in RA messages.

Format

router-preference maximum { **high** | **medium** | **low** }

undo router-preference maximum

Parameters

Parameter	Description	Value
high	Sets the highest route preference in RA messages to high preference.	-
medium	Sets the highest route preference in RA messages to medium preference.	-
low	Sets the highest route preference in RA messages to low preference.	-

Views

IPv6 RA guard policy view

Default Level

2: Configuration level

Usage Guidelines

RA messages carry the route preference field. Route preferences are classified into high preference (with the value 1), medium preference (with the value 0), and low preference (with the value 3). After receiving an RA message, a host updates its default route list and selects a route in descending order of the route preference.

After a rule is configured in an IPv6 RA guard policy to match RA messages against the highest route preference in RA messages, the interface to which the policy is applied checks the route preference of the received RA messages and forwards the RA messages only when the route preference of the messages is lower than or equal to that configured in the rule. Otherwise, the interface discards the messages.

Example

In the IPv6 RA guard policy **p1**, set the highest route preference used to match RA messages to medium preference.

```
<HUAWEI> system-view
[HUAWEI] nd raguard policy p1
[HUAWEI-nd-raguard-policy-p1] router-preference maximum medium
```

14.10.15 reset nd raguard statistic

Function

The **reset nd raguard statistic** command clears statistics about RA messages discarded by interfaces.

Format

reset nd raguard statistic [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears statistics about RA messages discarded by a specified interface.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

To collect statistics about RA messages discarded on interfaces within a certain period, run the **reset nd raguard statistic** command to clear the existing statistics and then run the **display nd raguard statistic** command.

Example

Clear statistics about RA messages discarded by interfaces.

```
<HUAWEI> reset nd raguard statistic
```

14.11 PPPoE+ Configuration Commands

14.11.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.11.2 display pppoe intermediate-agent information encapsulation

Function

The **display pppoe intermediate-agent information encapsulation** command displays the fields and vendor ID added to PPPoE packets.

Format

display pppoe intermediate-agent information encapsulation

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the fields and vendor ID added to PPPoE packets, you can run **display pppoe intermediate-agent information encapsulation** command to view the information.

Example

Display the fields and vendor ID added to PPPoE packets.

```
<HUAWEI> display pppoe intermediate-agent information encapsulation
 The vendor id is: 2011
 Encapsulation content contains: Circuit-id and Remote-id
```

Table 14-82 Description of the display pppoe intermediate-agent information encapsulation command output

Item	Description
The vendor id is	Vendor ID added to PPPoE packets. You can run the **pppoe intermediate-agent information vendor-id** *vendor-id* command to set this parameter.
Encapsulation content contains	Fields added to PPPoE packets. You can run the **pppoe intermediate-agent information encapsulation** { **circuit-id** | **remote-id** } * command to set this parameter.

14.11.3 display pppoe intermediate-agent information format

Function

The **display pppoe intermediate-agent information format** command displays formats of circuit ID and remote ID that are configured globally.

Format

display pppoe intermediate-agent information format

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After PPPoE+ is enabled globally, you can run the **display pppoe intermediate-agent information format** command to check whether the configuration of the circuit ID or remote ID added to PPPoE packets is correct.

Example

Display formats of circuit ID and remote ID that are configured globally.

```
<HUAWEI> display pppoe intermediate-agent information format
 The current information format :
  Circuit ID : EXTEND
  Remote  ID : COMMON
```

```
For example:
 interface GigabitEthernet0/0/1 SVLAN:200 CVLAN:100
 The PPPOE Intermediate Agent information is as follows:
 Circuit ID:00 04 00 c8 00 00
 Remote  ID:0022-0033-0044
```

Table 14-83 Description of the **display pppoe intermediate-agent information format** command output

Item	Description
Circuit ID	Format of the circuit ID - COMMON: indicates the standard fill format. - EXTEND: indicates the extended fill format. - USER DEFINE: indicates user-defined fill format. You can run the **pppoe intermediate-agent information format** command to set this parameter. If the **portdescription** keyword is specified in the user-defined circuit-id and no interface description is configured, the **Circuit ID** in **For example** displays **portdescription**.
Remote ID	Format of the remote ID - COMMON: indicates the standard fill format. - EXTEND: indicates the extended fill format. - USER DEFINE: indicates user-defined fill format. You can run the **pppoe intermediate-agent information format** command to set this parameter. Remote IDs vary according to devices. If the **portdescription** keyword is specified in the user-defined **remote-id** and no interface description is configured, the **Remote ID** in **For example** displays **portdescription**.

14.11.4 display pppoe intermediate-agent information policy

Function

The **display pppoe intermediate-agent information policy** command displays the global policy for processing original fields in PPPoE packets at the user side and PPPoE server side.

Format

display pppoe intermediate-agent information policy

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pppoe intermediate-agent information policy** command displays the global policy for processing original fields in PPPoE packets at the user side and PPPoE server side.

Example

Display the global policy for processing original information fields in PPPoE packets at the user side and PPPoE server side.

```
<HUAWEI> display pppoe intermediate-agent information policy
The current information Policy :REPLACE
The current ignore-reply Policy:ENABLE
```

Table 14-84 Description of the display pppoe intermediate-agent information policy command output

Item	Description
The current information Policy	Global policy for processing original information fields in PPPoE packets at the user side: ● DROP: removes original information fields from PPPoE packets. ● REPLACE: replaces original fields in PPPoE packets according to the field format. ● KEEP: reserves the content and format of original fields in PPPoE packets. You can run the **pppoe intermediate-agent information policy (system view)** command to set this parameter.
The current ignore-reply Policy	Global policy for processing PPPoE reply packets sent by the PPPoE server: ● ENABLE: indicates that the device does not process PPPoE reply packets sent by the PPPoE server. ● DISABLE: indicates that the device processes PPPoE reply packets sent by the PPPoE server. You can run the **pppoe intermediate-agent information ignore-reply** command to set this parameter.

14.11.5 pppoe intermediate-agent information enable

Function

The **pppoe intermediate-agent information enable** command enables PPPoE+ globally.

The **undo pppoe intermediate-agent information enable** command disables PPPoE+.

By default, PPPoE+ is disabled.

Format

pppoe intermediate-agent information enable

undo pppoe intermediate-agent information enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After PPPoE+ is enabled globally, the device can add information about the interface connected to the PPPoE client such as the slot ID/subcard ID/interface number to PPPoE packets. The user account and access interface information are both authenticated, preventing user account embezzling.

After the **pppoe intermediate-agent information enable** command is executed in the system view, PPPoE+ is enabled on all interfaces.

NOTE

If PPPoE+ is enabled on the device that has no ACL resources, the system displays the following message "Warning: Allocate acl resources failed." In this case, PPPoE+ does not work.

After PPPoE+ is enabled in a VPLS scenario, traffic cannot be forwarded.

Example

Enable PPPoE+ globally.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
```

14.11.6 pppoe intermediate-agent information encapsulation

Function

The **pppoe intermediate-agent information encapsulation** command configures fields added to PPPoE packets.

The **undo pppoe intermediate-agent information encapsulation** command restores the default fields added to PPPoE packets.

By default, the device adds the **circuit-id** and **remote-id** fields to PPPoE packets.

Format

pppoe intermediate-agent information encapsulation { **circuit-id** | **remote-id** } *

undo pppoe intermediate-agent information encapsulation

Parameters

Parameter	Description	Value
circuit-id	Indicates the circuit ID (CID).	-
remote-id	Indicates the remote ID (RID).	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After PPPoE+ is enabled, the device adds the **circuit-id** and **remote-id** fields to PPPoE packets by default. If the remote non-Huawei PPPoE server can identify only the **circuit-id** or **remote-id** field, run the **pppoe intermediate-agent information encapsulation** command to configure the device only to add the **circuit-id** or **remote-id** fields to PPPoE packets.

Prerequisites

The PPPoE+ function has been enabled by running the **pppoe intermediate-agent information enable** command in the system view.

Example

Configure the device only to add the **circuit-id** field to PPPoE packets.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information encapsulation circuit-id
```

14.11.7 pppoe intermediate-agent information format

Function

The **pppoe intermediate-agent information format** command configures the format of fields added to PPPoE packets.

The **undo pppoe intermediate-agent information format** command restores the format of fields added to PPPoE packets to default values.

By default, the format of fields **circuit-id** and **remote-id** added to PPPoE packets is **common**.

Format

pppoe intermediate-agent information [**vlan** *vlan-id*] [**ce-vlan** *cevlan-id*] **format** { **circuit-id** | **remote-id** } { **common** | **extend** | **user-defined** *text* }

undo pppoe intermediate-agent information format all

undo pppoe intermediate-agent information [**vlan** *vlan-id*] [**ce-vlan** *cevlan-id*] **format** { **circuit-id** | **remote-id** }

Parameters

Parameter	Description	Value
vlan *vlan-id*	Indicates the outer VLAN ID. **NOTE** This parameter is not supported in the system view.	The value is an integer that ranges from 1 to 4094.
ce-vlan *cevlan-id*	Indicates the end inner VLAN ID. **NOTE** This parameter is not supported in the system view.	The value is an integer that ranges from 1 to 4094.
circuit-id	Indicates the circuit ID (CID).	-
remote-id	Indicates the remote ID (RID).	-

Parameter	Description	Value
common	Indicates the standard fill format. ● CID format: {eth|trunk}slot ID/subcard ID/port ID:svlan.cvlan host name0/0/0/0/0, in ASCII format ● RID format: device MAC address (6 bytes), in ASCII format	-
extend	Indicates the extended format. ● CID format: circuit-id type (0) + length (4) + S-VLAN ID (2 bytes) + slot ID (5 bits) + subslot ID (3 bits) + port (1 byte), in hexadecimal notation ● RID format: remote-id type (0) + length (6) + MAC address (6 bytes), in hexadecimal notation In the format of the CID or RID, the values in parentheses without a unit are fixed values of the fields, and the values in parentheses with a unit indicate the length of the corresponding fields.	-
user-defined *text*	Indicates the user-defined format.	The *text* parameter specifies a user-defined format, and the value is a string of 1 to 127 characters. The details about the customized format string are provided in Precautions.

Parameter	Description	Value
all	Indicates the all format of fields. **NOTE** This parameter is not supported in the system view.	-

Views

System view and interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After PPPoE+ is enabled globally, the default policy for processing user-side PPPoE packets is **replace**. The device replaces original information fields in the PPPoE packets received at the user side with those in common format. You can run the **pppoe intermediate-agent information format** command to change the format of information fields.

When the policy for processing user-side PPPoE packets is **replace** and the **pppoe intermediate-agent information format** command is executed, all interfaces add fields in a specified format to received PPPoE packets in the system view.

When the **pppoe intermediate-agent information format** command is configured, the device uses the following matching rules to encapsulate the information fields in PPPoE packets:

- For a double-tagged packet, the device matches the VLAN IDs in both the outer and inner VLAN tags. If the match fails, the device matches the VLAN ID in the inner VLAN tag, followed by that in the outer VLAN tag. If the match still fails, the device considers the packet does not carry a VLAN ID, and does not encapsulate the packet.
- For a single-tagged packet, the device matches the VLAN ID in the outer VLAN tag. If the match fails, the device considers the packet does not carry a VLAN ID, and does not encapsulate the packet.

If the **pppoe intermediate-agent information format** command is configured in both the interface and system views, the configuration in the interface view takes effect.

NOTE

Fields in PPPoE Intermediate-Agent Information packets support the following formats: **common**, **extend**, and **user-defined**. The formats are the same as those of DHCP Option 82. For description of the three parameters, see **dhcp option82 format**.

Prerequisites

PPPoE+ has been enabled globally by running the **pppoe intermediate-agent information enable** command.

Precautions

You can use the following keywords to define the format. The format string can use the hexadecimal notation, ASCII format, or combination of the two formats.

- sysname: indicates the ID of the access point. This keyword is valid only in ASCII format.
- portname: indicates the name of a port. For example, GigabitEthernet0/0/1. This keyword is valid only in ASCII format.
- porttype: indicates the type of a port. This keyword is valid in ASCII or hexadecimal notation.
- iftype: indicates the type of an interface. This keyword is valid only in ASCII format.
- mac: indicates the MAC address of an interface. In ASCII format, the value is expressed as H-H-H in hexadecimal notation, and the value is a number of six bytes.
- Slot: specifies the slot ID. This keyword is valid in ASCII or hexadecimal notation.
- subslot: indicates the subslot ID. This keyword is valid in ASCII or hexadecimal notation.
- port: indicates the port number. This keyword is valid in ASCII or hexadecimal notation.
- svlan: indicates the outer VLAN ID. The value ranges from 0 to 4095. This keyword is valid in ASCII or hexadecimal notation.
- cvlan: indicates the inner VLAN ID. The value ranges from 0 to 4095. This keyword is valid in ASCII or hexadecimal notation.
- n: specifies the value of the svlan or cvlan keyword if the outer VLAN tag or inner VLAN tag does not exist. The n keyword is on the left of the svlan or cvlan keyword. If the corresponding VLAN does not exist, the default value of the svlan or cvlan keyword is 4096 in ASCII format and is all Fs in hexadecimal notation. If the keyword n is added to the left of the svlan or cvlan keyword, the svlan or cvlan keyword is set to 0. This keyword is valid in ASCII or hexadecimal notation.
- length: indicates the total length of the keywords following the length keyword.
- portdescription: indicates the interface description. It is available only in ASCII format.

NOTE

Separators must be added between keywords; otherwise, they cannot be parsed. The separators cannot be numbers.

The symbols used in the format string are as follows:

- The symbol % followed by a keyword indicates the format of the keyword.
- A number between the % symbol and a keyword indicates the length of the keyword. In an ASCII character string, %05 has the same meaning as %05d in the C language. In a hexadecimal character string, the number indicates the length of the corresponding keyword in bits.

- The [] symbol indicates an optional keyword. Each pair of brackets can contain only one keyword, svlan or cvlan. The keyword in the [] symbol is added to information fields only if the corresponding VLAN ID exists. To facilitate syntax check, the system does not support nested [] symbols.
- The \ symbol is an escape character. The %, \, and [] symbols following the escape character indicate themselves. For example, \\ represents \.
- The content in quotation marks (" ") is expressed in a character string, and the content outside the quotation marks are expressed in hexadecimal notation.
- Other symbols are processed as common characters. The rules for setting the format string in ASCII format or hexadecimal notation are as follows:
  - An ASCII character string can contain letters, numerals, and symbols ! @ # $ % ^ & * () _ + | - = \ [] {} ; : '" / . , <> `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.
  - A hexadecimal notation string can contain numerals, space characters, %, and the keywords.
  - In a hexadecimal notation string, numbers are encapsulated in information fields. A number in the range of 0-255 occupies one byte; a number in the range of 256-65535 occupies two bytes; a number in the range of 65536-4294967295 occupies four bytes. Numbers larger than 4294967295 are not supported. Multiple numbers must be separated by space characters; otherwise, they are considered as a number.
  - All the space characters in a hexadecimal character string are ignored.
  - By default, each slot ID, subslot ID, port number, and VLAN ID in a hexadecimal notation string occupy two bytes. The length field occupies one byte.
  - If the length of each keyword in a hexadecimal character string is specified, the total length of the hexadecimal character string must be a multiple of 8. If the specified length of a keyword is longer than 32 bits, the first 32 bits of the keyword are the actual keyword value, and other bits are set to 0.
  - A hexadecimal character string can contain only the keywords whose values are numbers. Other keywords, such as the port name, cannot be added to the hexadecimal character string.
  - If a string is not contained in quotation marks, it is encapsulated in hexadecimal notation. To encapsulate to the string in the ASCII format, add the string into a pair of quotation marks. For example, the slot ID is 3, and the port ID is 4. If the format string is %slot %port, the value of the string after encapsulation is a hexadecimal number 00030004. If the format string is "%slot %port", the value of the string after encapsulation is 3 4.
  - A format string can contain both hexadecimal strings and ASCII strings, for example, %slot %port "%sysname %portname:%svlan.%cvlan."

Example

Configure the extended format for the **remote-id** field added to PPPoE packets.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information format remote-id extend
```

Configure the user-defined format for the **circuit-id** field added to PPPoE packets and encapsulate the port name, outer VLAN ID, inner VLAN ID, and host name in ASCII format.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information format circuit-id user-defined "%portname:%svlan.
%cvlan %sysname"
```

Configure the extended format for the **remote-id** field added to PPPoE packets on GE1/0/1.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] interface gigabitethernet 1/0/1
[HUAWEI-GigabitEthernet1/0/1] pppoe intermediate-agent information format remote-id extend
```

14.11.8 pppoe intermediate-agent information ignore-reply

Function

The **pppoe intermediate-agent information ignore-reply** command configures the device whether to directly forward PPPoE reply packets sent by the PPPoE server.

The **undo pppoe intermediate-agent information ignore-reply** command restores the default policy for processing PPPoE packets sent by the PPPoE server.

By default, the device does not process PPPoE reply packets sent by the PPPoE server.

Format

pppoe intermediate-agent information ignore-reply { **disable** | **enable** }

undo pppoe intermediate-agent information ignore-reply

Parameters

Parameter	Description	Value
disable	Indicates that the device processes PPPoE reply packets sent by the PPPoE server.	-
enable	Indicates that the device does not process PPPoE reply packets sent by the PPPoE server.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, the device does not process PPPoE reply packets and directly forwards them to the PPPoE client. Only when the PPPoE client cannot identify PPPoE packets that the device directly forwards, the device needs to process the PPPoE reply packets sent by the PPPoE server to ensure communication between the PPPoE server and PPPoE client. The PPPoE reply packets are processed as follows:

- When the policy for processing original fields in PPPoE packets is **replace** or **keep**:
  - If fields are not contained in PPPoE reply packets sent by the PPPoE server, the device directly forwards PPPoE reply packets.
  - If fields are contained in PPPoE reply packets sent by the PPPoE server and the format and content are consistent with those of the fields added to the user-side PPPoE packets, the device removes the original fields from PPPoE packets and forwards the packets. If the format and content are different from those of the fields added to the user-side PPPoE packets, the device directly forwards PPPoE reply packets.
- When the policy for processing original fields in PPPoE packets is **drop**, the device directly forwards the PPPoE packets:

Precautions

The **pppoe intermediate-agent information ignore-reply** command takes effect only after PPPoE+ is enabled globally. To modify the configuration, disable PPPoE+ globally first.

If the device is configured to process the PPPoE reply packets sent by the PPPoE server, the user access rate is reduced when the PPPoE server sends a large number of PPPoE+ packets.

Example

Configure the device to process PPPoE reply packets sent by the PPPoE server.

```
<HUAWEI> system-view
[HUAWEI] undo pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information ignore-reply disable
[HUAWEI] pppoe intermediate-agent information enable
```

14.11.9 pppoe intermediate-agent information policy (interface view)

Function

The **pppoe intermediate-agent information policy** command configures the policy for a specified interface to process original fields in user-side PPPoE packets.

The **undo pppoe intermediate-agent information policy** command restores the default policy for a specified interface to process original fields in user-side PPPoE packets.

By default, the policy configured on an interface to process original fields in user-side PPPoE packets is **replace**.

Format

pppoe intermediate-agent information policy { **drop** | **replace** | **keep** }

undo pppoe intermediate-agent information policy

Parameters

Parameter	Description	Value
drop	Removes the original fields from PPPoE packets.	-
replace	Replaces original fields in PPPoE packets according to the field format.	-
keep	Reserves the content and format of original fields in PPPoE packets.	-

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the policy for processing original fields in user-side PPPoE packets is configured, the device can add information about the interface connected to the PPPoE client such as the slot ID/subcard ID/interface number, VLAN ID, and MAC address to PPPoE packets. The user account and access interface information are both authenticated, preventing user account embezzling. If received PPPoE packets contain fields related to the interface that connected to the PPPoE client, the device removes or reserves original fields as required.

You can run the **pppoe intermediate-agent information policy (system view)** command to configure the PPPoE packet processing policy for all interfaces in the system view. To use a different policy on a specified interface, run the **pppoe intermediate-agent information policy** command. In this case, the policy for processing PPPoE packets on the interface depends on the interface configuration.

Prerequisites

PPPoE+ has been enabled globally by running the **pppoe intermediate-agent information enable** command.

Example

Configure GE0/0/1 to replace original fields in the received PPPoE packets with the circuit ID and remote ID of the local device.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] pppoe intermediate-agent information policy replace
```

14.11.10 pppoe intermediate-agent information policy (system view)

Function

The **pppoe intermediate-agent information policy** command configures the policy for all interfaces to process original fields in user-side PPPoE packets.

The **undo pppoe intermediate-agent information policy** command restores the policy for all interfaces to process original fields in user-side PPPoE packets.

By default, the policy configured on all interfaces to process original fields in user-side PPPoE packets is **replace**.

Format

pppoe intermediate-agent information policy { **drop** | **replace** | **keep** }

undo pppoe intermediate-agent information policy

Parameters

Parameter	Description	Value
drop	Removes the original fields from PPPoE packets.	-
replace	Replaces original information fields in PPPoE packets according to the field format.	-
keep	Reserves the content and format of original fields in PPPoE packets. If a PPPoE packet does not contain the fields, the device adds the fields to the packet according to the configuration.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the policy for processing original fields in user-side PPPoE packets is configured, the device can add information about the interface connected to the PPPoE client such as the slot ID/subcard ID/interface number, VLAN ID, and MAC address to PPPoE packets. The user account and access interface information are both authenticated, preventing user account embezzling. If received PPPoE packets contain fields related to the interface that connected to the PPPoE client, the device removes or reserves original fields as required.

After the command is executed, the policy for processing PPPoE packets takes effect on all interfaces. To configure a policy on a specified interface, run the **pppoe intermediate-agent information policy (interface view)** command. In this case, the policy for processing PPPoE packets on the interface depends on the interface configuration.

Prerequisites

PPPoE+ has been enabled globally by running the **pppoe intermediate-agent information enable** command.

Example

Configure all interfaces to replace original fields in the received PPPoE packets with the circuit ID and remote ID of the local device.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information policy replace
```

14.11.11 pppoe intermediate-agent information vendor-id

Function

The **pppoe intermediate-agent information vendor-id** command sets the vendor ID that the device adds to PPPoE packets.

The **undo pppoe intermediate-agent information vendor-id** command restores the default vendor ID that the device adds to PPPoE packets.

The default vendor ID that the device adds to PPPoE packets is 2011.

Format

pppoe intermediate-agent information vendor-id *vendor-id*

undo pppoe intermediate-agent information vendor-id

Parameters

Parameter	Description	Value
vendor-id *vendor-id*	Specifies a vendor ID added to PPPoE packets.	The value is an integer ranging from 0 to 4294967295. The default value is 2011.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After PPPoE+ is enabled, the device must negotiate with the PPPoE server using PPPoE packets containing the vendor ID. By default, the device adds vendor ID 2011 to PPPoE packets. If the device is connected to a non-Huawei PPPoE server, the vendor ID may not be 2011; for example, the vendor ID is 3561. In this case, run the **pppoe intermediate-agent information vendor-id** *vendor-id* command to set the vendor ID to be the same as that in PPPoE packets sent from the non-Huawei PPPoE server.

Prerequisites

Example

Set the vendor ID added to PPPoE packets to 3561.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] pppoe intermediate-agent information vendor-id 3561
```

14.11.12 pppoe uplink-port trusted

Function

The **pppoe uplink-port trusted** command configures an interface as a trusted interface.

The **undo pppoe uplink-port trusted** command restores an interface to be untrusted.

By default, all interfaces are untrusted interfaces.

Format

pppoe uplink-port trusted

undo pppoe uplink-port trusted

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent bogus PPPoE servers and the security risk caused by PPPoE packets forwarded to non-PPPoE service interfaces, the interface connecting the device and the PPPoE server must be configured as the trusted interface. Then PPPoE protocol packets are forwarded to the PPPoE server through the trusted interface only. In addition, only the PPPoE protocol packets received on the trusted interface can be forwarded to the PPPoE client.

Prerequisites

PPPoE+ has been enabled globally by running the **pppoe intermediate-agent information enable** command.

Precautions

The trusted interface controls PPPoE protocol packets at the PPPoE discovery stage only. PPPoE service packets at the PPPoE session stage are not controlled.

If the trusted interface is configured on the device that has no ACL resources, the system displays the following message "Warning: Allocate acl resources failed." In this case, the trusted interface fails to be configured.

Example

Configure GE0/0/1 as the PPPoE trusted interface.

```
<HUAWEI> system-view
[HUAWEI] pppoe intermediate-agent information enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] pppoe uplink-port trusted
```

14.12 IP Source Guard Configuration Commands

14.12.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.12.2 display dhcp static user-bind

Function

The **display dhcp static user-bind** command displays information about a static binding table.

Format

display dhcp static user-bind { { **interface** *interface-type interface-number* | **ip-address** *ip-address* | **mac-address** *mac-address* | **vlan** *vlan-id* } * | **all** } [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays binding entries mapping a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
ip-address *ip-address*	Displays the binding entry mapping a specified IP address.	The value is in dotted decimal notation.
mac-address *mac-address*	Displays the binding entry mapping a specified MAC address.	The value is in hexadecimal notation.
vlan *vlan-id*	Displays the binding entry mapping a specified VLAN ID.	The value is an integer that ranges from 1 to 4094.
all	Displays all entries in the binding table.	-
verbose	Displays detailed information about the binding table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to view information about a configured static binding table. The information includes the IP address, MAC address, VLAN information, and interface information.

Example

Display information about the static binding table.

```
<HUAWEI> display dhcp static user-bind all
DHCP static Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
IP Address           MAC Address   VSI/VLAN(O/I/P) Interface
--------------------------------------------------------------------------------
10.1.1.1           00e0-fc02-0003 10 /-- /--      GE0/0/1
--------------------------------------------------------------------------------
Print count:      1     Total count:      1
```

Display detailed information about the static binding table.

```
<HUAWEI> display dhcp static user-bind all verbose
DHCP static Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping
--------------------------------------------------------------------------------
 IP Address  : 10.21.21.254
 MAC Address : --
 VSI         : --
 VLAN(O/I/P) : 10  /--  /--
 Interface   : GE0/0/1
 IPSG Status : IPv4 effective slot: <0>
--------------------------------------------------------------------------------
Print count:           1          Total count:           1
```

Table 14-85 Description of the **display dhcp static user-bind** command output

Item	Description
DHCP static Bind-table	Static DHCP binding entries. To configure a static DHCP binding table, run the **user-bind static** command.
Flags:O - outer vlan ,I - inner vlan ,P - Vlan-mapping	VLAN ID. ● O: Outer VLAN ● I: Inner VLAN ● P: Vlan-mapping
IP Address	User IP address.
MAC Address	User MAC address.
VSI	Name of the VSI that the online user belongs to.
VLAN(O/I/P)	Inner VLAN ID, outer VLAN ID, or VLAN mapping information of the online user.
Interface	User access interface.

Item	Description
IPSG Status	Whether the binding table is effective for IP packet checking after IP packet checking is enabled. The value can be: - IPv4 effective slot: <0> indicates that the binding table is effective for IPv4 packet checking in slot 0. - Ineffective This field is invalid if IP packet checking is not enabled.

14.12.3 display dhcpv6 static user-bind

Function

The **display dhcpv6 static user-bind** command displays the IPv6 binding table.

Format

display dhcpv6 static user-bind { { **interface** *interface-type interface-number* | **ipv6-address** { *ipv6-address* | **all** } | **mac-address** *mac-address* | **vlan** *vlan-id* } * | **all** } [**verbose**]

display dhcpv6 static user-bind ipv6-prefix { *prefix/prefix-length* | **all** } [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the binding entry mapping a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
ipv6-address *ipv6-address*	Displays the binding entry mapping a specified IPv6 address.	The address is a 32-digit hexadecimal number, in the format of X:X::X:X.
mac-address *mac-address*	Displays the binding entry mapping a specified MAC address.	The value is in hexadecimal notation.

Parameter	Description	Value
vlan *vlan-id*	Displays the binding entry mapping a specified VLAN ID.	The value is an integer that ranges from 1 to 4094.
ipv6-prefix	Displays an IPv6 prefix binding entry.	-
prefix/*prefix-length*	Displays the binding entry mapping a specified IPv6 prefix.	*prefix* is a 32-digit hexadecimal number, in the format of X:X::X:X. *prefix-length* is an integer that ranges from 1 to 128.
all	Displays all entries in the binding table.	-
verbose	Displays detailed information about the binding table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to view information about a configured DHCPv6 static binding table. The information includes the IPv6 address, MAC address, VLAN information, and interface information. If prefix delegation (PD) users exist on the network, the device generates an IPv6 prefix binding entry. The **display dhcpv6 static user-bind ipv6-prefix** command displays the static IPv6 prefix binding entries.

Example

Display the DHCPv6 static binding table.

```
<HUAWEI> display dhcpv6 static user-bind all
DHCPV6 static Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - map vlan
IP Address                      MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Interface
--------------------------------------------------------------------------------
fc00:1::1                     0001-0002-0003  10  /--  /--    --
--------------------------------------------------------------------------------
Print count:          1          Total count:          1
```

Display detailed information about the DHCPv6 static binding table.

```
<HUAWEI> display dhcpv6 static user-bind all verbose
DHCPV6 static Bind-table:
-------------------------------------------------------------------------------
 IP Address  : fc00:1::1
 MAC Address : 0001-0002-0003
 VSI         : --
 VLAN(O/I/P) : 10  /--  /--
 Interface   : --
 IPSG Status : IPv6 effective slot: <0>
-------------------------------------------------------------------------------
Print count:           1          Total count:           1
```

Display the IPv6 prefix static binding table.

```
<HUAWEI> display dhcpv6 static user-bind ipv6-prefix all
PD static Bind-table:
Flags:O - outer vlan ,I - inner vlan ,P - map vlan
IPv6 Prefix                     MAC Address     VSI/VLAN(O/I/P)/(BD-VLAN) Interface
-------------------------------------------------------------------------------
fc00:1000::12/32                0001-0002-0003  10  /--  /--    --
-------------------------------------------------------------------------------
Print count:           1          Total count:           1
```

Table 14-86 Description of the display dhcpv6 static user-bind command output

Item	Description
DHCPV6 static Bind-table	Static DHCPv6 binding entries. To configure a static DHCPv6 binding table, run the **user-bind static** command.
Flags:O - outer vlan ,I - inner vlan ,P - map vlan	VLAN ID. ● O: Outer VLAN ● I: Inner VLAN ● P: Map VLAN
IPv6 Prefix	User IPv6 prefix.
IP Address	User IPv6 address.
MAC Address	User MAC address.
VSI	Name of the VPN instance that the online user belongs to.
VLAN(O/I/P)	Outer VLAN ID, inner VLAN ID, or VLAN mapping information of the online user.
(BD-VLAN)	BD and the VLAN to which the BD is bound.
Interface	User access interface.

Item	Description
IPSG Status	Whether the binding table is effective for IP packet checking after IP packet checking is enabled. The value can be: ● IPv6 effective slot: <0> indicates that the binding table is effective for IPv6 packet checking in slot 0. ● ineffective This field is invalid if IP packet checking is not enabled.

14.12.4 display ip source check user-bind

Function

The **display ip source check user-bind** command displays the IPSG configurations.

Format

display ip source check user-bind interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the IP packet check configuration on a specified interface. The interface is specified by the interface type and number. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ip source check user-bind** command displays the IP packet check configuration on an interface, including IP packet check items and the alarm function of IP packet check.

Example

Display the IP packet check configuration on GE0/0/1.

```
<HUAWEI> display ip source check user-bind interface gigabitethernet 0/0/1
 ipv4 source check user-bind enable
 ipv6 source check user-bind enable
 ip source check user-bind check-item ip-address
 ip source check user-bind alarm enable
 ip source check user-bind alarm threshold 200
```

Table 14-87 Description of the display ip source check user-bind command output

Item	Description
ipv4 source check user-bind enable	IPv4 packet check is enabled.
ipv6 source check user-bind enable	IPv6 packet check is enabled.
ip source check user-bind check-item ip-address	IP packet check items. An IP packet check item can contain the IP address, MAC address, VLAN ID, and interface number. To specify check items, run the **ip source check user-bind check-item (interface view)** or **ip source check user-bind check-item (VLAN view)** commands.
ip source check user-bind alarm enable	Alarm function of IP packet check is enabled. To enable the alarm function of IP packet check, run the **ip source check user-bind alarm enable** command.
ip source check user-bind alarm threshold 200	Alarm threshold for IP packet check. To set the alarm threshold for IP packet check, run the **ip source check user-bind alarm threshold** command.

14.12.5 display mac-address snooping

Function

The **display mac-address snooping** command displays snooping MAC address entries generated based on the snooping binding table.

Format

display mac-address snooping [*interface-type interface-number* | **vlan** *vlan-id*] * [**verbose**]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays the static MAC address entry on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
vlan *vlan-id*	Displays all the static MAC address entries on all the interfaces in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
verbose	Displays detailed information about static MAC address entries.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you run the **user-bind ip sticky-mac** command in the interface view, the device generates snooping MAC address entries based on the snooping binding table. A snooping MAC address entry includes the user MAC address and VLAN ID. The **display mac-address snooping** command displays snooping MAC address entries generated based on the snooping binding table. If no interface or VLAN is specified, all the snooping MAC address entries generated based on the snooping binding table are displayed.

Example

Display the snooping MAC address entries generated based on the snooping binding table on the device.

```
<HUAWEI> display mac-address snooping
-------------------------------------------------------------------------------
MAC Address    VLAN/VSI/BD                       Learned-From        Type
-------------------------------------------------------------------------------
00e0-fc02-0602 10/-/-                            GE0/0/1             snooping
-------------------------------------------------------------------------------
Total items displayed = 1
```

Table 14-88 Description of the **display mac-address snooping** command output

Item	Description
MAC Address	User MAC address.
VLAN/VSI/BD	ID of the VLAN, name of the VSI, or ID of the BD that the user belongs to.
Learned-From	Port number.
Type	Type of a MAC address entry, including: ● static: indicates a static MAC address entry. ● blackhole: indicates a blackhole MAC address entry. ● dynamic: indicates a dynamic MAC address entry. ● security: indicates a security MAC address entry. ● sticky: indicates a sticky MAC address entry. ● snooping: indicates a MAC address entry generated based on the snooping binding table.

14.12.6 ip anti-attack source-ip equals destination-ip drop

Function

The **ip anti-attack source-ip equals destination-ip drop** command enables the device to discard IP packets with the same source and destination IP addresses.

The **undo ip anti-attack source-ip equals destination-ip drop** command disables the device from discarding IP packets with the same source and destination IP addresses.

By default, the device does not discard IP packets with the same source and destination IP addresses.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ip anti-attack source-ip equals destination-ip drop

undo ip anti-attack source-ip equals destination-ip drop

Parameters

None

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, IP packets with the same source and destination IP addresses can be forwarded. When you determine that the IP packets are attack packets, you can use the **ip anti-attack source-ip equals destination-ip drop** command to enable the device to discard the IP packets.

Precautions

On the following models, the device discards IP packets with the same source and destination IP addresses:

S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S6720S-S, S5735S-H, S5736-S

Example

Enable the device to discard IP packets with the same source and destination IP addresses.

```
<HUAWEI> system-view
[HUAWEI] ip anti-attack source-ip equals destination-ip drop
```

14.12.7 ip source check user-bind alarm enable

Function

The **ip source check user-bind alarm enable** command enables the alarm function of IP packet check.

The **undo ip source check user-bind alarm enable** command disables the alarm function of IP packet check.

By default, the alarm function of IP packet check is disabled.

Format

ip source check user-bind alarm enable

undo ip source check user-bind alarm enable

Parameters

None

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ip source check user-bind alarm enable** command enables the log and alarm function for IP packet check. If the number of discarded packets reaches the threshold, the device sends an alarm to the NMS device.

Prerequisites

IP packet check has been enabled using the **ip source check user-bind enable** command on the interface.

Follow-up Procedure

Run the **ip source check user-bind alarm threshold** command to set the alarm threshold.

Precautions

If the alarm function of IP packet check is enabled both in the VLAN view and in the view of the interface added to the VLAN, it takes effect in the view where it was first enabled. To change the order in which the function takes effect, disable it in the view where it has taken effect, and then enable it in the desired view.

Example

Enable the alarm function for IP packet check on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind alarm enable
```

14.12.8 ip source check user-bind alarm threshold

Function

The **ip source check user-bind alarm threshold** command sets the alarm threshold for IP packet check.

The **undo ip source check user-bind alarm threshold** command restores the default alarm threshold for IP packet check.

By default, the alarm threshold is 100.

Format

ip source check user-bind alarm threshold *threshold*

undo ip source check user-bind alarm threshold

Parameters

Parameter	Description	Value
threshold	Specifies an alarm threshold for IP packet check.	The value is an integer that ranges from 1 to 1000.

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the alarm function of IP packet check is enabled, run the **ip source check user-bind alarm threshold** command to set the alarm threshold for IP packet check.

Prerequisites

The alarm function of IP packet check has been enabled using the **ip source check user-bind alarm enable** command.

Example

Set the alarm threshold for IP packet check to 200 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind alarm enable
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind alarm threshold 200
```

14.12.9 ip source check user-bind check-item (interface view)

Function

The **ip source check user-bind check-item** command configures IP packet check items on an interface.

The **undo ip source check user-bind check-item** command restores the default IP packet check items.

By default, the check items contain the IP address, MAC address, VLAN and interface information..

Format

ip source check user-bind check-item { **ip-address** | **mac-address** | **vlan** } *

undo ip source check user-bind check-item

Parameters

Parameter	Description	Value
ip-address	Checks whether the IP address of an IP packet matches a binding entry.	-
mac-address	Checks whether the MAC address of an IP packet matches a binding entry.	-
vlan	Checks whether VLAN information of an IP packet matches a binding entry.	-

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you check an IP packet against the binding table, run the **ip source check user-bind check-item (interface view)** command to specify items in the IP packet to be checked on a specified interface. When the device receives an IP packet, it checks the items against the binding table. Only packets that match the binding entries can be forwarded; otherwise, packets are discarded. The optional check items of an IP packet contain the source IP address, source MAC address, and VLAN information. Interface information is a mandatory check item.

Prerequisites

IP packet check has been enabled using the **ip source check user-bind enable** command in the interface view.

Precautions

When a large number of binding entries exist, it may take a long time to check IP packets, reducing forwarding efficiency.

This command is valid only for dynamic binding entries. The device checks the received packets against entries in the static binding table.

Example

Enable IP packet check on GE0/0/1 to check whether the IP address in the IP packet matches the binding entry.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind enable
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind check-item ip-address
```

14.12.10 ip source check user-bind check-item (VLAN view)

Function

The **ip source check user-bind check-item** command configures IP packet check items in a VLAN.

The **undo ip source check user-bind check-item** command restores the default IP packet check items in a VLAN.

By default, the check items contain the IP address, MAC address, VLAN and interface information.

Format

ip source check user-bind check-item { **ip-address** | **mac-address** | **interface** } *

undo ip source check user-bind check-item

Parameters

Parameter	Description	Value
ip-address	Checks whether the IP address of an IP packet matches a binding entry.	-
mac-address	Checks whether the MAC address of an IP packet matches a binding entry.	-
interface	Checks whether interface information of an IP packet matches a binding entry.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you check an IP packet against the binding table, run the **ip source check user-bind check-item (VLAN view)** command to configure IP packet check items in a specified VLAN. When the device receives an IP packet, it checks the items against the binding table. Only packets that match the binding entries can be forwarded; otherwise, packets are discarded. The optional check items of an IP packet contain the source IP address, source MAC address, and interface information. VLAN information is a mandatory check item.

Prerequisites

IP packet check has been enabled using the **ip source check user-bind enable** command in the VLAN view.

Precautions

When a large number of binding entries exist, it may take a long time to check IP packets, reducing forwarding efficiency.

This command is valid only for dynamic binding entries. The device checks the received packets against entries in the static binding table.

Example

Enable IP packet check in VLAN 100 and check whether the IP address in the IP packet matches the binding entry.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] ip source check user-bind enable
[HUAWEI-vlan100] ip source check user-bind check-item ip-address
```

14.12.11 ip source check user-bind enable

Function

The **ip source check user-bind enable** command enables IP packet check.

The **undo ip source check user-bind enable** command disables IP packet check.

By default, IP packet check is disabled.

Format

ip source check user-bind enable

undo ip source check user-bind enable

ipv4 source check user-bind enable

undo ipv4 source check user-bind enable

ipv6 source check user-bind enable

undo ipv6 source check user-bind enable

Parameters

None

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Unauthorized users often send bogus packets with the source IP address and MAC address of authorized users to access or attack the network. Then authorized users cannot access stable and secure networks. To address this problem, you can configure IP packet check.

When IP packet check is enabled, the device checks the IP address, MAC address, VLAN information, and interface information against the binding table. You can run the **ip source check user-bind check-item** or **ip source check user-bind check-item** command to specify IP packet check items. Only packets that match the binding entries can be forwarded; otherwise, packets are discarded.

Prerequisites

The IP packet check is based by binding table. So,

- The dynamic DHCP snooping binding table has been generated for DHCP users.
- The static binding table has been configured manually for users using static IP addresses.
- The dynamic ND snooping binding table has been generated for users dynamically obtaining IPv6 addresses through Stateless Address Autoconfiguration.

Precautions

After IP packet check is enabled using the **ip source check user-bind enable** command, the device checks the source IPv4 and IPv6 addresses of users' IP packets. The configuration file is displayed as follows:

```
ipv4 source check user-bind enable
ipv6 source check user-bind enable
```

To check only IPv4 or IPv6 packets, run the **ipv4 source check user-bind enable** or **ipv6 source check user-bind enable** command.

Example

Enable IPv4 and IPv6 packet check on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ip source check user-bind enable
```

Enable IPv4 packet check on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ipv4 source check user-bind enable
```

14.12.12 user-bind static

Function

The **user-bind static** command configures a static binding table.

The **undo user-bind static** command deletes a static binding table.

By default, no static binding table is configured.

Format

user-bind static { { { **ip-address** | **ipv6-address** } { *start-ip* [**to** *end-ip*] } &<1-10> | **ipv6-prefix** *prefix/prefix-length* } | **mac-address** *mac-address* } * [**interface** *interface-type interface-number*] [**vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*]]

undo user-bind static [{ **ip-address** { *start-ip* [**to** *end-ip*] } &<1-10> | **ipv6-address** [*start-ip* [**to** *end-ip*]] &<1-10> | **ipv6-prefix** [*prefix/prefix-length*] } | **mac-address** *mac-address* | **interface** *interface-type interface-number* | **vlan** *vlan-id* [**ce-vlan** *ce-vlan-id*]] *

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the interface connected to a user in a static binding entry. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
ip-address	Indicates the static IPv4 address.	-
ipv6-address	Indicates the static IPv6 address.	-

Parameter	**Description**	**Value**
start-ip [**to** *end-ip*]	Specifies the user IP address in a static binding entry. - *start-ip* specifies the first IP address. - **to** *end-ip* specifies the last IP address. The value of *end-ip* must be larger than the value of *start-ip*. *start-ip* and *end-ip* identify a VLAN range. If **to** *end-ip* is not specified, only the start IP address is added to the static binding entry. You can specify a maximum of 10 VLAN ranges at a time. The entered VLAN ranges cannot overlap.	The IPv4 address is in dotted decimal notation in the format of X.X.X.X. The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-prefix *prefix/prefix-length*	Specifies the prefix of an IPv6 address	The prefix consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X. *prefix-length* is an integer that ranges from 1 to 128.
mac-address *mac-address*	Specifies the user MAC address in a static binding entry.	The value is in hexadecimal notation. The value is in the format of H-H-H.
vlan *vlan-id*	Specifies the user VLAN ID in a static binding entry.	The value is an integer that ranges from 1 to 4094.
ce-vlan *ce-vlan-id*	Specifies the inner VLAN tag of a QinQ packet in a static binding entry.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When DHCP snooping is enabled, a dynamic binding table is automatically generated for dynamic users. However, a static binding table cannot be generated for static users. If IP source guard is enabled but no static binding table is available, the device discards all static users' forwarding packets. To enable the device to forward static users' packets, run the **user-bind static** command to configure a static binding table.

Precautions

After a static binding table is configured and IP source guard is enabled, the device performs a match check on IP packets based on the configured binding entries. If the match check fails, the device discards the IP packets.

Example

Configure a static binding entry for a user in VLAN 2 with the IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] user-bind static ip-address 10.1.1.1 vlan 2
```

14.12.13 user-bind ip sticky-mac

Function

The **user-bind ip sticky-mac** command enables the device to generate snooping MAC entries.

The **undo user-bind ip sticky-mac** command disables the device from generating snooping MAC entries.

By default, the device does not generate snooping MAC entries.

Format

user-bind ip sticky-mac

undo user-bind ip sticky-mac

Parameters

None

Views

VLAN view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent the users with unauthorized MAC addresses from attacking the network, run the **user-bind ip sticky-mac** command to configure the device to generate snooping MAC entries on the interface that is prone to attack. After the device is configured to generate snooping MAC entries, it translates the dynamic MAC entries learned by the interface into snooping MAC entries (snooping MAC entries are a type of static MAC entries) based on the DHCP snooping binding table and ND snooping binding table, or generates snooping MAC entries based on the static binding entries.

After the configuration is complete, the interface forwards only the IP packets of which the source MAC addresses are included in the static MAC entries (static and snooping), and discards other IP packets.

NOTE

- To view MAC entry information on the device, see **display mac-address**.
- If a binding entry is modified, the matching snooping MAC entry is also modified.

Prerequisites

Before using the **user-bind ip sticky-mac** command, ensure that the DHCP snooping function has been enabled by the **dhcp snooping enable** command.

Precautions

- To ensure correct packet forwarding for authorized static users on an interface, you can run the **user-bind static** command to configure static binding entries, which generate static MAC entries, or run the **mac-address static** command to configure static MAC entries.
- When configuring a static binding entry, specify the MAC address, VLAN ID, and interface number. The VLAN ID must already exist on the device. If you do not specify the three parameters, a snooping MAC entry cannot be generated based on this static binding entry.
- To allow DHCPv6 users to go online, enable both DHCP snooping and ND snooping.
- To check whether the snooping MAC address entries are successfully delivered, you can use **display mac-address summary** to check the total number of snooping MAC address entries. If the snooping MAC address entries fail to be delivered, the possible cause is a hash conflict.
- The **user-bind ip sticky-mac** command cannot be used together with the following commands.

Command	Description
dot1x enable	Enables 802.1X authentication on an interface.
mac-authen	Enables MAC address-based authentication on an interface.
authentication-profile (Interface view or VAP profile view)	Applies an authentication profile to the interface or VAP profile.
mac-address learning disable (Interface view and VLAN view)	Enables MAC address learning.

Command	Description
mac-limit	Sets the maximum number of MAC addresses to be learned.
port vlan-mapping vlan map-vlan **port vlan-mapping vlan inner-vlan**	Enables VLAN mapping.
port-security enable	Enables port security.

Example

Configure the GE0/0/1 interface to generate snooping MAC entries based on the snooping binding table.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] user-bind ip sticky-mac
```

14.13 SAVI Configuration Commands

14.13.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.13.2 savi max dad-delay

Function

The **savi max dad-delay** command sets the time for listening to an NA packet responding to address conflicts.

The **undo savi max dad-delay** command restores the default setting.

By default, the time for listening to an NA packet responding to address conflicts is 2 seconds.

Format

savi max dad-delay *value*

undo savi max dad-delay

Parameters

Parameter	Description	Value
value	Specifies the time for listening to an NA packet responding to address conflicts.	The value is an integer that ranges from 1 to 100, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **savi max dad-delay** command is applicable only for SLAAC-Only scenarios and DHCPv6+SLAAC scenarios.

- In SLAAC-Only scenarios:

  When obtaining an IP address in SLAAC mode, an ND client generates the IPv6 address based on the prefix in the RA packet. After the IPv6 address is generated, the ND client sends an NS packet to check whether duplicate addresses exist on the network. When detecting the NS packet in the DAD process from the ND client, the device generates an ND snooping entry, sets the entry to the detect state, and listens to the mapping NA packet.

  - If a mapping NA packet is detected in the configured listening period, IPv6 address conflict occurs and the device deletes this ND snooping entry.
  - If no mapping NA packet is detected in the configured listening period, the IPv6 address is available and the device sets the ND snooping entry to the bound state. The device deletes the ND snooping entry only when the entry ages out. If automatic user status detection for users mapping ND snooping dynamic binding entries is enabled using the **nd user-bind detect enable** command on the device, and no NA packet is returned from the user after NS packets are sent for times configured using the **nd user-bind detect retransmit** *retransmit-times* **interval** *retransmit-interval* command, the device considers the user to be offline and deletes the mapping ND snooping entry.
- In DHCPv6+SLAAC scenarios:
  - The procedure for processing packets by SAVI in SLAAC mode is the same as that in SLAAC-Only scenarios.
  - When obtaining an IP address in DHCPv6 mode, a DHCPv6 client may send an NS packet to check whether duplicate addresses exist on the network. When detecting the NS packet in the DAD process from the DHCPv6 client, the device sets the mapping DHCPv6 snooping entry to the detect state, and listens to the mapping NA packet.

  - If a mapping NA packet is detected in the configured listening period, IPv6 address conflict occurs and the device deletes this DHCPv6 snooping entry.
  - If no mapping NA packet is detected in the configured listening period, the IPv6 address is available and the device sets the DHCPv6 snooping entry to the bound state.

When the DHCPv6 Snooping entry is in detection state, the device deletes this entry after detecting the NA packets within the time of listening on NA packets with response address conflicts. When the DHCPv6 Snooping entry is in bound state, the device deletes this entry after detecting the DHCPv6 Decline or DHCPv6 Release packets sent from the DHCPv6 clients.

Prerequisites

The SAVI function has been enabled using the **savi enable** command.

Precautions

This command is used together with ND snooping and DHCPv6 snooping.

Example

Set the time for listening to an NA packet responding to address conflicts to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] savi enable
[HUAWEI] savi max dad-delay 5
```

14.13.3 savi max dad-prepare-delay

Function

The **savi max dad-prepare-delay** command sets the time for listening to the duplicate address detection performed by the DHCPv6 client.

The **undo savi max dad-prepare-delay** command restores the default setting.

By default, the time for listening to the duplicate address detection performed by the DHCPv6 client is 2 seconds.

Format

savi max dad-prepare-delay *value*

undo savi max dad-prepare-delay

Parameters

Parameter	Description	Value
value	Specifies the time for listening to the duplicate address detection performed by the DHCPv6 client.	The value is an integer that ranges from 1 to 100, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **savi max dad-prepare-delay** command is applicable only for DHCPv6-Only scenarios and DHCPv6+SLAAC scenarios.

After detecting that the DHCPv6 client obtains the IPv6 address, the device detects whether the DHCPv6 client sends an NS packet for duplicate address detection.

- In DHCPv6-Only scenarios:
  - If no NS packet in the DAD process is detected in the configured listening period, the device sets the DHCPv6 snooping entry to the bound state. It indicates that the DHCPv6 does not perform the duplicate address detection on the obtained IPv6 address or no duplicate IPv6 address exists.
  - If an NS packet in the DAD process is detected in the configured listening period, the device does not change the status of the mapping DHCPv6 snooping entry. The device sets the DHCPv6 snooping entry to the bound state only when the listening period expires.

  In DHCPv6-Only scenarios, when detecting the DHCPv6 Decline packet or DHCPv6 Release packet from the DHCPv6 client, the device deletes the corresponding DHCPv6 snooping entry.
- In DHCPv6+SLAAC scenarios:
  - If no NS packet in the DAD process is detected in the configured listening period, the device sets the DHCPv6 snooping or ND snooping entry to the bound state. It indicates that the client does not perform the duplicate address detection on the obtained IPv6 address or no duplicate IPv6 address exists, and the client can use this IPv6 address.
  - If an NS packet in the DAD process is detected in the configured listening period, the device sets the mapping DHCPv6 snooping or ND snooping entry to the detection state, and listens to the mapping NA packet. For the listening method, see **savi max dad-delay**.

Prerequisites

The SAVI function has been enabled using the **savi enable** command.

Precautions

This command is used together with ND snooping and DHCPv6 snooping.

Example

Set the time for listening to the duplicate address detection performed by the DHCPv6 client to 5 seconds.

```
<HUAWEI> system-view
[HUAWEI] savi enable
[HUAWEI] savi max dad-prepare-delay 5
```

14.13.4 savi max-binding-table

Function

The **savi max-binding-table** command sets the maximum number of SAVI binding entries on an interface.

The **undo savi max-binding-table** command restores the default maximum number of SAVI binding entries on an interface.

By default, the maximum number of SAVI binding entries is the same as the number of binding entries supported by the device.

Format

savi max-binding-table *max-number*

undo savi max-binding-table

Parameters

Parameter	Description	Value
max-number	Specifies the maximum number of SAVI binding entries on an interface.	The value is an integer that varies depending on product models.

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An SAVI binding table is a set of the ND snooping binding table and DHCPv6 snooping binding table. When the sum of ND snooping binding entries and DHCPv6 snooping binding entries on an interface reaches the configured maximum number of SAVI binding entries, subsequent users cannot connect to the network. After the maximum number of SAVI binding entries is set, the device does not process many ND packets and DHCPv6 packets with invalid source addresses to defend against attacks.

Prerequisites

Ensure that SAVI has been enabled globally using the **savi enable** command.

Example

Set the maximum number of SAVI binding entries on the GE0/0/1 to 8.

```
<HUAWEI> system-view
[HUAWEI] savi enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] savi max-binding-table 8
```

14.13.5 savi enable

Function

The **savi enable** command enables the SAVI function.

The **undo savi enable** command disables the SAVI function.

By default, the SAVI function is disabled.

Format

savi enable

undo savi enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the SAVI function is enabled, the device checks the validity of the source addresses in the ND, DHCPv6, and IPv6 data packets based on the bindings between IP addresses and ports and filters out invalid packets. The bindings between IP addresses and ports are generated based on ND snooping and DHCPv6 snooping.

Precautions

The SAVI function must be used together with ND snooping, DHCPv6 snooping, or IP source guard.

After the SAVI function is enabled, only when both ND snooping and IP source guard are enabled or both DHCPv6 snooping and IP source guard are enabled on an interface, the device checks the validity of the source addresses in IPv6 data packets received on this interface.

Example

Enable the SAVI function.

```
<HUAWEI> system-view
[HUAWEI] savi enable
```

14.14 URPF Configuration Commands

14.14.1 Command Support

Only the following switch models support URPF:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

14.14.2 urpf (interface view)

Function

The **urpf** command enables URPF on an interface and configures the URPF mode.

The **undo urpf** command disables URPF on an interface.

By default, URPF is disabled on an interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

For the S6735-S, S6720-EI, and S6720S-EI, only Layer 2 Ethernet interfaces support URPF strict check.

Format

urpf { **loose** | **strict** } [**allow-default-route**]

undo urpf

Parameters

Parameter	Description	Value
loose	Indicates URPF check in loose mode. A packet passes the check as long as the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet is not required to be the same as the outbound interface of the route.	-
strict	Indicates URPF check in strict mode. A packet passes the check only when the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet should be the same as the outbound interface of the route.	-
allow-default-route	Allows the route to the source IP address of the packet to be configured as the default route. If this parameter is not configured, the device does not allow the route to the source IP address of the packet to be configured as the default route during the URPF check.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A Denial of Service (DoS) attack disables users from connecting to a server. DoS attacks aim to occupy many resources by sending a large number of connection requests to a specified server. The attacked server cannot respond to authorized users.

URPF searches for the route to the source IP address in the routing table based on the source IP address of the packet, and checks whether the inbound interface of the packet is the same as the outbound interface of the route. If no route to the source IP address of the packet exists in the routing table, or the inbound interface of the packet is different from the outbound interface of the route, the packet is discarded. This prevents IP spoofing attacks, especially DoS attacks with bogus source IP address.

In a complicated networking environment, asymmetric routes may exist. That is, the routes recorded on the local end and remote end are different. A URPF-enabled device on this network may discard the packets transmitted along the correct path, but forward the packets transmitted along incorrect paths. The device provides the following two URPF modes to solve this problem:

- **Strict mode**

  In strict mode, a packet passes the check only when the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet should be the same as the outbound interface of the route.

  If route symmetry is ensured, you are advised to use the URPF strict mode. For example, if there is only one path between two network edge devices, URPF strict mode can be used to ensure network security.

- **Loose mode**

  In loose mode, a packet passes the check as long as the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet is not required to be the same as the outbound interface of the route.

  If route symmetry is not ensured, you are advised to use the URPF loose mode. For example, if there are multiple paths between two network edge devices, URPF loose mode can be used to ensure network security and prevent the packets transmitted along the correct path from being discarded.

Prerequisites

For the S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, and S6720S-EI, configurations on the interface take effect only after global URPF is enabled using the **urpf** command.

Precautions

In the Eth-Trunk interface view, this command conflicts with the **service type tunnel**, **service type multicast-tunnel**, or **service type vxlan-tunnel** command and cannot be run in the same Eth-Trunk interface view.

For the S6720-EI, S6735-S and S6720S-EI, even if no default route is configured, the **urpf loose allow-default-route** command takes effect when the resource allocation mode is set to **enhanced-ipv4** or **ipv4-ipv6 6:1** using the **assign resource-mode** command. The device allows the route to the source IP address of the packet to be configured as the default route during the URPF loose check.

For the S5735-S-I, only URPF check in loose mode is supported. For the S5735-S and S5735S-S, V200R019C10 and later versions support only URPF check in loose mode. If URPF check in strict mode is configured in V200R019C00, the configuration will be changed to URPF check in loose mode after the version is upgraded to V200R019C10 or later.

Example

Enable URPF strict check on a Layer 2 interface GE0/0/1 and allow the route to the source IP address of the packet to be configured as the default route.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] urpf strict allow-default-route
```

Enable URPF loose check on a Layer 3 interface GE0/0/2 and allow the route to the source IP address of the packet to be configured as the default route.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/2
[HUAWEI-GigabitEthernet0/0/2] undo portswitch
[HUAWEI-GigabitEthernet0/0/2] urpf loose allow-default-route
```

14.14.3 urpf (system view)

Function

The **urpf** command enables global URPF.

The **undo urpf** command disables global URPF.

By default, the switch does not enable global URPF.

NOTE

Only S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6735-S, S6720-EI, and S6720S-EI support this command.

Format

For S5720I-SI, S5735S-H, S6720S-S, and S5736-S:

urpf [**slot** *slot-id*]

undo urpf [**slot** *slot-id*]

For S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, and S6720S-EI:

urpf slot *slot-id* [**based-logic-port**]

undo urpf slot *slot-id* [**based-logic-port**]

Parameters

Parameter	Description	Value
slot *slot-id*	- Specifies the slot ID if stacking is not configured. - Specifies the stack ID if stacking is configured.	Set the value according to the device configuration.
based-logic-port	- If this parameter is specified, URPF check configured on logical interfaces takes effect, including VLANIF interfaces and subinterfaces, and URPF check configured on Ethernet interfaces does not take effect, including Layer 2 and Layer 3 Ethernet interfaces. - If this parameter is not specified, URPF check configured on Ethernet interfaces takes effect, and URPF check configured on logical interfaces does not take effect.	-

Usage Guidelines

Usage Scenario

A Denial of Service (DoS) attack disables users from connecting to a server. DoS attacks aim to occupy many resources by sending a large number of connection requests to a specified server. The attacked server cannot respond to authorized users.

URPF searches for the route to the source IP address in the routing table based on the source IP address of the packet, and checks whether the inbound interface of the packet is the same as the outbound interface of the route. If no route to the source IP address of the packet exists in the routing table, or the inbound interface of the packet is different from the outbound interface of the route, the packet is discarded. This prevents IP spoofing attacks, especially DoS attacks with bogus source IP address.

In a complicated networking environment, asymmetric routes may exist. That is, the routes recorded on the local end and remote end are different. A URPF-enabled device on this network may discard the packets transmitted along the correct path, but forward the packets transmitted along incorrect paths. The device provides the following two URPF modes to solve this problem:

- **Strict mode**

  In strict mode, a packet passes the check only when the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet should be the same as the outbound interface of the route.

  If route symmetry is ensured, you are advised to use the URPF strict mode. For example, if there is only one path between two network edge devices, URPF strict mode can be used to ensure network security.

- **Loose mode**

  In loose mode, a packet passes the check as long as the device has a route to the source IP address of the packet in the routing table, and the inbound interface of the packet is not required to be the same as the outbound interface of the route.

  If route symmetry is not ensured, you are advised to use the URPF loose mode. For example, if there are multiple paths between two network edge devices, URPF loose mode can be used to ensure network security and prevent the packets transmitted along the correct path from being discarded.

Precautions

- Enabling or disabling global URPF will affect packet forwarding in a short period of time.
- The S5720I-SI, S5735S-H, S6720S-S, and S5736-S only support URPF strict check.
- For the S5720I-SI, S5735S-H, S6720S-S, and S5736-S, after a stack is set up, if **slot** *slot-id* is not specified when the **urpf (system view)** command is executed, URPF takes effect only on the master switch.

- For the S6720-EI and S6720S-EI, the number of FIB entries are reduced by half if URPF is enabled. You are advised to enable URPF before services are deployed. If you need to enable URPF after services are deployed, configure URPF when less traffic is transmitted and ensure that network requirements are met if the number of FIB entries is reduced by half.
- If both the **urpf slot** *slot-id* and **urpf slot** *slot-id* **based-logic-port** commands are executed, the last configured one takes effect.

Follow-up Procedure

For the S5735-S, S5735S-S, S5735-S-I, S6735-S, S6720-EI, and S6720S-EI, run the **urpf(interface view)** command to enable URPF on an interface and configure the URPF mode.

Example

Enable global URPF on the device.

```
<HUAWEI> system-view
[HUAWEI] urpf slot 0
Warning: Changing the global URPF status may interrupt some services for several seconds and FIB entries
supported may be reduced. Continue? [Y/N]:y
```

Change URPF from Ethernet interface-based to logical interface-based.

```
<HUAWEI> system-view
[HUAWEI] urpf slot 0 based-logic-port
Warning: Changing the global URPF status may interrupt some services for several seconds and FIB entries
supported may be reduced. Continue? [Y/N]: y
Warning: The global URPF mode will be changed from physical interface-based to logical interface-based.
The URPF configuration on all Layer 2 or Layer 3 physical interfaces of the card will become invalid. Are
you sure to continue? [Y/N]: y
```

Change URPF from logical interface-based to Ethernet interface-based.

```
<HUAWEI> system-view
[HUAWEI] urpf slot 0
Warning: Changing the global URPF status may interrupt some services for several seconds and FIB entries
supported may be reduced. Continue? [Y/N]: y
Warning: The global URPF mode will be changed from logical interface-based to physical interface-based.
The URPF configuration on all sub-interfaces or VLANIF interfaces of the card will become invalid. Are you
sure to continue? [Y/N]: y
```

14.15 Keychain Configuration Commands

14.15.1 Command Support

Only the following switch models support Keychain:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

14.15.2 algorithm

Function

The **algorithm** command configures the authentication algorithm of a key.

The **undo algorithm** command deletes the authentication algorithm of a key.

By default, no authentication algorithm is configured.

Format

algorithm { **hmac-md5** | **hmac-sha-256** | **hmac-sha1-12** | **hmac-sha1-20** | **md5** | **sha-1** | **sha-256** | **simple** | **sm3** }

undo algorithm

Parameters

Parameter	Description	Value
hmac-md5	Specifies HMAC-MD5 as the authentication algorithm.	-
hmac-sha-256	Specifies HMAC-SHA-256 as the authentication algorithm.	-
hmac-sha1-12	Specifies HMAC-SHA1-12 as the authentication algorithm.	-
hmac-sha1-20	Specifies HMAC-SHA1-20 as the authentication algorithm.	-
md5	Specifies MD5 as the authentication algorithm.	-
sha-1	Specifies SHA-1 as the authentication algorithm.	-
sha-256	Specifies SHA-256 as the authentication algorithm.	-
simple	Indicates that the configured key is used for packet authentication.	-
sm3	Specifies SM3 as the authentication algorithm.	-

2: Configuration Level

Usage Guidelines

Usage Scenario

A keychain ensures secure protocol packet transmission by dynamically changing the authentication algorithm and key string. A keychain consists of multiple keys, each of which needs to be configured with an authentication algorithm. Different keys are valid within different time periods, ensuring dynamic change of keychain authentication algorithms.

Packets are authenticated and encrypted based on the authentication algorithm and key string associated with a specified key. This improves the packet transmission security.

The characteristics of each authentication algorithm are as follows:

- MD5(Message Digest 5): The 128-bit MD5 message digest is calculated based on the entered message of any length.
- SHA-1(Secure Hash Algorithm): The 160-bit SHA-1 message digest is calculated based on the entered message with the length shorter than the 64th power of 2.
- HMAC-MD5(Keyed-Hashing for Message Authentication-md5): The 128-bit HMAC-MD5 message digest is calculated based on the 512-bit message that is converted from the entered message of any length.

  NOTE

  If the length of an entered message is less than 512 bits, 0s are added to make up a 512-bit message. If the length of an entered message is greater than 512 bits, the message is converted into a 128-bit message based on the MD5 algorithm. Then, 0s are added to make up a 512-bit message.
- HMAC-SHA1-12: The 160-bit HMAC-SHA1-12 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. The leftmost 96 bits (12 x 8) are used as the authentication code.
- HMAC-SHA1-20: The 160-bit HMAC-SHA1-20 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 160 bits are used as the authentication code.
- SHA-256: The 256-bit SHA-2 message digest is calculated based on the entered message with the length shorter than the 64th power of 2.
- HMAC-SHA-256: The 256-bit HMAC-SHA-256 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 256 bits are used as the authentication code.
- SM3: The 256-bit SM3 message digest is calculated based on the entered message of any length. All the 256 bits are used as the authentication code.

Prerequisites

key-id has been configured.

Precautions

SHA-1 has low security, for higher security purposes, you are advised to specify the **hmac-sha-256** or **sha2-256** parameter.

Keys configured on the sender and receiver of packets must correspond to the same authentication and encryption algorithms. Otherwise, packet transmission fails for not passing the authentication.

If algorithm is not configured, key will never be active.

Different protocols support different algorithms.

- RIP supports MD5 and simple.
- BGP and BGP4+ support MD5.
- IS-IS supports HMAC-MD5 and simple.
- OSPF supports MD5, simple and HMAC-MD5.
- MSDP supports MD5.
- MPLS LDP supports MD5. MPLS TE supports HMAC-MD5.

Example

Specify sha-256 as the authentication algorithm of key-id 1.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] key-id 1
[HUAWEI-keychain-test-keyid-1] algorithm sha-256
```

14.15.3 default send-key-id

Function

The **default send-key-id** command configures a particular key as the default send key for that keychain.

The **undo default send-key-id** command deletes default send key.

By default, no key is configured as default send key.

Format

default send-key-id

undo default send-key-id

Parameters

None

Views

Key-ID view

Default Level

2: Configuration Level

Usage Guidelines

Usage Scenario

In keychain authentication mode, secure protocol packet transmission is provided by changing the authentication algorithm and key sting dynamically. This can reduce the workload of changing the algorithm and key manually. A keychain consists of multiple authentication keys, each of which is valid within different time periods. When a key becomes valid, the authentication algorithm corresponding to the key is used, and packets passing the authentication will be sent or received.

If a key for packet sending is not configured in a keychain or no key for packet sending is valid within a certain period, protocol packets cannot be authenticated and encrypted. As a result, protocol packet transmission fails. To address such a problem, configure a default key for packet sending. If no key is valid, the default key for packet sending is used.

Precautions

Each keychain can have only one default key for packet sending.

- If the default key for packet sending is an existing key, the authentication and encryption algorithms, and key corresponding to the key are used.
- If the default key for packet sending is a newly created key, configure the authentication and encryption algorithms.

Example

Configure the key-1 as default send key in keychain test.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] key-id 1
[HUAWEI-keychain-test-keyid-1] default send-key-id
```

14.15.4 display keychain

Function

The **display keychain** command displays the configuration of a specified keychain.

Format

display keychain *keychain-name* [**key-id** *key-id*]

Parameters

Parameter	Description	Value
keychain-name	Displays the configuration of a keychain with a specified name.	The keychain must already exist.

Parameter	Description	Value
key-id *key-id*	Displays the configuration of a specified key in the keychain.	The key must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To troubleshoot a keychain authentication failure or collect required information before configuration, run the **display keychain** command to view configurations of a specified keychain.

Example

Display the configuration of keychain **test** when no key ID is configured for the keychain.

```
<HUAWEI> display keychain test
 Keychain Information:
 ---------------------
 Keychain Name              : test
   Timer Mode               : Absolute
   Time Type                : Lmt
   Receive Tolerance(min)   : 0
   TCP Kind                 : 254
   TCP Algorithm IDs        :
     HMAC-MD5               : 5
     HMAC-SHA1-12           : 2
     HMAC-SHA1-20           : 6
     HMAC-SHA-256           : 7
     SHA-256                : 8
     MD5                    : 3
     SHA1                   : 4
 Number of Key IDs          : 0
 Active Send Key ID         : None
 Active Receive Key IDs     : None
 Default send Key ID        : Not configured
```

Display the configuration of keychain **test** when a key ID is configured for the keychain.

```
<HUAWEI> display keychain test
 Keychain Information:
 ---------------------
 Keychain Name              : test
   Timer Mode               : Absolute
   Time Type                : Lmt
   Receive Tolerance(min)   : 100
   TCP Kind                 : 182

Table 14-89 Description of the display keychain command output

Item	Description
Keychain Name	Name of a keychain. To set the keychain name, run the **keychain** command.
Timer Mode	Time mode of a keychain. ● Absolute: The keychain takes effect in an absolute time range. ● Daily periodic: The keychain is valid on a daily basis. ● Weekly periodic: The keychain is valid on a weekly basis. ● Monthly periodic: The keychain is valid on a monthly basis. ● Yearly periodic: The keychain is valid on a yearly basis. To set the time mode, run the **keychain** command.
Time Type	Specifies the timing type of the keychain.
Receive Tolerance(min)	Receive tolerance time configured for a keychain. To set the receive tolerance time, run the **receive-tolerance** command.
TCP Kind	TCP kind value configured for a keychain. To set the TCP kind value, run the **tcp-kind** command.

Item	Description
TCP Algorithm IDs	TCP algorithm ID configured for a keychain. The characteristics of each authentication algorithm are as follows: ● MD5(Message Digest 5): The 128-bit MD5 message digest is calculated based on the entered message of any length. ● SHA-1(Secure Hash Algorithm): The 160-bit SHA-1 message digest is calculated based on the entered message with the length shorter than the 64th power of 2. ● HMAC-MD5(Keyed-Hashing for Message Authentication-md5): The 128-bit HMAC-MD5 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. **NOTE** If the length of an entered message is less than 512 bits, 0s are added to make up a 512-bit message. If the length of an entered message is greater than 512 bits, the message is converted into a 128-bit message based on the MD5 algorithm. Then, 0s are added to make up a 512-bit message. ● HMAC-SHA1-12: The 160-bit HMAC-SHA1-12 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. The leftmost 96 bits (12 x 8) are used as the authentication code. ● HMAC-SHA1-20: The 160-bit HMAC-SHA1-20 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 160 bits are used as the authentication code. ● SHA-256: The 256-bit SHA-2 message digest is calculated based on the entered message with the length shorter than the 64th power of 2. ● HMAC-SHA-256: The 256-bit HMAC-SHA-256 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 256 bits are used as the authentication code. ● SM3: The 256-bit SM3 message digest is calculated based on the entered message of any length. All the 256 bits are used as the authentication code. To set the TCP algorithm ID, run the **tcp-algorithm-id** command.
Number of Key IDs	Number of key IDs.
Active Send Key ID	ID of the active send key.

Item	Description
Active Receive Key IDs	ID of the active receive key.
Default send Key ID	ID of the default send key.
Key ID	Key configured in a keychain. To set the key ID, run the **key-id** command.
Key string	Key string configured for the key. To set the key string, run the **key-string** command.

Item	Description
Algorithm	Algorithm configured for the key. To set the algorithm for a key, run the **algorithm** command. The characteristics of each authentication algorithm are as follows: ● MD5(Message Digest 5): The 128-bit MD5 message digest is calculated based on the entered message of any length. ● SHA-1(Secure Hash Algorithm): The 160-bit SHA-1 message digest is calculated based on the entered message with the length shorter than the 64th power of 2. ● HMAC-MD5(Keyed-Hashing for Message Authentication-md5): The 128-bit HMAC-MD5 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. **NOTE** If the length of an entered message is less than 512 bits, 0s are added to make up a 512-bit message. If the length of an entered message is greater than 512 bits, the message is converted into a 128-bit message based on the MD5 algorithm. Then, 0s are added to make up a 512-bit message. ● HMAC-SHA1-12: The 160-bit HMAC-SHA1-12 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. The leftmost 96 bits (12 x 8) are used as the authentication code. ● HMAC-SHA1-20: The 160-bit HMAC-SHA1-20 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 160 bits are used as the authentication code. ● SHA-256: The 256-bit SHA-2 message digest is calculated based on the entered message with the length shorter than the 64th power of 2. ● HMAC-SHA-256: The 256-bit HMAC-SHA-256 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 256 bits are used as the authentication code. ● SM3: The 256-bit SM3 message digest is calculated based on the entered message of any length. All the 256 bits are used as the authentication code.

Item	Description
SEND TIMER	Send time of a key. To set the send time of a key, run the **send-time** command.
Start time	Time when a key becomes valid.
End time	Time when a key becomes invalid.
Status	Status of send/receive keys: ● Active ● Inactive
RECEIVE TIMER	Receive time of a key. To set the receive time of a key, run the **receive-time** command.
DEFAULT SEND KEY ID INFORMATION	Information about the default send key.
Default	Configuration of the default send key: ● Not configured ● Configured
Status	Status of the default send key: ● Active ● Inactive

14.15.5 keychain

Function

The **keychain** command creates a new set of keychain rules or displays the keychain view.

The **undo keychain** command deletes the keychain configuration.

By default, no keychain is configured.

Format

keychain *keychain-name* { **mode** { **absolute** | **periodic** { **daily** | **weekly** | **monthly** | **yearly** } } }

undo keychain *keychain-name*

Parameters

Parameter	Description	Value
keychain-name	Specifies the keychain name. All the applications identify the set of keychain rules by keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
mode	Indicates the time mode of a keychain. **NOTE** ● The time mode of a keychain must be specified when a keychain is created. ● You do not need to specify the time mode for a created keychain.	-
absolute	Indicates that the given keychain is non-periodic.	-
periodic	Indicates that the given keychain is periodic.	-
daily	Indicates that the given keychain is day-periodic.	-
weekly	Indicates that the given keychain is week-periodic.	-
monthly	Indicates that the given keychain is month-periodic.	-
yearly	Indicates that the given keychain is year-periodic.	-

Usage Guidelines

Usage Scenario

In keychain authentication mode, secure protocol packet transmission is provided by dynamically changing the authentication algorithm and key string. This can prevent unauthorized users from obtaining the key string, and authentication and encryption algorithms, and reduce the workload of manually changing the algorithm and key string.

Each keychain consists of multiple keys that are valid within different time periods and each key is configured with an authentication algorithm. When a key becomes valid, the corresponding authentication algorithm is used.

There are two keychain time modes:

- Absolute time range: In this mode, keychains are valid within a certain period.
- Periodic time range: In this mode, keychains are valid periodically.

Follow-up Procedure

Run the **key-id** command to configure a key. If the key is not configured, the keychain cannot authenticate and encrypt protocol packets.

The time mode of a key must be the same as the time mode of the keychain.

Precautions

A keychain supports a maximum of 64 keys.

The **keychain** *keychain-name* command displays a specific keychain view. If the keychain specified by *keychain-name* does not exist, the **keychain** *keychain-name* command cannot be executed. To create a keychain, run the **keychain** *keychain-name* **mode** { **absolute** | **periodic** { **daily** | **weekly** | **monthly** | **yearly** } } command.

Example

Configure the keychain **test** and enter keychain view.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test]
```

14.15.6 key-id

Function

The **key-id** command creates a new set of key-ids or displays the key-id view.

The **undo key-id** command deletes the key-id configuration.

By default, no key-id is configured.

Format

key-id *key-id*

undo key-id *key-id*

Parameters

Parameter	Description	Value
key-id	Specifies the key identification number of a keychain.	The integer value ranges from 0 to 63.

Views

Keychain view

Default Level

2: Configuration Level

Usage Guidelines

Usage Scenario

In keychain authentication mode, secure protocol packet transmission is provided by changing the authentication algorithm and key string dynamically. This can reduce the workload of manually changing the algorithm and key.

The dynamic change of the keychain authentication algorithm is implemented based on the keys. Each keychain consists of multiple keys that are valid within different time periods and each key is configured with an authentication algorithm. When a key becomes valid, the corresponding authentication algorithm is used.

Follow-up Procedure

After key-id is specified, perform the following operations:

- Run the **algorithm** command to configure an algorithm used by the key.
- Run the **key-string** command to specify a key string.
- Run the **send-time** command to specify the send time of the key.
- Run the **receive-time** command to specify the receive time of the key.

Precautions

A **key-id** represents a key on the device.

A keychain supports 64 keys, but only one key takes effect during one period.

No active key can be used to authenticate and encrypt protocol packets at the intervals of keys. Therefore, run the **default send-key-id** command to specify a default key.

The time mode of the key must be the same as the time mode of Keychain.

Example

Configure key-id 1.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
```

```
[HUAWEI-keychain-test] key-id 1
[HUAWEI-keychain-test-keyid-1]
```

14.15.7 key-string

Function

The **key-string** command specifies a key used for keychain authentication.

The **undo key-string** command deletes a key used for keychain authentication.

By default, no key is configured for keychain authentication.

Format

key-string { **plain** *plain-text* | [**cipher**] *cipher-text* }

undo key-string

Parameters

Parameter	Description	Value
plain *plain-text*	Indicates the plain text used for authentication. The configured text will be stored as unencrypted text and displayed as unencrypted text. **NOTE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is case-sensitive and ranges from 1 to 255 characters. Spaces are not supported. If a password contains a space, the password must be placed into a pair of double quotation marks. Only one pair of double quotation marks can be used for each user name.
cipher	Specifies the cipher key string used for encryption and decryption.	-

Parameter	Description	Value
cipher-text	Indicates the cipher text used for authentication.	The value is a string of case-sensitive characters that can be letters or digits. The authentication password can be a string of 1 to 255 characters in plaintext or a string of 20 to 392 characters in ciphertext. If a password contains a space, the password must be placed into a pair of double quotation marks. Only one pair of double quotation marks can be used for each user name.

Usage Guidelines

Usage Scenario

In keychain authentication mode, secure protocol packet transmission is provided by dynamically changing the authentication algorithm and key string. This can prevent unauthorized users from obtaining the key string, and authentication and encryption algorithms, and reduce the workload of manually changing the algorithm and key string.

Each keychain consists of multiple keys that are valid within different time periods and each key is configured with an authentication algorithm. When a key becomes valid, the corresponding authentication algorithm is used.

Precautions

An authentication key configured in cipher text mode will be also displayed in cipher text mode. Therefore, remember the plaintext key string when configuring the key in cipher text mode.

If the authentication key is not configured, the corresponding key remains in inactive state.

Example

Configure the key string **test@1234**.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] key-id 1
[HUAWEI-keychain-test-keyid-1] key-string cipher test@1234
```

14.15.8 receive-time

Function

The **receive-time** command configures a key as a receive key for the specified interval of time.

The **undo receive-time** command deletes the receive time configuration.

By default, no receive time is configured.

Format

receive-time *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

receive-time daily *start-time* **to** *end-time*

receive-time day { *start-day-name* **to** *end-day-name* | *day-name* &<1-7> }

receive-time date { *start-date-value* **to** *end-date-value* | *date-value* &<1-31> }

receive-time month { *start-month-name* **to** *end-month-name* | *month-name* &<1-12> }

undo receive-time

Parameters

Parameter	Description	Value
start-time	Specifies the start receive time.	In HH:MM format. The value ranges from 00:00 to 23:59.
start-date	Specifies the start date.	In YYYY-MM-DD format. The value ranges from 1970-01-01 to 2050-12-31.
duration *duration-value*	Specifies the duration of the receive time in minutes.	The value ranges from 1 to 26280000.
infinite	Indicates that the key will be acting as an active receive key forever from the configured start time.	-
to	Indicates a separator.	-

Parameter	Description	Value
end-time	Specifies the end receive time.	In HH:MM format. The value ranges from 00:00 to 23:59. The end time must be later than the start time.
end-date	Specifies the end date.	In YYYY-MM-DD format. The value ranges from 1970-01-01 to 2050-12-31.
daily	Specifies the daily receive time for the given key.	-
day	Specifies the days of the week.	-
start-day-name	Specifies the day of the week to be configured as the start receive day for the given key.	It can be Mon, Tue, Wed, Thur, Fri, Sat, and Sun.
end-day-name	Specifies the end receive day for the given key.	It can be Tue, Wed, Thur, Fri, Sat, and Sun. The end day must be later than the start day.
day-name &<1-7>	Specifies the day of the week to be configured as the receive day for the given key.	It can be Mon, Tue, Wed, Thur, Fri, Sat, and Sun. One or more days can be configured.
date	Specifies the date of the month.	-
start-date-value	Specifies the start date of the month to be configured as the receive date for the given key.	The value ranges from 1 to 31.
end-date-value	Specifies the end receive date of the month.	The value ranges from 2 to 31. The end date must be later than the start date.
date-value &<1-31>	Specifies the date of the month to be configured as the receive date for the given key.	The value ranges from 1 to 31. One or more dates can be configured.
month	Specifies the months of the year.	-

Parameter	Description	Value
start-month-name	Specifies the month of the year to be configured as the start receive month for the given key.	It can be Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
end-month-name	Specifies the end receive month. The end month must be greater than the start month.	The end month must be later than the start month. It can be Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
month-name &<1-12>	Specifies the month of the year to be configured as the receive month for the given key.	It can be Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec. One or more months can be configured.

2: Configuration Level

Usage Guidelines

Usage Scenario

Each keychain consists of multiple keys that are valid within different time periods and each key is configured with an authentication algorithm and key string. When a key becomes valid, the corresponding authentication algorithm and the key string are used. Configure different keys for packet sending and receiving to be valid within different time periods.

When the system time is within the specified interval, the receive key is in active state.

There are two keychain validity modes:

- Absolute time range: In this mode, keychains are valid within a certain period.
- Periodic time range: In this mode, keychains are valid periodically.

The mode in which receive keys become valid must be the same as that configured for the keychain.

Precautions

Multiple receive keys can be active at the same time. The device will select a key for decryption based on the received packet.

Example

Configure the time for packet receiving with the timing mode as absolute and range as infinite.

```
<HUAWEI> system-view
[HUAWEI] keychain one mode absolute
[HUAWEI-keychain-one] key-id 5
[HUAWEI-keychain-one-keyid-5] receive-time 14:52 2014-11-1 duration infinite
```

Configure the time for packet receiving with the timing mode as absolute.

```
<HUAWEI> system-view
[HUAWEI] keychain two mode absolute
[HUAWEI-keychain-two] key-id 5
[HUAWEI-keychain-two-keyid-5] receive-time 14:52 2014-11-1 to 14:52 2040-10-1
```

Configure the time for packet receiving with the timing mode as daily periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain three mode periodic daily
[HUAWEI-keychain-three] key-id 5
[HUAWEI-keychain-three-keyid-5] receive-time daily 14:52 to 18:10
```

Configure the time for packet receiving with the timing mode as weekly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain four mode periodic weekly
[HUAWEI-keychain-four] key-id 5
[HUAWEI-keychain-four-keyid-5] receive-time day mon
```

Configure the time for packet receiving with the timing mode as monthly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain five mode periodic monthly
[HUAWEI-keychain-five] key-id 5
[HUAWEI-keychain-five-keyid-5] receive-time date 12 to 25
```

Configure the time for packet receiving with the timing mode as yearly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain six mode periodic yearly
[HUAWEI-keychain-six] key-id 5
[HUAWEI-keychain-six-keyid-5] receive-time month oct to dec
```

14.15.9 receive-tolerance

Function

The **receive-tolerance** command sets receive tolerance for all the receive keys in the keychain.

The **undo receive-tolerance** command deletes the receive tolerance configuration.

By default, no receive tolerance is configured.

Format

receive-tolerance { *value* | **infinite** }

undo receive-tolerance

Parameters

Parameter	Description	Value
value	Specifies the receive tolerance value for a keychain.	The integer value ranges from 1 to 14400 in minutes.
infinite	Indicates that the receive tolerance is infinite. That is, the receive key is always valid.	-

Views

Keychain view

Default Level

2: Configuration Level

Usage Guidelines

Usage Scenario

In keychain authentication mode, secure protocol packet transmission is provided by changing the authentication algorithm and key string dynamically. Each key is configured with an authentication algorithm and a key string. When a key becomes valid, the corresponding authentication algorithm is used.

Due to the networking environment or clock asynchronization on the packet sender and receiver, packets may be delayed. The receiver may receive a packet sent from the sender after its key for packet receiving becomes invalid. As a result, the receiver discards the packet and packet transmission is interrupted. To address this problem, set a tolerance time to ensure that the validity period of the receive key on the receiver expires after all packets sent from the sender reach the receiver.

Implementation Procedure

After a tolerance time is set, the tolerance time is added to the start time and end time when the key ID for packet receiving becomes valid.

Precautions

A tolerance time is required for each keychain. The configured tolerance time takes effect for all keys in the keychain.

Example

Configure the receive tolerance time as 570 minutes.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] receive-tolerance 570
```

14.15.10 send-time

Function

The **send-time** command configures a key as a send key at a specified interval.

The **undo send-time** command deletes the send time configuration.

By default, no send-time is configured.

Format

send-time *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

send-time daily *start-time* **to** *end-time*

send-time day { *start-day-name* **to** *end-day-name* | *day-name* &<1-7> }

send-time date { *start-date-value* **to** *end-date-value* | *date-value* &<1-31> }

send-time month { *start-month-name* **to** *end-month-name* | *month-name* &<1-12> }

undo send-time

Parameters

Parameter	Description	Value
start-time	Specifies the start send time.	The value is in HH:MM format. The value ranges from 00:00 to 23:59.
start-date	Specify the start date.	The value is in YYYY-MM-DD format. The value ranges from 1970-01-01 to 2050-12-31.
duration *duration-value*	Specifies the duration of the send time, in minutes.	The value ranges from 1 to 26280000.
infinite	Indicates that the key will act as a send key forever from the configured start time.	-
to	Indicates a separator.	-
end-time	Specifies the end send time.	The value is in HH:MM format. The value ranges from 00:00 to 23:59. The end time must be later than the start time.

Parameter	Description	Value
end-date	Specifies the end date.	The value is in YYYY-MM-DD format. The value ranges from 1970-01-01 to 2050-12-31.
daily	Specifies the daily send time for the given key.	-
day	Specifies the days of the week.	-
start-day-name	Specifies the day of the week to be configured as the start send day for the given key.	It can be Mon, Tue, Wed, Thur, Fri, Sat, and Sun.
end-day-name	Specifies the end send day for the given key.	It can be Tue, Wed, Thur, Fri, Sat, and Sun. The end day must be later than the start day.
day-name &<1-7>	Specifies the day of the week to be configured as the send day for the given key.	It can be Mon, Tue, Wed, Thur, Fri, Sat, and Sun. One or more days can be configured.
date	Specifies the date of the month.	-
start-date-value	Specifies the start date of the month to be configured as the send date for the given key.	The value ranges from 1 to 31.
end-date-value	Specifies the end date of the month to be configured as the send date for the given key.	The value ranges from 2 to 31. The end date must be greater than the start date.
date-value &<1-31>	Specifies the date of the month to be configured as the send date for the given key.	The value ranges from 1 to 31. One or more dates can be configured.
month	Specifies the months of the year.	-
start-month-name	Specifies the month of the year to be configured as the start send month for the given key.	It can be Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.

Parameter	Description	Value
end-month-name	Specifies the end send month. The end month must be greater than the start month.	It can be Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec. The end month must be later than the start month.
month-name &<1-12>	Specifies the month of the year to be configured as the send month for the given key.	It can be Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec. One or more months can be configured.

Views

Key-ID view

2: Configuration Level

Usage Guidelines

Usage Scenario

Each keychain consists of multiple keys that are valid within different time periods and each key is configured with an authentication algorithm and a key string. When a key becomes valid, the corresponding authentication algorithm and the key string are used. Configure different send and receive keys to be valid within different time periods.

When the system is within the send time range of the key, the device will use the algorithm and key of the configured key to encrypt the packet.

There are two keychain validity modes:

- Absolute time range: In this mode, keychains are valid within a certain period.
- Periodic time range: In this mode, keychains are valid periodically.

The mode in which send keys become valid must be the same as that configured for the keychain.

Precautions

Multiple receive keys cannot be active at the same time. Only one key takes effect during a period in a keychain.

Example

Configure the time for packet sending with the timing mode as absolute.

```
<HUAWEI> system-view
[HUAWEI] keychain one mode absolute
[HUAWEI-keychain-one] key-id 5
[HUAWEI-keychain-one-keyid-5] send-time 14:52 2014-11-1 to 14:52 2040-10-1
```

Configure the time for packet sending with the timing mode as daily periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain two mode periodic daily
[HUAWEI-keychain-two] key-id 5
[HUAWEI-keychain-two-keyid-5] send-time daily 14:52 to 18:10
```

Configure the time for packet sending with the timing mode as weekly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain three mode periodic weekly
[HUAWEI-keychain-three] key-id 5
[HUAWEI-keychain-three-keyid-5] send-time day mon
```

Configure the time for packet sending with the timing mode as monthly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain four mode periodic monthly
[HUAWEI-keychain-four] key-id 5
[HUAWEI-keychain-four-keyid-5] send-time date 12
```

Configure the time for packet sending with the timing mode as yearly periodic.

```
<HUAWEI> system-view
[HUAWEI] keychain five mode periodic yearly
[HUAWEI-keychain-five] key-id 5
[HUAWEI-keychain-five-keyid-5] send-time month apr
```

Configure the time for packet sending with the timing mode as yearly periodic, and a few months are available.

```
<HUAWEI> system-view
[HUAWEI] keychain six mode periodic yearly
[HUAWEI-keychain-six] key-id 5
[HUAWEI-keychain-six-keyid-5] send-time month oct to dec
```

14.15.11 tcp-algorithm-id

Function

The **tcp-algorithm-id** command specifies an algorithm ID to represent a TCP authentication algorithm supported by the keychain.

The **undo tcp-algorithm-id** command restores the default settings.

By default, mapping between the TCP authentication algorithm and algorithm ID supported by IANA is used.

Format

tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sha1-12** | **hmac-sha1-20** | **md5** | **sha-1** | **sha-256** } *algorithm-id*

undo tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hmac-sha1-12** | **hmac-sha1-20** | **md5** | **sha-1** | **sha-256** }

Parameters

Parameter	Description	Value
hmac-md5	Specifies the HMAC-MD5 authentication algorithm.	-
hmac-sha-256	Specifies the HMAC-SHA-256 authentication algorithm.	-
hmac-sha1-12	Specifies the HMAC-SHA1-12 authentication algorithm.	-
hmac-sha1-20	Specifies the HMAC-SHA1-20 authentication algorithm.	-
md5	Specifies the MD5 authentication algorithm.	-
sha-1	Specifies the SHA-1 authentication algorithm.	-
sha-256	Specifies the SHA-256 authentication algorithm.	-
algorithm-id	Specifies the algorithm ID to represent a TCP authentication algorithm.	The value ranges from 1 to 63. Default algorithm IDs for algorithm types are: **md5** is 3, **hmac-sha-256** is 7, **hmac-md5** is 5, **hmac-sha1-12** is 2, **hmac-sha1-20** is 6 and **sha-256** is 8.

Views

Keychain view

Default Level

2: Configuration Level

Usage Guidelines

Usage Scenario

A keychain ensures secure protocol packet transmission by dynamically changing the authentication algorithm and key string. Packets to be transmitted over non-TCP and TCP connections are authenticated using authentication and encryption algorithms and key string corresponding to a key. The TCP connection needs to be authenticated to enhance security.

The TCP connection is authenticated using the authentication algorithm specified by the algorithm ID. The algorithm ID is not defined by IANA. Different vendors use different algorithm IDs to identify authentication algorithms. When two devices of different vendors are connected, ensure that algorithm IDs configured on the two devices are the same.

The characteristics of each authentication algorithm are as follows:

- MD5(Message Digest 5): The 128-bit MD5 message digest is calculated based on the entered message of any length.
- SHA-1(Secure Hash Algorithm): The 160-bit SHA-1 message digest is calculated based on the entered message with the length shorter than the 64th power of 2.
- HMAC-MD5(Keyed-Hashing for Message Authentication-md5): The 128-bit HMAC-MD5 message digest is calculated based on the 512-bit message that is converted from the entered message of any length.

  NOTE

  If the length of an entered message is less than 512 bits, 0s are added to make up a 512-bit message. If the length of an entered message is greater than 512 bits, the message is converted into a 128-bit message based on the MD5 algorithm. Then, 0s are added to make up a 512-bit message.
- HMAC-SHA1-12: The 160-bit HMAC-SHA1-12 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. The leftmost 96 bits (12 x 8) are used as the authentication code.
- HMAC-SHA1-20: The 160-bit HMAC-SHA1-20 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 160 bits are used as the authentication code.
- SHA-256: The 256-bit SHA-2 message digest is calculated based on the entered message with the length shorter than the 64th power of 2.
- HMAC-SHA-256: The 256-bit HMAC-SHA-256 message digest is calculated based on the 512-bit message that is converted from the entered message of any length. All the 256 bits are used as the authentication code.
- SM3: The 256-bit SM3 message digest is calculated based on the entered message of any length. All the 256 bits are used as the authentication code.

Prerequisites

Before configuring algorithm IDs for the communicating parties, run the **tcp-kind** command to configure TCP types for the communicating parties.

Precautions

SHA-1 has low security, for higher security purposes, you are advised to specify the **hmac-sha-256** or **sha2-256** parameter.

Each algorithm has a unique algorithm ID. And the algorithm IDs configured for the two communication devices must be identical.

Example

Specify 1 as the algorithm ID of **hmac-sha-256**.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] tcp-algorithm-id hmac-sha-256 1
```

14.15.12 tcp-kind

Function

The **tcp-kind** command specifies the option type in the TCP enhanced authentication option.

The **undo tcp-kind** command restores the default TCP kind value.

By default, the default kind value is 254.

Format

tcp-kind *kind-value*

undo tcp-kind

Parameters

Parameter	Description	Value
kind-value	Specifies the TCP kind value to be used for that keychain.	The value ranges from 28 to 255.

Views

Keychain view

Default Level

2: Configuration Level

Usage Guidelines

Usage Scenario

A keychain ensures secure protocol packet transmission by dynamically changing the authentication algorithm and key string. Packets to be transmitted over non-TCP and TCP connections are authenticated using authentication and encryption algorithms and key string corresponding to a key. The TCP connection needs to be authenticated to enhance security.

TCP connection request packets carry enhanced authentication options and are authenticated by a specified authentication algorithm. Different vendors use different kind values to specify the enhanced authentication option. Kind values configured for the communicating parties must be the same.

Follow-up Procedure

After configuring the same TCP kind value for the communicating parties, run the **tcp-algorithm-id** command to specify TCP algorithm IDs for the communicating parties.

Precautions

Communicating parties using the keychain authentication must establish a TCP connection when configuring the kind value. Otherwise, the TCP authentication does not take effect.

If TCP connection request packets carry enhanced authentication options, the kind value must be specified in the packets.

Example

Configure the TCP kind value as 252 for the keychain **test**.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] tcp-kind 252
```

14.15.13 time mode

Function

The **time mode** command configures the time mode for Keychain.

The **undo time mode** command restores the default time mode for Keychain.

By default, the time mode of Keychain is Local Mean Time (LMT).

Format

time mode { **utc** | **lmt** }

undo time mode

Parameters

Parameter	Description	Value
utc	Specifies that the configured time is in Universal Time Coordinated (UTC) format.	-
lmt	Specifies that the configured time is in LMT format.	-

Views

Keychain view

Default Level

2: Configuration level

Usage Guidelines

Each keychain consists of multiple key IDs that are valid within different time periods and each key ID is configured with an authentication algorithm. When a key ID becomes valid, the corresponding authentication algorithm is used, ensuring the dynamic change of authentication algorithms. Configure different key IDs for packet sending and receiving to be valid within different time periods.

To configure the time mode for Keychain, run the **time mode** command. You can configure UTC or LMT for Keychain based on the network planning. Ensure that the time mode remains the same on the entire network.

Example

Configure the time mode for Keychain as UTC.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] time mode utc
```

14.16 MPAC Configuration Commands

14.16.1 Command Support

Only the following switch models support MPAC:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

14.16.2 description (MPAC policy)

Function

The **description** command configures the description for an MPAC policy.

The **undo description** command deletes the description of an MPAC policy.

By default, an MPAC policy does not have a description.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of an MPAC policy.	The value is a string of 1 to 255 case-sensitive characters with spaces supported.

Views

MPAC policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure description for a created MPAC policy, use the **description** command. The descriptions facilitate MPAC policy management on the device.

Prerequisites

An MPAC policy has been created using the **service-security policy** command.

Example

Configure a description for an MPAC policy.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
[HUAWEI-service-sec-test] description SwitchA-GE0/0/1 to SwitchB-GE0/0/1
```

14.16.3 display service-security binding

Function

The **display service-security binding** command displays the MPAC policies bound to an interface or bound globally.

Format

display service-security binding { **ipv4** | **ipv6** } [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
ipv4	Indicates the IPv4 MPAC policy.	-
ipv6	Indicates the IPv6 MPAC policy.	-
interface *interface-type interface-number*	Indicates the interface to which MPAC policies are bound.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check information about bound MPAC policies, run this command.

The **display service-security binding** { **ipv4** | **ipv6** } command displays all MPAC policies bound to interfaces and bound globally.

The **display service-security binding** { **ipv4** | **ipv6** } **interface** *interface-type interface-number* command displays the MPAC policies bound to a specified interface.

Example

Display all IPv4 MPAC policies bound on the device.

```
<HUAWEI> display service-security binding ipv4
Configured  : Global
Policy Name : test

Interface  : GigabitEthernet0/0/1
Policy Name: A1

Interface  : Eth-Trunk1
Policy Name: A2
```

Display the IPv4 MPAC policies bound to GE0/0/1.

```
<HUAWEI> display service-security binding ipv4 interface GigabitEthernet 0/0/1
Interface  : GigabitEthernet0/0/1
Policy Name: A1
```

Table 14-90 Description of the display service-security binding command output

Item	Description
Configured	The MPAC policy bound globally. This field has a fixed value of **Global**. If no MPAC policy is bound globally, this field is not displayed.
Interface	Interface to which MPAC policies are bound.
Policy Name	Name of an MPAC policy.

14.16.4 display service-security policy

Function

The **display service-security policy** command displays MPAC policy configurations.

Format

display service-security policy { **ipv4** | **ipv6** } [*security-policy-name*]

Parameters

Parameter	Description	Value
ipv4	Displays the specified IPv4 MPAC policy.	-
ipv6	Displays the specified IPv6 MPAC policy.	-
security-policy-name	Specifies the name of an MPAC policy to be displayed.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An MPAC policy protects device security by controlling the packets destined for the CPUs.

To check the MPAC rules, step, and description configured on a device, run the **display service-security policy** command.

Example

Display all IPv4 MPAC policy configurations on a device.

```
<HUAWEI> display service-security policy ipv4
Policy Name : A1
Step        : 5

Policy Name : test
Description : RouterA-GE0/0/1 to ROUTERB-GE0/0/1
Step        : 5
 rule 5 permit protocol udp source-port 3503
```

Display the configuration of the IPv4 MPAC policy **test**.

```
<HUAWEI> display service-security policy ipv4 test
Policy Name : test
Step        : 5
 rule 5 permit protocol tcp source-ip 127.1.1.1 0 source-port 1000
 rule 10 permit protocol ip source-ip 10.10.1.0 0.0.0.255
```

Table 14-91 Description of the display service-security policy command output

Item	Description
Policy Name	Name of an MPAC policy.
Description	Description of an MPAC policy.
Step	Step between two MPAC rule IDs.
rule	MPAC rules.

14.16.5 display service-security statistics

Function

The **display service-security statistics** command displays statistics about matched rules in MPAC policies.

Format

display service-security statistics { **ipv4** | **ipv6** } [*security-policy-name*]

Parameters

Parameter	Description	Value
ipv4	Displays statistics about matched rules in IPv4 MPAC policy.	-
ipv6	Displays statistics about matched rules in IPv6 MPAC policy.	-
security-policy-name	Indicates the name of an MPAC policy.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An MPAC policy protects device security by controlling the packets destined for the CPUs.

The **display service-security statistics** command displays MPAC policy information and how many times MPAC rules are matched.

Example

Display statistics about matched rules in all IPv4 MPAC policies.

```
<HUAWEI> display service-security statistics ipv4
Policy Name : A1
Step        : 5

Policy Name : beijing
Description : mpac policy for ipv4
Step        : 2
 rule 2 permit protocol any (0 times matched)
 rule 4 deny protocol any (0 times matched)
 rule 6 permit protocol bgp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (1 times matched)
 rule 12 permit protocol ftp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 14 permit protocol ip source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 16 permit protocol ldp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 20 permit protocol ntp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 22 permit protocol ospf source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0times matched)
 rule 24 permit protocol rip source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 26 permit protocol rsvp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0times matched)
 rule 28 permit protocol snmp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0times matched)
 rule 30 permit protocol ssh source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 32 permit protocol tcp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 34 permit protocol telnet source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)
 rule 36 permit protocol tftp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0times matched)
 rule 38 permit protocol udp source-ip 10.1.1.1 0 destination-ip 10.1.1.2 0 (0 times matched)

Policy Name : test
Step        : 5
 rule 5 permit protocol tcp source-ip 127.1.1.1 0 source-port 1000 (10 times matched)
 rule 10 permit protocol ip source-ip 10.10.1.0 0.0.0.255 (1 times matched)
```

Display statistics about matched rules in the IPv4 MPAC policy named **test**.

```
<HUAWEI> display service-security statistics ipv4 test
Policy Name : test
Step        : 5
 rule 5 permit protocol tcp source-ip 127.1.1.1 0 source-port 1000 (10 times matched)
 rule 10 permit protocol ip source-ip 10.10.1.0 0.0.0.255 (1 times matched)
```

Table 14-92 Description of the display service-security statistics command output

Item	Description
Policy Name	Name of an MPAC policy.
Description	Description of an MPAC policy.
Step	Step between two MPAC rule IDs.
rule	MPAC rules.
(0 times matched)	Number of times the MPAC rules are matched.

14.16.6 reset service-security counters

Function

The **reset service-security counters** command deletes MPAC policy statistics.

Format

reset service-security counters { **ipv4** | **ipv6** } [*security-policy-name*]

Parameters

Parameter	Description	Value
ipv4	Deletes IPv4 MPAC policy statistics.	-
ipv6	Deletes IPv6 MPAC policy statistics.	-
security-policy-name	Specifies the name of an MPAC policy to be deleted.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If excess MPAC policy statistics are generated on a device and you want to view new MPAC information, run the **reset service-security counters** to delete the existing statistics first.

With the *security-policy-name* parameter specified, you can delete statistics about the specified IPv4 or IPv6 MPAC policy. Without the *security-policy-name* parameter specified, you can delete statistics about all IPv4 or IPv6 MPAC policies.

Precautions

All existing MPAC policy statistics will be deleted after this command is executed.

Example

Delete statistics about the IPv4 MPAC policy **test**.

```
<HUAWEI> reset service-security counters ipv4 test
```

14.16.7 rule (MPAC policy)

Function

The **rule** command adds a rule to the MPAC policy view.

The **undo rule** command deletes a rule or some configurations from the MPAC policy view.

By default, an MPAC policy does not have a rule.

Format

rule [*rule-id*] { **permit** | **deny** } **protocol** { *protocol-number* | **ftp** | **ssh** | **snmp** | **telnet** | **tftp** | **bgp** | **ldp** | **rsvp** | **ospf** | **rip** | **ntp** | **lsp-ping** | **dhcp-c** | **dhcp-r** | **ip** } [[**source-ip** { *source-ipv4-address* { *source-ipv4-mask* | 0 } | **any** }] | [**destination-ip** { *destination-ipv4-address* { *destination-ipv4-mask* | 0 } | **any** }]] *

rule [*rule-id*] { **permit** | **deny** } **protocol** { **tcp** | *tcp-protocol-number* | **udp** | *udp-protocol-number* } [[**source-port** *source-port-number*] | [**destination-port** *destination-port-number*] | [**source-ip** { *source-ipv4-address* { *source-ipv4-mask* | 0 } | **any** }] | [**destination-ip** { *destination-ipv4-address* { *destination-ipv4-mask* | 0 } | **any** }]] *

rule [*rule-id*] { **deny** | **permit** } **protocol** { **any** | **isis** }

rule [*rule-id*] { **permit** | **deny** } **protocol** { *protocol-number* | **ftp** | **ssh** | **snmp** | **telnet** | **tftp** | **bgp** | **ldp** | **rsvp** | **ospf** | **rip** | **ntp** | **lsp-ping** | **dhcp-c** | **dhcp-r** | **ip** } [[**source-ip** { *source-ipv6-address source-ipv6-prefix-length* | *source-ipv6-address/prefix-length* | **any** }] | [**destination-ip** { *destination-ipv6-address destination-ipv6-prefix-length* | *destination-ipv6-address/prefix-length* | **any** }]] *

rule [*rule-id*] { **permit** | **deny** } **protocol** { **tcp** | *tcp-protocol-number* | **udp** | *udp-protocol-number* } [[**source-port** *source-port-number*] | [**destination-port** *destination-port-number*] | [**source-ip** { *source-ipv6-address source-ipv6-prefix-length* | *source-ipv6-address/prefix-length* | **any** }] | [**destination-ip** { *destination-ipv6-address destination-ipv6-prefix-length* | *destination-ipv6-address/prefix-length* | **any** }]] *

undo rule *rule-id* [**source-ip** | **destination-ip** | **source-port** | **destination-port**] *

Parameters

Parameter	Description	Value
rule-id	Indicates the MPAC rule ID.	The value is an integer that ranges from 0 to 4294967294.

Parameter	Description	Value
deny	Prevents protocol packets matching the rules from being sent to the CPU.	-
permit	Allows the protocol packets matching the rules to be sent to the CPU.	-
protocol	Specifies the protocol name or number.	-
tcp	Indicates the Transmission Control Protocol (TCP).	-
tcp-protocol-number	Indicates the TCP protocol number.	It has a fixed value of 6.
udp	Indicates the User Datagram Protocol (UDP).	-
udp-protocol-number	Indicates the UDP protocol number.	It has a fixed value of 17.
source-port *source-port-number*	Specifies the source port number of protocol packets.	The value is an integer that ranges from 1 to 65535.
destination-port *destination-port-number*	Specifies the destination port number of protocol packets.	The value is an integer that ranges from 1 to 65535.
protocol-number	Specifies a protocol number.	The value is an integer that ranges from 1 to 255.
ftp	Indicates the File Transfer Protocol (FTP).	-
ssh	Indicates the Secure Shell (SSH) protocol.	-
snmp	Indicates the Simple Network Management Protocol (SNMP).	-
telnet	Indicates the Telnet protocol.	-
tftp	Indicates the Trivial File Transfer Protocol (TFTP).	-

Parameter	Description	Value
bgp	Indicates the Border Gateway Protocol (BGP).	-
ldp	Indicates the Label Distribution Protocol (LDP).	-
rsvp	Indicates the Resource Reservation Protocol (RSVP).	-
ospf	Indicates the Open Shortest Path First (OSPF) protocol.	-
rip	Indicates the Routing Information Protocol (RIP).	-
ntp	Indicates the Network Time Protocol (NTP).	-
lsp-ping	Indicates the Label Switched Path (LSP)-PING protocol.	-
dhcp-c	Indicates the Dynamic Host Configuration Protocol-C (DHCP-C) protocol.	-
dhcp-r	Indicates the DHCP-R protocol.	-
ip	Indicates the Internet Protocol (IP).	-
source-ip	Indicates the source address of protocol packets.	-
source-ipv4-address	Specifies a source IPv4 address.	The value is in dotted decimal notation.

Parameter	Description	Value
source-ipv4-mask | 0	Specifies the mask of the source IPv4 address. The protocol packets from the specified subnet are allowed to be sent to the CPU or discarded. 0 Specifies the source host name. The protocol packets from the specified host are allowed to be sent to the CPU or discarded.	The value is in dotted decimal notation.
destination-ip	Indicates the destination address of protocol packets.	-
destination-ipv4-address	Specifies a destination IPv4 address.	The value is in dotted decimal notation.
destination-ipv4-mask | 0	Specifies the mask of the destination IPv4 address. The protocol packets destined for the specified subnet are sent to the CPU or discarded. 0 Specifies the destination host name. The protocol packets destined for the specified host are sent to the CPU or discarded.	The value is in dotted decimal notation.
any	Indicates any IP address.	-
isis	Indicates the Intermediate System to Intermediate System (IS-IS) protocol.	-
source-ipv6-address	Specifies a source IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
source-ipv6-prefix-length	Specifies the prefix length of a source IPv6 address.	The value is an integer that ranges from 1 to 128.

Parameter	Description	Value
source-ipv6-address/ prefix-length	Specifies the source IPv6 address and prefix length.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X/M. M is an integer that ranges from 1 to 128.
destination-ipv6-address	Specifies a destination IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
destination-ipv6-prefix-length	Specifies the prefix length of a destination IPv6 address.	The value is an integer that ranges from 1 to 128.
destination-ipv6-address/ prefix-length	Specifies the destination IPv6 address and prefix length.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X/M. M is an integer that ranges from 1 to 128.

Views

MPAC policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To match specific users or packets, run the **rule** command with the protocol name or five packet attributes specified.

The MPAC matching rules for TCP/UDP are described in **Table 14-93**.

Table 14-93 Description of the MPAC matching rules for TCP/UDP

Protocol	TCP/UDP	Description
FTP	TCP	The source/destination port number is 21.
SSH	TCP	The source/destination port number is 22.

Protocol	TCP/UDP	Description
Telnet	TCP	The source/destination port number is 23.
BGP	TCP	The source/destination port number is 179.
LDP	TCP/UDP	TCP: The source/destination port number is 646. UDP: The destination port number is 646.
DHCP-R	UDP	IPv4: The destination port number is 67. IPv6: The destination port number is 547.
DHCP-C	UDP	IPv4: The destination port number is 68. IPv6: The destination port number is 546.
NTP	UDP	The destination port number is 123.
SNMP	UDP	The destination port number is 161.
RIP	UDP	IPv4: The destination port number is 520. IPv6: The destination port number is 521.
LSP-PING	UDP	The source/destination port number is 3503.

Prerequisites

An MPAC policy has been created using the **service-security policy** command.

Precautions

- The MPAC rules configured in the service6-sec policy view do not support ISIS.
- Exercise caution when using the **rule** [*rule-id*] **deny protocol any** command. If this command is executed in the system view, no protocol packets can be sent to the CPU, causing the device to be out of management.
- If a whitelist is configured for an MPAC IPv6 policy, run the **rule permit protocol** *58* command to allow ICMPv6 packets to pass.

Example

Add a rule to an MPAC policy.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
```

```
[HUAWEI-service-sec-test] rule 5 permit protocol udp source-port 3503 destination-ip 127.0.0.1
255.255.255.255
```

14.16.8 service-security binding

Function

The **service-security binding** command binds an MPAC policy to an interface.

The **undo service-security binding** command unbinds an MPAC policy from an interface.

By default, no MPAC policy is applied to an interface.

Format

service-security binding { **ipv4** | **ipv6** } *security-policy-name*

undo service-security binding { **ipv4** | **ipv6** }

NOTE

The **ipv6** parameter is not supported in the subinterface view.

Parameters

Parameter	Description	Value
ipv4	Binds an IPv4 MPAC policy to an interface.	-
ipv6	Binds an IPv6 MPAC policy to an interface.	-
security-policy-name	Specifies the name of an MPAC policy.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Views

Ethernet interface view, Ethernet sub-interface view, GE interface view, MultiGE interface view, MultiGE sub-interface view, GE sub-interface view, XGE interface view, 25GE interface view, XGE sub-interface view, 25GE sub-interface view, 40GE interface view, 40GE sub-interface view, 100GE interface view, 100GE sub-interface view, Eth-Trunk interface view, Eth-Trunk sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Some attackers may pose as authorized users to send protocol packets to network devices or control these devices. Such attacks affect network running. You can configure MPAC on network devices to allow the specified protocol packets to be sent to the CPUs or discard these packets, improving device security and reliability.

After an MPAC policy is created, run the **service-security binding** command to bind it to interfaces.

Prerequisites

An MPAC policy has been created using the **service-security policy** command.

Example

Create an IPv4 MPAC policy and apply it to an interface.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
[HUAWEI-service-sec-test] rule 5 permit protocol tcp source-port 1000 source-ip 127.1.1.1 0
[HUAWEI-service-sec-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] service-security binding ipv4 test
```

Create an IPv6 MPAC policy and apply it to an interface.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv6 test1
[HUAWEI-service6-sec-test1] rule 10 deny protocol tcp
[HUAWEI-service6-sec-test1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] service-security binding ipv6 test1
```

14.16.9 service-security global-binding

Function

The **service-security global-binding** command binds an MPAC policy to a device globally.

The **undo service-security global-binding** command unbinds an MPAC policy from a device.

By default, no MPAC policy is globally applied.

Format

service-security global-binding { **ipv4** | **ipv6** } *security-policy-name*

undo service-security global-binding { **ipv4** | **ipv6** }

Parameters

Parameter	Description	Value
ipv4	Binds an IPv4 MPAC policy to a device globally.	-
ipv6	Binds an IPv6 MPAC policy to a device globally.	-
security-policy-name	Specifies the name of an MPAC policy to be bound.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Some attackers may pose as authorized users to send protocol packets to network devices or control these devices. Such attacks affect network running. You can configure MPAC on network devices to allow the specified protocol packets to be sent to the CPUs or discard these packets, improving device security and reliability.

After an MPAC policy is created, run the **service-security global-binding** command to bind it to a device globally.

Prerequisites

An MPAC policy has been created using the **service-security policy** command.

Example

Create an IPv4 MPAC policy and apply it to a device globally.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
[HUAWEI-service-sec-test] rule 5 permit protocol tcp source-port 1000 source-ip 127.1.1.1 0
[HUAWEI-service-sec-test] quit
[HUAWEI] service-security global-binding ipv4 test
```

Create an IPv6 MPAC policy and apply it to a device globally.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv6 test1
[HUAWEI-service6-sec-test1] rule 10 deny protocol tcp
[HUAWEI-service6-sec-test1] quit
[HUAWEI] service-security global-binding ipv6 test1
```

14.16.10 service-security policy

Function

The **service-security policy** command creates an MPAC policy and displays its view.

The **undo service-security policy** command deletes an MPAC policy.

By default, no MPAC policy exists on a device.

Format

service-security policy { **ipv4** | **ipv6** } *security-policy-name*

undo service-security policy { **ipv4** | **ipv6** } [*security-policy-name*]

Parameters

Parameter	Description	Value
ipv4	Creates an IPv4 MPAC policy and displays its view.	-
ipv6	Creates an IPv6 MPAC policy and displays its view.	-
security-policy-name	Specifies the name of an MPAC policy.	The value is a string of 1 to 31 case-sensitive characters without spaces. It must start with a letter.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Some attackers may pose as authorized users to send protocol packets to network devices or control these devices. Such attacks affect network running. You can configure MPAC on network devices to allow the specified protocol packets to be sent to the CPUs or discard these packets, improving device security and reliability.

Example

Create an IPv4 MPAC policy.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
[HUAWEI-service-sec-test]
```

Create an IPv6 MPAC policy.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv6 test1
[HUAWEI-service6-sec-test1]
```

14.16.11 step (MPAC policy)

Function

The **step** command sets the step between two MPAC rule IDs.

The **undo step** command restores the default step between MPAC rule IDs.

By default, the step between two MPAC rule IDs is 5.

Format

step *step-value*

undo step

Parameters

Parameter	Description	Value
step-value	Specifies the step between two MPAC rule IDs.	The value is an integer that ranges from 1 to 20.

Views

MPAC policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A step is an increment between neighboring MPAC rule IDs automatically allocated by the system. For example, if the step is 5, the system allocates MPAC rules with IDs 5, 10, 15, 20...

To allow insertion of new rules, set a step for MPAC rule IDs by using the **step** command.

Prerequisites

MPAC policies have been created using the **service-security policy** command.

Configuration Impact

After you set a step, all the rule IDs in the MPAC policy are re-arranged using the new step.

Precautions

Setting the step only changes rule IDs, but will not change the rule priorities.

Example

Set the step for MPAC rule IDs to 10.

```
<HUAWEI> system-view
[HUAWEI] service-security policy ipv4 test
[HUAWEI-service-sec-test] step 10
```

14.17 Traffic Isolation Between the Service and Management planes Configuration Commands

14.17.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.17.2 management-plane isolate enable

Function

The **management-plane isolate enable** command enables management plane separation.

The **undo management-plane isolate enable** command disables the function.

By default, management plane separation is enabled.

Format

management-plane isolate enable

undo management-plane isolate enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **management-plane isolate enable** command enables separation of the management plane to prevent unauthorized users from attacking the management network through the service network. After the command is run, the switch prevents unauthorized users from accessing the management interface through a service interface. That is, if the destination address of a packet received by a service interface is the management interface address, the user cannot access the switch. The access from the management interface to service interface is not restricted.

Precautions

- Disabling this function may cause the management network port to be attacked. Therefore, you are advised not to disable this function.
- The **management-port isolate enable** and **management-plane isolate enable** command functions are different. The **management-port isolate enable** command isolates traffic between the management and service interfaces by marking the network segment routes with the outbound interfaces being the management interface as the blackhole route, whereas the **management-plane isolate enable** command isolates service interfaces from the management interface by marking the host and broadcast routes with the outbound interfaces being the management interface as the blackhole route.
- When a version earlier than V200R005C02 (except V200R005C00SPC500) is upgraded to V200R005C02, a version later than V200R005C02, or V200R005C00SPC500, the **undo management-plane isolate enable** configuration is automatically generated.

Example

Enables management plane separation.

```
<HUAWEI> system-view
[HUAWEI] management-plane isolate enable
```

14.17.3 management-port isolate enable

Function

The **management-port isolate enable** command isolates management interfaces from service interfaces.

The **undo management-port isolate enable** command disables the function.

By default, management interface separation is enabled.

Format

management-port isolate enable

undo management-port isolate enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **management-port isolate enable** command enables separation of the management interface to prevent unauthorized users from attacking the packet forwarding service. After the command is run, the switch forbids packet exchange between the management and service interfaces. That is, the packets received by the management interface will not be sent out through a service interface, and the packets received by a service interface will not be sent out through the management interface.

Precautions

- Disabling this function may cause the management network port to be attacked. Therefore, you are advised not to disable this function.
- For the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, when disabling this function, also run the **arp-miss message-cache disable** command to disable the function of packetizing ARP Miss messages. Otherwise, disabling management interface separation cannot take effect. After management interface separation is disabled, the device needs to send ICMP unreachable and redirection packets, which however cannot be sent when the function of packetizing ARP Miss messages is enabled.
- The interval between management-port isolate enable and undo management-port isolate enable command must be longer than 30 seconds.
- When a version earlier than V200R005C02 (except V200R005C00SPC500) is upgraded to V200R005C02, a version later than V200R005C02, or V200R005C00SPC500, the **undo management-port isolate enable** configuration is automatically generated.

Example

Isolate management interfaces from service interfaces.

```
<HUAWEI> system-view
[HUAWEI] management-port isolate enable
```

14.18 Security Risk Commands

14.18.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.18.2 display security risk

Function

The **display security risk** command displays security risks in the system and suggested solutions for the risks.

Format

display security risk [**trap-info**] [**feature** *feature-name*] [**level** { **high** | **medium** | **low** }]

Parameters

Parameter	Description	Value
trap-info	Displays alarm information of security risk.	-
feature *feature-name*	Displays security risks of a specified feature.	Enumerated type. The value depends on the registered module.
level high	Displays security risks of High level.	-
level medium	Displays security risks of Medium level.	-
level low	Displays security risks of Low level.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Protocols have different security performances, and some protocols may have security risks. Run the **display security risk** command to identify security risks in the system. Then clear the security risks according to the repair action in the command output. For example, if SNMPv1 is configured, the **display security risk** command output will prompt for the use of SNMPv3.

You can filter the security risks by specifying the security level, feature, or both.

Precautions

The security risks that are displayed vary with user levels. The system administrators can view all security risks in the system. Other users can only view the security risks matching their levels.

Example

Display security risks in the system.

```
<HUAWEI> display security risk
Risk level       : high
Feature name     : SNMP
Risk information : SNMPv1/SNMPv2c is enabled.
Repair action    : Use SNMPv3.

Risk level       : high
Feature name     : TELNET
Risk information : None authentication is configured for Telnet
users.
Repair action    : Use AAA authentication.

Risk level       : medium
Feature name     : CONSOLE
Risk information : No authentication is configured, password authentication is configured but no password
is specified, or none auth
entication is configured on the console interface.
Repair action    : Use AAA authentication.

Risk level       : medium
Feature name     : TELNET
Risk information : The Telnet server function is used.
Repair action    : Use Stelnet.
```

Display security risks of the TELNET feature.

```
<HUAWEI> display security risk feature telnet
Risk level       : high
Feature name     : TELNET
Risk information : None authentication is configured for Telnet
users.
Repair action    : Use AAA authentication.

Risk level       : medium
Feature name     : TELNET
Risk information : The Telnet server function is used.
Repair action    : Use Stelnet.
```

Display security risks of Medium level.

```
<HUAWEI> display security risk level medium
Risk level       : medium
Feature name     : CONSOLE
Risk information : No authentication is configured, password authentication is configured but no password
is specified, or none auth
entication is configured on the console interface.
Repair action    : Use AAA authentication.
```

```
Risk level       : medium
Feature name     : TELNET
Risk information : The Telnet server function is used.
Repair action    : Use Stelnet.
```

NOTE

The command output provided here is used for reference only. The actual output information depends on the situation.

Table 14-94 Description of the **display security risk** command output

Item	Description
Risk level	Security risk level. It can be any value of the following: ● high; ● medium; ● low.
Feature name	Feature name.
Risk information	Information about the security risks.
Repair action	Suggested solutions for the security risks.

14.19 PKI Configuration Commands

14.19.1 Command Support

All models of S300, S500, S2700, S5700, and S6700 series switches (except the S5731-L and S5731S-L) support PKI.

14.19.2 auto-enroll

Function

The **auto-enroll** command enables automatic certificate enrollment and update.

The **undo auto-enroll** command disables automatic certificate enrollment and update.

By default, the automatic certificate enrollment and update are disabled.

Format

auto-enroll [*percent*] [**regenerate** [*key-bit*]] [**updated-effective**]

undo auto-enroll [**updated-effective**]

Parameters

Parameter	Description	Value
percent	Specifies the percentage of the certificate's validity period after which a new certificate is requested automatically.	The value is an integer that ranges from 10 to 100. The default value is 100. When the old certificate expires, the system requests a new certificate.
regenerate	Indicates the RSA key pair will be generated during certificate updates.	-
key-bit	Specifies the number of bits in the RSA key pair generated during certificate updates.	The value is an integer that ranges from 2048 to 4096. The default value is 2048.
updated-effective	Indicates that the certificate takes effect immediately after being updated. By default, an updated certificate takes effect only after the old one expires.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Automatic certificate enrollment: When the certificates are unavailable, will expire, or have expired, an entity automatically requests a new certificate or renews the certificate using the Simple Certification Enrollment Protocol (SCEP).

By default, the automatic certificate enrollment and update function is disabled. When a certificate has expired, you must request a certificate for an entity manually. You can still request a certificate for an entity manually when the automatic certificate enrollment and update function is enabled.

Precautions

- If you do not specify **regenerate**, the system uses the original RSA key pairs during automatic updates.
- If you specify **regenerate**, the system generates new RSA key pairs during certificate updates for certificate requests and overwrites the original certificates and RSA key pairs with the new ones.
- After this command is run, the device checks whether the certificate has expired every 60 minutes. If the certificate has expired, the device updates it.

Example

Enable automatic certificate enrollment and update for the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] auto-enroll 50 regenerate
```

14.19.3 ca id

Function

The **ca id** command specifies a certificate authority (CA) trusted by a PKI realm.

The **undo ca id** command deletes the CA trusted by a PKI realm.

By default, no trusted CA is configured in a PKI realm.

Format

ca id *ca-name*

undo ca id

Parameters

Parameter	Description	Value
ca-name	Specifies the name of a CA trusted by a PKI realm.	The value is a string of 1 to 64 case-sensitive characters.

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

After the **ca id** command is executed to specify the CA trusted by the device, the device's local certificate is requested, obtained, revoked, or queried through the CA.

Example

Specify the CA **root_ca** trusted by the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] ca id root_ca
```

14.19.4 cdp-url

Function

The **cdp-url** command configures the CRL distribution point (CDP) URL.

The **undo cdp-url** command deletes the configured CDP URL.

By default, no CDP URL is configured.

Format

cdp-url [**esc**] *url-addr*

cdp-url from-ca

undo cdp-url

Parameters

Parameter	Description	Value
esc	Indicates that the URL address is in ASCII mode.	-
url-addr	Specifies the CDP URL.	The value is a string starting with http:// and consisting of 1 to 128 case-sensitive characters without spaces.
from-ca	Specifies that the CDP URL address is obtained from the CA certificate.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a PKI entity needs to use HTTP to update CRL, it must set up a connection with the HTTP server based on CDP URL, and obtain the CRL from the HTTP server. By default, a PKI entity locates and downloads CRL based on the method (HTTP) in the CDP information of the local certificate. If you do not want to download CRL based on the CDP URL in the local certificate, run this command to configure the PKI entity to obtain CDP URL from the CA certificate or manually configure the CDP URL.

When CRL is automatically updated by SCEP, you can also manually configure a CDP URL address.

Precautions

Manually configuring a CDP URL address overwrites the CDP carried in the certificate. If the certificate does not contain CDP information and no CDP URL address is manually configured, the device requests the CRL from the CA server using SCEP.

Keyword **esc** only supports the URLs that include the question mark (?) in ASCII code. The URL must be in **\x3f** format, and **3f** is the hexadecimal ASCII code for the question mark (?). For example, if a user wants to enter **http://***.com?page1**, the URL is **http://***.com\x3fpage1**. If a user wants to enter **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the URL is **http://www.***.com\x3fpage1\\\x3f**.

Example

Set the CDP URL to http://10.1.1.1/certenroll/ca_root.crl.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl scep
[HUAWEI-pki-realm-d1] cdp-url http://10.1.1.1/certenroll/ca_root.crl
```

Set the CDP URL to **http://www.***.com/certenroll/ca_root.crl**.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl scep
[HUAWEI-pki-realm-d1] cdp-url http://www.***.com/certenroll/ca_root.crl
```

14.19.5 certificate-check

Function

The **certificate-check** command sets the method of checking whether a certificate in the PKI realm is revoked.

The **undo certificate-check** command cancels the method of checking whether a certificate in the PKI realm is revoked.

By default, the method of checking whether a certificate in the PKI realm is revoked is **crl**.

Format

certificate-check { { **crl** | **ocsp** } * [**none**] | **none** }

undo certificate-check

NOTE

Only devices in NETCONF mode support the **ocsp** parameter.

Parameters

Parameter	Description	Value
crl	Sets the check method to Certificate Revocation List (CRL).	-
ocsp	Sets the check method to Online Certificate Status Protocol (OCSP).	-
none	Indicates that the system does not check whether a certificate is revoked.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

After this command is executed, the PKI entity validates the peer certificate, for example, whether the peer certificate has expired and whether it is added to CRL. In this case, you can run the **certificate-check** command to check the peer certificate status.

The system supports the following methods to check whether a certificate in the PKI realm is revoked:

- CRL
  - If the CA server can function as a CDP, the certificate issued by CA contains the CDP information about obtaining the certificate CRL. The PKI

entity then uses the specified method (HTTP) to find the CRL from the specified location and download the CRL. If the CDP URL is configured in the PKI realm, the PKI entity obtains the CRL from the specified URL.

  - If the CA does not support CDPs and no CDP URL is configured on the PKI entity, the PKI entity uses the SCEP protocol to obtain the CRL.

- OCSP

  The PKI entity can use OCSP to check certificate status online, and you do not need to frequently download CRLs.

  When two PKI entities use certificates to perform IPsec negotiation, they check the peer certificate status through OCSP in real time.

- None

  This mode is used when no CRL or OCSP server is available to the PKI entity or the PKI entity does not need to check the peer certificate status. In this mode, the PKI entity does not check whether a certificate has been revoked.

Select the following configurations:

- If the **certificate-check crl** command is configured for a certificate, the CRL mode is used.
- If the **certificate-check ocsp** command is configured for a certificate, the OCSP mode is used.
- If the **certificate-check crl none** command is configured for a certificate, the CRL mode is used first. If the CRL mode is unavailable, the certificate is regarded as valid.
- If the **certificate-check ocsp none** command is configured for a certificate, the OCSP mode is used first. If the OCSP mode is unavailable, the certificate is regarded as valid.
- If the **certificate-check crl ocsp** command is configured for a certificate, the CRL mode is used first. If the CRL mode is unavailable, the OCSP mode is used. If the OCSP mode is unavailable, the certificate is regarded as invalid.
- If the **certificate-check ocsp crl** command is configured for a certificate, the OCSP mode is used first. If the OCSP mode is unavailable, the CRL mode is used. If the CRL mode is unavailable, the certificate is regarded as invalid.
- If the **certificate-check crl ocsp none** command is configured for a certificate, the CRL mode is used first. If the CRL mode is unavailable, the OCSP mode is used. If the OCSP mode is unavailable, the certificate is regarded as valid.
- If the **certificate-check ocsp crl none** command is configured for a certificate, the OCSP mode is used first. If the OCSP mode is unavailable, the CRL mode is used. If the CRL mode is unavailable, the certificate is regarded as valid.
- If the **certificate-check none** command is configured for a certificate, the certificate is regarded as valid.

Precautions

After the **certificate-check crl** command is configured, if the device does not have the CRL file, the device fails the certificate verification, and the certificate becomes invalid.

If **certificate-check** is set to **none**, the system does not check whether a certificate is revoked, which poses security risks. Therefore, this method is not recommended.

Example

Set the certificate check method to **crl none** in PKI realm **test**. If the CRL mode is unavailable, the certificate is regarded as valid.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] certificate-check crl none
```

14.19.6 certificate auto-update enable

Function

The **certificate auto-update enable** command enables CMPv2-based automatic certificate update.

The **undo certificate auto-update enable** command disables CMPv2-based automatic certificate update.

By default, the CMPv2-based automatic certificate update is disabled.

Format

certificate auto-update enable

undo certificate auto-update enable

Parameters

None

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

If a certificate obtained through CMPv2 is about to expire, run this command to enable CMPv2-based automatic certificate update to ensure certificate validity. After the command is executed, the system performs checks (for example, referenced PKI entity, URL for the CMPv2 server, RSA key pair for CMPv2-based certificate application). The configuration is successful only when the conditions are met.

When the system detects that the remaining validity period of the local certificate has reached the value specified in **certificate update expire-time**, the system automatically initiates the certificate update request and decides whether to create an RSA key pair based on the **cmp-request rsa local-key-pair** configuration. After the new certificate is obtained, the system replaces the previous certificate and RSA key pair with the new ones. The replacement files include the files in device storage, certificate in memory, and configuration used in IKE negotiation.

Example

Enable CMPv2-based automatic certificate update.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] certificate auto-update enable
```

14.19.7 certificate update expire-time

Function

The **certificate update expire-time** command specifies when the certificate starts to update. The time is represented by a percentage of the total validity period.

The **undo certificate update expire-time** command restores the default certificate update time.

By default, the certificate is automatically updated when the validity period is only 50% left.

Format

certificate update expire-time *valid-percent*

undo certificate update expire-time

Parameters

Parameter	Description	Value
valid-percent	Specifies the remaining percentage of the validity period.	The value is an integer that ranges from 10 to 100. The default value is 50.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

If the automatic certificate update through CMPv2 is enabled, the system sends an update request to the CMPv2 server when the specified updated time is reached.

This command sets the time (percentage of the total validity period) to update the certificate.

Example

Enable the automatic certificate update when the used time is 60% of the validity period of the certificate.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] certificate update expire-time 60
```

14.19.8 cmp-request authentication-cert

Function

The **cmp-request authentication-cert** command configures the certificate for identity authentication in the request through CMPv2.

The **undo cmp-request authentication-cert** command deletes the certificate for identity authentication in the request through CMPv2.

By default, no certificate for identity authentication in the request through CMPv2 is configured.

Format

cmp-request authentication-cert *cert-name*

undo cmp-request authentication-cert

Parameters

Parameter	Description	Value
cert-name	Specifies the name of a certificate file.	The value must be an existing certificate file name.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run this command to configure the certificate for identity authentication if you need to apply for a certificate through CMPv2. For different requests through CMPv2, the required certificates are as follows:

- For Initialization Requests (IR), the required certificate is an external identity certificate.
- For certification requests (CR), the required certificate is the one that the CA has already issued to the device.
- For the key update requests (KUR), the required certificate is the one that the CA has already issued to the device and is also the one to be updated.

Prerequisites

An identity authentication in the request through CMPv2 exists.

Example

Configure the certificate for identity authentication in the request through CMPv2.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request authentication-cert bb.cer
```

14.19.9 cmp-request ca-name

Function

The **cmp-request ca-name** command sets a CA name for the CMP session.

The **undo cmp-request ca-name** command deletes the CA name of the CMP session.

By default, no CA name is configured for a CMP session.

Format

cmp-request ca-name *ca-name*

undo cmp-request ca-name

Parameters

Parameter	Description	Value
ca-name	Indicates the name of the CA and is the field of subject in the CA certificate.	The value starts and ends with the quotation mark (") and is a string of 1 to 128 characters (including the quotation marks). A comma (,) is used to separate adjacent fields in the string.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

A trusted authority enrolls and issues certificates to entities. Therefore, a trusted CA name must be configured.

The field order in the CA name must be the same as that in the actual CA certificate. Otherwise, the server regards the name as incorrect.

Example

Set the CA name for CMP session **test**.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request ca-name "C=cn,ST=beijing,L=shangdi,O=BB,OU=BB,CN=BB"
```

14.19.10 cmp-request entity

Function

The **cmp-request entity** command sets the entity name used to apply for certificate through CMPv2.

The **undo cmp-request entity** command deletes the entity name used to apply for certificate through CMPv2.

By default, the entity name used to apply for certificate through CMPv2 is not configured.

Format

cmp-request entity *entity-name*

undo cmp-request entity

Parameters

Parameter	Description	Value
entity-name	Specifies the entity name for certificate application through CMPv2.	The value must be an existing PKI entity name.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To apply for a certificate through CMPv2, create a CMP session and specify the entity name in the CMP session.

Prerequisites

1. A PKI entity has been created using the **pki entity** command.
2. A PKI entity common name has been created using the **common-name** command.

Precautions

The specified entity can be referenced only by one CMP session or PKI realm.

Example

Set the entity name the device uses when applying for a certificate through CMPv2 to **entity1**.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] common-name test1
[HUAWEI-pki-entity-entity1] quit
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request entity entity1
```

14.19.11 cmp-request message-authentication-code

Function

The **cmp-request message-authentication-code** command configures the reference value and secret value of the message authentication code (MAC).

The **undo cmp-request message-authentication-code** command deletes the reference value and secret value of the MAC.

By default, the reference value and secret value of the MAC are not configured.

Format

cmp-request message-authentication-code *reference-value secret-value*

undo cmp-request message-authentication-code

Parameters

Parameter	Description	Value
reference-value	Specifies the reference value of the MAC.	The value is a string of 1 to 128 case-sensitive characters without spaces and question marks. If the character string is enclosed in double quotation marks, it can contain spaces.

Parameter	Description	Value
secret-value	Specifies the secret value of the MAC.	The length of the plaintext ranges from 1 to 128. The length of the encrypted ciphertext ranges from 48 to 188. The value is a case-sensitive character string without question marks.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

When a device is configured to use MAC for initial request (IR), you need to check the reference value and secret value of the MAC from the CMPv2 server in out-of-band mode, and then run this command to set the values on the device.

Example

Configure the reference value and secret value of the MAC.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request message-authentication-code 1234 YsHsjx_202206
```

14.19.12 cmp-request origin-authentication-method

Function

The **cmp-request origin-authentication-method** command configures the authentication method used for initial request (IR) through CMPv2.

The **undo cmp-request origin-authentication-method** command restores the default authentication method used for IR through CMPv2.

By default, the authentication method used for IR through CMPv2 is MAC.

Format

cmp-request origin-authentication-method { **message-authentication-code** | **signature** }

undo cmp-request origin-authentication-method

Parameters

Parameter	Description	Value
message-authentication-code	Indicates the MAC method for the IR.	-
signature	Indicates the signature method for the IR.	-

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

During the IR using CMPv2, a security protection measure needs to be taken:

- After you select the MAC method, run the **cmp-request message-authentication-code** command to configure the reference value and secret value. The device uses the reference value and secret value to protect messages during the IR.
- After you select the signature method, run the **cmp-request authentication-cert** command to configure the external certificate. The device uses the external certificate to protect signatures during the IR.

Example

Configure the authentication method used for IR through CMPv2.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request origin-authentication-method signature
```

14.19.13 cmp-request realm

Function

The **cmp-request realm** command specifies a PKI realm to which the CMPv2 server certificate belongs.

The **undo cmp-request realm** command deletes the specified PKI realm.

By default, no PKI realm is specified for the CMP server certificate.

Format

cmp-request [**https**] **realm** *realm-name*

undo cmp-request realm

Parameters

Parameter	Description	Value
https	Specifies the communication mode with the CMPv2 server to HTTPS.	-
realm *realm-name*	Specifies the PKI realm name of the imported certificate.	The value must be an existing PKI realm name. **NOTE** If the specified PKI realm is the default realm, there may be security risks.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When applying for a certificate through CMPv2, run the **cmp-request realm** command to specify the PKI realm to which the CMPv2 server certificate belongs.

By default, the device uses HTTP to communicate with the CMPv2 server. To improve the security, you can specify **https** to use HTTPS for communication.

Prerequisites

A PKI realm has been created using the **pki realm** command.

Precautions

If the device communicates with the CMPv2 server using HTTPS, the *url-addr* parameter must start with **https://** when the **cmp-request server url** *url-addr* command is to configure the server URL.

Example

Set a PKI realm name of the CMPv2 server certificate to **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request realm abc
```

14.19.14 cmp-request rsa local-key-pair

Function

The **cmp-request rsa local-key-pair** command configures the RSA key pair used for certificate application through CMPv2.

The **undo cmp-request rsa local-key-pair** command deletes the RSA key pair used for certificate application through CMPv2.

By default, the RSA key pair used to apply for certificate through CMPv2 is not configured.

Format

cmp-request rsa local-key-pair *key-name* [**regenerate** [*key-bit*]]

undo cmp-request rsa local-key-pair

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair.	The value must be an existing RSA key pair name.
regenerate	Indicates that the RSA key pair is updated together with certificate update.	-
key-bit	Specifies the bits of the RSA key pair generated during the certificate update.	The value is an integer that ranges from 3072 to 4096. The default value is 3072. After the WEAKEA plug-in is installed, the value is an integer that ranges from 2048 to 4096. A key of less than 3072 bits has security risks. You are advised to use a key of 3072 bits or more.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When CMPv2 is used to apply for a certificate, the certificate request message sent by the PKI entity to CA must contain public key information. Therefore, you need to configure an RSA key pair for certificate application through CMPv2. Note the following during the configuration:

- If **regenerate** is unspecified, the system uses the original RSA key pairs during automatic updates.
- If **regenerate** is specified, the system generates new RSA key pairs during certificate updates for the application for certificates and overwrites the original certificates and RSA key pairs with the new ones.

Prerequisites

The RSA key pair for certificate application has been created using the **pki rsa local-key-pair create** command or the RSA key pair has been imported to the memory using the **pki import rsa-key-pair** command.

Precautions

One RSA key pair can be referenced only by one CMP session.

Example

Configure the RSA key pair to be referenced by CMP session **test** and update the RSA key pair during the certificate update.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create test
 Info: The name of the new key-pair will be: test
 The size of the public key ranges from 2048 to 4096.
 Input the bits in the modules:4096
 Generating key-pairs...
........................+++
................................................................................
........+++
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request rsa local-key-pair test regenerate 4096
```

14.19.15 cmp-request server url

Function

The **cmp-request server url** command specifies the URL address of a CMPv2 server.

The **undo cmp-request server url** command deletes the URL address of a CMPv2 server.

By default, the URL of a CMPv2 server is not configured.

Format

cmp-request server url [**esc**] *url-addr*

undo cmp-request server url

Parameters

Parameter	Description	Value
esc	Specifies the entering of URLs in the ASCII code.	-
url-addr	Specifies the URL of the CMPv2 server.	The value is a string starting with **http://** or **https://** and consisting of 1 to 128 case-insensitive characters without spaces.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Configure a URL for the CMPv2 server before certificate application. Then the PKI entity sends a request message to the server's URL. The device can communicate with the server through HTTPS for higher security. In this case, *url-addr* must start with **https://**.

A user cannot enter command lines that include a question mark (?). Therefore, keyword **esc** supports the entering of URLs that include the question mark (?) in the ASCII code. The URL must be in **\x3f** format, and **3f** is the hexadecimal ASCII code for the question mark (?). For example, if a user wants to enter **http://***.com?page1**, the URL is **http://***.com\x3fpage1**. If a user wants to enter **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the URL is **http://www.***.com\x3fpage1\\\\x3f**.

Example

Set the URL of the CMPv2 server for CMP session **test** to **http://10.1.1.1:8080**.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request server url http://10.1.1.1:8080
```

Set the URL of the CMPv2 server for CMP session **test** to **http://www.***.com?page1\x3f**.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request server url esc http://www.***.com\x3fpage1\\x3f
```

14.19.16 cmp-request signature-algorithm

Function

The **cmp-request signature-algorithm** command configures a signature algorithm for CMPv2-based certificate application.

The **undo cmp-request signature-algorithm** command restores the default configuration.

By default, the signature algorithm used for CMPv2-based certificate application is SHA-256.

Format

cmp-request signature-algorithm [**sha1** | **sha256**]

undo cmp-request signature-algorithm

NOTE

The system software does not contain the **sha1** parameter. To use this parameter, you need to install the WEAKEA plug-in. However, the SHA-1 algorithm is less secure. For security purposes, you are advised to specify the **sha256** parameter. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Parameters

Parameter	Description	Value
sha1	Specifies the SHA-1 authentication algorithm.	-
sha256	Specifies the SHA-256 authentication algorithm.	-

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When applying for or updating a local certificate for a PKI entity using CMPv2, you can run the **cmp-request signature-algorithm** [**sha1** | **sha256**] command in the CMP session view to change the signature algorithm depending on the support of the CA server.

Precautions

After the system software is upgraded to V200R022C00 or later versions, the default signature algorithm used for CMPv2-based certificate application is SHA-1. However, this algorithm is insecure. For security purposes, you are advised to use the SHA-256 authentication algorithm.

Example

Set the signature algorithm to SHA-256 for CMPv2-based certificate application.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request signature-algorithm sha256
```

14.19.17 cmp-request timeout

Function

The **cmp-request timeout** command sets the timeout interval for communication between the device and CMPv2 server.

The **undo cmp-request timeout** command restores the default setting.

By default, the timeout interval for communication between the device and CMPv2 server is 30 seconds.

Format

cmp-request timeout *timeout*

undo cmp-request timeout

Parameters

Parameter	Description	Value
timeout	Specifies the timeout interval for communication with the CMPv2 server.	The value is an integer in the range from 0 to 60, in seconds. The default value is 30. The value 0 indicates that the communication is always attempted.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

If it takes a long time for a device to communicate with the CMPv2 server for applying for a certificate, certificate application resources are occupied. As a result, other CMP sessions fail to obtain certificates. To avoid this, you can run the **cmp-request timeout** *timeout* command to set a proper timeout interval to release certificate application resources in time.

Example

Set the timeout interval for communication between the device and CMPv2 server to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request timeout 10
```

14.19.18 cmp-request verification-cert

Function

The **cmp-request verification-cert** command configures the certificate file for verifying the CA response signature.

The **undo cmp-request verification-cert** command deletes the certificate file for verifying the CA response signature.

By default, no certificate file for verifying the CA response signature is configured.

Format

cmp-request verification-cert *cert-file-name*

undo cmp-request verification-cert

Parameters

Parameter	Description	Value
cert-file-name	Specifies the certificate file name.	The value must be an existing certificate file name.

Views

CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this command is executed, the device uses the configured certificate to verify the CA response signature. This command configures the CA certificate.

If this command is not executed and the CA response mode is signature, the device constructs a certificate chain based on the certificates in the response messages sent by the device itself and CA to verify the CA response signature. If the MAC mode is set, the device uses the MAC to verify the CA response signature. That is, this command does not take effect.

Prerequisites

The certificate file for verifying the CA response signature exists.

Example

Configure the certificate file for verifying the CA response signature.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] cmp-request verification-cert aa.der
```

14.19.19 common-name

Function

The **common-name** command configures a common name for a PKI entity.

The **undo common-name** command cancels the configuration.

By default, a PKI entity does not have a common name.

Format

common-name *common-name*

undo common-name

Parameters

Parameter	Description	Value
common-name	Specifies the common name of a PKI entity.	The value is a string of 1 to 64 case-sensitive characters, including letters, numerals, apostrophes ('), equal signs (=), parentheses (), plus signs (+), commas (,), minus signs (-), periods (.), slashes (/), colons (:), and spaces.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

After a PKI entity is created, a common name must be configured to uniquely identify the PKI entity.

After the common name is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this name. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the common name of the PKI entity.

Example

Set the common name to **test** for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] common-name test
```

14.19.20 country (PKI entity view)

Function

The **country** command configures a country code for a PKI entity.

The **undo country** command deletes the country code of a PKI entity.

By default, no country code is configured for a PKI entity.

Format

country *country-code*

undo country

Parameters

Parameter	Description	Value
country-code	Specifies the country code of a PKI entity.	A country code must be two-character long. If the entered country code contains lower case letters, the system automatically changes the lower case letters into upper case letters when you create a certificate request file. You can query country codes in ISO3166. For example, CN is the legitimate country code of China, and US is the legitimate country code of the USA.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure the country code for the PKI entity, which is used as an alias of the entity.

After the country code is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this country code. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the country code of the PKI entity.

Example

Configure the country code to CN for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] country CN
```

14.19.21 crl auto-update enable

Function

The **crl auto-update enable** command enables the automatic CRL update function.

The **undo crl auto-update enable** command disables the automatic CRL update function.

By default, automatic CRL update is enabled.

Format

crl auto-update enable

undo crl auto-update enable

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

To configure the automatic CRL update function, enable the function first.

Example

Enable the automatic CRL update function.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl auto-update enable
```

14.19.22 crl cache

Function

The **crl cache** command configures the device to use the cached CRL.

The **undo crl cache** command configures the device to retrieve the latest CRL each time.

By default, the PKI realm is allowed to use cached CRLs.

Format

crl cache

undo crl cache

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

The system overwrites the CRL in memory with the cached URL for certificate verification. If the PKI realm is not allowed to use cached CRL, the system must download the latest CRL every time to overwrite the CRL in memory.

Example

Allow the device to use the cached CRL in the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] crl cache
```

14.19.23 crl http

Function

The **crl http** command enables automatic CRL update using HTTP.

By default, the CRL is updated automatically using HTTP.

Format

crl http

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

This command is required when CRL is updated using HTTP, and ensure that there is sufficient space in the device storage for the CRL file.

Example

Configure automatic CRL update using HTTP.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl http
```

14.19.24 crl scep

Function

The **crl scep** command configures a device to use SCEP to automatically update a CRL.

By default, a device uses HTTP to automatically update a CRL.

Format

crl scep

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

This command is required when CRL is updated using SCEP, and ensure that there is sufficient space in the device storage for the CRL file.

Example

Use SCEP to automatically update a CRL.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl scep
```

14.19.25 crl update-period

Function

The **crl update-period** command sets the interval for automatic CRL update.

The **undo crl update-period** command restores the default interval for automatic CRL update.

By default, the automatic CRL update interval is 8 hours.

Format

crl update-period *interval*

undo crl update-period

Parameters

Parameter	Description	Value
interval	Specifies the interval at which a CRL is automatically updated.	The value is an integer that ranges from 1 to 720, in hours.

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

The CRL update interval is the interval at which a PKI entity using a certificate downloads a CRL from the CRL storage server. The CA/RA does not issue the CRL to an entity. Instead, the entity initiates CRL query to obtain a CRL.

Example

Set the interval at which a CRL is automatically updated to 21 hours.

```
<HUAWEI> system-view
[HUAWEI] pki realm d1
[HUAWEI-pki-realm-d1] crl update-period 21
```

14.19.26 display pki ca-capability

Function

The **display pki ca-capability** command displays the CA capabilities of a PKI realm.

Format

display pki ca-capability realm *realm-name*

Parameters

Parameter	Description	Value
realm *realm-name*	Indicates the name of a PKI realm.	The PKI realm name must already exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

The **display pki ca-capability** command displays the CA capabilities of a PKI realm.

Example

Display the CA capabilities of the PKI realm **asdf**.

```
<HUAWEI> display pki ca-capability realm asdf
PKI CA Capabilities :
  GetNextCACert      :  ----
  POSTPKIOperation   :  ----
```

```
Renewal           :  ----
SHA-512           :  ----
SHA-256           :  ----
SHA-1             :  ----
DES3              :  ----
```

Table 14-95 Description of the **display pki ca-capability** command output

Item	Description
PKI CA Capabilities	PKI CA capabilities.
GetNextCACert	Get next CA certificate.
POSTPKIOperation	Post PKI operation messages.
Renewal	Certificate renewal.
SHA-512	SHA-512 algorithm.
SHA-256	SHA-256 algorithm.
SHA-1	SHA-1 algorithm.
DES3	DES3 algorithm.

14.19.27 display pki cert-req

Function

The **display pki cert-req** command displays the content of a certificate request file.

Format

display pki cert-req filename *file-name*

Parameters

Parameter	Description	Value
filename *file-name*	Specifies the name of a certificate request file.	The certificate request file name must already exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

This command displays content of a certificate request file, including the subject, public key algorithm, key modulus, attributes, and signature algorithm.

Example

Display the content of a certificate request file named **test.req**.

```
<HUAWEI> display pki cert-req filename test.req
Certificate Request:
    Data:
        Version: 0 (0x0)

Table 14-96 Description of the **display pki cert-req** command output

Item	Description
Certificate Request	Information about a certificate request file.

Item	Description
Data	Data of a certificate request file.
Version	Version of a certificate request file.
Subject	Subject of a certificate request file. The subject includes the following attributes: ● C: country code of a PKI entity. It is configured using the **country(PKI entity view)** command. ● ST: name of the state or province to which a PKI entity belongs. It is configured using the **state(PKI entity view)** command. ● L: geographic area where a PKI entity is located. It is configured using the **locality** command. ● O: organization to which a PKI entity belongs. It is configured using the **organization** command. ● OU: department to which a PKI entity belongs. It is configured using the **organization-unit** command. ● CN: common name of a PKI entity. It is configured using the **common-name** command.
Subject Public Key Info	Information about the subject public key of a certificate request file.
Public Key Algorithm	Public key algorithm.
Public-Key	RSA public key. It is configured using the **rsa local-key-pair** command.
Modulus	Key modulus.
Exponent	Key exponent.
Attributes	Attributes of a certificate request file.
challengePassword	The challenge password used in certificate application. It is configured using the **pki enroll-certificate** command.
Requested Extensions	Certificate request extension.
X509v3 Subject Alternative Name	Alternative name of the X.509v3 subject.

Item	Description
IP Address	IP address of a PKI entity. It is configured using the **ip-address** command.
DNS	DNS name of a PKI entity. It is configured using the **fqdn** command.
email	Email address of a PKI entity. It is configured using the **email** command.
Signature Algorithm	Signature algorithm. It is configured using the **enrollment-request signature message-digest-method** command.

14.19.28 display pki certificate

Function

The **display pki certificate** command displays the content about the CA or local certificate loaded to the device and OCSP server certificate.

Format

display pki certificate { **ca** | **local** | **ocsp** } **realm** *realm-name*

NOTE

Only devices in NETCONF mode support the **ocsp** parameter.

Parameters

Parameter	Description	Value
ca	Displays content about the CA certificate.	-
local	Displays content about the local certificate.	-
ocsp	Displays content about the Online Certificate Status Protocol (OCSP) server's certificate.	-
realm *realm-name*	Specifies the PKI realm name of a certificate to be checked.	The PKI realm name must already exist.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

This command shows information about the CA certificate, local certificate, and OCSP server's certificate, including signature algorithm, issuer, validity period, subject, and subject public key.

Example

Display information about the CA certificate.

```
<HUAWEI> display pki certificate ca realm abc
 The x509 object type is certificate:
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:
            0c:f0:1a:f3:67:21:44:9a:4a:eb:ec:63:75:5d:d7:5f
    Signature Algorithm: sha1WithRSAEncryption
        Issuer: CN=ca_root

Certificate peer name: -
```

Table 14-97 Description of the **display pki certificate** command output

Item	Description
The x509 object type is certificate	X.509 object type is certificate.
Certificate	Information about a certificate.
Data	Data of a certificate.
Version	Version of a certificate.
Serial Number	Serial number of a certificate.
Signature Algorithm	Signature algorithm of a certificate.
Issuer	Issuer of a certificate.
Validity	Validity period of a certificate.

Item	Description
Subject	Subject of a certificate. For details about the attributes that are not mentioned below, see the *Equipment Identifier Specification of Wireless Local Area Network*. - C: country code of a PKI entity. - ST: name of the state or province to which a PKI entity belongs. - L: geographic area where a PKI entity is located. - O: organization to which a PKI entity belongs. - OU: department to which a PKI entity belongs. - CN: common name of a PKI entity. - DC: forcible domain. - ASUE: user equipment.
Subject Public Key Info	Information about the public key of a certificate.
Public Key Algorithm	Public key algorithm.
Public-Key	Public key.
Modulus	Key modulus.
Exponent	Key exponent.
X509v3 extensions	X.509v3 certificate extensions.
X509v3 Key Usage	X509v3 key usage.
X509v3 Basic Constraints	Basic constraints.
CA	Whether the CA can be trusted.
X509v3 Subject Key Identifier	Identifier of a subject key.
X509v3 CRL Distribution Points	CRL distribution points (CDP).
Full Name	Full name of the CDP.
Pki realm name	PKI realm name.
Certificate file name	Certificate file name.
Certificate peer name	Certificate peer name.

14.19.29 display pki certificate enroll-status

Function

The **display pki certificate enroll-status** command displays the certificate enrollment status.

Format

display pki certificate enroll-status [**realm** *realm-name*]

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the PKI realm name of a certificate to be checked.	The PKI realm name must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pki certificate enroll-status** command displays the certificate enrollment status.

Example

Display the certificate enrollment status.

```
<HUAWEI> display pki certificate enroll-status realm abc
 Certificate Request Transaction 1
    Status: Pending
    Key Usage: ENC&SIG
    Entity name: test
    Remain polling count: 1
    Next polling after : 35 seconds
<HUAWEI> display pki certificate enroll-status realm abc
 info: No certificate request transaction in realm abc.
```

Table 14-98 Description of the **display pki certificate enroll-status** command output

Item	Description
Certificate Request Transaction	Certificate enrollment request process.
Status	Certificate enrollment status. Pending: A certificate is being enrolled.

Item	Description
Key Usage	Functions of a certificate public key: - ENC: The public key is used for encryption. - SIG: The public key is used for signature.
Entity name	Entity name.
Remain polling count	Number of times a certificate enrollment request can be initiated again.
Next polling after	Next time a certificate enrollment request is initiated.
No certificate request transaction	There is no certificate enrollment request process.

14.19.30 display pki certificate filename

Function

The **display pki certificate filename** command displays the content of a certificate.

Format

display pki certificate filename *file-name*

Parameters

Parameter	Description	Value
filename *file-name*	Specifies the name of a certificate file.	The value must be an existing certificate file name.

Views

All views

Default Level

3: Management level

Usage Guidelines

This command shows information about the certificate including signature algorithm, issuer, validity period, subject, and subject public key.

Example

Display information about the certificate **ca.cer**.

```
<HUAWEI> display pki certificate filename ca.cer
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

Table 14-99 Description of the **display pki certificate filename** command output

Item	Description
Certificate	Information about a certificate.
Data	Data of a certificate.
Version	Version of a certificate.
Serial Number	Serial number of a certificate.
Signature Algorithm	Signature algorithm of a certificate.
Issuer	Issuer of a certificate.
Validity	Validity period of a certificate.
Subject	Subject of a certificate. The subject includes the following attributes: ● C: country code of a PKI entity. ● ST: name of the state or province to which a PKI entity belongs. ● L: geographic area where a PKI entity is located. ● O: organization to which a PKI entity belongs. ● OU: department to which a PKI entity belongs. ● CN: common name of a PKI entity.
Subject Public Key Info	Information about the public key of a certificate.
Public Key Algorithm	Public key algorithm.
RSA Public-Key	Public key.
Modulus	Key modulus.
Exponent	Key exponent.
X509v3 extensions	X.509v3 certificate extensions.
X509v3 Basic Constraints	Basic constraints.
CA	Whether the CA can be trusted.
X509v3 Key Usage	X.509v3 key usage.
X509v3 Subject Key Identifier	Identifier of a subject key.
Netscape Cert Type	Netscape certificate type.

14.19.31 display pki cmp statistics

Function

The **display pki cmp statistics** command displays CMP session statistics.

Format

display pki cmp statistics [**session** *session-name*]

Parameters

Parameter	Description	Value
session *session-name*	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays CMP session statistics, including the number of sent IR packets, sent CR packets, sent KUR packets, and received IP packets.

If a CMP session is specified, the statistics of the session are displayed. If no CMP session is specified, the statistics of all sessions are displayed.

Example

Display the statistics of the CMP session **test**.

```
<HUAWEI> display pki cmp statistics session test
 CMP Context Name: test
  Initialization request      : 0
  Certification request       : 0
  Key update request          : 0
 PKI Status:
  Accepted                    : 0
  Granted with modifications : 0
  Rejection                   : 0
  Waiting                     : 0
  Revocation warning          : 0
  Revocation notification     : 0
  Key update warning          : 0
```

Table 14-100 Description of the **display pki cmp statistics** command output

Item	Description
CMP Context Name	Name of a CMP session.
Initialization request	Total number of initialization requests sent during the session.
Certification request	Total number of certificate requests sent during the session.
Key update request	Total number of key update requests sent during the session.
PKI Status	Status of the PKI realm.
Accepted	Number of received certificate applications.
Granted with modifications	The certificate server returns an application request, but the change needs to be confirmed.
Rejection	The certificate server rejects the application request.
Waiting	The certificate server has not handled the application request.
Revocation warning	The certificate is about to be revoked.
Revocation notification	The certificate has been revoked.
Key update warning	The certificate key has been updated.

14.19.32 display pki credential-storage-path

Function

The **display pki credential-storage-path** command displays the default path where a PKI certificate is stored.

By default, the certificate file is stored in **flash:/**.

Format

display pki credential-storage-path

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pki credential-storage-path** command displays the default path where a PKI certificate is stored.

Example

Display the default path where a PKI certificate is stored.

```
<HUAWEI> display pki credential-storage-path
 The pki credential-storage-path is flash:/ .
```

14.19.33 display pki crl

Function

The **display pki crl** command displays the content of the CRL in the device.

Format

display pki crl { **realm** *realm-name* | **filename** *filename* }

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the name of the PKI realm associated with the CRL.	The PKI realm name must already exist.
filename *filename*	Specifies the file name of the certificate to be imported.	The certificate file name must already exist.

Views

All views

Default Level

3: Management level

Usage Guidelines

This command shows information about local CRL, including signature algorithm, issuer, update time, revoked certificate, CRL sequence number, and revocation time.

Example

Display information about the CRL associated with the PKI realm **abc**.

```
<HUAWEI> display pki crl realm abc
 The x509 object type is CRL:
Certificate Revocation List (CRL):
        Version 2 (0x1)

Table 14-101 Description of the **display pki crl** command output

Item	Description
The x509 object type is CRL	x509 object type is CRL.
Certificate Revocation List (CRL)	Information about the CRL.
Signature Algorithm	Algorithm of signature.
Issuer	Information of issuer.
Last Update	Last time the CRL has been updated.
Next Update	Next time the CRL will be updated.
CRL extensions	CRL extended attribute.
X509v3 Authority Key Identifier	X.509v3 authority key identifier.
X509v3 CRL Number	X.509v3 CRL number.
Revoked Certificates	Certificate that is revoked.
Serial Number	Serial number of the CRL.
Revocation Date	Date when the certificate was revoked.
CRL entry extensions	CRL entry extensions.
X509v3 CRL Reason Code	Reason why CRL is revoked.
Signature Algorithm	Signature algorithm. It is configured using the **enrollment-request signature message-digest-method** command.
Pki realm name	PKI realm name. It is configured using the **pki realm(system view)** command.
CRL file name	CRL file name. It is configured using the **pki import-crl** command.

14.19.34 display pki entity

Function

The **display pki entity** command displays information about PKI entities.

Format

display pki entity [*entity-name*]

Parameters

Parameter	Description	Value
entity-name	Specifies the name of a PKI entity. If the *entity-name* parameter is not specified, information about all entities is displayed.	The value must be an existing PKI entity name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays information about PKI entities, including names, common names, countries, province, and location where the entities reside, and organizations to which entities belong.

Example

Display information about all PKI entities.

```
<HUAWEI> display pki entity
PKI Entity Information:

  Entity Name       : a
  Common name       : chi
  Country           : -
  State             : A
  Locality          : -
  Organization      : A
  Organization unit: -
  FQDN              : www. e
  IP address        : -
  Email             : -
  Serial-number     : -
 Total Number: 1
```

Table 14-102 Description of the **display pki entity** command output

Item	Description
PKI Entity Information	Information of the PKI entity.
Entity Name	Entity name. It is configured using the **pki entity** command.

Item	Description
Common name	Common name of the entity. It is configured using the **common-name** command.
Country	Country where a PKI entity resides. It is configured using the **country (PKI entity view)** command.
State	Province where a PKI entity resides. It is configured using the **state (PKI entity view)** command.
Locality	Location of a PKI entity. It is configured using the **locality** command.
Organization	Organization to which a PKI entity belongs. It is configured using the **organization** command.
Organization unit	Organization unit to which a PKI entity belongs. It is configured using the **organization-unit** command.
FQDN	FQDN name of a PKI entity. It is configured using the **fqdn** command.
IP address	IP address of a PKI entity. It is configured using the **ip-address** command.
Email	Email address. It is configured using the **email** command.
Serial-number	Serial number of the entity. It is configured using the **serial-number** command.

14.19.35 display pki ocsp cache statistics

Function

The **display pki ocsp cache statistics** command displays statistics about cached OCSP responses.

Format

display pki ocsp cache statistics

NOTE

This command is available only on NETCONF-supporting switch models.

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command shows statistics about cached OCSP responses, including the maximum number of OCSP responses that can be cached, cache update interval, and number of cached responses.

Example

Display statistics about cached OCSP responses.

```
<HUAWEI> display pki ocsp cache statistics

==================================================
   OCSP Cache Function: Enable
   OCSP Cache Max Number: 2
   OCSP Cache Refresh Interval: 5 minutes
   OCSP Cache Current Number: 0
==================================================
```

Table 14-103 Description of the **display pki ocsp cache statistics** command output

Item	Description
OCSP Cache Function	Whether OCSP caching is enabled. - Enable - Disable It is configured using the **pki ocsp response cache enable** command.
OCSP Cache Max Number	Maximum size of OCSP cache. It is configured using the **pki ocsp response cache number** command.

Item	Description
OCSP Cache Refresh Interval	OCSP cache update interval. It is configured using the **pki ocsp response cache refresh interval** command.
OCSP Cache Current Number	Number of cached OCSP responses.

14.19.36 display pki ocsp cache detail

Function

The **display pki ocsp cache detail** displays the detail information of the OCSP cache.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

display pki ocsp cache detail

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

You can run this command to view detail information of the OCSP cache.

Example

Display the detail information of the OCSP cache.

```
<HUAWEI> display pki ocsp cache detail
=====================================================
Cache Hash Status Info:
num_items              = 0
num_nodes              = 8
num_alloc_nodes        = 16
num_expands            = 0
num_expand_reallocs    = 0
num_contracts          = 0
```

```
num_contract_reallocs = 0
num_hash_calls        = 0
num_comp_calls        = 0
num_insert            = 0
num_replace           = 0
num_delete            = 0
num_no_delete         = 0
num_retrieve          = 0
num_retrieve_miss     = 0
num_hash_comps        = 0
Cache Hash Node Status Info:

node      0 ->   0
node      1 ->   0
node      2 ->   0
node      3 ->   0
node      4 ->   0
node      5 ->   0
node      6 ->   0
node      7 ->   0
Cache Hash Node Usage Status Info:

0 nodes used out of 8
0 items
====================================================
```

Table 14-104 Description of the **display pki ocsp cache detail** command output

Item	Description
Cache Hash Status Info	Hash status of the OCSP cache.
num_items	Number of available hash elements.
num_nodes	Number of requested hash nodes.
num_alloc_nodes	Maximum number of hash nodes that can be expanded.
num_expands	Number of hash node expansion application times.
num_expand_reallocs	Number of expanded hash nodes.
num_contracts	Number of hash node reduction times.
num_contract_reallocs	Number of reduced hash nodes.
num_hash_calls	Number of times the hash function is invoked.
num_comp_calls	Number of times the hash comparison function is invoked.
num_insert	Number of inserted hash nodes.
num_replace	Number of replaced hash nodes.
num_delete	Number of deleted hash nodes.
num_no_delete	Number of undeleted hash nodes.

Item	Description
num_retrieve	Number of times the hash nodes in the OCSP cache are matched.
num_retrieve_miss	Number of times the hash nodes in the OCSP cache are not matched.
num_hash_comps	Number of times the hash nodes in the OCSP cache are compared.
Cache Hash Node Status Info	Hash node status in the OCSP cache. For example, **node 0 -> 0** indicates that the number 0 node is unused; **node 0 -> 1** indicates that the number 0 node is in use.
Cache Hash Node Usage Status Info	Hash node use status in the OCSP cache.
n nodes used out of 8	There are 8 hash nodes, and n nodes are in use.
n items	nth hash element.

14.19.37 display pki ocsp server down-information

Function

The **display pki ocsp server down-information** command displays the Down state information of the OCSP server recorded on the device.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

display pki ocsp server down-information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

There is a mechanism to determine whether the OCSP server is Down. When the OCSP server corresponding to a URL cannot be accessed, the server status is set to Down. In this case, the device will not send OCSP requests to the URL within 10 minutes.

Example

Display the Down state information of the OCSP server.

```
<HUAWEI> display pki ocsp server down-information

=====================================================

  Server URL: http://10.1.1.1/ocsp
  Timeout Times: 1
  Last timeout until now: 5 seconds
=====================================================
```

Table 14-105 Description of the **display pki ocsp server down-information** command output

Item	Description
Server URL	URL of an unreachable OCSP server. It is configured using the **ocsp url** command.
Timeout Times	Connection timeouts.
Last timeout until now	Time elapsed since the last connection timeout and now.

14.19.38 display pki peer-certificate

Function

The **display pki peer-certificate** command displays the imported certificates of the remote device.

Format

display pki peer-certificate { **name** *peer-name* | **all** }

Parameters

Parameter	Description	Value
name *peer-name*	Specifies the name of peer certificate.	The value must be an existing peer certificate file name.

Parameter	Description	Value
all	Displays brief information about all certificates of the remote device.	-

Views

All views

Default Level

2: Configuration level

Usage Guidelines

This command shows information about imported certificates of the remote device, including signature algorithm, issuer, validity period, subject, public key, and PKI realm.

Example

Display brief information about all certificates of the remote device.

```
<HUAWEI> display pki peer-certificate all
  Peer certificate name :abcd
  Serial Number:
    12 19 3c d3 00 00 00 00 04 9a
  Subject:
    CN=a

Total Number: 1
```

Display detailed information about the certificate **abcd** of the remote device.

```
<HUAWEI> display pki peer-certificate name abcd
The x509 object type is certificate:
Certificate:
    Data:
        Version: 3 (0x2)

Certificate peer name: abcd
```

Table 14-106 Description of the **display pki peer-certificate** command output

Item	Description
Peer certificate name	Peer certificate name.
The x509 object type is certificate	X.509 object type is certificate.
Certificate	Information about a certificate.
Data	Data of a certificate.
Version	Version of a certificate.
Serial Number	Serial number of a certificate.
Signature Algorithm	Signature algorithm of a certificate.
Issuer	Issuer of a certificate.
Validity	Validity period of a certificate.

Item	Description
Subject	Subject of the certificate.
Subject Public Key Info	Public key of the certificate.
Public Key Algorithm	Algorithm of the Public key.
Public-Key	Information about the RSA public key.
Modulus	Key modulus.
Exponent	Key exponent.
X509v3 extensions	X.509v3 certificate extensions.
X509v3 Subject Key Identifier	Identifier of a subject key.
X509v3 CRL Distribution Points	CRL distribution points.
Full Name	Full name of CDP.
Authority Information Access	Authority information access.
Pki realm name	PKI realm name.
Certificate file name	Certificate file name.
Certificate peer name	Certificate peer name.

14.19.39 display pki realm

Function

The **display pki realm** command displays PKI realm information.

Format

display pki realm [*realm-name*]

Parameters

Parameter	Description	Value
realm-name	Displays detailed information about a PKI realm. If the parameter is left blank, information about all PKI realms is displayed.	The PKI realm name must already exist.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays details about PKI realms, including PKI realm name, associated CA, CA certificate subject name, URL of the certificate enrolled through SCEP, PKI entity name, digital fingerprint algorithm of CA certificate, and digital fingerprint of CA certificate.

Example

Display information about all PKI realms.

```
<HUAWEI> display pki realm abc
 Realm Name : abc
 CA ID: CA_ROOT
 CA Name: "/CN=ca_root"
 Enrollment URL: http://10.136.7.196:8080/certsrv/mscep/mscep.dll
 Certificate Request Interval(Minutes): 1
 Certificate Request Times: 5
 Enrollment Mode: RA
 Enrollment Method: SCEP
 Entity Name: abc
 CA Certificate Fingerprint Arithmetic: sha256
 CA Certificate Fingerprint: e71add0744360e91186b828412d279e06dcc15a4ab4bb3d1384
2820396b526a0
 OCSP Nonce: Enable
 OCSP URL: -
 Method for Getting CRL: HTTP
 CDP URL: -
 Certificate Revocation Check Method: -
 RSA Key Name: abc
 Auto-enroll: Enable
 Auto-enroll Percent: 100%
 Auto-enroll Regenerate: Enable
 Auto-enroll Regenerate Key-size: 2048
 Auto-enroll Updated-effective: Disable
 Password Cipher: Enable
 Password: ******
 Crl Update-period(Hours): 8
 Crl Cache: Enable
 Key-usage: -
```

```
Vpn-instance: -
Source IP: -
Enrollment-request Signature Message-digest-method: SHA256

Total Number: 1
```

Table 14-107 Description of the **display pki realm** command output

Item	Description
Realm Name	PKI realm name. It is configured using the **pki realm (system view)** command.
CA ID	ID of the CA associated with the PKI realm.
CA Name	Subject name of a CA certificate.
Enrollment URL	URL of the certificate enrolled on the SCEP server. It is configured using the **enrollment-url** command.
Certificate Request Interval(Minutes)	Interval between two certificate enrollment status queries.
Certificate Request Times	Maximum number of certificate enrollment status queries.
Enrollment Mode	Certificate enrollment mode (whether enrolled through RA). It is configured using the **enrollment-url** command.
Enrollment Method	Certificate enrollment method, including: ● SCEP: obtains certificate from CA using the SCEP protocol. ● Self-Signed: obtains certificate using self-signature.
Entity Name	PKI entity name. It is configured using the **entity** command.
CA Certificate Fingerprint Arithmetic	Fingerprint algorithm of the CA certificate. It is configured using the **fingerprint** command.
CA Certificate Fingerprint	Digital fingerprint of the CA certificate. It is configured using the **fingerprint** command.
OCSP Nonce	Whether a nonce extension is added to the OCSP request sent by a PKI entity. ● Enable: A nonce extension is added to the OCSP request sent by a PKI entity. ● Disable: A nonce extension is not added to the OCSP request sent by a PKI entity. It is configured using the **ocsp nonce enable** command.
OCSP URL	OCSP server's URL. It is configured using the **ocsp url** command.

Item	Description
Method for Getting CRL	Method of obtaining CRL. - SCEP: updates the CRL automatically using SCEP. It is configured using the **crl scep** command. - HTTP: updates the CRL automatically using HTTP. It is configured using the **crl http** command.
CDP URL	URL of the CDP. It is configured using the **cdp-url** command.
Crl Cache	Whether the PKI realm is allowed to use the CRL in cache. - Enable: The PKI realm is allowed to use the CRL in cache. - Disable: The PKI realm is not allowed to use the CRL in cache. To configure whether to allow the PKI realm to use the CRL in cache, run the **crl cache** command.
Certificate Revocation Check Method	Certificate status check method. It is configured using the **certificate-check** command.
RSA Key Name	RSA key. It is configured using the **rsa local-key-pair** command.
Auto-enroll	Whether automatic certificate enrollment is enabled: - Enable: Automatic certificate enrollment is enabled. - Disable: Automatic certificate enrollment is disabled. It is configured using the **auto-enroll** command.
Auto-enroll Percent	The percentage of the certificate's validity period. It is configured using the **auto-enroll** command.
Auto-enroll Regenerate	Whether the RSA key pair will be generated during certificate updates: - Enable: The RSA key pair will be generated during certificate updates. - Disable: The RSA key pair will not be generated during certificate updates. It is configured using the **auto-enroll** command.
Auto-enroll Regenerate Key-size	RSA key length. It is configured using the **auto-enroll** command.

Item	Description
Auto-enroll Updated-effective	Whether the certificate takes effect immediately after being updated. - Enable: The certificate takes effect immediately after being updated. - Disable: The certificate does not take effect immediately after being updated. It is configured using the **auto-enroll** command.
Password Cipher	Whether the challenge password can be used: - Enable: The challenge password can be used. - Disable: The challenge password cannot be used.
Password	Password used to apply for or revoke a certificate. It is configured using the **password (PKI realm view)** command.
Crl Update-period(Hours)	CRL update interval. It is configured using the **crl update-period** command.
Key-usage	Purpose information carried in a certificate request packet. It is configured using the **key-usage** command.
Vpn-instance	VPN to which the PKI realm is added. It is configured using the **vpn-instance** command.
Source IP	Source IP address used by the device to communicate with the PKI server. It is configured using the **source** command.
Enrollment-request Signature Message-digest-method	Digest method used for the enrollment request packet of signed certificate. It is configured using the **enrollment-request signature message-digest-method** command.

14.19.40 display pki rsa local-key-pair

Function

The **display pki rsa local-key-pair** command displays RSA key pairs and public keys.

Format

display pki rsa local-key-pair { **pem** | **pkcs12** } *filename* [**password** *password*]

display pki rsa local-key-pair [**name** *key-name*] **public** [**temporary**]

NOTE

The **pem** *file-name* parameter is supported only when the WEAKEA plug-in is installed. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Parameters

Parameter	Description	Value
pem	Indicates that the file format is PEM.	-
pkcs12	Indicates that the file format is PKCS12.	-
filename	Specifies the name of the file that contains the RSA key pair.	The file name must already exist.
password *password*	Specifies the decryption password for the RSA key pair file. The value must be the same as the password configured using the **pki export rsa-key-pair** command.	The value must be the name of an existing decryption password of the RSA key pair.
name *key-name*	Specifies the RSA key pair name.	The RSA key pair name must already exist.
temporary	Displays information about the RSA key pair saved in the temporary zone.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

This command shows information about the RSA key pair and public key, including key pair creation time, key pair name, whether the key can be exported, and public key information.

If *key-name* is not specified, all RSA key pairs and public keys are displayed. If *key-name* is specified, the specified RSA key pair and public key are displayed.

Example

Display information about all RSA key pairs.

```
<HUAWEI> display pki rsa local-key-pair public

====================================================
Time of Key pair created: 17:43:42  2016/4/18
Key Name: abc
Key Index: 0
Key Modules: 2048 bit
Key Exportable: Yes
Key Type: RSA signature key
====================================================
Key code:

Table 14-108 Description of the **display pki rsa local-key-pair** command output

Item	Description
Time of Key pair created	Time when the RSA key pair is created.
Key Name	Name of a key pair. It is configured using the **pki rsa local-key-pair create** command.
Key Index	Index of the key.
Key Modules	Number of bits of the key.
Key Exportable	Whether the key can be exported.
Key Type	Type of the key.
Key code	Public key in the RSA key pair.

14.19.41 email

Function

The **email** command configures an email address for a PKI entity.

The **undo email** command cancels the configuration.

By default, no email address is configured for a PKI entity.

Format

email *email-address*

undo email

Parameters

Parameter	Description	Value
email-address	Specifies the email address of a PKI entity.	The value is a string of 1 to 128 case-sensitive characters, including letters, numerals, apostrophes ('), equal signs (=), parentheses (), plus signs (+), minus signs (-), periods (.), slashes (/), colons (:), at signs (@), underscores (_), and spaces.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure an email address for the PKI entity, which is used as an alias of the entity.

After the email address is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this email address. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the email address of the PKI entity.

Example

Set the email address to **test@example.com** for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] email test@example.com
```

14.19.42 enrollment self-signed

Function

The **enrollment self-signed** command configures self-signed certificate obtaining in the PKI realm.

The **undo enrollment self-signed** command restores the default certificate obtaining method.

By default, self-signed certificate obtaining in the PKI realm is not configured.

Format

enrollment self-signed

undo enrollment self-signed

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **enrollment self-signed** command configures self-signed certificate obtaining in the PKI realm. The device can use the self-signed certificate obtained from the PKI realm to support default HTTPS functions. The certificate issuer name is in the format: device name-Self-Signed-Certificate-ESN.

Prerequisites

The RSA key pair has been configured by using the **rsa local-key-pair** command.

Precautions

The device generates a self-signed certificate only when the PKI domain is applied to the service.

The device does not support lifecycle management for self-signed certificates. For example, self-signed certificates cannot be registered, updated, or revoked on the device. To ensure security of the device and certificates, it is recommended the user's certificate be used.

To configure self-signed certificate obtaining, delete the certificate in the PKI realm.

After the **enrollment self-signed** command is run, the device will not generate certificate expiration logs when its self-signed certificate expires.

Example

Configure self-signed certificate obtaining in the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] enrollment self-signed
```

14.19.43 enrollment-request signature message-digest-method

Function

The **enrollment-request signature message-digest-method** command configures the digest algorithm used to sign certificate enrollment requests.

The **undo enrollment-request signature message-digest-method** command restores the default digest algorithm used to sign certificate enrollment requests.

By default, the digest algorithm used to sign certificate enrollment requests is **sha-256**.

Format

enrollment-request signature message-digest-method { **md5** | **sha1** | **sha-256** | **sha-384** | **sha-512** }

undo enrollment-request signature message-digest-method

Parameters

Parameter	Description	Value
md5	Specifies the digest algorithm used to sign certificate enrollment requests to MD5.	-
sha1	Specifies the digest algorithm used to sign certificate enrollment requests to SHA1.	-
sha-256	Specifies the digest algorithm used to sign certificate enrollment requests to SHA2-256.	-
sha-384	Specifies the digest algorithm used to sign certificate enrollment requests to SHA2-384.	-
sha-512	Specifies the digest algorithm used to sign certificate enrollment requests to SHA2-512.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

In SCEP local certificate application mode, after a CA server receives a certificate enrollment request from a PKI entity, the CA server requests a signature for authentication, and generates a local certificate only after the authentication is successful.

For security purposes, SHA2 is recommended. You are not advised to configure MD5 and SHA1.

Example

Set the digest algorithm used to sign certificate enrollment requests to **sha-384**.

```
<HUAWEI> system-view
[HUAWEI] pki realm e
[HUAWEI-pki-realm-e] enrollment-request signature message-digest-method sha-384
```

14.19.44 enrollment-url

Function

The **enrollment-url** command configures the URL of the CA server.

The **undo enrollment-url** command deletes the URL of the CA server.

By default, the URL of the CA server is not configured.

Format

enrollment-url [**esc**] *url* [**interval** *minutes*] [**times** *count*] [**ra**]

undo enrollment-url

Parameters

Parameter	Description	Value
esc	Indicates that the URL address is in ASCII mode.	-
url	Specifies the URL of the CA server. The URL is in the format of *http://server_location/ca_script_location*. *server_location* can use only the IP address format and domain name resolution. *ca_script_location* is the path where CA server host's application script is located, for example, **http://10.137.145.158:8080/certsrv/mscep/mscep.dll**.	The value is a string starting with **http://** and consisting of 1 to 128 case-sensitive characters without spaces.

Parameter	Description	Value
interval *minutes*	Specifies the interval between two certificate enrollment status queries.	The value is an integer that ranges from 1 to 1440, in minutes. The default value is 1.
times *count*	Specifies the maximum number of certificate enrollment status queries.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
ra	Configures an RA to authenticate a PKI entity's identity information during local certificate application. By default, a CA authenticates a PKI entity's identity information during local certificate application.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

The URL refers to the address provided by a CA server for certificate application. For example, a CA server running Windows Server 2008 uses a URL address in the format http://host:port/certsrv/mscep/mscep.dll, in which *host* indicates the IP address of the CA server and *port* indicates the port number.

The keyword **esc** supports the entering of URLs that include the question mark (?) in ASCII code. The URL must be in **\x3f** format, and **3f** is the hexadecimal ASCII code for the question mark (?). For example, if a user wants to enter **http://***.com?page1**, the URL is **http://***.com\x3fpage1**. If a user wants to enter **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the URL is **http://www.***.com\x3fpage1\\\x3f**.

Example

Create a PKI realm **test** and configure the URL in HTTP mode for the CA server.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] enrollment-url http://10.13.14.15:8080/certsrv/mscep/mscep.dll ra
```

14.19.45 entity

Function

The **entity** command specifies a PKI entity that applies for a certificate.

The **undo entity** command cancels a PKI entity.

By default, no PKI entity is specified.

Format

entity *entity-name*

undo entity

Parameters

Parameter	Description	Value
entity-name	Specifies the name of a PKI entity.	The value must be an existing PKI entity name.

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a PKI entity requests the local certificate in the PKI realm, the device encapsulates the configuration of the specified PKI entity into the certificate request.

Prerequisites

1. The specified PKI entity has been configured by using the **pki entity** command.
2. The common name of the PKI entity has been configured using the **common-name** command.

Precautions

A PKI realm can be bound to only one PKI entity.

Example

Bind the PKI entity **a** to the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki entity a
[HUAWEI-pki-entity-a] common-name test
[HUAWEI-pki-entity-a] quit
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] entity a
```

14.19.46 fingerprint

Function

The **fingerprint** command configures the CA certificate fingerprint used in CA certificate authentication.

The **undo fingerprint** command deletes the CA certificate fingerprint used in CA certificate authentication.

By default, no CA certificate fingerprint is configured for CA certificate authentication.

Format

fingerprint { **md5** | **sha1** | **sha256** } *fingerprint*

undo fingerprint

Parameters

Parameter	Description	Value
md5	Sets the digital fingerprint algorithm to MD5.	-
sha1	Sets the digital fingerprint algorithm to SHA1.	-
sha256	Sets the digital fingerprint algorithm to SHA256.	-

Parameter	Description	Value
fingerprint	Specifies the digital fingerprint value. This value needs to be obtained from the CA server offline. For example, from a CA server running Windows Server 2008, you can obtain the digital fingerprint at http://*host*:*port*/certsrv/mscep_admin/, in which *host* indicates the server's IP address and *port* indicates the port number.	The digital fingerprint value is a hexadecimal string of case-insensitive characters. ● An MD5 fingerprint consists of 32 characters (16 bytes). ● An SHA1 fingerprint consists of 40 characters (20 bytes). ● An SHA256 fingerprint consists of 64 characters (32 bytes).

Views

PKI realm view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When obtaining a CA certificate, the device uses an algorithm to calculate the CA certificate fingerprint and compares the CA certificate fingerprint with the configured fingerprint. If the two values are the same, the device receives the CA certificate. When verifying a certificate, the device uses the public key of the CA certificate to authenticate the digital signature. If the digital signature can be decrypted, the certificate is verified.

Precautions

You can configure an algorithm to calculate the CA certificate fingerprint. If you run the **fingerprint** command multiple times in the same PKI realm view, only the latest configuration takes effect.

The MD5 and SHA1 algorithms have a low security level. SHA256 is recommended.

Example

Configure the CA certificate fingerprint used in CA certificate authentication.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
```

```
[HUAWEI-pki-realm-test] fingerprint sha256
e71add0744360e91186b828412d279e06dcc15a4ab4bb3d13842820396b526a0
```

14.19.47 fqdn

Function

The **fqdn** command configures a fully qualified domain name (FQDN) for a PKI entity.

The **undo fqdn** command cancels the configuration.

By default, no FQDN is configured for a PKI entity.

Format

fqdn *fqdn-name*

undo fqdn

Parameters

Parameter	Description	Value
fqdn-name	Specifies the FQDN of a PKI entity.	The value is a string of 1 to 255 case-sensitive characters, including letters, numerals, apostrophes ('), equal signs (=), parentheses (), plus signs (+), minus signs (-), periods (.), slashes (/), colons (:), at signs (@), underscores (_), and spaces.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure an FQDN for the PKI entity, which is used as an alias of the entity.

An FQDN is the unique identifier of a PKI entity. It consists of a host name and a domain name, and can be translated into an IP address. A sample of an FQDN is www.example.com.

After the FQDN is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this FQDN. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the FQDN of the PKI entity.

Example

Set the FQDN to **example.com** for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] fqdn example.com
```

14.19.48 ip-address

Function

The **ip-address** command configures an IP address for a PKI entity.

The **undo ip-address** command deletes the configuration.

By default, a PKI entity does not have an IP address.

Format

ip-address { *ipv4-address* | *interface-type interface-number* }

undo ip-address

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a PKI entity.	The value is in dotted decimal notation.
interface-type interface-number	Specifies an interface IP address of a PKI entity. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity include the identity information of the PKI entity. The CA identifies a certificate applicant based on identity information provided by a PKI entity. To facilitate applicant identification, configure an IP address for the PKI entity, which is used as an alias of the PKI entity.

After an IP address is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this IP address. After receiving the certificate request packet, the CA server verifies the packet. For each valid packet, the CA server generates a digital certificate carrying the device IP address.

Example

Set an IP address 10.1.1.1 for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] ip-address 10.1.1.1
```

14.19.49 key-usage

Function

The **key-usage** command configures the purpose description for a certificate public key.

The **undo key-usage** command deletes the purpose description of a certificate public key.

By default, a certificate public key does not have a purpose description.

Format

key-usage { **ike** | **ssl-client** | **ssl-server** } *

undo key-usage { **ike** | **ssl-client** | **ssl-server** } *

Parameters

Parameter	Description	Value
ike	Specifies the usage of a key as ike. That is, the key is used to set up an IPSec tunnel.	-
ssl-client	Specifies the usage of a key as ssl-client. That is, the key is used by the SSL client to set up an SSL session.	-
ssl-server	Specifies the usage of a key as ssl-server. That is, the key is used by the SSL server to set up an SSL session.	-

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

To improve certificate security, you can add the usage information of a key to the certificate request packet sent from the device to the CA server.

After receiving the certificate request packet, the CA server verifies the packet. For each valid packet, the CA server generates a digital certificate carrying the usage information of the key.

For example, when setting up an SSL session, the SSL client adds a digital signature and encrypts the key by using the certificate. After you specify the usage of a key as ssl-client by using the **key-usage ssl-client** command, the certificate generated by the CA server carries the usage information, including a digital signature and encrypted key. If you use this key to encrypt data, the key will be invalid.

Example

Specify the usage of a key as ssl-client.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] key-usage ssl-client
```

14.19.50 locality

Function

The **locality** command configures a locality name for a PKI entity.

The **undo locality** command cancels the configuration.

By default, a PKI entity does not have a locality name.

Format

locality *locality-name*

undo locality

Parameters

Parameter	Description	Value
locality-name	Specifies the locality name of a PKI entity.	The value is a string of 1 to 32 case-sensitive characters, including letters, numerals, apostrophes ('), equal signs (=), parentheses (), plus signs (+), commas (,), minus signs (-), periods (.), slashes (/), colons (:), and spaces.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure a locality name for the PKI entity, which is used as an alias of the entity.

After the locality name is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this locality name. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the locality name of the PKI entity.

Example

Set the locality name to **Beijing** for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] locality Beijing
```

14.19.51 ocsp nonce enable

Function

The **ocsp nonce enable** command adds a nonce extension to the OCSP request sent by a PKI entity.

The **undo ocsp nonce enable** command cancels the configuration.

By default, the OCSP request sent by a PKI entity contains a nonce extension.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

ocsp nonce enable

undo ocsp nonce enable

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

To improve security and reliability of communication between a PKI entity and OCSP server, this command adds a nonce extension (a random value) to the OSCP request sent by the PKI entity. If the nonce extension values on the PKI entity and OCSP server are different, communication fails.

Example

Add a nonce extension to the OCSP request sent by a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] ocsp nonce enable
```

14.19.52 ocsp signature enable

Function

The **ocsp signature enable** command enables the function of signing OCSP request packets.

The **undo ocsp signature enable** command disables the function of signing OCSP request packets.

By default, the function of signing OCSP request packets is disabled.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

ocsp signature enable

undo ocsp signature enable

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

When the certificate check mode is set to OCSP, the device sends OCSP request packets to the OCSP server. To improve access security, run the **ocsp signature enable** command to enable the function of signing OCSP request packets.

Example

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] ocsp signature enable
```

14.19.53 ocsp url

Function

The **ocsp url** command configures the Uniform Resource Locator (URL) address for an Online Certificate Status Protocol (OCSP) server.

The **undo ocsp url** command deletes the URL address of an OCSP server.

By default, an OCSP server does not have a URL address.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

ocsp url [**esc**] *url-address*

undo ocsp url

Parameters

Parameter	Description	Value
esc	Indicates that the URL address is in ASCII mode.	-
url-address	Indicates the OCSP server's URL address.	The value is a string starting with **http://** and consisting of 1 to 128 case-sensitive characters without spaces.

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

If a certificate to be checked through OCSP does not contain the AIA option, run this command to configure the OCSP server's URL. If the certificate contains the AIA option, run the **ocsp-url from-ca** command to configure the PKI entity to obtain OSCP server's URL from the AIA option.

The keyword **esc** supports the entering of URLs that include the question mark (?) in ASCII code, and **3f** is the hexadecimal ASCII code for the question mark (?). Therefore, the entered URL must be in **\x3f** format. For example, the URL that an administrator needs to enter is **http://www.***.com\x3fpage1**, instead of **http://www.***.com?page1**. If the administrator wants to configure **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the administrator should add an escape character (\\) to \x3f and enter **http://www.***.com\x3fpage1\\\\x3f**.

Example

Set the OCSP server's URL address to http://10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] ocsp url http://10.1.1.1
```

14.19.54 ocsp-url from-ca

Function

The **ocsp-url from-ca** command configures a PKI entity to obtain the OCSP server's URL from the Authority Info Access (AIA) option in a CA certificate.

The **undo ocsp-url from-ca** command disables a PKI entity from obtaining the OCSP server's URL from the AIA option in a CA certificate.

By default, a PKI entity does not obtain OCSP server's URL from a CA certificate's AIA option.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

ocsp-url from-ca

undo ocsp-url from-ca

Parameters

None

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

If a certificate to be checked through OCSP contains the AIA option, run this command to configure the PKI entity to obtain OSCP server's URL from the AIA option. If the certificate does not contain the AIA option, run the **ocsp url** command to configure the OCSP server's URL.

Example

Configure a PKI entity to obtain OCSP server's URL from a CA certificate's AIA option.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] ocsp-url from-ca
```

14.19.55 organization-unit

Function

The **organization-unit** command configures the department name for a PKI entity.

The **undo organization-unit** command restores the default setting.

By default, no department name is configured for a PKI entity.

Format

organization-unit *organization-unit-name*

undo organization-unit

Parameters

Parameter	Description	Value
organization-unit-name	Specifies the department name for a PKI entity.	The department name is a string of 1 to 31 case-sensitive characters. Names of departments are separated by commas (,). The total length of all department names ranges from 1 to 191. The characters can be letters, integers, apostrophe ('), equal sign (=), brackets (), plus sign (+), comma (,), minus sign (-), dot (.), slash (/), colon (:), and spaces.

Views

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure an organization name for the PKI entity, which is used as an alias of the entity.

After the organization name is configured for a PKI entity, the certificate request packet sent by the device to the CA server carries this organization name. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the organization name of the PKI entity.

Example

Set the organization name of a PKI entity to **org1**.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] organization org1
```

14.19.57 password (PKI realm view)

Function

The **password** command sets the challenge password used for certificate application through SCEP, which is also used to revoke a certificate.

The **undo password** command deletes the challenge password used for certificate application through SCEP.

By default, no challenge password is configured.

Format

password cipher *password*

undo password

Parameters

Parameter	Description	Value
cipher *password*	Specifies the challenge password used for certificate application through SCEP. The password is displayed in ciphertext.	The value is a string of case-sensitive characters. It cannot contain question marks (?). *password* is in plaintext that contains 1 to 64 characters or in ciphertext that contains 48 to 108 characters. **NOTE** To improve communication security, it is recommended that the password contain at least three types of lowercase letters, uppercase letters, numerals, and special characters, and contain at least 8 characters.

Views

PKI realm view

Default Level

3: Management level

Usage Guidelines

When a PKI entity uses SCEP to apply for a certificate from a CA, the CA needs to verify the challenge password of the entity. The CA accepts the certificate application request only when the challenge password is correct. You need to run this command to set a challenge password for the PKI entity.

The challenge password is also used to revoke a certificate. It avoids misoperations in certificate revocation.

Example

Set the challenge password used to apply for certificate through SCEP.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] password cipher YsHsjx_202206
```

14.19.58 pki cmp certificate-request session

Function

The **pki cmp certificate-request session** command configures a device to send a certificate request (CR) to the CMPv2 server based on CMP session information.

Format

pki cmp certificate-request session *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device has a certificate issued by a CA, the device can send a CR to apply for a certificate for another device.

After this command is executed, the system checks whether the configuration in the CMP session can be used for certificate application. If not, the system displays an error message. If so, the system initiates the CR according to the configuration. The obtained certificate is saved in a file on the CF card or Hda1, but not imported to the memory.

NOTE

The device does not support the message authentication code mode. If the CMP session mode is set to message authentication code, the system displays an error message.

Prerequisites

A CMP session has been created using the **pki cmp session** command.

Example

Send a CR to the CMPv2 server.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] quit
[HUAWEI] pki cmp certificate-request session test
 Info: Initializing configuration.
 Info: Creatting certification request packet.
 Info: Connectting to CMPv2 server.
 Info: Sending certification request packet.
 Info: Waitting for certification response packet.
 Info: Creatting confirm packet.
 Info: Connectting to CMPv2 server.
 Info: Sending confirm packet.
 Info: Waitting for confirm packet from server.
 Info: CMPv2 operation finish.
```

14.19.59 pki cmp initial-request session

Function

The **pki cmp initial-request session** command configures a device to send an initial request (IR) to the CMPv2 server based on CMP session information.

Format

pki cmp initial-request session *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the command is executed, the system checks whether the configuration in the CMP session can be used for certificate application. If not, the system displays an error message. If so, the system performs an IR according to the configuration. The obtained certificate is saved in a file on the CF card or Hda1, but not imported to the memory. If the server issues the CA certificate during the response period, the CA certificate is also saved in a file.

Prerequisites

A CMP session has been created using the **pki cmp session** command.

Example

Send an IR to the CMPv2 server.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] quit
[HUAWEI] pki cmp initial-request session test
 Info: Initializing configuration.
 Info: Creatting initial request packet.
 Info: Connectting to CMPv2 server.
 Info: Sending initial request packet.
 Info: Waitting for initial response packet.
 Info: Creatting confirm packet.
 Info: Connectting to CMPv2 server.
 Info: Sending confirm packet.
 Info: Waitting for confirm packet from server.
 Info: CMPv2 operation finish.
```

14.19.60 pki cmp keyupdate-request session

Function

The **pki cmp keyupdate-request session** command configures a device to send a key update request (KUR) to the CMPv2 server based on CMP session information.

Format

pki cmp keyupdate-request session *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device has a certificate issued by a CA, the device can send a KUR to update the certificate.

After the command is executed, the system checks whether the configuration in the CMP session can be used for certificate update application. If not, the system displays an error message. If so, the system initiates a KUR according to the configuration. The updated certificate is saved in a file on the device storage, but not imported to the memory.

NOTE

The device does not support the message authentication code mode. If the CMP session mode is set to message authentication code, the system displays an error message.

Prerequisites

A CMP session has been created using the **pki cmp session** command.

Example

Send a KUR to the CMPv2 server.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] quit
[HUAWEI] pki cmp keyupdate-request session test
 Info: Initializing configuration.
 Info: Creatting key update request packet.
 Info: Connectting to CMPv2 server.
 Error: CMPv2 server connect failed.
 Info: CMPv2 operation finish.
```

14.19.61 pki cmp session

Function

The **pki cmp session** command creates a CMP session and displays the CMP session view, or displays the view of an existing CMP session.

The **undo pki cmp session** command deletes a CMP session.

By default, no CMP session exists.

Format

pki cmp session *session-name*

undo pki cmp session *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a CMP session.	The value is a string of 1 to 63 case-insensitive characters without spaces or question marks.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before choosing CMPv2 for certificate application, run the **pki cmp session** command to create a CMP session. CMPv2 configuration is performed in the CMP session view.

Example

Create the CMP session **test** and enter the CMP session view.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test]
```

14.19.62 pki create-certificate

Function

The **pki create-certificate** command creates a self-signed certificate.

Format

pki create-certificate self-signed filename *file-name*

Parameters

Parameter	Description	Value
self-signed	Creates a self-signed certificate.	-
filename *file-name*	Specifies the name of a certificate file.	The value is a string of 1 to 64 case-insensitive characters without spaces or question marks.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a self-signed certificate or local certificate is generated by the device, the certificate file is saved in the storage device as a PEM file. You can export the certificate for other devices to use. This simplifies certificate issue process.

When you run the **pki create-certificate** command, the system asks you to enter certificate information, for example, PKI entity parameters, certificate file name, certificate validity period, and RSA key length.

Precautions

The device does not provide lifecycle management for self-signed certificates. For example, self-signed certificates cannot be updated or revoked on the device. To ensure security of the device and certificates, a local certificate is recommended.

Example

Create a self-signed certificate **test**.

```
<HUAWEI> system-view
[HUAWEI] pki create-certificate self-signed filename test
```

14.19.63 pki delete replaced-file to recycle-bin enable

Function

The **pki delete replaced-file to recycle-bin enable** command moves overwritten files to the recycle bin.

The **undo pki delete replaced-file to recycle-bin enable** command cancels moving overwritten files to the recycle bin.

By default, overwritten files are permanently deleted.

Format

pki delete replaced-file to recycle-bin enable

undo pki delete replaced-file to recycle-bin enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Overwritten files are permanently deleted by default and cannot be restored. If you want to restore overwritten files in case that new files are unavailable, run the **pki delete replaced-file to recycle-bin enable** command to move these files to the recycle bin.

The **pki delete replaced-file to recycle-bin enable** command applies only to the following scenarios:

- The existing certificates have been overwritten using the **pki get-certificate** command.
- The existing certificates and CRL have been overwritten using the **pki http** command.
- The existing certificates have been overwritten using the **pki cmp initial-request session** command.
- The existing certificates have been overwritten using the **pki cmp certificate-request session** command.
- The existing certificates have been overwritten using the **pki cmp keyupdate-request session** command.
- The existing CRL has been overwritten using the **pki get-crl** command.
- The existing certificates have been overwritten using the **pki enroll-certificate** command.
- The existing certificates have been overwritten using the **pki create-certificate** command.
- The existing certificates have been overwritten using the **pki export-certificate** command.
- The existing RSA key pair has been overwritten using the **pki export rsa-key-pair** command.
- The existing certificates have been overwritten using the **pki import-certificate peer** command.
- The existing CRL has been overwritten using the **pki import-crl** command.
- The existing RSA key pair and certificates have been overwritten using the **pki import rsa-key-pair** command.

Example

Enable the function of moving overwritten files to the recycle bin.

```
<HUAWEI> system-view
[HUAWEI] pki delete replaced-file to recycle-bin enable
```

14.19.64 pki delete-certificate

Function

The **pki delete-certificate** command deletes a certificate from the memory.

Format

pki delete-certificate { **ca** | **local** | **ocsp** } **realm** *realm-name*

NOTE

Only devices in NETCONF mode support the **ocsp** parameter.

Parameters

Parameter	Description	Value
ca	Deletes a CA certificate.	-
local	Deletes a local certificate.	-
ocsp	Deletes an Online Certificate Status Protocol (OCSP) server's certificate.	-
realm *realm-name*	Specifies the name of the PKI realm to which a certificate belongs.	The value must be an existing PKI realm name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the certificate expires or you want to apply for a new certificate, run this command to delete the CA certificate, OCSP server certificate, or local certificate from the memory.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Precautions

Deleting a certificate may interrupt certificate-related services.

Updating the security engine signature database requires the default_ca.cer certificate in the default domain. Therefore, if the security engine has been enabled using the **defence engine enable** command, deleting the certificate in the default domain will fail. To delete the certificate in the default domain, run the **update server** command to replace the certificate for updating the security engine signature database with another certificate.

Example

Delete the local certificate from the memory.

```
<HUAWEI> system-view
[HUAWEI] pki delete-certificate local realm abc
```

14.19.65 pki delete-crl

Function

The **pki delete-crl** command deletes a CRL from the memory.

Format

pki delete-crl realm *realm-name*

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the name of the PKI realm that the certificate belongs to.	The value must be an existing PKI realm name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a CRL expires, run this command to delete a CRL file from the memory. This command will not delete the CRL files in storage card.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Example

Delete the CRL of PKI realm **abc** from the memory.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
```

```
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki delete-crl realm abc
```

14.19.66 pki enroll-certificate

Function

The **pki enroll-certificate** command configures manual certificate enrollment.

Format

pki enroll-certificate realm *realm-name* [**pkcs10** [**filename** *filename*]] [**password** *password*]

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the name of a PKI realm.	The PKI realm name must already exist.
pkcs10	Uses the PKCS#10 format to display the local certificate request information. It can be used to request certificates in offline mode.	-
filename *filename*	Saves the certificate request information in a specified file. The certificate request information is saved in the file in PKCS#10 format and is sent to the CA in outband mode.	The value is a string of 1 to 64.

Parameter	Description	Value
password *password*	Indicates a challenge password, which is used to request certificates in online mode. When the CA server processes the certificate request using the challenge password, you must set a challenge password on the entity, and the challenge password must be the same as the password configured on the CA server.	The value is a string of case-sensitive characters without question marks (?) or spaces. It can be a plain-text string of 1 to 64 characters or a cipher-text string of 48 to 108 characters. **NOTE** To improve certificate security, it is recommended that a password consist of at least two of the following: lowercase letters, uppercase letters, numerals and special characters. In addition, the password must contain at least eight characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Manual certificate application is online or offline.

- Online mode (in-band mode)

  The device requests certificates online by communicating with the CA server through SCEP. Then the device stores the obtained certificates on the flash.

- Offline mode (outband mode)

  The device generates a certificate request file. The administrator sends the file to the CA server using methods such as disks and emails.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Precautions

- If **pkcs10** is specified, an entity applies to a CA for a certificate in offline mode. The entity saves the certificate request information in a file in PKCS#10 format and sends the file to the CA in outband mode.
- If **pkcs10** is not specified, an entity applies to a CA for a certificate in online mode.

- In online mode, a PKI entity obtains a CA certificate and imports it to memory, and then obtains a local certificate and imports it to memory.
- After the **enrollment self-signed** command is used in the PKI realm, it is not allowed to use the **pki enroll-certificate** command to configure manual certificate enrollment.

Example

Enroll a certificate for the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki enroll-certificate realm abc
```

14.19.67 pki entity

Function

The **pki entity** command creates a PKI entity and displays the PKI entity view, or displays the view of an existing PKI entity.

The **undo pki entity** command deletes a PKI entity.

By default, no PKI entity is configured.

Format

pki entity *entity-name*

undo pki entity *entity-name*

Parameters

Parameter	Description	Value
entity-name	Specifies the name of a PKI entity.	The value is a string of 1 to 64 case-sensitive characters without spaces or slashes (/).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

A PKI entity refers to the applicant or user of a certificate. A PKI entity is required when you use PKI features. After a PKI entity is created, you can configure attributes for it, for example, common name, country code, email address, FQDN, IP address, geographic area, organization, department, state, and province. These attributes include identity information of the PKI entity. The identity information will be added to the subject of a PKI entity.

NOTE

Windows Server 2003 has a low processing performance. For the device to connect to a Windows Server 2003, the device cannot have too many entities configured or use a large-sized key pair.

Example

Configure a PKI entity **entity1** and enter the PKI entity view.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1]
```

14.19.68 pki export-certificate

Function

The **pki export-certificate** command exports a certificate to the device storage.

Format

pki export-certificate { **ca** | **local** | **ocsp** } **realm** *realm-name* { **pem** | **pkcs12** }

NOTE

Only devices in NETCONF mode support the **ocsp** parameter.

Parameters

Parameter	Description	Value
ca	Exports a CA certificate.	-
local	Exports a local certificate.	-
ocsp	Exports the Online Certificate Status Protocol (OCSP) certificate.	-
realm *realm-name*	Specifies the PKI realm name of a certificate.	The PKI realm name must already exist.
pem	Exports a certificate in PEM format.	-
pkcs12	Exports a certificate in P12 format.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To copy a certificate to another device, run the **pki export-certificate** command to export a certificate to the flash of the local device first, and then transfer the certificate to another device using a file transfer protocol.

Before using this command, run the **display pki certificate** command to view information about certificates on the device.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Precautions

When the exported certificate file does not contain a private key, the device does not encrypt this file.

If the exported certificate is in PEM format, you need to install the WEAKEA plug-in to export the certificate containing a private key. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

When you export the private key, the system asks you to enter the private key file name. If the private key file name and the certificate file name are the same, the private key and certificate are stored in the same file. If they are different, they are stored in different files.

When you export the private key, the system asks you to enter the private key file format and set the password. The password will be used when you run the **pki import-certificate** command to import this private key.

After the **enrollment self-signed** command is used in the PKI realm, you cannot use the **pki export-certificate** command to export certificates to files.

Example

Export the local certificate in the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki export-certificate local realm abc pem
 Please enter the name of certificate file <length 1-127>: aa
 If you only export the certificate, do not export the private key.
 You can directly enter empty of private key file.
 Please enter the name of private key file <length 1-127>:
 Info: Succeeded in exporting the certificate.
```

14.19.69 pki export rsa-key-pair

Function

The **pki export rsa-key-pair** command exports the RSA key pair to the flash and allows the export of the associated certificate.

Format

pki export rsa-key-pair *key-name* [**and-certificate** *certificate-name*] { **pem** *file-name* **aes** | **pkcs12** *file-name* } **password** *password*

NOTE

The **pem** *file-name* parameter is supported only when the WEAKEA plug-in is installed. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair on the device.	The value must be an existing RSA key pair name.
and-certificate *certificate-name*	Indicates that the certificate related to the RSA key pair are exported.	The value must be an existing certificate file name.
pem *file-name*	Indicates that the RSA key pair to be exported is in the PEM format and specifies the name of the file to be exported.	The value is a string of 1 to 64 case-insensitive characters without spaces and question marks (?). When the value contains a directory, it is a string of 1 to 127 characters, for example, flash:/8ab3/ab3.pem.
pkcs12 *file-name*	Indicates that the RSA key pair to be exported is in the PKCS12 format and specifies the name of the file to be exported.	The value is a string of 1 to 64 case-insensitive characters without spaces and question marks (?). When the value contains a directory, it is a string of 1 to 127 characters, for example, flash:/8ab3/ab3.pem.

Parameter	Description	Value
aes	Sets the encryption algorithm to AES if a file is exported in the PEM format. The default value is AES.	-
password *password*	Specifies the encryption password for the RSA key pair file. This password is used when you import an RSA key pair file.	The value is a string of 8 to 32 case-sensitive characters without question marks (?). For security purposes, a password must meet the minimum strength requirements, that is, the password needs to contain at least three types of the following characters: uppercase letters, lowercase letters, numerals, and special characters, such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To transfer or back up an RSA key pair, run this command to generate the PEM or PKCS12 file carrying this RSA key pair (which may include the certificate) in the flash.

Before using this command, run the **display pki rsa local-key-pair** command to view information about the RSA key pairs on the device.

Prerequisites

The RSA key pair has been created and configured to be exportable using the **pki rsa local-key-pair create** command or the RSA key pair has been imported to the memory using the **pki import rsa-key-pair** command.

Precautions

The RSA key pair is sensitive information. Delete and destroy the exported RSA key pair on the device or storage device immediately after you do not need it.

The system software does not contain the **3des** and **des** parameters. To use these parameters, you need to install the WEAKEA plug-in. However, this algorithm is less secure. For security purposes, you are advised to use other algorithms.

Example

Export the RSA key pair **key1** in PEM format to the **aaa.pem** file with the AES encryption mode after installing the WEAKEA plug-in.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create key1 exportable
 Info: The name of the new key-pair will be: key1
 The size of the public key ranges from 512 to 4096.
 Input the bits in the modules:2048
 Generating key-pairs...
......+++
...................+++
[HUAWEI] pki export rsa-key-pair key1 pem aaa.pem aes password YsHsjx_202206
 Warning: Exporting the key pair impose security risks, are you sure you want to
 export it? [y/n]:y
 Info: Succeeded in exporting the RSA key pair in PEM format.
```

14.19.70 pki file-format

Function

The **pki file-format** command sets the format for the saved certificate request, certificate, and CRL.

By default, the device stores certificate request, certificate, and CRL in PEM format.

Format

pki file-format { **der** | **pem** }

Parameters

Parameter	Description	Value
der	Indicates that the format of a certificate request file is DER.	-
pem	Indicates that the format of a certificate request file is PEM.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To change the format for the saved certificate request, certificate, and CRL, for example, to use the certificate and CRL obtained through CMPv2, SCEP, run the **pki file-format** command.

However, the certificate and CRL obtained through HTTP are downloaded directly and are not saved in the format configured using this command. The created self-signed certificate or local certificate can only be saved in PEM format.

Example

Set the format of saved certificate request, certificate, and CRL to DER.

```
<HUAWEI> system-view
[HUAWEI] pki file-format der
```

14.19.71 pki get-certificate

Function

The **pki get-certificate** command downloads a certificate to the device storage.

Format

pki get-certificate ca realm *realm-name*

Parameters

Parameter	Description	Value
ca	Specifies a CA or RA certificate to be obtained.	-
realm *realm-name*	Specifies the PKI realm name of a certificate to be obtained.	The value must be an existing PKI realm name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you request a local certificate for the PKI entity through SCEP, run this command to download a CA certificate to the device storage, and request a local certificate using the encrypted CA public key.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Precautions

After obtaining a CA certificate, the device automatically imports the certificate to the device memory.

If the same certificate exists on the device, delete the existing one; otherwise, the certificate cannot be obtained.

Example

Obtain the CA certificate in the PKI realm **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki get-certificate ca realm abc
```

14.19.72 pki get-crl

Function

The **pki get-crl** command updates CRL immediately.

Format

pki get-crl realm *realm-name*

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the PKI realm name of the CRL.	The value must be an existing PKI realm name, which is a string of 1 to 52 case-insensitive characters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The CRL status is checked periodically when it is updated automatically. If the CRL on the device is likely to expire, configure this command to update CRL immediately.

After this command is executed, the new CRL replaces the old CRL in the storage, and is automatically imported to the memory to replace the old one.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command.

Example

Configure CRL immediate update.

```
<HUAWEI> system-view
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] quit
[HUAWEI] pki get-crl realm test
```

14.19.73 pki http

Function

The **pki http** command configures a device to use HTTP to download a CA certificate, local certificate, or CRL.

Format

pki http [**esc**] *url-address save-name*

Parameters

Parameter	Description	Value
esc	Specifies the URL in ASCII code.	-
url-address	Specifies the URL of the CA certificate, local certificate, or CRL.	The value is a string of 1 to 128 case-sensitive characters.
save-name	Specifies the name of a CA certificate, local certificate, or CRL saved on the flash of the device.	The value is a string of 1 to 64 case-insensitive characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Before you configure a device to use HTTP to download a CA certificate, local certificate, or CRL, ensure that the flash of the device has enough space to accommodate the CA certificate, local certificate, or CRL.

The keyword **esc** supports the entering of URLs that include the question mark (?) in ASCII code, and **3f** is the hexadecimal ASCII code for the question mark (?). Therefore, the entered URL must be in **\x3f** format. For example, the URL that an administrator needs to enter is **http://www.***.com\x3fpage1**, instead of **http://www.***.com?page1**. If the administrator wants to configure **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the administrator should add an escape character (\\) to **\x3f** and enter **http://www.***.com\x3fpage1\\\x3f**.

Example

Configure a device to use HTTP to download a local certificate.

```
<HUAWEI> system-view
[HUAWEI] pki http http://10.1.1.1/test.cer local.cer
```

Configure a device to use HTTP to download a local certificate.

```
<HUAWEI> system-view
[HUAWEI] pki http esc http://www.***.com\x3fpage1\\x3f local.cer
```

14.19.74 pki import-certificate

Function

The **pki import-certificate** command imports a certificate to the device memory.

Format

pki import-certificate { **ca** | **local** } **realm** *realm-name* { **der** | **pkcs12** | **pem** } [**filename** *filename*] [**replace**] [**no-check-validate**] [**no-check-hash-alg**]

pki import-certificate { **ca** | **local** } **realm** *realm-name* **pkcs12 filename** *filename* [**no-check-validate**] [**no-check-hash-alg**] **password** *password*

pki import-certificate ocsp realm *realm-name* { **der** | **pkcs12** | **pem** } [**filename** *filename*]

pki import-certificate ocsp realm *realm-name* **pkcs12 filename** *filename* **password** *password*

NOTE

Only devices in NETCONF mode support the **ocsp** parameter.

Parameters

Parameter	Description	Value
ca	Imports a CA certificate. For example, when the device works as an SSL proxy, import the SSL proxy CA certificate and use the private key in the certificate to sign the SSL client certificate again.	-
local	Imports a local certificate.	-
realm *realm-name*	Specifies the PKI realm name of the imported certificate.	The PKI realm name must already exist. **NOTE** The domain name cannot contain spaces. Otherwise, the certificate cannot be imported.
der	Imports a certificate in DER format.	-
pkcs12	Imports a certificate in PKCS12 format.	-
pem	Imports a certificate in PEM format.	-
filename *filename*	Specifies the name of the imported certificate.	The file name must already exist.
replace	Deletes the original certificate and RSA key pair and imports the new certificate when there are repeated certificates in the domain. **NOTE** If the RSA key pair of the original certificate is not referenced by other domains, the certificate and key pair are deleted. If the RSA key pair of the original certificate is referenced by other domains or a CMP session, only the original certificate is deleted but the key pair is not deleted.	-
no-check-validate	Indicates whether to perform validity check on the validity period of the imported certificate.	-
no-check-hash-alg	Indicates whether to check the hash algorithm used for the signature of the imported certificate.	-
ocsp	Imports the Online Certificate Status Protocol (OCSP) server's certificate.	-

Parameter	Description	Value
password *password*	Specifies the decryption password of the certificate. The password is the same as the password configured using the **pki export-certificate** command.	The value must be the name of an existing decryption password of the certificate.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a certificate is saved to the storage, run this command to import the certificate to the memory for it to take effect.

The device supports the following certificate import modes:

- terminal: Import or copy the certificate file of the peer to the local device. That is, you can open the PEM certificate file using a text tool and copy the certificate content to the local device.
- file: The **filename** parameter is specified to import the certificate file of the peer.

Multiple certificates can be imported on the device, including the CA certificate, local certificate, and private key.

NOTE

If you do not know the format of the certificate you want to import, configure each format in turn and check whether the certificate is successfully imported.

Prerequisites

The PKI realm has been created using the **pki realm (system view)** command, and the certificate file already exists on the storage device.

Precautions

If a certificate file contains a key pair file, the **pki import-certificate** command imports only the certificate file, but not the key pair file. To import the key pair file, run the **pki import rsa-key-pair** command after the **pki import-certificate** command, or run the **pki import rsa-key-pair** command to import the certificate and key pair files simultaneously.

It is not recommended that multiple local certificates be imported into the same PKI realm. Otherwise, certificate-related services may use the certificates that do not match the services, causing services to become unavailable.

When a certificate in **pkcs12** format is imported, the PKI system deletes the file name extension of the original certificate file, adds **_local.cer** to generate a new file name, and saves it to the storage component. Therefore, the name of the certificate file to be imported should be less than 50 characters, so the total certificate file name does not exceed 64 characters, and the certificate file cannot be imported to the storage component.

The device supports the import of digital certificates generated through the RSA encryption algorithm or SM2 key hash algorithm.

Example

Import a local certificate to the PKI realm **abc** in file transfer mode.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki import-certificate local realm abc pem filename local.cer
 Info: Succeeded in importing the certificate.
```

14.19.75 pki import-certificate peer

Function

The **pki import-certificate peer** command imports a certificate of the remote device to the device memory.

Format

pki import-certificate peer *peer-name* { **der** | **pem** | **pkcs12** } **filename** [*filename*]

pki import-certificate peer *peer-name* **pkcs12 filename** *filename* **password** *password*

Parameters

Parameter	Description	Value
peer-name	Specifies the name of a peer certificate. A certificate cannot be imported to multiple peers.	The value is a string of 1 to 32 case-insensitive characters without spaces. If the character string is enclosed in double quotation marks, it can contain spaces.
der	Imports a certificate of the remote device in DER format.	-
pem	Imports a certificate of the remote device in PEM format.	-

Parameter	Description	Value
pkcs12	Imports a certificate of the remote device in P12 format.	-
filename *filename*	Imports a certificate of the remote device in file mode.	The value is an existing certificate name of the remote device.
password *password*	Specifies the decryption password of the certificate. The password is the same as the password configured using the **pki export-certificate** command.	The value must be the name of an existing decryption password of the certificate.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Where digital envelop authentication is used, configure the public key of the remote device. The public key can be obtained from the public and private key management module or certificate of the remote device.

Prerequisites

The certificate file of the remote device must already exist on the storage device.

Precautions

When a certificate in **pkcs12** format is imported, the PKI system deletes the file name extension of the original certificate file, adds **_localx.cer** to generate a new file name, and saves it to the storage component. Therefore, the name of the certificate file to be imported cannot exceed 50 characters. Otherwise, the total certificate file name will exceed 64 characters, and the certificate file cannot be imported to the storage component.

You can import a peer certificate generated using the RSA encryption algorithm or SM2 key hash algorithm to the device.

Example

Import the certificate **aa.pem** of the remote device in the file mode.

```
<HUAWEI> system-view
[HUAWEI] pki import-certificate peer abcd pem file aa.pem
 Info: Succeeded in importing the peer certificate.
```

14.19.76 pki import-crl

Function

The **pki import-crl** command imports the CRL to the memory.

Format

pki import-crl realm *realm-name* **filename** *file-name*

Parameters

Parameter	Description	Value
realm *realm-name*	Specifies the PKI realm name.	The value must be an existing PKI realm name.
filename *file-name*	Specifies the name of an imported certificate or CRL file. The certificates only support PEM and DER formats.	The value must be an existing certificate or CRL file name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To enable the CRL that is obtained in out-of-band mode or is updated manually, run this command to import the CRL to the memory.

Prerequisites

A PKI realm has been created using the **pki realm (system view)** command and the CRL file has been downloaded using HTTP.

Example

Import the CRL in the PKI realm to the memory.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] quit
```

```
[HUAWEI] pki http esc http://www.***.com\x3fpage1\\x3f abc.crl
[HUAWEI] pki import-crl realm abc filename abc.crl
```

14.19.77 pki import rsa-key-pair

Function

The **pki import rsa-key-pair** command imports the RSA key pair to the device memory.

Format

pki import rsa-key-pair *key-name* [**include-cert realm** *realm-name*] { **pem** | **pkcs12** } *file-name* [**exportable**] [**password** *password*]

pki import rsa-key-pair *key-name* **der** *file-name* [**exportable**]

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair on the device.	The value is a string of 1 to 64 characters and case-sensitive without spaces or question marks (?). If the character string is enclosed in double quotation marks (" "), the character string can contain spaces.
include-cert	Indicates that the certificates in the file will be imported.	-
realm *realm-name*	Specifies the PKI realm name of the imported certificate.	The value must be an existing PKI realm name.
pem *file-name*	Indicates that the RSA key pair to be imported is in the PEM format and specifies the file name to store the RSA key pair.	The value must be an existing certificate file name that stores the RSA key pair and the certificate.
pkcs12 *file-name*	Indicates that the RSA key pair to be imported is in the PKCS12 format and specifies the file name to store the RSA key pair.	The value must be an existing certificate file name that stores the RSA key pair and the certificate.

Parameter	Description	Value
der *file-name*	Indicates that the RSA key pair to be imported is in the DER format and specifies the file name to store the RSA key pair.	The value must be an existing certificate file name that stores the RSA key pair and the certificate.
exportable	Indicates that the imported RSA key pair can be exported.	-
password *password*	Specifies the decryption password of the RSA key pair. The password is the same as the password configured using the **pki export rsa-key-pair** command.	The value must be the name of an existing decryption password of the RSA key pair. **NOTE** If the RSA key pair file does not have a decryption password, you need to enter any character. Otherwise, the import will fail.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Run this command to use the RSA key pair generated by other entities. After the configuration, the imported RSA key pair can be referenced by the PKI module for operations such as signing.

NOTE

Windows Server 2003 has a low processing performance. For the device to connect to a Windows Server 2003, the device cannot have too many entities configured or use a large-sized key pair.

If you do not know the format of the key pair you want to import, configure each format in turn and check whether the key pair is successfully imported.

Prerequisites

The RSA key pair must already exist on the storage device.

Example

Import the RSA key pair **aaa.pem**. In the system, the RSA key pair is named **key-1**, is marked **exportable** and has the decryption password YsHsjx_202206.

```
<HUAWEI> system-view
[HUAWEI] pki import rsa-key-pair key-1 pem aaa.pem exportable password YsHsjx_202206
 Info: Succeeded in importing the RSA key pair in PEM format.
```

14.19.78 pki key enhance enable

Function

The **pki key enhance enable** command enables the PKI module to use the enhanced key algorithm for encryption and decryption.

The **undo pki key enhance enable** command disables the PKI module from using the enhanced key algorithm for encryption and decryption.

By default, the PKI module is enabled to use the enhanced key algorithm for encryption and decryption.

Format

pki key enhance enable

undo pki key enhance enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In V200R020C00SPC300 and later versions, the PKI module uses the enhanced key algorithm for encryption and decryption by default. The enhanced key algorithm is incompatible with the key algorithm used by the PKI module in versions earlier than V200R020C00SPC300. Therefore, before downgrading a device from V200R020C00SPC300 or a later version to a version earlier than V200R020C00SPC300, run the **undo pki key enhance enable** command to disable this function so that the PKI module uses the same key algorithm before and after the device downgrade, ensuring service continuity.

Precautions

When a device is upgraded from a version earlier than V200R020C00SPC300 to V200R020C00SPC300 or a later version, the **undo pki key enhance enable** command is automatically added to the configuration file of the device to ensure upgrade compatibility.

Example

Before a device is downgraded from V200R020C00SPC300 or a later version to a version earlier than V200R020C00SPC300, disable the PKI module from using the enhanced key algorithm for encryption and decryption so that the key algorithms before and after the downgrade are the same.

```
<HUAWEI> system-view
[HUAWEI] undo pki key enhance enable
 Warning: The current operation has security risks. You are not advised to perform this operation.
```

14.19.79 pki match-rsa-key

Function

The **pki match-rsa-key** command configures a device to search for the RSA key pair associated with a specific certificate.

Format

pki match-rsa-key certificate-filename *file-name*

Parameters

Parameter	Description	Value
certificate-filename *file-name*	Specifies the name of a certificate file.	The value must be an existing certificate file name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Run this command to check the RSA key pair corresponding to a certificate. After configuration, the system searches for all the local RSA key pairs, compares them with the specified certificate and outputs the matched RSA key pair name once it is searched out.

Example

Configure a device to search for the RSA key pair that matches the certificate file **local.cer**.

```
<HUAWEI> system-view
[HUAWEI] pki match-rsa-key certificate-filename local.cer
 Info: The file local.cer contains certificates 1.
 Info: Certificate 1 from file local.cer matches RSA key rsa2.key.
```

14.19.80 pki ocsp response cache enable

Function

The **pki ocsp response cache enable** command enables a PKI entity to cache OCSP responses.

The **undo pki ocsp response cache enable** command disables a PKI entity from caching OCSP responses.

By default, OCSP response caching is disabled on a PKI entity.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

pki ocsp response cache enable

undo pki ocsp response cache enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

After you enable a PKI entity to cache OCSP responses, the PKI entity first searches its cache for the certificate revocation status. If the search fails, the PKI entity sends a request to the OCSP server. In addition, the PKI entity caches valid OCSP responses for subsequent query. OCSP responses have a validity period. With OCSP response caching enabled, a PKI entity refreshes the cached OCSP responses every minute to clear expired OCSP responses.

Example

Enable a PKI entity to cache OCSP responses.

```
<HUAWEI> system-view
[HUAWEI] pki ocsp response cache enable
```

14.19.81 pki ocsp response cache number

Function

The **pki ocsp response cache number** command sets the maximum number of OCSP responses that can be cached on a PKI entity.

The **undo pki ocsp response cache number** command restores the default maximum number of OCSP responses that can be cached on a PKI entity.

By default, the maximum number of OCSP responses that can be cached on a PKI entity is 2.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

pki ocsp response cache number *number*

undo pki ocsp response cache number

Parameters

Parameter	Description	Value
number	Specifies the maximum number of OCSP responses that can be cached on a PKI entity.	The value is an integer in the range from 1 to 1000.

Views

System view

Default Level

3: Management level

Usage Guidelines

A PKI entity caches valid OCSP responses for subsequent query. If the number of cached OCSP responses reaches the value specified by *number*, the PKI entity stops caching OCSP responses.

Example

Set the maximum number of OCSP responses that can be cached on a PKI entity to 3.

```
<HUAWEI> system-view
[HUAWEI] pki ocsp response cache number 3
```

14.19.82 pki ocsp response cache refresh interval

Function

The **pki ocsp response cache refresh interval** command sets the interval at which the OCSP response cache is refreshed.

The **undo pki ocsp response cache refresh interval** command restores the default interval at which a PKI entity refreshes the OCSP response cache.

By default, the interval at which a PKI entity refreshes the OCSP response cache is 5 minutes.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

pki ocsp response cache refresh interval *interval*

undo pki ocsp response cache refresh interval

Parameters

Parameter	Description	Value
interval	Specifies the interval at which the OCSP response cache is refreshed.	The value is an integer that ranges from 1 to 1440, in minutes. The default value is 5.

Views

System view

Default Level

3: Management level

Usage Guidelines

A PKI entity refreshes the OCSP response cache periodically and deletes the OCSP responses that have expired based on the *interval* value.

Example

Set the interval at which the OCSP response cache is refreshed to 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] pki ocsp response cache refresh interval 30
```

14.19.83 pki realm (system view)

Function

The **pki realm** command creates a PKI realm and displays the PKI realm view, or displays the view of an existing PKI realm.

The **undo pki realm** command deletes a PKI realm.

By default, the device has a PKI realm named **default**. This realm can only be modified but cannot be deleted.

Format

pki realm *realm-name*

undo pki realm *realm-name*

Parameters

Parameter	Description	Value
realm-name	Specifies the name of a PKI realm.	The value is a string of 1 to 64 case-insensitive characters. It cannot contain spaces or slashes (/).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A PKI realm is a set of identity information required when a PKI entity enrolls a certificate.

Precautions

A PKI realm configured on a device is unavailable to certificate authorities (CAs) or other devices.

When a certificate is requested using a PKI realm, the system names the certificate file *PKI realm name***_local.cer**. Therefore, ensure that the name of a created PKI realm does not exceed 50 characters. Otherwise, the certificate file name may exceed 64 characters and cannot be saved on a storage device.

The name of a CRL file requested using a PKI realm is suffixed with .crl. Therefore, ensure that the name of a created PKI realm does not exceed 52 characters. Otherwise, the CRL file name may exceed 64 characters and cannot be saved on a storage device.

Example

Create a PKI realm named **abc**.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc]
```

14.19.84 pki release-certificate peer

Function

The **pki release-certificate peer** command releases a certificate of the remote device.

Format

pki release-certificate peer { **name** *peer-name* | **all** }

Parameters

Parameter	Description	Value
name *peer-name*	Specifies the name of peer certificate to be released.	The value must be an existing peer certificate file name.
all	Releases all certificates of the remote device.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the specified certificate of the remote device is not required, run the **pki release-certificate peer** command to release the certificate of the remote device.

Before using this command, run the **display pki peer-certificate** command to view the certificate information of the remote device.

Prerequisites

The **pki import-certificate peer** command has been used to import the certificate of the remote device.

Example

Release the certificate **test** of the remote device.

```
<HUAWEI> system-view
[HUAWEI] pki release-certificate peer name test
 Info: Succeeded in releasing the peer certificate.
```

14.19.85 pki rsa local-key-pair create

Function

The **pki rsa local-key-pair create** command creates the specified RSA key pair.

Format

pki rsa local-key-pair create *key-name* [**modulus** *modulus-size*] [**exportable**]

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair to be created.	The value is a string of 1 to 64 case-sensitive characters without question marks (?) and spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
modulus *modulus-size*	Specifies the size of the RSK key pair.	The value is an integer that ranges from 3072 to 4096. The default value is 3072. After the WEAKEA plug-in is installed, the value is an integer that ranges from 2048 to 4096. A key of less than 3072 bits has security risks. You are advised to use a key of 3072 bits or more.
exportable	Indicates that the new RSA key pair can be exported from the device.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When a PKI entity requests a certificate from the CA, the certificate enrollment request that it sends contains information such as the public key. Run this command to create the RSA key pair for the certificate request.

NOTE

Windows Server 2003 has a low processing performance. For the device to connect to a Windows Server 2003, the device cannot have too many entities configured or use a large-sized key pair.

Precautions

When creating the key pair, the system prompts the user to enter the number of bits of the RSA key pair. The longer the key pair, the harder it is to crack, and the more secure but slow the encryption algorithm. It is recommended that the number of bits of the RSA key pair exceed 2048; otherwise, it has security risks.

The name of an RSA key pair cannot exceed 50 characters. Because when an RSA key pair is imported, if the certificate is imported at the same time, the PKI system adds **_localx.cer** after the name of the RSA key pair to generate a new certificate file name, and saves it to the storage component. If the name exceeds 50 characters, the total number of characters exceeds 64, and the certificate file cannot be saved to the storage component.

The RSA key pair referenced by PKI realms cannot be overwritten. They can be overwritten only after the reference relationship is removed.

If the name of the new RSA key pair is the same as that of a pair on the device, the system prompts the user to decide whether to overwrite the existing pair.

Example

Create 4096-bit RSA key pair **test**.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create test
 Info: The name of the new key-pair will be: test
 The size of the public key ranges from 3072 to 4096.
 Input the bits in the modules:4096
 Generating key-pairs...
......+++
.......+++
```

14.19.86 pki rsa local-key-pair destroy

Function

The **pki rsa local-key-pair destroy** command deletes the specified RSA key pair.

Format

pki rsa local-key-pair destroy *key-name*

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair to be deleted.	The value must be the name of an existing key pair.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

It is recommended that you run this command to destroy the specified RSA key pair if it is leaked, damaged, unused, or lost.

After this command is executed, the specified RSA key pair is deleted from the active device and the standby device.

Prerequisites

The RSA key pair has been created using the **pki rsa local-key-pair create** command or the RSA key pair has been imported to the memory using the **pki import rsa-key-pair** command.

Precautions

The RSA key pair in the creation process cannot be deleted.

The RSA key pair referenced by a PKI realm or CMP session cannot be deleted. They can be deleted only after the reference relationship is removed.

Example

Delete the RSA key pair **test**.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create test
 Info: The name of the new key-pair will be: test
 The size of the public key ranges from 512 to 4096.
 Input the bits in the modules:2048
 Generating key-pairs...
.....+++
```

```
.........................+++
[HUAWEI] pki rsa local-key-pair destroy test
 Warning: The name of the key pair to be deleted is test.
 Are you sure you want to delete the key pair? [y/n]:y
 Info: Delete RSA key pair success.
```

14.19.87 pki set-certificate expire-prewarning

Function

The **pki set-certificate expire-prewarning** command sets the expiration warning date for the local certificate and the CA certificate in the memory.

The **undo pki set-certificate expire-prewarning** command restores the default expiration warning date for the local certificate and the CA certificate in the memory.

By default, the expiration warning date for the local certificate and the CA certificate in the memory is 90 days.

Format

pki set-certificate expire-prewarning *day*

undo pki set-certificate expire-prewarning

Parameters

Parameter	Description	Value
day	Specifies the expiration warning date.	The value is an integer that ranges from 7 to 180. By default, the value is 90.

Views

System view

Default Level

3: Management level

Usage Guidelines

After this command is executed, you will be prompted the expiration of a certificate in advance. If the system detects that a certificate in the memory is to expire in less than *day*, the device sends an expiration warning to the user.

Example

Set the expiration warning date for the local certificate and the CA certificate in the memory as 30 days.

```
<HUAWEI> system-view
[HUAWEI] pki set-certificate expire-prewarning 30
```

14.19.88 pki validate ocsp-server-certificate enable

Function

The **pki validate ocsp-server-certificate enable** command enables the function that uses the OCSP server certificate to verify OCSP server packets.

The **undo pki validate ocsp-server-certificate enable** command disables the function that uses the OCSP server certificate to verify OCSP server packets.

By default, the function that uses the OCSP server certificate to verify OCSP server packets is enabled.

Format

pki validate ocsp-server-certificate enable

undo pki validate ocsp-server-certificate enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

For security purposes, you are advised to enable the function that uses the OCSP server certificate to verify OCSP server packets. If OCSP server packets fail the verification, the device discards these packets.

Precautions

If the imported OCSP server certificate is not the correct one, OCSP server packets fail the verification, causing the local certificate to become unavailable. To prevent this problem, import the correct OCSP server certificate. If no OCSP server certificate can be obtained, run the **undo pki validate ocsp-server-certificate enable** command to disable the function that uses the OCSP server certificate to verify OCSP server packets.

Example

Enable the function that uses the OCSP server certificate to verify OCSP server packets.

```
<HUAWEI> system-view
[HUAWEI] pki validate ocsp-server-certificate enable
```

14.19.89 pki validate-certificate

Function

The **pki validate-certificate** command allows you to verify the validity of a CA certificate or a local certificate.

Format

pki validate-certificate { **ca** | **local** } **realm** *realm-name*

Parameters

Parameter	Description	Value
ca	Checks validity of the CA certificate.	-
local	Checks validity of the local certificate.	-
realm *realm-name*	Specifies the PKI realm name of a certificate to be checked.	The value must be an existing PKI realm name.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When an end entity verifies a peer certificate, it checks the status of the peer certificate. For example, the end entity checks whether the peer certificate has expired and whether the certificate is in a CRL.

To verify the validity of a CA certificate or a local certificate, run the **pki validate-certificate** command.

Prerequisites

A PKI realm has been configured using the **pki realm (system view)** command.

Precautions

The **pki validate-certificate ca** command allows you to verify only the root CA certificate, but not subordinate CA certificates. When multiple CA certificates are imported on a device, you can use only the **pki validate-certificate local** command to verify the validity of subordinate certificates.

Example

Configure the device to check validity of the local certificate using CRL.

```
<HUAWEI> system-view
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] certificate-check crl
[HUAWEI-pki-realm-abc] quit
[HUAWEI] pki validate-certificate local realm abc
 Info: It will take a few seconds or more to validate specified certificate. Please wait a moment.
 Info: Local encryption certificate is valid.
 Info: It will take a few seconds or more to validate specified certificate. Please wait a moment.
 Info: Local signature certificate is valid.
```

14.19.90 reset pki cmp statistics

Function

The **reset pki cmp statistics** command clears the statistics on CMP sessions.

Format

reset pki cmp statistics [**session** *session-name*]

Parameters

Parameter	Description	Value
session *session-name*	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

If a CMP session is specified, this command will clear the statistics of the session. If no CMP session is specified, this command will clear the statistics of all sessions.

Example

Clear statistics on the CMP session **test**.

```
<HUAWEI> reset pki cmp statistics session test
```

14.19.91 reset pki ocsp response cache

Function

The **reset pki ocsp response cache** command resets an OCSP response cache.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

reset pki ocsp response cache

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The PKI entity caches valid OCSP responses for future searches. If the number of cached OCSP responses reaches the maximum value, no more OCSP responses can be cached. To ensure that the latest OCSP responses can be cached, you can run this command to clear the OCSP response cache first.

Example

Reset an OCSP response cache.

```
<HUAWEI> reset pki ocsp response cache
```

14.19.92 reset pki ocsp server down-information

Function

The **reset pki ocsp server down-information** command clears Down state information of the OCSP server recorded on the device.

NOTE

This command is available only on NETCONF-supporting switch models.

Format

reset pki ocsp server down-information [**url** [**esc**] *url-addr*]

Parameters

Parameter	Description	Value
url [**esc**] *url-addr*	Specifies the OCSP server's URL address. If no URL address is specified, clear Down state information of all OCSP servers. If the **esc** parameter is specified, the URL address in ASCII format is supported.	The value is a string starting with http:// and consisting of 1 to 128 case-sensitive characters without spaces.

Views

User view

Default Level

3: Management level

Usage Guidelines

There is a mechanism to determine whether the OCSP server is Down. When the OCSP server corresponding to a URL cannot be accessed, the server status is set to Down. In this case, the device will not send OCSP requests to the URL within 10 minutes. However, this mechanism may falsely set the state of a transiently disconnected server to Down. Using this command, the user can manually clear the falsely reported Down state of the OCSP server so that the device can send OCSP requests to the server.

The keyword **esc** supports the entering of URLs that include the question mark (?) in ASCII code. The URL must be in **\x3f** format, and **3f** is the hexadecimal ASCII code for the question mark (?). For example, if a user wants to enter **http://***.com?page1**, the URL is **http://***.com\x3fpage1**. If a user wants to enter **http://www.***.com?page1\x3f** that includes both a question mark (?) and **\x3f**, the URL is **http://www.***.com\x3fpage1\\x3f**.

Example

Clear the OCSP server Down information of the specified URL.

```
<HUAWEI> reset pki ocsp server down-information
```

14.19.93 rsa local-key-pair

Function

The **rsa local-key-pair** command configures the RSA key pair used to request a certificate using SCEP or in offline mode.

The **undo rsa local-key-pair** command deletes the RSA key pair used to request a certificate using SCEP or in offline mode.

By default, the system does not configure the RSA key pair used to request a certificate using SCEP or in offline mode.

Format

rsa local-key-pair *key-name*

undo rsa local-key-pair

Parameters

Parameter	Description	Value
key-name	Specifies the name of the RSA key pair.	The value must be an existing RSA key pair name.

Views

PKI realm view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The PKI entity that requests a certificate from the CA using SCEP or in offline PKCS#10 mode must contain a public key. Run this command to configure the RSA key pair.

Prerequisites

The RSA key pair for certificate application has been created using the **pki rsa local-key-pair create** command or the RSA key pair has been imported to the memory using the **pki import rsa-key-pair** command.

Precautions

- An RSA key pair can be referenced by only one PKI realm.

Example

Configure the RSA key pair that is referenced by the PKI realm **test**.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create test
 Info: The name of the new key-pair will be: test
 The size of the public key ranges from 2048 to 4096.
 Input the bits in the modules:2048
 Generating key-pairs...
.........................+++
```

```
.................................................................................
........+++
[HUAWEI] pki realm test
[HUAWEI-pki-realm-test] rsa local-key-pair test
```

14.19.94 serial-number

Function

The **serial-number** command adds the serial number of a device to a PKI entity.

The **undo serial-number** command restores the default setting.

By default, the serial number of a device is not added to a PKI entity.

Format

serial-number

undo serial-number

Parameters

None

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity include the identity information of the PKI entity. The CA identifies a certificate applicant based on identity information provided by a PKI entity. To further identify the applicant, add the serial number of the device to the PKI entity.

After the serial number of the device is added to a PKI entity, the certificate request packet sent by the device to the CA server carries this serial number. After receiving the certificate request packet, the CA server verifies the packet. For each valid packet, the CA server generates a digital certificate carrying the device serial number.

Example

Add the serial number of the device to a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] serial-number
```

14.19.95 source

Function

The **source** command configures the source address used in TCP connection setup.

The **undo source** command restores the default setting.

By default, the device uses an outbound interface's IP address as the source IP address used in TCP connection setup.

Format

source { **interface** *interface-type interface-number* | *ip-address* }

undo source

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies an interface's IP address as the source IP address used in TCP connection setup. - *interface-type* indicates the interface type. - *interface-number* indicates the interface number.	-
ip-address	Specifies the source address used in TCP connection setup.	An IPv4 address is in dotted decimal notation, whereas an IPv6 address is in colon-separated hexadecimal notation. **NOTE** The CMP session view does not support the configuration of an IPv6 address. The value is in dotted decimal notation.

Views

PKI realm view or CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the device needs to establish a TCP connection with an SCEP or OCSP server, you must run the **source** command to specify the source IP address used in TCP connection setup.

In the multi-output scenario, if the interfaces for sending and receiving a TCP packet are different, the IP address in the received TCP packet is different from the IP address of the receiving interface. Then the TCP packet is dropped, and the TCP connection is torn down. In this situation, you can run this command to specify the loopback interface address.

Precautions

If the source interface used in TCP connection setup has been specified, the source interface must be a Layer 3 interface with an IP address configured.

The VPN instance bound to the interface specified by the **source interface** command in the CMP session view must be the same as the VPN instance configured in the **vpn-instance**. If they are inconsistent, either **source interface** or **vpn-instance**, which is configured later, cannot be executed successfully.

Example

Configure the IP address of VLANIF 100 as the source address used in TCP connection setup.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.136.2.25 24
[HUAWEI-Vlanif100] quit
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] source interface vlanif 100
```

14.19.96 state (PKI entity view)

Function

The **state** command configures a state or province name for a PKI entity.

The **undo state** command deletes the configuration.

By default, no state or province name is configured for a PKI entity.

Format

state *state-name*

undo state

Parameters

Parameter	Description	Value
state-name	Specifies the state or province name of a PKI entity.	The value is a string of 1 to 32 case-sensitive characters, including letters, numerals, apostrophes ('), equal signs (=), parentheses (), plus signs (+), commas (,), minus signs (-), periods (.), slashes (/), colons (:), and spaces.

Views

PKI entity view

Default Level

2: Configuration level

Usage Guidelines

The parameters of a PKI entity contain the identity information of the entity. The CA identifies a certificate applicant based on identity information provided by the entity. To facilitate applicant identification, configure a state or province name for a PKI entity.

After the state or province name is configured for a PKI entity, the certificate request packet sent by the device to the CA server contains this province name. The CA server verifies every received certificate request packet. For each valid packet, the CA server generates a digital certificate carrying the state or provision name of the PKI entity.

Example

Configure the province name to **Jiangsu** for a PKI entity.

```
<HUAWEI> system-view
[HUAWEI] pki entity entity1
[HUAWEI-pki-entity-entity1] state Jiangsu
```

14.19.97 undo pki cmp poll-request session

Function

The **undo pki cmp poll-request session** command cancels CMP polling requests.

Format

undo pki cmp poll-request session *session-name*

Parameters

Parameter	Description	Value
session-name	Specifies the name of a CMP session.	The value must be an existing CMP session name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the server cannot deliver the results immediately after the client initiates certificate-related requests, the server requires the client to send the requests in polling mode until the server deliver the final result. The process duration varies with the actual situation. To cancel the process, run the command. Then the certificate-related request is also canceled.

Prerequisites

A CMP session has been created using the **pki cmp session** command.

Example

Cancel CMP polling requests.

```
<HUAWEI> system-view
[HUAWEI] pki cmp session test
[HUAWEI-pki-cmp-session-test] quit
[HUAWEI] undo pki cmp poll-request session test
```

14.19.98 vpn-instance

Function

The **vpn-instance** command adds a PKI realm to a specified VPN.

The **undo vpn-instance** command unbinds a PKI realm from a specified VPN.

By default, a PKI realm is not added to any VPN.

Format

PKI realm view

vpn-instance *vpn-instance-name*

undo vpn-instance

CMP session view

vpn-instance { **vpn-name** *vpn-instance-name* }

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

PKI realm view or CMP session view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To obtain and verify certificates, the device needs to communicate with the CA or SCEP server. When the CA or SECP server is in a VPN, add the PKI realm to the specified VPN.

Prerequisites

1. A VPN instance has been created using the **ip vpn-instance** command.
2. The RD has been configured using the **route-distinguisher** command.

Precautions

The VPN instance bound to the interface specified by the **source** command in the CMP session view must be the same as the VPN instance configured in the **vpn-instance**. If they are inconsistent, either **source** or **vpn-instance**, which is configured later, cannot be executed successfully.

Example

Add a PKI realm to the VPN named **vrf1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] route-distinguisher 22:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] quit
[HUAWEI-vpn-instance-vrf1] quit
[HUAWEI] pki realm abc
[HUAWEI-pki-realm-abc] vpn-instance vrf1
```

14.20 OLC Configuration Commands

14.20.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

14.20.2 cpu-overload-control

Function

The **cpu-overload-control** command configures the CPU usage thresholds and adjustment factor of the leak rate.

The **undo cpu-overload-control** command restores the default CPU usage thresholds and adjustment factor of the leak rate.

By default, the level-1 CPU usage threshold is 95%, the level-2 CPU usage threshold is 98%, and the adjustment factor of the leak rate is 10.

Format

cpu-overload-control { **threshold1** *threshold1–value* | **threshold2** *threshold2–value* | **adjustfactor** *adjustfactor–value* } * **slot** *slot-id*

undo cpu-overload-control { **threshold1** *threshold1–value* | **threshold2** *threshold2–value* | **adjustfactor** *adjustfactor–value* } * **slot** *slot-id*

Parameters

Parameter	Description	Value
threshold1 *threshold1–value*	Specifies the level-1 CPU usage threshold.	The value is an integer in the range from 70 to 95, in percentages.
threshold2 *threshold2–value*	Specifies the level-2 CPU usage threshold.	The value is an integer in the range from 71 to 100, in percentages.
adjustfactor *adjustfactor–value*	Specifies the adjustment factor of the leak rate.	The value is an integer in the range from 1 to 1000.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Only when the CPU usage reaches the OLC start threshold (the same as the level-1 CPU usage threshold), the OLC function is started to lower the leak rate so that the rate of packets sent to the CPU is lowered. When the CPU usage reaches the level-2 CPU usage threshold, the system lowers the leak rate twice as fast. When the CPU usage falls below the OLC stop threshold (the level-1 CPU usage threshold minus 20%), the OLC function is stopped. The adjustment factor specifies the frequency at which the leak rate is adjusted. The smaller the adjustment factor, the faster the adjustment frequency, and vice versa. A smaller adjustment factor will allow the system to adjust more quickly to service changes but may lead t o flapping of the leak rate. The default leak rate is recommended.

Example

Set the level-1 CPU usage threshold to 90%, level-2 CPU usage threshold to 95%, and adjustment factor of the leak rate to 15 in slot 0.

```
<HUAWEI> system-view
[HUAWEI] cpu-overload-control threshold1 90 threshold2 95 adjustfactor 15 slot 0
```

14.20.3 cpu-overload-control alarm disable

Function

The **cpu-overload-control alarm disable** command disables the OLC alarm function.

The **undo cpu-overload-control alarm disable** command enables the OLC alarm function.

By default, the OLC alarm function is enabled.

Format

cpu-overload-control alarm disable

undo cpu-overload-control alarm disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, the OLC alarm function is enabled. When the CPU usage is greater than the OLC start threshold or lower than the OLC stop threshold, an alarm is generated to notify users of the CPU running status and the status of the OLC function.

When the service traffic of monitored protocols or tasks on the live network is light and the CPU usage remains stably low, you can disable the OLC alarm function.

Example

Enable the OLC alarm function.

```
<HUAWEI> system-view
[HUAWEI] undo cpu-overload-control alarm disable
```

14.20.4 cpu-overload-control bucket-weight

Function

The **cpu-overload-control bucket-weight** command configures the weight of a protocol or task leaky bucket.

The **undo cpu-overload-control bucket-weight** command restores the default weight of a protocol or task leaky bucket.

The default weight of the leaky bucket is 90 for 8021x-1st, 200 for 8021x-other, 290 for arp-request, arp-reply, icmp, dhcp, arp-miss, igmp, ttl-expired, ip-frag, fib-hit, icmpv6, dhcpv6, mld, and nd, 250 for cos-4, 240 for cos-3, 200 for cos-2, 150 for cos-1, 100 for cos-0, and 2500 for acl and arpa tasks.

Format

cpu-overload-control { **packet-type** *packet-type* | **task** *task-name* } **bucket-weight** *bucket-weight-value* **slot** *slot-id*

undo cpu-overload-control { **packet-type** *packet-type* | **task** *task-name* } **bucket-weight** *bucket-weight-value* **slot** *slot-id*

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies a protocol type.	The value is of the enumerated type: - 8021x-1st: first fragment of an 802.1X packet - 8021x-other: non-first fragments of an 802.1X packet - arp-request: ARP Request packet - arp-reply: ARP Reply packet - icmp: ICMP packet - dhcp: DHCP packet - arp-miss: ARP Miss packet - igmp: IGMP packet - ttl-expired: IPv4 TTL-expired packet - ip-frag: IP fragment - fib-hit: packet matching a route - icmpv6: ICMPv6 packet - dhcpv6: DHCPv6 packet - mld: MLD packet - nd: IPv6 neighbor discovery packet - cos-4: packet with priority 4 or higher (excluding whitelisted protocol packets) - cos-3: packet with priority 3 (excluding whitelisted protocol packets) - cos-2: packet with priority 2 (excluding whitelisted protocol packets) - cos-1: packet with priority 1 (excluding

Parameter	Description	Value
		whitelisted protocol packets) - cos-0: packet with priority 0 (excluding whitelisted protocol packets) **NOTE** S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S do not support arp-miss parameter.
task *task-name*	Specifies a task name.	The value is of the enumerated type: - acl: indicates the ACL task. - arpa: indicates the ARP broadcast task.
bucket-weight-value	Specifies the weight of the leaky bucket for the protocol or task.	The value is an integer in the range from 50 to 5000.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Each protocol or task for which OLC is enabled is associated with a bottom leaky bucket. By default, the device assigns each leaky bucket a weight based on priorities of the monitored protocols and tasks. The weight of a leaky bucket determines its weighted water level (that is, the number of tokens that it can apply for). You can run this command to configure weights of the leaky buckets for monitored protocols and tasks based on service requirements.

Example

Set the weight of the leaky bucket for the DHCP protocol to 500 in slot 0.

```
<HUAWEI> system-view
[HUAWEI] cpu-overload-control packet-type dhcp bucket-weight 500 slot 0
```

14.20.5 cpu-overload-control disable

Function

The **cpu-overload-control disable** command disables the OLC function.

The **undo cpu-overload-control disable** command enables the OLC function.

By default, the OLC function is enabled.

Format

cpu-overload-control disable slot *slot-id*

undo cpu-overload-control disable slot *slot-id*

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a complex live network, the CPU may be overloaded if a large amount of service traffic is sent to the CPU or the CPU is attacked by unauthorized services. CPU overload will affect both the device's performance and its ability to process services.

OLC monitors certain CPU-bound protocol packets and tasks. According to the priorities of different services, OLC rate-limits the monitored protocol packets and tasks if the CPU usage exceeds a certain threshold. In this way, OLC not only reduces consumption of CPU resources but also prevents CPU overload from affecting normal processing of other services.

When the service traffic of monitored protocols or tasks on the live network is light and the CPU usage remains stably low, you can disable the OLC function.

Precautions

The OLC function configured for a protocol or task takes effect only after the OLC function is enabled.

Example

Enable the OLC function in slot 0.

```
<HUAWEI> system-view
[HUAWEI] undo cpu-overload-control disable slot 0
```

14.20.6 cpu-overload-control packet-type disable

Function

The **cpu-overload-control packet-type disable** command disables the OLC function for a monitored protocol.

The **undo cpu-overload-control packet-type disable** command enables the OLC function for a monitored protocol.

By default, the OLC function is enabled for all monitored protocols.

Format

cpu-overload-control packet-type *packet-type* &<1-20> **disable slot** *slot-id*

undo cpu-overload-control packet-type *packet-type* &<1-20> **disable slot** *slot-id*

Parameters

Parameter	Description	Value
packet-type	Specifies a protocol type.	The value is of the enumerated type: - 8021x-1st: first fragment of an 802.1X packet - 8021x-other: non-first fragments of an 802.1X packet - arp-request: ARP Request packet - arp-reply: ARP Reply packet - icmp: ICMP packet - dhcp: DHCP packet - arp-miss: ARP Miss packet - igmp: IGMP packet - ttl-expired: IPv4 TTL-expired packet - ip-frag: IP fragment - fib-hit: packet matching a route - icmpv6: ICMPv6 packet - dhcpv6: DHCPv6 packet - mld: MLD packet - nd: IPv6 neighbor discovery packet - cos-4: packet with priority 4 or higher (excluding whitelisted protocol packets) - cos-3: packet with priority 3 (excluding whitelisted protocol packets) - cos-2: packet with priority 2 (excluding whitelisted protocol packets) - cos-1: packet with priority 1 (excluding

Parameter	Description	Value
		whitelisted protocol packets) - cos-0: packet with priority 0 (excluding whitelisted protocol packets) **NOTE** S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S do not support arp-miss parameter. One or more of the preceding protocol types can be selected.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the OLC function is enabled for all monitored protocols to prevent CPU overload caused by a large number of CPU-bound packets of a certain protocol or attacks from unauthorized services. When the service traffic of a monitored protocol on the live network is light, you can disable the OLC function for the protocol.

Precautions

The OLC function configured for a protocol takes effect only after the OLC function is enabled.

Example

Enable the OLC function for the DHCP protocol in slot 0.

```
<HUAWEI> system-view
[HUAWEI] undo cpu-overload-control packet-type dhcp disable slot 0
```

14.20.7 cpu-overload-control task enable

Function

The **cpu-overload-control task enable** command enables OLC for a specified monitoring task.

The **undo cpu-overload-control task enable** command disables OLC for a specified monitoring task.

By default, OLC is disabled for all monitoring tasks.

Format

cpu-overload-control task *task-name* &<1-2> **enable slot** *slot-id*

undo cpu-overload-control task *task-name* &<1-2> **enable slot** *slot-id*

Parameters

Parameter	Description	Value
task-name	Specifies the task name.	The value is of the enumerated type: - acl: indicates the ACL task. - arpa: indicates the ARP broadcast task. You can select one or two of the preceding task names.
slot *slot-id*	Specifies the slot ID.	The value must be the ID of an existing chip on the device.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, OLC is disabled for ACL tasks and ARP broadcast tasks. To prevent CPU overload due to a type of tasks sending a large number of packets to the CPU, you can enable OLC for this type of tasks.

Precautions

OLC of the monitoring task takes effect only after the function is enabled.

Example

Enable OLC for ACL tasks in slot 0.

```
<HUAWEI> system-view
[HUAWEI] cpu-overload-control task acl enable slot 0
```

14.20.8 display cpu-overload-control configuration

Function

The **display cpu-overload-control configuration** command displays the OLC configuration.

Format

display cpu-overload-control configuration [**packet-type** *packet-type* | **task** *task-name*] **slot** *slot-id*

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies a protocol type.	The value is of the enumerated type: - 8021x-1st: first fragment of an 802.1X packet - 8021x-other: non-first fragments of an 802.1X packet - arp-request: ARP Request packet - arp-reply: ARP Reply packet - icmp: ICMP packet - dhcp: DHCP packet - arp-miss: ARP Miss packet - igmp: IGMP packet - ttl-expired: IPv4 TTL-expired packet - ip-frag: IP fragment - fib-hit: packet matching a route - icmpv6: ICMPv6 packet - dhcpv6: DHCPv6 packet - mld: MLD packet - nd: IPv6 neighbor discovery packet - cos-4: packet with priority 4 or higher (excluding whitelisted protocol packets) - cos-3: packet with priority 3 (excluding whitelisted protocol packets) - cos-2: packet with priority 2 (excluding whitelisted protocol packets) - cos-1: packet with priority 1 (excluding

Parameter	Description	Value
		whitelisted protocol packets) - cos-0: packet with priority 0 (excluding whitelisted protocol packets) **NOTE** S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S do not support arp-miss parameter. If this parameter is not specified, the OLC configuration in the specified slot is displayed.
task *task-name*	Specifies a task name.	The value is of the enumerated type: - acl: indicates the ACL task. - arpa: indicates the ARP broadcast task. If this parameter is not specified, the OLC configuration in the specified slot is displayed.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Table 14-111 Description of the **display cpu-overload-control configuration** command output

Item	Description
CPU OLC Status	Whether the OLC function is enabled: - enable - disable For details, see **cpu-overload-control disable**.

Item	Description
Alarm Status	Whether the OLC alarm function is enabled: ● enable ● disable For details, see **cpu-overload-control alarm disable**.
Low Threshold	Level-1 CPU usage threshold. For details, see **cpu-overload-control**.
High Threshold	Level-2 CPU usage threshold. For details, see **cpu-overload-control**.
Adjustfactor	Adjustment factor of the leak rate. For details, see **cpu-overload-control**.
Total Weight	Total weights of all protocol or task leaky buckets.
Task	Task name.
Protocol	Protocol type.
Weight	Weight of the leaky bucket for the protocol or task. For details, see **cpu-overload-control bucket-weight**.
Enable	Whether the OLC function is enabled for the protocol or task. For details, see **cpu-overload-control packet-type disable** and **cpu-overload-control task enable**.

14.20.9 display cpu-overload-control statistics

Function

The **display cpu-overload-control statistics** command displays OLC statistics.

Format

display cpu-overload-control statistics [**packet-type** *packet-type* | **task** *task-name*] **slot** *slot-id*

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies a protocol type.	The value is of the enumerated type: ● 8021x-1st: first fragment of an 802.1X packet ● 8021x-other: non-first fragments of an 802.1X packet ● arp-request: ARP Request packet ● arp-reply: ARP Reply packet ● icmp: ICMP packet ● dhcp: DHCP packet ● arp-miss: ARP Miss packet ● igmp: IGMP packet ● ttl-expired: IPv4 TTL-expired packet ● ip-frag: IP fragment ● fib-hit: packet matching a route ● icmpv6: ICMPv6 packet ● dhcpv6: DHCPv6 packet ● mld: MLD packet ● nd: IPv6 neighbor discovery packet ● cos-4: packet with priority 4 or higher (excluding whitelisted protocol packets) ● cos-3: packet with priority 3 (excluding whitelisted protocol packets) ● cos-2: packet with priority 2 (excluding whitelisted protocol packets) ● cos-1: packet with priority 1 (excluding

Parameter	Description	Value
		whitelisted protocol packets) - cos-0: packet with priority 0 (excluding whitelisted protocol packets) **NOTE** S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S do not support arp-miss parameter. If this parameter is not specified, OLC statistics in the specified slot are displayed.
task *task-name*	Specifies a task name.	The value is of the enumerated type: - acl: indicates the ACL task. - arpa: indicates the ARP broadcast task. If this parameter is not specified, OLC statistics in the specified slot are displayed.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Usage Guidelines

You can run this command to view OLC statistics of a specified protocol, task, or slot, including the number of protocol packets leaving or dropped by the leaky bucket, total running time of a task, and delay in processing a task.

Example

Display OLC statistics of the DHCP protocol in slot 0.

```
<HUAWEI> display cpu-overload-control statistics packet-type dhcp slot 0
-------------------------------------------------------------------------------
Protocol     Total pass     Total drop       Average pass     Average drop
             (packet)       (packet)         (packet)         (packet)
-------------------------------------------------------------------------------
dhcp         0              0                0                0
-------------------------------------------------------------------------------
```

Display OLC statistics of the ACL task in slot 0.

```
<HUAWEI> display cpu-overload-control statistics task ACL slot 0
-------------------------------------------------------------------------------
Task         Total Runtime  Total Delaytime  Average Runtime  Average Delaytime
               (ms)           (ms)             (ms)             (ms)
-------------------------------------------------------------------------------
acl          0              0                0                0
-------------------------------------------------------------------------------
```

Display OLC statistics in slot 0.

```
<HUAWEI> display cpu-overload-control statistics slot 0
-------------------------------------------------------------------------------
Task         Total Runtime  Total Delaytime  Average Runtime  Average Delaytime
               (ms)           (ms)             (ms)             (ms)
-------------------------------------------------------------------------------
arpa         3170           0                0                0
acl          0              0                0                0
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Protocol     Total Pass     Total Drop       Average Pass     Average Drop
             (packet)       (packet)         (packet)         (packet)
-------------------------------------------------------------------------------
8021x-1st    0              0                0                0
8021x-other  0              0                0                0
arp-request  0              0                0                0
arp-reply    0              0                0                0
icmp         0              0                0                0
dhcp         0              0                0                0
arp-miss     0              0                0                0
igmp         0              0                0                0
ttl-expired  0              0                0                0
ip-frag      0              0                0                0
fib-hit      0              0                0                0
icmpv6       0              0                0                0
dhcpv6       0              0                0                0
nd           0              0                0                0
mld          0              0                0                0
cos-4        0              0                0                0
cos-3        0              0                0                0
cos-2        0              0                0                0
cos-1        0              0                0                0
cos-0        0              0                0                0
-------------------------------------------------------------------------------
```

Table 14-112 Description of the **display cpu-overload-control statistics** command output

Item	Description
Task	Task name.
Total Runtime	Total running time of the task, in milliseconds.
Total Delaytime	Total delay in processing the task, in milliseconds.
Average Runtime	Running time of the task in the last second, in milliseconds.
Average Delaytime	Delay in processing the task in the last second, in milliseconds.
Protocol	Protocol type.
Total Pass	Total number of protocol packets leaving the leaky bucket.
Total Drop	Total number of protocol packets dropped by the leaky bucket.
Average Pass	Number of protocol packets leaving the leaky bucket in the last second.
Average Drop	Number of protocol packets dropped by the leaky bucket in the last second.

14.20.10 reset cpu-overload-control statistics

Function

The **reset cpu-overload-control statistics** command clears OLC statistics.

Format

reset cpu-overload-control statistics [**packet-type** *packet-type* | **task** *task-name*] **slot** *slot-id*

Parameters

Parameter	Description	Value
packet-type *packet-type*	Specifies a protocol type.	The value is of the enumerated type: - 8021x-1st: first fragment of an 802.1X packet - 8021x-other: non-first fragments of an 802.1X packet - arp-request: ARP Request packet - arp-reply: ARP Reply packet - icmp: ICMP packet - dhcp: DHCP packet - arp-miss: ARP Miss packet - igmp: IGMP packet - ttl-expired: IPv4 TTL-expired packet - ip-frag: IP fragment - fib-hit: packet matching a route - icmpv6: ICMPv6 packet - dhcpv6: DHCPv6 packet - mld: MLD packet - nd: IPv6 neighbor discovery packet - cos-4: packet with priority 4 or higher (excluding whitelisted protocol packets) - cos-3: packet with priority 3 (excluding whitelisted protocol packets) - cos-2: packet with priority 2 (excluding whitelisted protocol packets) - cos-1: packet with priority 1 (excluding

Parameter	Description	Value
		whitelisted protocol packets) - cos-0: packet with priority 0 (excluding whitelisted protocol packets) **NOTE** S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S do not support arp-miss parameter. If this parameter is not specified, OLC statistics in the specified slot are cleared.
task *task-name*	Specifies a task name.	The value is of the enumerated type: - acl: indicates the ACL task. - arpa: indicates the ARP broadcast task. If this parameter is not specified, OLC statistics in the specified slot are cleared.
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To obtain OLC statistics in a specified period to locate faults of monitored protocols or tasks, you can run the **reset cpu-overload-control statistics** command to clear the previous OLC statistics of a specified protocol, task, or slot, and then run the **display cpu-overload-control statistics** command after a period of time to view the OLC statistics.

Precautions

The deleted OLC statistics cannot be restored. Therefore, exercise caution when running this command.

Example

Clear OLC statistics of the DHCP protocol in slot 0.

```
<HUAWEI> reset cpu-overload-control statistics packet-type dhcp slot 0
```

Clear OLC statistics of the ACL task in slot 0.

```
<HUAWEI> reset cpu-overload-control statistics task acl slot 0
```

Clear OLC statistics in slot 0.

```
<HUAWEI> reset cpu-overload-control statistics slot 0
```

14.21 ECA Configuration Commands

14.21.1 Command Support

Only the following switch models support ECA:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S

14.21.2 defence engine enable

Function

The **defence engine enable** command enables the IAE.

The **undo defence engine enable** command disables the IAE.

By default, the IAE is disabled.

Format

defence engine enable

undo defence engine enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To configure the ECA function, you need to run the **defence engine enable** command to enable the IAE.

Precautions

To enable the IAE in a stack, reserve at least 20 MB storage space on each member device.

Example

Enable the IAE.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
```

14.21.3 decoding uri-cache

Function

The **decoding uri-cache enable** command enables the URI cache function.

The **decoding uri-cache disable** command disables the URI cache function.

By default, the URI cache function is enabled.

Format

decoding uri-cache enable

decoding uri-cache disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If no threat is detected from the corresponding session traffic after the URI cache function is enabled, the system will not inspect the session traffic with the same URI in a period of time. If all traffic must be inspected, disable the URI cache function.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the URI cache function.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] decoding uri-cache enable
```

14.21.4 display decoding statistics

Function

The **display decoding statistics** command displays decoding statistics.

Format

display decoding statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view statistics about the decoding function, including the event statistics, traffic statistics, and file statistics of each application.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display IPS statistics.

```
<HUAWEI> display decoding statistics
Decoding statistic on slot 0 cpu 0 :
-----------------------------------------------------------------------------
Decoding Statistic Table
-----------------------------------------------------------------------------
 Traffic statistic:
-----------------------------------------------------------------------------
   Total Traffic  :                             0
 ----------------------------------------------------------------------------
   Application                   Traffic
 ----------------------------------------------------------------------------
   HTTP                           0
   FTP                            0
   SMTP                           0
   POP3                           0
   NFS                            0
   SMB                            0
   IMAP                           0
   OTHER                          0
-----------------------------------------------------------------------------

 File statistic:
-----------------------------------------------------------------------------
   Total File  :                                0
 ----------------------------------------------------------------------------
   Application                   File
 ----------------------------------------------------------------------------
 ---- More ----
```

Table 14-113 Description of the **display decoding statistics** command output

Item	Description
Decoding statistic on slot 0 cpu 0	Displays decoding statistic from a specific slot ID and CPU ID.
Decoding Statistic Table	Decoding statistic table
Traffic statistic	Traffic statistics.
Total Traffic	All traffic.
Application	Application name.
Traffic	Traffic of the current application protocol.
File statistic	File statistics.
Total File	Total number of files.
Application	Application name.

Item	Description
File	Number of files of the current application protocol.

14.21.5 display engine information

Function

The **display engine information** command displays the running status of the Intelligent Awareness Engine (IAE) and the version of the SA signature database.

Format

display engine information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To view the IAE's running status and the version of the SA signature database, run the **display engine information** command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the IAE's running status and the version of the SA signature database.

```
<HUAWEI> display engine information
==============================================================================
VSP Software Version               : V200R020C00SPC700B005
==============================================================================
Engine on CPU 0 in slot 0:
==============================================================================
  Engine Status                    : Ready
  Compile Status                   : Commit Succeeded
  SA Signature Database Version    : 2018041202
------------------------------------------------------------------------------
```

Table 14-114 Description of the **display engine information** command output

Item	Description
VSP Software Version	Software version of the VSP.
Engine on CPU *X* in slot *Y*	Engine information on CPU *X* in slot *Y*.
Engine Status	Engine status, which can be: ● Not Run: The engine is not running. ● Initializing: The engine is initializing. ● Ready: The engine is ready.
Compile Status	Compilation status, which can be: ● Idle ● Committing ● Commit Succeeded ● Commit Failed ● Commit Time Out ● Updating ● Update Succeeded ● Update Failed ● Update Time Out
SA Signature Database Version	Version of the SA signature database.

14.21.6 display engine session statistics

Function

The **display engine session statistics** command displays session statistics for the engine.

Format

display engine session statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The session statistics of the specified virtual system or all systems can be viewed only in the root system. In a virtual system, you can view only the session statistics of the virtual system.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Displays session statistics for the engine.

```
<HUAWEI> display engine session statistics

Engine session statistic on slot 0 cpu 0 :
------------------------------------------------------------------------------

  Engine Session Statistic Information of All Threads:
------------------------------------------------------------------------------
  Total Current Sessions              :            0
  Total Current UDP Sessions          :            0
  Total Current TCP Sessions          :            0
  Total Blocked Sessions              :            0
  Total Current Free Sessions         :        10000
  Total Current Buffered TCP Segments  :            0
  Total Out-of-sequence TCP Segments   :            0
  Total Overlapping TCP Segments      :            0
  Total Current Free TCP Segments     :         1000
------------------------------------------------------------------------------
  Engine Session Statistic Information of Each Thread:
------------------------------------------------------------------------------
  T00: NgeSess       0, sent:           0 rcv:           0 lost:           0
```

Table 14-115 Description of the **display engine session statistics** command output

Item	Description
Engine Session Statistic Information of All Threads	Session statistics for the engines used by all threads
Total Current Sessions	Total number of all sessions
Total Current UDP Sessions	Total number of UDP sessions
Total Current TCP Sessions	Total number of TCP sessions

Item	Description
Total Blocked Sessions	Total number of blocked sessions
Total Current Free Sessions	Total number of idle session nodes
Total Current Buffered TCP Segments	Total number of cached TCP segments
Total Out-of-sequence TCP Segments	Total number of out-of-sequence TCP segments
Total Overlapping TCP Segments	Total number of overlapped TCP segments
Total Current Free TCP Segments	Total number of TCP segments that can be cached
Engine Session Statistic Information of Each Thread	Session statistics for the engine used by each thread
NgeSess	Number of sessions
sent	Number of sent packets
rcv	Number of received packets
lost	Number of discarded packets

14.21.7 display engine session statistics app-type

Function

The **display engine session statistics app-type** command displays application statistics about an ECA session.

Format

display engine session statistics app-type [**slot** *slot-id*]

display engine session statistics interface [*interface-type interface-number*] **app-type**

Parameters

Parameter	Description	Value
slot *slot-id*	Displays application statistics about the ECA sessions in the specified slot. If the slot ID is not specified, application statistics about ECA sessions in all slots are displayed.	The value varies depending on the device configuration.

Parameter	Description	Value
interface *interface-type* *interface-number*	Displays application statistics about the ECA sessions on the specified interface. If the interface type and number are not specified, application statistics about ECA sessions on all interfaces are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check application statistics about an ECA session and know about service traffic distribution, you can run the **display engine session statistics app-type** command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

ECA session statistics may be inaccurate because collection of these statistics depends on NetStream packet statistics, which have no impact on the ECA function.

Example

Display application statistics about the ECA sessions on GE0/0/1.

```
<HUAWEI> display engine session statistics interface gigabitethernet 0/0/1 app-type
 GigabitEthernet0/0/1
 ------------------------------------------------------------------------------------
  App-Name                     Connect-Packet        Connect-Byte         Percent
 ------------------------------------------------------------------------------------
  Telnet                    8933              750614              80.05%
  HTTPS                       547              182102              19.42%
  HTTP                       51               4923               0.52%
 ------------------------------------------------------------------------------------
 Total:3
```

Table 14-116 Description of the **display engine session statistics app-type** command output

Item	Description
App-Name	Application name.
Connect-Packet	Number of connection packets.
Connect-Byte	Number of connection bytes.
Percent	Percentage of the application.
Total	Total number of applications.

14.21.8 display engine session statistics interface

Function

The **display engine session statistics interface** command displays ECA session flow statistics on a specified interface.

Format

display engine session statistics interface *interface-type interface-number* **flow** { **by-time** | **by-packet** }

Parameters

Parameter	Description	Value
interface-type interface-number	Displays ECA session flow statistics on an interface with the specified interface type and number.	-
flow	Displays ECA session flow statistics.	-
by-time	Displays ECA session flow statistics in descending order of time.	-
by-packet	Displays ECA session flow statistics in descending order of packet quantity.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

To check ECA session flow statistics on a specified interface and know about traffic distribution, run the **display engine session statistics interface** command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display ECA session flow statistics on GE0/0/1 in descending order of packet quantity.

```
<HUAWEI> display engine session statistics interface gigabitethernet 0/0/1 flow by-packet

Table 14-117 Description of the **display engine session statistics interface** command output

Item	Description
Source-ip	Source IP address of an ECA session flow.
Destination-ip	Destination IP address of an ECA session flow.
Sport	Source port number of an ECA session flow.
Dport	Destination port number of an ECA session flow.
Connect-Packet	Number of connection packets of an ECA session flow.
Connect-Byte	Number of connection bytes of an ECA session flows.
Percent	Percentage of an ECA session flow.
App-name	Application name of an ECA session flow.
Total	Total number of ECA session flows.

14.21.9 display engine session table

Function

The **display engine session table** command displays the details about the IPv4 session table of an engine.

Format

display engine session table [**source-ip** *source-ip-address* | **source-port** *source-port-number* | **destination-ip** *destination-ip-address* | **destination-port** *destination-port-number* | **protocol** { **tcp** | **udp** } | [**application** *application-name*]]* [**verbose**] [**slot** *slot-id* **cpu** *cpu-id* [**thread** *thread-id*]]

Parameters

Parameter	Description	Value
source-ip *source-ip-address*	Indicates a source IP address.	The value is in dotted decimal notation.
source-port *source-port-number*	Indicates a source port.	The value is an integer that ranges from 0 to 65535.
destination-ip *destination-ip-address*	Indicates a destination IP address.	The value is in dotted decimal notation.
destination-port *destination-port-number*	Indicates a destination port.	The value is an integer that ranges from 0 to 65535.
protocol	Specifies the protocol in a session table.	-
tcp	Indicates a TCP session.	-
udp	Indicates a UDP session.	-
application *application-name*	Specifies an application name.	-
verbose	Displays session details.	-
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.

Parameter	Description	Value
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.
thread *thread-id*	Indicates a thread ID.	The value range depends on the device configuration.

Usage Guidelines

Usage Scenario

In a virtual system, you can view only the session statistics of the virtual system. The session information of the specified virtual system or all systems can be viewed only in the root system.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display details about the IPv4 session table of an engine.

```
<HUAWEI> display engine session table verbose
Engine session table on slot 0 cpu 0 :
-------------------------------------------------------------------------------
VSys:0 Vpn:0 Thread:0 UDP 10.0.0.1:80-->10.0.0.2:132 ttl:20 left-time:132 app: (45,QQ)
-------------------------------------------------------------------------------
```

Table 14-118 Description of the **display engine session table verbose** command output

Item	Description
Engine session table on slot 0 cpu 0	Engine session table on a specified slot and CPU
VSys	Name of a virtual system
Vpn	Name of a VPN instance
Thread	Thread ID
UDP	UDP

Item	Description
TCP	TCP
10.0.0.1:80-->10.0.0.2:132	Source address (10.0.0.1), source port (80), destination address (10.0.0.2), and destination port (132)
ttl	Aging time of a session
left-time	Remaining aging time of a session
app: (45,QQ)	Port number (45) and protocol (QQ) of the application

14.21.10 display engine statistics

Function

The **display engine statistics** command displays IAE engine statistics.

Format

display engine statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display engine statistics.

```
<HUAWEI> display engine statistics
Engine statistic on slot 0 cpu 0 :
------------------------------------------------------------------------------
Engine Statistic Table
------------------------------------------------------------------------------
 Event statistic:
------------------------------------------------------------------------------
   Total Alert Events  :          0
   Total Block Events  :          0
 -----------------------------------------------------------------------------
   Application                        Alert Events          Block Events
 -----------------------------------------------------------------------------
------------------------------------------------------------------------------

 Traffic statistic:
------------------------------------------------------------------------------
   Total Traffic  :               0
 -----------------------------------------------------------------------------
   Application                              Traffic
 -----------------------------------------------------------------------------
   DECODING                                          0
------------------------------------------------------------------------------

 File statistic:
------------------------------------------------------------------------------
   Total File  :               0
 -----------------------------------------------------------------------------
   Application                                File
 -----------------------------------------------------------------------------
   DECODING                                          0
------------------------------------------------------------------------------
```

Table 14-119 Description of the **display engine statistics** command output

Item	Description
Engine Statistic Table	Engine statistics table
Event statistic	Event statistics
Total Alert Events	Total number of alarm events
Total Block Events	Total number of block events
Application	Feature name
Alert Events	Number of alarm events corresponding to a feature
Block Events	Number of block events corresponding to a feature
Traffic statistic	Traffic statistics
Total Traffic	Total volume of traffic
Traffic	Volume of traffic processed in a feature
File statistic	File statistics

Item	Description
Total File	File size
File	Size of files processed in a feature
DECODING	Number of decoding.

14.21.11 display flow-probe metadata-collect information

Function

The **display flow-probe metadata-collect information** command displays configuration information about the function of metadata collection through the ECA flow probe.

Format

display flow-probe metadata-collect information

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display configuration information about the function of metadata collection through the ECA flow probe.

```
<HUAWEI> display flow-probe metadata-collect information
 Flow-Probe Metadata-Collect Information on slot 0 cpu 0:
--------------------------------------------------------------------------------
  Global Config:
--------------------------------------------------------------------------------
  Enable                          : Yes
  Transfer Method                 : UDP
  Server IP                       : 0.0.0.0
  Server Port                     : 8514
  Source IP                       : 0.0.0.0
  Source Port                     : 0
  Source VPN Index                : 0
```

```
Source VPN Name              : -
Metadata aging time          : 300
Metadata Cache Max(Current number): 131072(0)
```

Table 14-120 Description of the **display flow-probe metadata-collect information** command output

Item	Description
Flow-Probe Metadata-Collect Information on slot 0 cpu 0	Metadata collection information through the ECA flow probe of in the specified slot and CPU.
Global Config	Global configuration.
Enable	Whether the function of metadata collection through the ECA flow probe is enabled: ● Yes: Enable ● No: Disable
Transfer Method	Transfer mode of metadata collected through the ECA flow probe, which can only be UDP.
Server IP	IP address of the peer HiSec Insight server.
Server Port	Port number of the peer HiSec Insight server.
Source IP	Source IP address of the packet sent from the ECA flow probe metadata to the HiSec Insight server.
Source Port	Source port of the packet sent from the ECA flow probe metadata to the HiSec Insight server.
Source VPN Index	VPN instance index of the packet sent from the ECA flow probe metadata to the HiSec Insight server.
Source VPN Name	VPN instance name of the packet sent from the ECA flow probe metadata to the HiSec Insight server.
Metadata aging time	Aging time of the ECA flow probe metadata.
Metadata Cache Max(Current number)	Max cache of the ECA flow probe metadata(Current number)

14.21.12 display flow-probe metadata-collect statistics

Function

The **display flow-probe metadata-collect statistics** command displays statistics about the function of metadata collection through the ECA flow probe.

Format

display flow-probe metadata-collect statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Displays statistics of metadata collection through the ECA flow probe in the specified slot.	The value range depends on the device configuration.
cpu *cpu-id*	Displays statistics of metadata collection through the ECA flow probe in the specified CPU.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display statistics about the function of metadata collection through the ECA flow probe.

```
<HUAWEI> display flow-probe metadata-collect statistics
 Flow-Probe Metadata-Collect Statistic Table (slot 0 cpu 0)
-------------------------------------------------------------------------------
  Statistics Information:
-------------------------------------------------------------------------------
  Engine Send By UDP                    : 0
  Engine UDP Send To Forward Success    : 0
  Engine UDP Send To Forward Fail       : 0
-------------------------------------------------------------------------------
```

Table 14-121 Description of the **display flow-probe metadata-collect statistics** command output

Item	Description
Flow-Probe Metadata-Collect Statistic Table (slot 0 cpu 0)	Statistics table for the metadata collection through the ECA flow probe in the specified slot and CPU.
Statistics Information	Statistics information for the metadata collection through the ECA flow probe.
Engine Send By UDP	Number of times UDP packets are sent.
Engine UDP Send To Fpath Success	Number of times that UDP packets are successfully sent.
Engine UDP Send To Fpath Fail	Number of times that UDP packets fail to be sent.

14.21.13 display fragment-reassemble configuration

Function

The **display fragment-reassemble configuration** command displays the global fragment reassembly configuration.

Format

display fragment-reassemble configuration [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the global fragment reassembly configuration.

```
<HUAWEI> display fragment-reassemble configuration
Fragment Reassembly statistics on slot 0 cpu 0 :
----------------------------------------------------------------------------
Fragment Reassembly Configuration:
-----------------------------------------------------------
  enable                : on
  overflow-mode         : forward
  overlap-mode          : consistency
  time-out(s)           : 5
  packet-cache(packets) : 255
  total-cache(packets)  : 1000
  defense-check         : off
  pass-through          : off
-----------------------------------------------------------
```

Table 14-122 Description of the **display fragment-reassemble configuration** command output

Item	Description
Fragment Reassembly statistics on slot 0 cpu 0	Fragment Reassembly statistics on a specific slot and CPU
Fragment Reassembly Configuration	Global fragment reassembly configuration
enable	State of the fragment reassembly function. ● on: The function is enabled. ● off: The function is disabled.
overflow-mode	Method for handling packets arriving at a full buffer in fragment reassembly: ● discard: Packets arriving at a full buffer are discarded. ● forward: Packets arriving at a full buffer are forwarded straight through.
overlap-mode	Policy to handle overlapping fragments: **consistency** indicates that overlapping fragments are processed based whether the overlapping parts have the same content.

Item	Description
time-out(s)	Fragment reassembly timeout in seconds
packet-cache(packets)	Fragment buffer size (in number of packets) for each packet
total-cache(packets)	Total buffer size in number of packets
defense-check	Status of the fragment attack defense function: ● on: The function is enabled. ● off: The function is disabled.
pass-through	Status of the fragment reassembly pass-through mode: ● on: The pass through mode is enabled. ● off: The pass through mode is disabled.

14.21.14 display fragment-reassemble session table

Function

The **display fragment-reassemble session table** command displays information about the IPv4/IPv6 fragmented packet-specific session table.

Format

display fragment-reassemble session table [**source-ip** *source-ip-address* | **destination-ip** *destination-ip-address*] * [**slot** *slot-id* **cpu** *cpu-id*]

display fragment-reassemble ipv6 session table [**source-ip** *source-ipv6-address* | **destination-ip** *destination-ipv6-address*] * [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
source-ip *source-ip-address*	Specifies the source IPv4 address.	The value is in dotted decimal notation.
destination-ip *destination-ip-address*	Specifies the destination IPv4 address.	The value is in dotted decimal notation.

Parameter	Description	Value
ipv6	Displays statistics on the fragment reassembly of IPv6 packets.	-
source-ip *source-ipv6-address*	Specifies the source IPv6 address.	The value consists of 128 bits, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format of X:X:X:X:X:X:X:X.
destination-ip *destination-ipv6-address*	Specifies the destination IPv6 address.	The value consists of 128 bits, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format of X:X:X:X:X:X:X:X.
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the IPv4 fragmented packet-specific session table.

```
<HUAWEI> display fragment-reassemble session table
Fragment Reassembly statistics on slot 0 cpu 0 :
------------------------------------------------------------------------------------------------------------------
  VSys:0 Vpn:0 10.1.1.1-->1.1.1.1(363) ttl:5 left-time:4 frag-num:32 flags:(first 1,last 0,overflow 0,result 0)

  VSys:0 Vpn:0 10.1.1.1-->1.1.1.1(363) ttl:5 left-time:3 frag-num:32 flags:(first 1,last 0,overflow 0,result 0)
------------------------------------------------------------------------------------------------------------------
```

Table 14-123 Description of the **display fragment-reassemble session table** command output

Item	Description
Fragment Reassembly statistics on slot 0 cpu 0	Fragment Reassembly statistics on a specific slot and CPU
VSys	Name of a virtual system
Vpn	Name of a VPN instance
ttl	Aging time of a fragment session
left-time	Remaining aging time of a fragment session
frag-num	Number of fragments
flags:(first 1,last 0,overflow 0,result 0)	Fragment flag, which can be: ● first: first fragment ● last: last fragment ● overflow: fragment cache overflow ● result: reassembly result

14.21.15 display fragment-reassemble statistics

Function

The **display fragment-reassemble statistics** command displays statistics on the fragment reassembly of IP packets.

Format

display fragment-reassemble [**ipv6**] **statistics** [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
ipv6	Displays statistics on the fragment reassembly of IPv6 packets.	-
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display statistics on the fragment reassembly of IP packets.

```
<HUAWEI> display fragment-reassemble statistics
Fragment Reassembly statistics on slot 0 cpu 0 :
------------------------------------------------------------------------------
Fragment Reassembly Statistics:
------------------------------------------------------------
  Total fragments              : 0
  Total cached fragments       : 0
  Total error packets          : 0
  Total discarded fragments    : 0
  Complete overlap processing : 0
  Partial overlap processing  : 0
  Total current sessions       : 0
  Total free sessions          : 1000
------------------------------------------------------------
```

Table 14-124 Description of the **display fragment-reassemble statistics** command output

Item	Description
Fragment Reassembly statistics on slot *X* cpu *Y*	Fragment reassembly statistics on CPU *Y* in slot *X*.
Fragment Reassembly Statistics	Statistics on fragment reassembly.
Total fragments	Number of received fragments.
Total cached fragments	Number of cached fragments.
Total error packets	Number of packets with error fragments.
Total discarded fragments	Number of discarded fragments.
Complete overlap processing	Complete overlap processing.
Partial overlap processing	Partial overlap processing
Total current sessions	Total number of current sessions.
Total free sessions	Total number of free sessions.

14.21.16 display stream-reassemble configuration

Function

The **display stream-reassemble configuration** command displays the global TCP stream reassembly configuration.

Format

display stream-reassemble configuration [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the global TCP stream reassembly configuration.

```
<HUAWEI> display stream-reassemble configuration
Stream reassemble configuration on slot 0 cpu 0 :
-------------------------------------------------------------------------------
Stream Reassembly Configuration:
-------------------------------------------------------------
  enable                : on
  overflow-mode         : discard
  overlap-mode          : overwrite
  session-cache(KB)     : 16
  total-cache(packets)  : 1000
  timestamp-check       : true
  tcp-option check      : true
  defense-check         : on
  session-timeout(s)    : 60
  enhanced-mode         : on
-------------------------------------------------------------
```

Table 14-125 Description of the **display stream-reassemble configuration** command output

Item	Description
Stream reassemble configuration on slot 0 cpu 0	TCP stream reassembly configuration on slot 0 cpu 0.
enable	Indicates the state of the TCP stream reassembly function. ● on: The function is enabled. ● off: The function is disabled.
overflow-mode	Indicates the method for handling packets arriving at a full buffer in stream reassembly. ● discard: Packets arriving at a full buffer are discarded. ● forward: Packets arriving at a full buffer are forwarded straight through.
overlap-mode	Indicates the policy to handle overlapping packets: ● overwrite: Indicate overwrite the original overlapped part. ● preserve: Indicate preserve the original overlapped part.
session-cache(KB)	Indicates the buffer size in KB for each session in TCP stream reassembly.
total-cache(packets)	Global buffer size in number of packets in stream reassembly.
timestamp-check	Indicates the state of the timestamp check function. ● true: The function is enabled. ● false: The function is disabled.
tcp-option check	Indicates the state of the TCP option check function. ● true: The function is enabled. ● false: The function is disabled.
defense-check	Indicates the status of the TCP attack defense function: ● on: The function is enabled. ● off: The function is disabled.

Item	Description
session-timeout(s)	Indicates the timeout of out-of-sequence TCP packet inspection, in seconds.
enhanced-mode	Status of enhanced traffic reassembly: ● on: The function is enabled. ● off: The function is disabled.

14.21.17 display update configuration

Function

The **display update configuration** command displays the update configuration of the application identification signature database.

Format

display update configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the update configuration of the application identification signature database.

```
<HUAWEI> display update configuration
Update Configuration Information:
------------------------------------------------------------
  Update Server              : sec.huawei.com
  Update Port                : 443
  Proxy State                : Disable
  Proxy Server               : -
  Proxy Port                 : -
  Proxy User                 : -
```

```
 Proxy Password              : -
 SA-SDB:
   Application Confirmation  : Disable
   Schedule Update           : Enable
   Schedule Update Frequency : Daily
   Schedule Update Time      : 04:16
------------------------------------------------------------
```

Table 14-126 Description of the **display update configuration** command output

Item	Description
Update Configuration Information	Update configuration of the application identification signature database.
Update Server	IP address or domain name of the update server. The default domain name is that of the update center.
Update Port	Port number of the update server.
Proxy State	Whether the proxy server is enabled. The value can be: ● Enable: The proxy server is enabled. ● Disable: The proxy server is disabled.
Proxy Server	IP address or domain name of the proxy server.
Proxy Port	Port number of the proxy server.
Proxy User	User name of the proxy server.
Proxy Password	Password of the proxy server.
SA-SDB	Update configuration of the application identification signature database.
Application Confirmation	Whether manual installation confirmation is enabled. The value can be: ● Enable: Confirmation is required before the installation of the update file. ● Disable: The update file is automatically installed.
Schedule Update	Whether the scheduled update function is enabled. The value can be: ● Enable ● Disable
Schedule Update Frequency	Scheduled update frequency. The value can be: ● Weekly ● Daily ● Hourly
Schedule Update Time	Scheduled update time

14.21.18 display update host source

Function

The **display update host source** command displays the interface and source IP address configurations used in online updating the application identification signature database.

Format

display update host source

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **update host source** command configures the source interface and IP address, and **display update host source** command displays the configurations.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the interface and source address configurations used in online updating the application identification signature database.

```
<HUAWEI> display update host source
----------------------------------------------------------------
Source IP Information:
        IP address                : 10.1.1.1
        vpn-instance               : -
Source Interface Information:
        interface name            : GigabitEthernet0/0/1
----------------------------------------------------------------
```

Table 14-127 Description of the **display update host source** command output

Item	Description
Source IP Information	Source IP address information.

Item	Description
IP address	IP address.
vpn-instance	VPN instance name.
Source Interface Information	Source interface information.
interface name	Interface name.

14.21.19 display update information all-sdb

Function

The **display update information all-sdb** command displays the last record on application identification signature database updates.

Format

display update information all-sdb

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the last record on application identification signature database updates.

```
<HUAWEI> display update information all-sdb
  Current Update Status:  Idle.
-----------------------------------------------------------------------------------------------
  SA-SDB latest update finish time           : 04:16:13 2018/07/03
  SA-SDB latest update result              : Error: Failed to perform DNS resolution.
-----------------------------------------------------------------------------------------------
```

Table 14-128 Description of the **display update information all-sdb** command output

Item	Description
Current Update Status	Current status of the update server, including: - Idle: indicates that no signature database is being updated. - Version Loading: indicates that the version is being loaded. - Live Updating: indicates live update. - Local Updating: indicates the local update. - Version Rollbacking: indicates that version rollback is being performed. - Stop Updating: indicates that the update is being stopped. - Version Applying: indicates that the version is being downloaded. - Version Restoring: indicates that the default version is being restored. - Version Uninstalling: indicates that the version is being uninstalled. - Update check: indicates that the update is being checked. - Engine start loading: indicates that the engine start is being loaded.
SA-SDB	Application identification signature database.
latest update finish time	Last update time of the application identification signature database.
latest update result	Last update result of the application identification signature database.
SA-SDB	Application identification signature database.

14.21.20 display update status

Function

The **display update status** command displays the update status of the application identification signature database.

Format

display update status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

View the current update status of the application identification signature database.

```
<HUAWEI> display update status
  Current Update Status: Idle.
```

Table 14-129 Description of the **display update status** command output

Item	Description
Current Update Status	Current update status of the application identification signature database consist of update type and update status. Update type: - Idle: indicates that no signature database is being updated. - Version Load: indicates that the version is being loaded. - Online Update: indicates online update. - Local Update: indicates the local update. - Version Rollback: indicates the version rollback. - Stop Update: indicates that the update is stopped. - Version Apply: indicates that the version is applied. - Version Restore: indicates that the default version is restored. - Version Uninstall: indicates that the version is being uninstalled. - Update check: indicates that the update is checked. - Engine start loading: indicates that the engine start is being loaded. Update status: - Ready to load The Update Package: indicates that the update package will be loaded soon. - Verify The Authority: indicates that permission is being verified. - Obtain The Update Package: indicates that the update package is being obtained. - Load The Update Package: indicates that the update package is being loaded. - Merge The Incremental Package: indicates that the incremental package is being merged. - Retry The Update: indicates that the update is being retried. For example: - Online Update, Obtain The Update Package.: indicates online update and an update package is being downloaded. - Version Rollback, Load The Update Package: indicates version rollback and a rollback package is being loaded.

Item	Description
	● Version Apply, Verify The Authority.: indicates that the version is being applied and the permission is being verified. ● Local Update, Load The Update Package: indicates local update and an update package is being loaded.

14.21.21 display version sa-sdb

Function

The **display version sa-sdb** command displays the version of the application identification signature database.

Format

display version sa-sdb

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

View the version of the application identification signature database.

```
<HUAWEI> display version sa-sdb
SA SDB Update Information List:
----------------------------------------------------------------
  Current Version:
    Signature Database Version    : 2018041202
    Signature Database Size(byte) : 871104
    Update Time                   : 17:47:51 2018/06/30
    Issue Time of the Update File : 17:03:54 2018/04/12

  Backup Version:
    Signature Database Version    :
    Signature Database Size(byte) : 0
    Update Time                   : 00:00:00 0000/00/00
```

```
  Issue Time of the Update File : 00:00:00 0000/00/00
------------------------------------------------------------------
```

Table 14-130 Description of the **display version sa-sdb** command output

Item	Description
SA SDB Update Information List	Update information list of the application identification signature database.
Current Version	Current version information about the engine or the application identification signature database.
Signature Database Version	Version of the engine or the application identification signature database.
Signature Database Size(byte)	Size of the engine or the application identification signature database(byte).
Update Time	Date and time when the application identification signature database was upgraded to this version
Issue Time of the Update File	Date and time when the file for the upgrade package to this version was released
Backup Version	Source version of the engine or the application identification signature database for rollbacks.

14.21.22 ec-analytics enable

Function

The **ec-analytics enable** command enables the ECA function on an interface.

The **undo ec-analytics enable** command disables the ECA function on an interface.

By default, the ECA function is disabled.

Format

ec-analytics enable [**inbound** | **outbound**]

undo ec-analytics enable [**inbound** | **outbound**]

Parameters

Parameter	Description	Value
inbound	Enables ECA traffic in the inbound direction.	-
outbound	Enables ECA for traffic in the outbound direction.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, VLANIF interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

To analyze encrypted traffic on a network and identify malicious communications in the encrypted traffic, you can run the **ec-analytics enable** command on an interface to enable the ECA function.

Precautions

- If the traffic direction is not specified, ECA is performed for traffic in both direction by default.
- If it is confirmed that firewalls have been deployed at the network egress, you are advised to enable ECA only for traffic in the inbound direction.
- When ECA is enabled on both upstream and downstream interfaces, only upstream interfaces take effect.

Example

Enable the ECA function for traffic in the inbound direction of GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ec-analytics enable inbound
```

14.21.23 ec-analytics enhanced-mode disable

Function

The **ec-analytics enhanced-mode disable** command disables the ECA enhanced mode.

The **undo ec-analytics enhanced-mode disable** command enables the ECA enhanced mode.

By default, the ECA enhanced mode is enabled.

Format

ec-analytics enhanced-mode disable

undo ec-analytics enhanced-mode disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In ECA enhanced mode, 50 packets are sent to the IAE for each ECA session flow, improving accuracy of encrypted traffic identification. However, the processing performance of the IAE deteriorates if it has to process enormous packets. When the device performance is limited, you can disable the ECA enhanced mode. After that, only 20 packets are sent to the IAE for each ECA session flow.

Precautions

You are advised to enable the ECA enhanced mode when the device performance meets requirements.

Example

Enable the ECA enhanced mode.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] undo ec-analytics enhanced-mode disable
```

14.21.24 ec-analytics whitelist

Function

The **ec-analytics whitelist** command configures an ECA whitelist. ECA is not performed for the whitelist traffic.

The **undo ec-analytics whitelist** command deletes an ECA whitelist.

By default, no ECA whitelist is configured on a device.

Format

ec-analytics whitelist acl *acl-number*

undo ec-analytics whitelist acl *acl-number*

Parameters

Parameter	Description	Value
acl *acl-number*	Adds the specified ACL number to the ECA whitelist.	The value is an integer in the range from 3000 to 3999.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **ec-analytics whitelist** command to add trusted network traffic to the whitelist so that ECA is not performed for such traffic.

Precautions

Advanced ACLs are applied in the ECA whitelist and only the 5-tuple information is supported.

When the ECA whitelist is configured, a maximum of 32 ACL rules with small rule numbers take effect.

Example

Add ACL 3000 to the ECA whitelist to prevent ECA from being performed for traffic with the source IP address 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule permit ip source 10.1.1.1 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] ec-analytics whitelist acl 3000
```

14.21.25 engine configuration commit

Function

The **engine configuration commit** command commits the configuration of security policies.

Format

engine configuration commit

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Newly configured security policies or the modified security policies do not take effect until you run the **engine configuration commit** command to commit the configuration. To save time, commit the configurations in batches after you have completed all security policy configurations.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Commit the security policy configurations.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] engine configuration commit
```

14.21.26 engine enhanced-detection

Function

The **engine enhanced-detection** command configures the engine to work in enhanced detection mode.

The **undo engine enhanced-detection** command configures the engine to work in common detection mode.

By default, the engine works in common detection mode.

Format

engine enhanced-detection

engine enhanced-detection protocol { **rtsp** | **others** }

undo engine enhanced-detection

undo engine enhanced-detection protocol { **rtsp** | **others** }

Parameters

Parameter	Description	Value
protocol rtsp	Configures the engine to work in enhanced detection mode for RTSP.	By default, the engine works in enhanced detection mode for RTSP.

Parameter	Description	Value
protocol others	Configures the engine to work in enhanced detection mode for protocols excluding RTSP.	By default, the engine works in common detection mode for protocols excluding RTSP.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After you configure the engine to work in enhanced detection mode, the detection capability of the device will be enhanced, and the detection speed will be decreased.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Configure the engine to work in enhanced detection mode.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] engine enhanced-detection
```

14.21.27 engine pass-through enable

Function

The **engine pass-through enable** command enables the pass-through mode of the engine.

The **undo engine pass-through enable** command disables the pass-through mode of the engine.

By default, the pass-through mode of the engine is disabled.

Format

engine pass-through enable [**slot** *slot-id* **cpu** *cpu-id*]

undo engine pass-through enable [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the pass-through mode of the engine is enabled, the system generates events, such as debugging information or log during service processing, but does not perform actual actions. Even a block action is configured for a service, the system does not block traffic but records the service event state.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the pass-through mode of the engine.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] engine pass-through enable
```

14.21.28 engine session timeout active

Function

The **engine session timeout active** command sets the active flow aging time of an ECA session.

The **undo engine session timeout active** command restores the default active flow aging time of an ECA session.

By default, the active flow aging time of an ECA session is 60 seconds.

Format

engine session timeout active *time*

undo engine session timeout active

Parameters

Parameter	Description	Value
time	Specifies the active flow aging time of an ECA session.	The value is an integer in the range from 1 to 300, in seconds. The default value is 60.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After ECA is configured on a device, the ECA session flow table ages out after a certain period. The flow table that is aged out is encapsulated and then sent to the HiSec Insight server as metadata. Active flow aging of ECA enables the device to periodically output the statistics about the flows that persist for a long period.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the active flow aging time of an ECA session to 15 seconds.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] engine session timeout active 15
```

14.21.29 engine session timeout inactive

Function

The **engine session timeout inactive** command sets the inactive flow aging time of an ECA session.

The **undo engine session timeout inactive** command restores the default inactive flow aging time of an ECA session.

By default, the inactive flow aging time of an ECA session is 15 seconds.

Format

engine session timeout inactive *time*

undo engine session timeout inactive

Parameters

Parameter	Description	Value
time	Specifies the inactive flow aging time of an ECA session.	The value is an integer in the range from 1 to 300, in seconds. The default value is 15.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After ECA is configured on a device, the ECA session flow table ages out after a certain period. The flow table that is aged out is encapsulated and then sent to the HiSec Insight server as metadata. Inactive flow aging of ECA requires the device to export statistics about the flows that persist for a short period. Once adding packets to a flow stops, the device exports flow statistics to conserve memory space.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the inactive flow aging time of an ECA session to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] engine session timeout active 10
```

14.21.30 flow-probe metadata-collect aging-time

Function

The **flow-probe metadata-collect aging-time** command configures the aging time of ECA flow probe metadata entries.

The **undo flow-probe metadata-collect aging-time** command restores the default aging time of ECA flow probe metadata entries.

By default, the aging time of ECA flow probe metadata entries is 300 seconds.

Format

flow-probe metadata-collect aging-time *time*

undo flow-probe metadata-collect aging-time

Parameters

Parameter	Description	Value
time	Specifies the aging time of ECA flow probe metadata entries.	The value is an integer in the range from 0 to 1200, in seconds. The default value is 300.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure the aging time of ECA flow probe metadata entries to adjust the rate of sending packets to the HiSec Insight server.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the aging time of ECA flow probe metadata entries to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] flow-probe metadata-collect aging-time 10
```

14.21.31 flow-probe metadata-collect enable

Function

The **flow-probe metadata-collect enable** command enables the function of metadata collection through the ECA flow probe.

The **undo flow-probe metadata-collect enable** command disables the function of metadata collection through the ECA flow probe.

By default, the function of metadata collection through the ECA flow probe is enabled.

Format

flow-probe metadata-collect enable

undo flow-probe metadata-collect enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the function of metadata collection through the ECA flow probe.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] flow-probe metadata-collect enable
```

14.21.32 flow-probe metadata-collect server

Function

The **flow-probe metadata-collect server** command configures the IP address and port number of the HiSec Insight server.

The **undo flow-probe metadata-collect server** command deletes the configured IP address and restores the configured port number to the default value.

By default, the IP address of the HiSec Insight server is not specified and the default port number is 8514.

Format

flow-probe metadata-collect server ip *ip-address* [**port** *port-number*]

undo flow-probe metadata-collect server

Parameters

Parameter	Description	Value
ip *ip-address*	Specifies the IP address of the HiSec Insight server.	The value is an IPv4 address in dotted decimal notation.
port *port-number*	Specifies the port number of the HiSec Insight server.	The value is an integer ranging from 1 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The default port number of the peer HiSec Insight server connected to the flow probe metadata collector is subject to the metadata collection and transmission mode. Currently, the switch only supports UDP for metadata transmission, and the default port number is 8514.

When configuring the IP address of the HiSec Insight server:

- If the HiSec Insight server is of the standard version, the IP address is the data dispatcher management plane IP address of the HiSec Insight server. Multiple data dispatcher management plane IP addresses may exist. You can select any one of them.
- If the HiSec Insight server is of the small-scale edition, the IP address is the Big Data cluster server management plane IP address of the HiSec Insight server. Multiple Big Data cluster server management plane IP addresses may exist. You can select any one of them.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the IP address and port number of the HiSec Insight server to **10.1.1.1** and **10** respectively.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] flow-probe metadata-collect server ip 10.1.1.1 port 10
```

14.21.33 flow-probe metadata-collect source

Function

The **flow-probe metadata-collect source** command configures the source IP address and VPN instance name of the packet sent from the ECA flow probe metadata to the HiSec Insight server.

The **undo flow-probe metadata-collect source** command restores the configured source IP address and VPN instance name to the default values.

By default, the source IP address of the packet sent from the ECA flow probe metadata to the HiSec Insight is empty.

Format

flow-probe metadata-collect source { **ip** *ip-address* **port** *port-number* | **vpn-instance** *vpn-instance-name* } *

undo flow-probe metadata-collect source

Parameters

Parameter	Description	Value
ip *ip-address*	Specifies the source IP address of the packet sent from the ECA flow probe metadata to the HiSec Insight server.	The value is in dotted decimal notation.
port *port-number*	Specifies the source port number of the packet sent from the ECA flow probe metadata to the HiSec Insight server.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the VPN instance name of the packet sent from the ECA flow probe metadata to the HiSec Insight server.	The value must be the name of an existing VPN instance.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring the source IP address of the packet sent from the ECA flow probe metadata to the HiSec Insight server, ensure that the IP address is the device interface IP address and that this interface IP address is reachable to the HiSec Insight server.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the source IP address and source port number of the packet sent from the ECA flow probe metadata to the HiSec Insight server to **10.1.1.1** and **port 1** respectively.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] flow-probe metadata-collect source ip 10.1.1.1 port 1
```

14.21.34 fragment-reassemble enable

Function

The **fragment-reassemble enable** command enables fragment reassembly.

The **undo fragment-reassemble enable** command disables fragment reassembly.

By default, fragment reassembly is enabled.

Format

fragment-reassemble enable

undo fragment-reassemble enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If fragment reassembly is disabled, fragments will not be reassembled and will not be inspected. Meanwhile, TCP stream reassembly may also fail.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable fragment reassembly.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] fragment-reassemble enable
```

14.21.35 fragment-reassemble overflow-mode

Function

The **fragment-reassemble overflow-mode** command configures the action to take on fragments that overflow the cache.

The **undo fragment-reassemble overflow-mode** command restores the default action to take on fragments that overflow the cache.

By default, the system forwards the fragments that overflow the cache to ensure services.

Format

fragment-reassemble overflow-mode { **discard** | **forward** }

undo fragment-reassemble overflow-mode

Parameters

Parameter	Description	Value
discard	Discards the fragments that overflow the cache.	-
forward	Forwards the fragments that overflow the cache.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the action is set to **discard**, the system discards the fragments that overflow the cache, which may interrupt services.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Configure the action to take on fragments that overflow the cache to **discard**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] fragment-reassemble overflow-mode discard
```

14.21.36 fragment-reassemble user-configure

Function

The **fragment-reassemble user-configure** command configures user-defined items for the fragment reassembly function.

The **undo fragment-reassemble user-configure** command cancels the configuration of user-defined items for the fragment reassembly function.

By default, all user-defined items of the fragment reassembly function are disabled.

Format

fragment-reassemble user-configure { **defense-check** | **pass-through** }

undo fragment-reassemble user-configure { **defense-check** | **pass-through** }

Parameters

Parameter	Description	Value
defense-check	Indicates fragment attack defense.	-
pass-through	Indicates the pass through mode.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the pass through mode is enabled (using the **fragment-reassemble user-configure pass-through** command), in some special fragment traffic scenarios (for example, the fragments completely overlap, and the overlapped part has the same content), the system will regard the traffic as abnormal traffic and will not reassemble the fragments. If the fragment attack defense function has been enabled (using the **fragment-reassemble user-configure defense-check** command), the abnormal fragments will be discarded. If the fragment attack defense function has not been enabled, the system will forward the fragments. After the pass through mode is disabled, the system assembles the fragments based on the normal processing flow.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the fragment attack defense function.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] fragment-reassemble user-configure defense-check
```

14.21.37 reset decoding statistics

Function

The **reset decoding statistics** command clears decoding statistics.

Format

reset decoding statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear decoding statistics.

```
<HUAWEI> reset decoding statistics
```

14.21.38 reset engine session statistics

Function

The **reset engine session statistics** command clears the session statistics of the engine.

Format

reset engine session statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Use caution before you decide to run this command. Once the session statistics of the engine are cleared, they cannot be restored.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear the session statistics of the engine.

```
<HUAWEI> reset engine session statistics
```

14.21.39 reset engine session statistics app-type

Function

The **reset engine session statistics app-type** command clears application statistics about an ECA session.

Format

reset engine session statistics app-type [**slot** *slot-id*]

reset engine session statistics interface [*interface-type interface-number*] **app-type**

Parameters

Parameter	Description	Value
slot *slot-id*	Clears application statistics about ECA sessions in a specified slot.	The value varies depending on the device configuration.
interface *interface-type interface-number*	Clears application statistics about ECA sessions on a specified interface. If the interface type and number are not specified, application statistics about ECA sessions on all interfaces are displayed.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **reset engine session statistics app-type** command to clear application statistics about ECA sessions.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear application statistics about ECA sessions on slot 0.

```
<HUAWEI> reset engine session statistics app-type slot 0
```

14.21.40 reset engine session statistics flow

Function

The **reset engine session statistics flow** command clears ECA session flow statistics.

Format

reset engine session statistics interface *interface-type interface-number* **flow** { **by-time** | **by-packet** }

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears ECA session flow statistics on a specified interface.	-
by-time	Clears ECA session flow statistics displayed in descending order of time.	-
by-packet	Clears ECA session flow statistics displayed in descending order of packet quantity.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

You can run the **reset engine session statistics interface** command to clear ECA session flow statistics on a specified interface.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear ECA session flow statistics displayed in descending order of packet quantity on GE0/0/1.

```
<HUAWEI> reset engine session statistics interface gigabitethernet 0/0/1 flow by-packet
```

14.21.41 reset engine session table

Function

The **reset engine session table** command clears the session information of the engine.

Format

reset engine session table [**source** *source-ip-address* | **destination** *destination-ip-address* | **destination-port** *destination-port-number* | **protocol** { **tcp** | **udp** }] * [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
source *source-ip-address*	Specifies the source IPv4 address.	The value is in dotted decimal notation.
destination *destination-ip-address*	Specifies the destination IPv4 address.	The value is in dotted decimal notation.
destination-port *destination-port-number*	Specifies the destination port number.	The value is an integer ranging from 0 to 65535.
protocol	Indicates a protocol.	-
tcp	Indicates Transmission Control Protocol (TCP).	-
udp	Indicates User Datagram Protocol (UDP).	-
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If no parameter is specified, all session information of the engine is cleared after you run the **reset engine session table** command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Use caution before you decide to run this command. Clearing the session information of the engine adversely affects the service operating.

Example

Clear all session information of the engine.

```
<HUAWEI> reset engine session table
Warning: Reseting session table will affect the engine's normal service. Continue? [Y/N]: y
```

14.21.42 reset engine statistics

Function

The **reset engine statistics** command clears engine statistics.

Format

reset engine statistics [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear engine statistics.

```
<HUAWEI> reset engine statistics
```

14.21.43 reset flow-probe metadata-collect statistics

Function

The **reset flow-probe metadata-collect statistics** command resets statistics about the function of metadata collection through the ECA flow probe.

Format

reset flow-probe metadata-collect statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After you run the **display flow-probe metadata-collect statistics** command to view statistics about the function of metadata collection through the ECA flow probe, you can run the **reset flow-probe metadata-collect statistics** command to reset the statistics and collect statistics again. Cleared statistics cannot be restored. Exercise caution when you run this command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Reset statistics about the function of metadata collection through the ECA flow probe.

```
<HUAWEI> reset flow-probe metadata-collect statistics
```

14.21.44 reset fragment-reassemble statistics

Function

The **reset fragment-reassemble statistics** command clears statistics on fragment reassembly.

Format

reset fragment-reassemble [**ipv6**] **statistics** [**slot** *slot-id* **cpu** *cpu-id*]

Parameters

Parameter	Description	Value
ipv6	Clears statistics of IPv6 packets on fragment reassembly.	-
slot *slot-id*	Specifies a slot ID.	The value range depends on the device configuration.
cpu *cpu-id*	Specifies a CPU ID.	The value range depends on the device configuration.

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Clear statistics on fragment reassembly.

```
<HUAWEI> reset fragment-reassemble statistics
```

14.21.45 stream-reassemble enable

Function

The **stream-reassemble enable** command enables TCP stream reassembly.

The **undo stream-reassemble enable** command disables TCP stream reassembly.

By default, TCP stream reassembly is enabled.

Format

stream-reassemble enable

undo stream-reassemble enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If TCP stream reassembly is disabled, TCP packets will not be reassembled and will not be inspected. Meanwhile, security inspections based on TCP streams may also fail.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable TCP stream reassembly.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble enable
```

14.21.46 stream-reassemble enhanced-mode

Function

The **stream-reassemble enhanced-mode** command enables the enhanced traffic reassembly mode.

The **undo stream-reassemble enhanced-mode** command disables the enhanced traffic reassembly mode.

By default, the enhanced traffic reassembly mode is disabled.

Format

stream-reassemble enhanced-mode

undo stream-reassemble enhanced-mode

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The command is used to enable the enhanced traffic reassembly mode in the bypass deployment scenario. After this mode is enabled, sequence number reassembly is supported when TCP data packets and three-way handshake packets are out of order.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the enhanced traffic reassembly mode.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble enhanced-mode
```

14.21.47 stream-reassemble overflow-mode

Function

The **stream-reassemble overflow-mode** command configures the action for cache overflow during TCP stream reassembly.

The **undo stream-reassemble overflow-mode** command restores the default action for cache overflow during TCP stream reassembly.

By default, the action for cache overflow during TCP stream reassembly is **forward**.

Format

stream-reassemble overflow-mode { **discard** | **forward** }

undo stream-reassemble overflow-mode

Parameters

Parameter	Description	Value
discard	Discards the packets that overflow the cache.	-
forward	Forwards the fragments that overflow the cache.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the action for cache overflow during TCP stream reassembly to **forward**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble overflow-mode forward
```

14.21.48 stream-reassemble overlap-mode

Function

The **stream-reassemble overlap-mode** command configures the action for overlapping packets during TCP stream reassembly.

The **undo stream-reassemble overlap-mode** command restores the default action for overlapping packets during TCP stream reassembly.

By default, the action for the overlapping packets during TCP stream reassembly is **preserve**.

Format

stream-reassemble overlap-mode { **preserve** | **overwrite** }

undo stream-reassemble overlap-mode

Parameters

Parameter	Description	Value
preserve	Preserves overlapping packets.	-
overwrite	Overwrites overlapping packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the action for the overlapping packets during TCP stream reassembly to **preserve**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble overlap-mode preserve
```

14.21.49 stream-reassemble session-cache

Function

The **stream-reassemble session-cache** command configures the maximum cache for each session during TCP stream reassembly for out-of-order packets.

The **undo stream-reassemble session-cache** command restores the default values.

By default , the maximum cache for each session during TCP stream reassembly for out-of-order packets is 128 KB.

Format

stream-reassemble session-cache *session-cache-value*

undo stream-reassemble session-cache

Parameters

Parameter	Description	Value
session-cache-value	Specifies the maximum cache for a session.	The value is an integer ranging from 0 to 256, in KB. The default value is 128.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the *session-cache-value* is 0 or the size of a single session exceeds the *session-cache-value*, the stream reassembly for out-of-order packets becomes invalid.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the maximum cache for each session to 16 KB during stream reassembly.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble session-cache 16
```

14.21.50 stream-reassemble session-timeout

Function

The **stream-reassemble session-timeout** command set the timeout time for out-of-sequence TCP packet inspection.

The **undo stream-reassemble session-timeout** command restores the default setting.

By default, the timeout time for out-of-sequence TCP packet inspection is 10 seconds.

Format

stream-reassemble session-timeout *session-timeout-value*

undo stream-reassemble session-timeout

Parameters

Parameter	Description	Value
session-timeout-value	Specifies the timeout time.	The value is an integer ranging from 0 to 1200, in seconds. The default value is 10.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, out-of-sequence TCP packet inspection is enabled on the switch.

- When *session-timeout-value* is 0, out-of-sequence TCP packet inspection is disabled.
- When *session-timeout-value* is greater than 0 and the time when TCP packets are out of order is smaller than or equal to *session-timeout-value*, the switch will attempt to reassemble traffic.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the timeout time for out-of-sequence TCP packet inspection to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble session-timeout 20
```

14.21.51 stream-reassemble tcp-option check

Function

The **stream-reassemble tcp-option check** command enables the TCP option check function.

The **undo stream-reassemble tcp-option check** command disables the TCP option check function.

By default, the TCP option check function is disabled.

Format

stream-reassemble tcp-option check

undo stream-reassemble tcp-option check

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this function is enabled, the engine directly discards packets with abnormal TCP options.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the TCP option check function.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble tcp-option check
```

14.21.52 stream-reassemble timestamp check

Function

The **stream-reassemble timestamp check** command enables timestamp check of TCP flow reassembly.

The **undo stream-reassemble timestamp check** command disables timestamp check of TCP flow reassembly.

By default, the timestamp check function is disabled.

Format

stream-reassemble timestamp check

undo stream-reassemble timestamp check

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you enable timestamp check of TCP flow reassembly, the device verifies the timestamp option of TCP packets. If the option is incorrect, the device discards the packets.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable timestamp check of TCP flow reassembly.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble timestamp check
```

14.21.53 stream-reassemble user-configure defense-check

Function

The **stream-reassemble user-configure defense-check** command enables the TCP attack defense function.

The **undo stream-reassemble user-configure defense-check** command disables the TCP attack defense function.

By default, the TCP attack defense function is disabled.

Format

stream-reassemble user-configure defense-check

undo stream-reassemble user-configure defense-check

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this function is enabled, the switch directly discards abnormal TCP packets.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the TCP attack defense function.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] stream-reassemble user-configure defense-check
```

14.21.54 update abort

Function

The **update abort** command aborts the update process of the application identification signature database.

Format

update abort

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In online/immediate updates, the device needs to connect to the update center. If the network rate is too low and impacts the services and device performance, you can run the **update abort** command to abort the update and then retry updating when appropriate. In update retires, you cannot perform other update operations. If you need to use another update method, run the **update abort** command to abort the update process first.

Prerequisites

The **update abort** command can only be used for online/immediate updates or update retries.

Example

Abort the immediate update process.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update online sa-sdb
[HUAWEI] update abort
```

14.21.55 update apply sa-sdb

Function

The **update apply sa-sdb** command installs the downloaded update files of the application identification signature database.

By default, the upgrade file is automatically installed after being downloaded in an online upgrade scenario. If manual installation confirmation has been enabled, the upgrade file need to be manually installed.

Format

update apply sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If manual installation confirmation has been enabled by the **update confirm sa-sdb enable** command, run the **update apply sa-sdb** command to install the update files.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Install the application identification signature database update files.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update apply sa-sdb
```

14.21.56 update confirm sa-sdb enable

Function

The **update confirm sa-sdb enable** command enables manual confirmation of the application identification signature database installation.

The **undo update confirm sa-sdb enable** command disables manual confirmation of the application identification signature database installation.

By default, the manual confirmation of the application identification signature database installation is disabled.

Format

update confirm sa-sdb enable

undo update confirm sa-sdb enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In an online upgrade scenario, the upgrade file is automatically installed after being downloaded by default. To make the upgrade file not to be automatically installed after being downloaded, run the **update confirm sa-sdb enable** command to enable manual confirmation of the application identification signature database installation and run the **update apply sa-sdb** command to manually install the upgrade file.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable manual confirmation for the application identification signature database installation.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update confirm sa-sdb enable
```

14.21.57 update download-server aging-time

Function

The **update download-server aging-time** command specifies the aging time of the download server.

The **undo update download-server aging-time** command prevents the download server from aging.

By default, the aging time of the download server is 7 days.

Format

update download-server aging-time *age-time*

undo update download-server aging-time

Parameters

Parameter	Description	Value
age-time	Aging time of the download server	The value is an integer ranging from 1 to 360, in days. The default value is 7.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the download server is normal and has not been expired, you do not need to re-obtain the IP address of the download server. You need to re-obtain the IP address of the download server when the server has expired or is abnormal. You can use this command to adjust the aging time of the download server.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the aging time of the download server to 10 days.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update download-server aging-time 10
```

14.21.58 update force apply sa-sdb

Function

The **update force apply sa-sdb** command forcibly installs the downloaded update files of the application identification signature database.

Format

update force apply sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you run the **update apply sa-sdb** command to download update files, the update fails in case of insufficient system memory. In this case, you can run the **update force apply sa-sdb** command to forcibly install downloaded update files.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Running the **update force apply sa-sdb** command causes the IAE not to take effect in a short time and resets all IAE-related session tables. Therefore, exercise cautions when using this command.

Example

Forcibly install the application identification signature database update files.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update force apply sa-sdb
```

14.21.59 update force local sa-sdb

Function

The **update force local sa-sdb** command configures forcible manual update of the local application identification signature database.

Format

update force local sa-sdb file *filename*

Parameters

Parameter	Description	Value
file *filename*	Indicates the file used for the update. You must upload the update files to the device memory before the update.	The absolute path of a file is a string of 1 to 64 characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you run the **update local sa-sdb** command to update the application identification signature database locally, the update fails in case of insufficient system memory. In this case, you can run the **update force local sa-sdb** command to forcibly update the local application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Running the **update force local sa-sdb** command causes the IAE not to take effect in a short time and resets all IAE-related session tables. Therefore, exercise cautions when using this command.

Example

Forcibly update the local application identification signature database using file hda1:/cnc_h10010000_2017111500.zip.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update force local sa-sdb file hda1:/cnc_h10010000_2017111500.zip
```

14.21.60 update force online sa-sdb

Function

The **update force online sa-sdb** command forcibly configures the immediate updates of the application identification signature database.

Format

update force online sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you run the **update online sa-sdb** command to immediately update the application identification signature database, the update fails in case of insufficient system memory. In this case, you can run the **update force online sa-sdb** command to immediately update the application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Running the **update force online sa-sdb** command causes the IAE not to take effect in a short time and resets all IAE-related session tables. Therefore, exercise cautions when using this command.

Example

Forcibly update the application identification signature database.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update force online sa-sdb
```

14.21.61 update force restore sdb-default sa-sdb

Function

The **update force restore sdb-default sa-sdb** command forcibly restores the application identification signature database to the factory default version.

Format

update force restoresdb-default sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you run the **update restore sdb-default sa-sdb** command to restore the application identification signature database to the default version, the restore fails if the system memory is insufficient. In this case, you can attempt to run the **update force restore sdb-default sa-sdb** command to forcibly restore the application identification signature database to the default version.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

- After you run the **update force restore sdb-default sa-sdb** command, the application identification signature database files corresponding to the rollback version and download version of the application identification signature database will be deleted.
- Running the **update force restore sdb-default sa-sdb** command causes the IAE not to take effect within a short period, resets all IAE-related session tables, and interrupts some services. Therefore, exercise caution when running this command.

Example

Forcibly restore the application identification signature database to the factory default version.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update force restore sdb-default sa-sdb
```

14.21.62 update force rollback sa-sdb

Function

The **update force rollback sa-sdb** command forcibly rolls back the version of the application identification signature database.

Format

update force rollback sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When you run the **update rollback sa-sdb** command to roll back the version of the application identification signature database, the rollback fails in case of insufficient system memory. In this case, you can run the **update force rollback sa-sdb** command to forcibly roll back the version of the application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Running the **update force rollback sa-sdb** command causes the IAE not to take effect in a short time and resets all IAE-related session tables. Therefore, exercise cautions when using this command.

Example

Forcibly roll back the version of the application identification signature database.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update force rollback sa-sdb
```

14.21.63 update host source

Function

The **update host source** command specifies the source IP address of online update request packets.

The **undo update host source** command deletes the specified source IP address of online update request packets.

By default, the system searches a route based on the IP address of the update center and uses the IP address of the outgoing interface as the source IP address of update request packets.

Format

update host source { *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance*] }

undo update host source [**ip**]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the IP address of the source interface of online update request packets.	-
ip *ip-address*	Specifies the source IP address of online update request packets.	The value is in dotted decimal notation.
vpn-instance *vpn-instance*	Specifies the name of a VPN instance.	The name is a string of 1 to 31 characters.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the device connects to the Internet through a VPN instance, these commands are mandatory. If the commands are not configured, the update will fail.

- When **update host source** *interface-type interface-number* is configured, the interface must be bound to the corresponding VPN instance name.
- When the **update host source ip** *ip-address* command is configured, **vpn-instance** *vpn-instance* must be specified.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

Instructions on these commands are as follows:

- The interface specified in the **update host source** *interface-type interface-number* command is not necessarily the outgoing interface of update request packets. This command actually specifies the IP address of a specific interface as the source IP address. To send update request packets, the system checks the route information to determine the outgoing interface.

  Do not specify an interface that is bound to a virtual system. Otherwise, the update will fail.
- If the interface has multiple IP addresses, run the **update host source ip** *ip-address* command to set the source IP address of update request packets and ensure that the device can receive the reply packets. Otherwise, the online update may fail.
- When both **update host source** *interface-type interface-number* and **update host source ip** *ip-address* [**vpn-instance** *vpn-instance*] are configured, the system preferentially uses the specified IP address as the source IP address of update request packets. That is, the **update host source** *interface-type interface-number* command does not take effect.

NOTE

After configuring this command, the device performs remote URL query within the VPN that the interface belongs to.

Example

Set the IP address of the interface used for online update to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet1/0/0] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet1/0/0] quit
[HUAWEI] update host source gigabitethernet 0/0/1
```

Set the source IP address of online update request packets to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update host source ip 10.1.1.1
```

14.21.64 update local sa-sdb

Function

The **update local sa-sdb** command configures manual update of the local application identification signature database.

Format

update local sa-sdb file *filename*

Parameters

Parameter	Description	Value
file *filename*	Specifies the update file. You must upload the update files to the device memory before the update.	The absolute path of a file is a string of 1 to 64 characters without spaces.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If the device cannot connect to the network, download the update files from the security center to a PC and upload the files to the device memory. Then run the **update local** command to update the application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Manually update the local application identification signature database using file hda1:/cnc_h10010000_2017111500.zip.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update local sa-sdb file hda1:/cnc_h10010000_2017111500.zip
```

14.21.65 update online sa-sdb

Function

The **update online sa-sdb** command configures the immediate updates of the application identification signature database.

Format

update online sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The online update modes of the application identification signature database include scheduled update and immediate update. Generally, scheduled update is used. In some case, the application identification signature database needs to be updated to the latest version immediately. If the scheduled update period does not expire, you can run the **update online sa-sdb** command to start immediate update. Before the update, you need to check whether the domain name or IP address of the update center (sec.huawei.com) is accessible.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Update the application identification signature database immediately.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update online sa-sdb
```

14.21.66 update proxy

Function

The **update proxy** command sets the IP address or domain name of the proxy server.

The **undo update proxy** command deletes the proxy server setting.

By default, no IP address or domain name is configured for the proxy server.

Format

update proxy { **domain** *domain-name* | **ip** *ip-address* } [**port** *port-number*] [**user** *user-name* [**password** *password*]]

undo update proxy

Parameters

Parameter	Description	Value
domain *domain-name*	Indicates the domain name of the proxy server.	The value is a string of 1 to 64 characters. It cannot contain spaces.
ip *ip-address*	Indicates the IP address of the proxy server.	The value is in dotted decimal notation.
port *port-number*	Indicates the port number of the proxy server.	The value is an integer in the range from 1 to 65535. The default value is 80.
user *user-name*	Indicates the user name for logging in to the proxy server.	The user name is a string and must have been set on the proxy server. If the user name does not contain spaces, it ranges from 1 to 32 characters. If the user name contains spaces, it ranges from 3 to 34 characters, and must be enclosed with double quotation marks (""), for example, "user for test".
password *password*	Indicates the password for logging in to the proxy server.	The password is a string and must be the same as the password corresponding to the user name of the proxy server. ● If the password does not contain spaces, it ranges from 1 to 32 characters. If the password contains spaces, it ranges from 3 to 34 characters, and must be enclosed with double quotation marks (""). ● The password cannot contain only asterisks (*).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

After the password for logging in to the proxy server is configured, you need to reconfigure the password if a version earlier than V200R021C10 is upgraded to V200R021C10 or later, or V200R021C10 or later is downgraded to a version earlier than V200R021C10.

Example

Configure the proxy server.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update proxy ip 192.168.2.33 port 8080 user test password Hello!123
```

14.21.67 update proxy enable

Function

The **update proxy enable** command enables the application identification signature database proxy update function.

The **undo update proxy enable** command disables the application identification signature database proxy update function.

By default, the application identification signature database proxy update function is disabled.

Format

update proxy enable

undo update proxy enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **update proxy enable** command used for updating the application identification signature database through a proxy server.

After this function is enabled, you must run the **update proxy** command to set the proxy server. Otherwise, the device cannot connect to the update server through the proxy server.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Precautions

During the application identification signature database update through a proxy server, HTTP will be used, causing security risks. You are advised to update the application identification signature database in local or direct update mode.

Example

Enable the application identification signature proxy update function.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update proxy enable
```

14.21.68 update restore engine

Function

The **update restore engine** command restores the engine to the factory default version.

Format

update restore engine

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Restore the engine to the factory default version.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update restore engine
```

14.21.69 update restore sdb-default sa-sdb

Function

The **update restore sdb-default sa-sdb** command restores the application identification signature database to the factory default version.

Format

update restore sdb-default sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After you run the **update restore sdb-default sa-sdb** command, the application identification signature database files corresponding to the rollback version and download version of the application identification signature database will be deleted. Therefore, exercise caution when running this command.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Restore the application identification signature database to the factory default version.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update restore sdb-default sa-sdb
```

14.21.70 update rollback sa-sdb

Function

The **update rollback sa-sdb** command rolls back the version of the application identification signature database.

Format

update rollback sa-sdb

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Run the **update rollback sa-sdb** command to roll back the current version of the application identification signature database to an earlier version. Only one earlier version is available for version rollback. If you run the **update rollback sa-sdb** command a second time, the version of the application identification signature database is rolled back to the current version again.

NOTE

The version rollback function is unavailable before the second update is complete.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Roll back the version of the application identification signature database.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update rollback sa-sdb
```

14.21.71 update schedule enable

Function

The **update schedule enable** command enables scheduled update time for the application identification signature database.

The **undo update schedule enable** command disables scheduled update time for the application identification signature database.

By default, scheduled update time for the application identification signature database is enabled.

Format

update schedule sa-sdb enable

undo update schedule sa-sdb enable

Parameters

Parameter	Description	Value
sa-sdb	Indicates the application identification signature database.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Enable the scheduled update time function for the application identification signature database.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update schedule sa-sdb enable
```

14.21.72 update schedule retry-download interval

Function

The **update schedule retry-download interval** command sets the retry interval for downloading the application identification signature database for scheduled update.

The **undo update schedule retry-download interval** command restores the default interval.

By default, the retry interval for downloading the application identification signature database for scheduled update is 3600 seconds.

Format

update schedule retry-download interval *interval-value*

undo update schedule retry-download interval

Parameters

Parameter	Description	Value
interval-value	Specifies the retry interval for downloading the application identification signature database for scheduled update.	The value is an integer ranging from 300 to 3600, in second. The default value is 3600.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In case of scheduled update, if the update server is busy, the application identification signature database may fail to be download, causing an update failure. Then, the device will retry downloading the application identification signature database. The **update schedule retry-download interval** command is used to set the retry interval for downloading the application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the retry interval for downloading the application identification signature database for scheduled update to 1800s.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update schedule retry-download interval 1800
```

14.21.73 update schedule retry-load interval

Function

The **update schedule retry-load interval** command sets the retry interval for loading the application identification signature database for scheduled update.

The **undo update schedule retry-load interval** command restores the default interval.

By default, the retry interval for loading the application identification signature database for scheduled update is 3600 seconds.

Format

update schedule retry-load interval *interval-value*

undo update schedule retry-load interval

Parameters

Parameter	Description	Value
interval-value	Specifies the retry interval for loading the application identification signature database for scheduled update.	The value is an integer ranging from 300 to 3600, in second. The default value is 3600.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

In case of scheduled update, if the memory of the device is insufficient, the device may fail to load the downloaded application identification signature database. Then, the device will retry loading the application identification signature database. The **update schedule retry-load interval** command is used to set the retry interval for loading the application identification signature database.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the retry interval for loading the application identification signature database for scheduled update to 1800s.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update schedule retry-load interval 1800
```

14.21.74 update schedule

Function

The **update schedule** command sets scheduled update time for the signature database.

By default, the scheduled update time for the signature database is not set.

Format

update schedule [**sa-sdb**] [{ **daily** | **weekly** { **Mon** | **Tue** | **Wed** | **Thu** | **Fri** | **Sat** | **Sun** } } *time*]

Parameters

Parameter	Description	Value
sa-sdb	Indicates scheduled update time of the application identification signature database.	-
daily	Indicates daily update of an application identification signature database.	-
weekly { **Mon** | **Tue** | **Wed** | **Thu** | **Fri** | **Sat** | **Sun** }	Indicates weekly update of an application identification signature database.	-

Parameter	Description	Value
time	Specifies the time in a day for the scheduled update of the application identification signature database.	The format is **hh:mm**. The hour and minute are separated by a colon (:). The **hh** value is an integer ranging from 0 to 23 and the **mm** value is an integer ranging from 0 to 59.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If time is not specified, the **update schedule** can update the application identification signature database daily at any point during the time range 22:00 to 08:00.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Configure a scheduled update of the application identification signature database at 02:00 every Wednesday.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update schedule weekly Wed 02:00
```

Configure a scheduled update of the application identification signature database at 03:00 every day.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update schedule daily 03:00
```

14.21.75 update server

Function

The **update server** command sets the IP address or domain name of the update server.

The **undo update server** command deletes the IP address or domain name of the update server.

By default, the domain name of the update server is sec.huawei.com.

Format

update server { { **domain** *domain-name* | **ip** *ip-address* } [**port** *port-number*] | **ca-certificate** *ca-certificate-name* }

undo update server

Parameters

Parameter	Description	Value
domain *domain-name*	Specifies the domain name of the update server.	The value is a string of 1 to 64 characters, spaces not supported.
ip *ip-address*	Specifies the IP address of the update server.	The value is in dotted decimal notation.
port *port-number*	Specifies the port number of the update server.	The value is an integer ranging from 1 to 65535.
ca-certificate *ca-certificate-name*	Specifies the CA certificate name of the update server.	The value is a string of 1 to 64 characters. The value must be the name of an existing CA certificate.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

By default, the domain name of the update server is sec.huawei.com, the HTTP port number is 80 and the HTTPS port number is 443.

Prerequisites

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Set the IP address of the update server to 10.1.1.1 and port number to 86.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] update server ip 10.1.1.1 port 86
```

14.22 Network Deception Configuration Commands

14.22.1 Command Support

Only the following switch models support deception:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S

14.22.2 deception

Function

The **deception** command creates and enters the deception view.

The **undo deception** command deletes the deception view.

By default, no deception view exists on the switch.

Format

deception

undo deception

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure the deception function, run this command to create and enter the deception view first.

Precautions

The **undo deception** command will delete all deception configurations. Therefore, confirm your operation before using this command.

Example

Create and enter the deception view.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception]
```

14.22.3 deception aci enable

Function

The **deception aci enable** command enables the Access Control Isolation (ACI) deception function.

The **undo deception aci enable** command disables the ACI deception function.

The ACI deception function is disabled by default.

Format

deception aci detect-network { **id** *id-number* | **all** } **enable**

undo deception aci detect-network { **id** *id-number* | **all** } **enable**

Parameters

Parameter	Description	Value
id *id-number*	Specifies the ID of a network segment to be detected.	The value is an integer ranging from 1 to 50.
all	Specifies all network segments to be detected.	-

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

ACI is an isolation scheme for controlling intranet communication through DNS access. After this function is enabled, the source or destination address in the detected network segment must be accessed through the domain name. If the IP address is directly accessed or the IP address that does not exist is accessed, traffic is deceived to the Decoy.

The DecoySensor parses DNS reply packets and establishes mappings between the source addresses of DNS request packets and the IP addresses corresponding to the domain names in DNS reply packets (that is, the ACI table). Subsequent TCP SYN packets and ICMP ping packets will match the ACI table. Traffic that fails to match the table is deceived to the Decoy for in-depth interactive detection.

ACI also supports the configuration of an ACI suffix using the **deception aci suffix** command. The default value is **aci**. An ACI suffix functions as an intranet access key. For example, if the IP address of the server in the detected network segment is 192.168.1.1, the server must be accessed through **192.168.1.1.aci** if the default ACI suffix is used. If the IP address of the server is directly accessed or the IP address with an incorrect ACI suffix is accessed, traffic is deceived to the Decoy for in-depth interactive detection.

The ACI deception function takes effect only after the deception function is enabled using **deception enable**.

Example

Enable the ACI deception function.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception aci detect-network all enable
```

14.22.4 deception aci lack decoy

Function

The **deception aci lack decoy** command sets the policy used in the case of a full ACI table to deceive.

The **undo deception aci lack decoy** sets the policy used in the case of a full ACI table to permit.

The policy used in the case of a full ACI table is permit by default.

Format

deception aci lack decoy

undo deception aci lack decoy

Parameters

None

2: Configuration level

Usage Guidelines

The ACI table is space-limited. If there are a large number of intranet DNS requests and the ACI table cannot store new mappings, traffic will be deceived or permitted based on the configuration of this command.

To prevent a full ACI table, you can run the **deception aci timeout** command to set a shorter aging time for ACI entries.

Example

Set the policy used in the case of a full ACI table to deceive.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception aci lack decoy
 Warning: If the configured ACI resources are insufficient, the default action is decoy which affects services.
Continue? [Y/N]:y
```

14.22.5 deception aci suffix

Function

The **deception aci suffix** command sets an ACI suffix.

The **undo deception aci suffix** command restores the default ACI suffix.

The ACI suffix is **aci** by default.

Format

deception aci suffix *suffix-value*

undo deception aci suffix

Parameters

Parameter	Description	Value
suffix-value	Specifies the ACI suffix.	The value is a string of at most eight characters, including letters, digits, and hyphens (-). It must start with a letter.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

An ACI suffix functions as an intranet access key. For example, if the IP address of the server in the detected network segment is 192.168.1.1, the server must be accessed only through **192.168.1.1.aci** if the default ACI suffix is used. If the IP address of the server is directly accessed or the IP address with an incorrect ACI suffix is accessed, traffic is deceived to the Decoy or discarded.

After the ACI suffix is changed, you need to run the **reset deception aci** command to update the ACI entries. Otherwise, the old ACI suffix becomes invalid only after the ACI entries age. After the ACI entries are updated, the access initiated by a terminal is deceived when the DNS record of the terminal does not age. Therefore, change the ACI suffix when no service traffic exists.

Example

Set the ACI suffix to **testaci**.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception aci suffix testaci
```

14.22.6 deception aci timeout

Function

The **deception aci timeout** command sets the aging time of ACI entries.

The **undo deception aci timeout** command restores the default aging time of ACI entries.

By default, the aging time of ACI entries is 60s. When a new DNS reply packet arrives, the corresponding ACI entry is updated.

Format

deception aci timeout *timeout-value*

undo deception aci timeout

Parameters

Parameter	Description	Value
timeout-value	Specifies the aging time of ACI entries.	The value is an integer ranging from 10 to 300, in seconds.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

The DecoySensor replaces the TTL in the DNS reply packet with the aging time configured in this command. The DNS TTL is the cache time of the DNS entries recorded by the terminal. After the time expires, the terminal initiates a DNS request again. After receiving the DNS reply packet, the DecoySensor updates the aging time of the corresponding ACI entry to ensure that the DNS entry recorded by the terminal and the ACI entry on the DecoySensor are aged or updated at the same time.

The ACI table is space-limited. If there are a large number of intranet DNS requests and the ACI table cannot store new mappings, traffic will be deceived or permitted based on the configuration of the **deception aci lack decoy** command. You can run the **deception aci timeout** command to set a shorter aging time for ACI entries.

If the intranet access is stable and there is a small number of DNS requests, you can set a longer aging time of ACI entries for better performance.

Example

Set the aging time of ACI entries to 100s.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception aci timeout 100
```

14.22.7 deception arp-request rate

Function

The **deception arp-request rate** command sets an IP address scanning threshold.

The **undo deception arp-request rate** command restores the IP address scanning threshold to the default value.

By default, the IP address scanning threshold is 10 times per 10 seconds.

Format

deception arp-request rate *rate-number*

undo deception arp-request rate

Parameters

Parameter	Description	Value
rate-number	Specifies an IP address scanning threshold.	The value is an integer in the range from 1 to 20000, in **"times per 10 seconds"**.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

If the frequency of scanning a destination IP address by a source IP address reaches the specified threshold, the switch considers the event to be a suspected attack. Once the switch detects that the scanned IP address is offline, it immediately lures the traffic to the Decoy for further detection.

Example

Set the IP address scanning threshold to 20 times per 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception arp-request rate 20
```

14.22.8 deception decoy-network

Function

The **deception decoy-network** command configures a bait network segment.

The **undo deception decoy-network** command deletes a bait network segment.

By default, no bait network segment is configured on the switch.

Format

deception decoy-network id *id-number* **destination** *ip-address* [*mask*] [**destination-port** *port* &<1-20>] [**vpn-instance** *vpn-instance-name*]

undo deception decoy-network { **all** | **id** *id-number* }

Parameters

Parameter	Description	Value
id *id-number*	Specifies the ID of a bait network segment.	The value is an integer in the range from 1 to 50.
destination *ip-address* [*mask*]	• *ip-address* specifies an IP address. • *mask* specifies the subnet mask of the bait network segment.	The value is in dotted decimal notation.
destination-port *port*	Specifies the destination TCP port number. **NOTE** If this parameter is specified, traffic will be lured immediately if this TCP port is scanned or the IP address corresponding to the TCP port is scanned.	The value is an integer in the range from 1 to 65535.

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the VPN instance for the bait network segment.	The VPN instance must be an existing one on the device.
all	Specifies all bait network segments.	-

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a bait network segment is configured, the switch does not detect whether the IP addresses on the bait network segment are online. If an IP address or TCP port on the bait network segment is scanned, the switch lures the scanning traffic to the Decoy for further attack detection. Therefore, you can add some idle IP addresses to the bait network segment.

Precautions

A deception whitelist configured using the **deception whitelist** command takes precedence over a bait network segment:

- If an IP address is in both the deception destination IP address whitelist and the bait network segment, the switch ignores IP address scanning and TCP port scanning on the IP address and does not lure the traffic destined for the IP address.
- If scanning is initiated by a whitelisted address and the scanned IP address is on the bait network segment, the switch does not lure the traffic.

A bait network segment cannot contain the device management address and any network segment (0.0.0.0). Otherwise, the devices cannot be managed remotely.

Example

Add 10.1.1.11 to the bait network segment.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception decoy-network id 1 destination 10.1.1.11
```

14.22.9 deception detect-network

Function

The **deception detect-network** command sets a network segment detected by the deception system.

The **undo deception detect-network** command deletes the detected network segment.

By default, no detected network segment is configured on the switch.

Format

deception detect-network id *id-number ip-address mask* [**vpn-instance** *vpn-instance-name*]

undo deception detect-network { **all** | **id** *id-number* }

Parameters

Parameter	Description	Value
id *id-number*	Specifies the ID of a detected network segment.	The value is an integer in the range from 1 to 50.
ip-address	Specifies the IP address of the detected network segment.	The value is in dotted decimal notation.
mask	Specifies the subnet mask of the detected network segment.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the VPN instance of the detected network segment.	The VPN instance must be an existing one on the device.
all	Indicates that all network segments are detected for deception.	-

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The detected network segment is protected by the deception system:

- IP address scanning: Deception is triggered only when the destination IP address of scanning packets is on the detected network segment.
- TCP port scanning: Deception is triggered when the source or destination IP address of scanning packets is on the detected network segment.

Precautions

If you have configured a bait network segment using the **deception decoy-network** command, deception is triggered when the IP addresses on the bait network segment are scanned, with no need to configure these IP addresses in the detected network segment.

Example

Configure the deception system to detect the network segment **10.1.1.0/24**.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception detect-network id 1 10.1.1.0 255.255.255.0
```

14.22.10 deception dns enable

Function

The **deception dns enable** command enables the unknown-domain-name deception function.

The **undo deception dns enable** command disables the unknown-domain-name deception function.

The unknown-domain-name deception function is disabled by default.

Format

deception dns enable

undo deception dns enable

Parameters

None

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

After the unknown-domain-name deception function is enabled, the DecoySensor identifies DNS requests on the network. When DNS requests are quickly sent from the same source IP address, it is suspected that domain name scanning is performed for obtaining the real intranet IP address. When the rate of domain name scans reaches the threshold and related information in the DNS reply packet indicates that the domain name does not exist, the DecoySensor automatically constructs and returns a DNS reply packet. The IP address in the DNS reply packet is the IP address in the bait network segment and is in the same network segment as the source address for sending the DNS request packet. The subsequent access and attack to this IP address will be deceived to the Decoy for in-depth interactive detection.

The deception operation is performed only after a bait network segment that is the same as the detected network segment is configured using **deception decoy-network**. If the bait network segment is not configured, the DecoySensor sends only domain name scan threshold-crossing logs.

The unknown-domain-name deception function takes effect only after the deception function is enabled using **deception enable**.

Example

Enable the unknown-domain-name deception function.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception dns enable
```

14.22.11 deception dns-request rate

Function

The **deception dns-request rate** command sets the domain name scan threshold.

The **undo deception dns-request rate** command restores the default domain name scan threshold.

By default, the domain name scan threshold is 5 scans per second.

Format

deception dns-request rate *rate-number*

undo deception dns-request rate

Parameters

Parameter	Description	Value
rate-number	Specifies the domain name scan threshold.	The value is an integer ranging from 1 to 20000, in scans per second.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

When the rate of domain name scans sent from the same source IP address reaches the threshold and related information carried in the DNS reply packet indicates that the domain name does not exist, the DecoySensor determines that it is an attack. The DecoySensor automatically constructs and returns a DNS reply packet. The IP address corresponding to the domain name in the constructed DNS reply packet is the IP address in the bait network segment, and is in the same network segment as the source address for sending the DNS request packet. The subsequent access and attack to this IP address will be deceived to the Decoy.

Example

Set the domain name scan threshold to 300 scans per second.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception dns-request rate 300
```

14.22.12 deception enable

Function

The **deception enable** command enables the deception function.

The **undo deception enable** command disables the deception function.

By default, the deception function is disabled.

Format

deception enable

undo deception enable

Parameters

None

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After deception is enabled, the DecoySensor identifies IP address and TCP port scanning activities on the network and lures suspicious traffic to the Decoy. If the configuration is incorrect, normal network traffic may be affected. Before enabling deception, run the **display this** command in the deception view to confirm the deception configuration.

Prerequisites

- The optimized ARP reply function has been disabled using the **arp optimized-reply disable** command, and the VLANIF interface has been configured to send ARP packets destined for other devices to the CPU using the **undo arp optimized-passby enable** command.
- You have configured **deception detect-network** or **deception decoy-network**, or both of them. Otherwise, the deception function does not take effect.

Example

Enable the deception function.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception enable
```

14.22.13 deception decoy

Function

The **deception decoy** command sets a Decoy IP address.

The **undo deception decoy** command deletes a Decoy IP address.

By default, no Decoy IP address is configured on the switch.

Format

deception decoy destination *destination-ip* [**source** *source-ip*] [**vpn-instance** *vpn-instance-name*] [**backup destination** *destination-ip* [**source** *source-ip*] [**vpn-instance** *vpn-instance-name*]]

undo deception decoy

Parameters

Parameter	Description	Value
source *source-ip*	Specifies the IP address used by a switch to connect to a Decoy. If this parameter is not specified, the IP address of the outbound interface is used.	The value is in dotted decimal notation.

Parameter	Description	Value
destination *destination-ip*	Specifies a Decoy IP address.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the VPN instance of the Decoy.	The VPN instance must be an existing one on the device.
backup	Indicates the standby Decoy.	-

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When detecting suspected attack traffic, the switch lures the traffic to a Decoy for further checks. Therefore, you must first run this command to configure the IP address of the Decoy.

If communication between the switch and active Decoy is abnormal, the switch sends the log and deceived traffic to the standby Decoy that can communicate with the switch.

Precautions

A switch cannot use the virtual IP address of a VRRP group or the IP address of the management network interface to connect to a Decoy.

Example

Set the Decoy IP address to **10.1.1.1**.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception decoy destination 10.1.1.1
```

14.22.14 deception ip-state detect rate

Function

The **deception ip-state detect rate** command configures the frequency of scanning IP addresses by the switch.

The **undo deception ip-state detect rate** command restores the default frequency of scanning IP addresses by the switch.

By default, the switch scans IP addresses 30 times per second.

Format

deception ip-state detect rate *rate-number*

undo deception ip-state detect rate

Parameters

Parameter	Description	Value
rate-number	Specifies the frequency of scanning IP addresses by the switch.	The value is an integer in the range from 1 to 4096, in **"times per second"**.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

The switch initiates IP address scanning on the network segment to be detected to check whether IP addresses are online. If the scanning frequency is too high, the network is affected. If the scanning frequency is too low, the switch takes a long time to learn about the online status of IP addresses. You need to configure a proper IP address scanning frequency based on the site requirements and live network quality.

Example

Set the frequency of scanning IP addresses by the switch to 40 times per second.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception ip-state detect rate 40
```

14.22.15 deception mac-address aging-time

Function

The **deception mac-address aging-time** command configures the interval at which the switch sends an ARP broadcast packet.

The **undo deception mac-address aging-time** command restores the default interval at which the switch sends an ARP broadcast packet.

By default, the switch sends an ARP broadcast packet at an interval of 290 seconds.

Format

deception mac-address aging-time *aging-time*

undo deception mac-address aging-time

Parameters

Parameter	Description	Value
aging-time	Specifies the interval at which the switch sends an ARP broadcast packet.	The value is an integer in the range from 10 to 1000000, in seconds.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

To perform spoofing on IP address scanning, the switch constructs a virtual MAC address and sends it to the scanning source. The scanning source then incorrectly considers that the IP address to be scanned is online, and the switch diverts subsequent traffic from the scanning source to a Decoy for attack detection. The Layer 2 switch records an ARP entry of the scanned IP address and virtual MAC address. To prevent packets destined for the scanned IP address from being broadcast on the network after the entry is aged out, the switch periodically sends an ARP broadcast packet that contains the mapping between the scanned IP address and the virtual MAC address to the Layer 2 switch. You can run the **deception mac-address aging-time** command to adjust the interval at which the switch sends an ARP broadcast packet.

Example

Set the interval at which the switch sends an ARP broadcast packet to 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception mac-address aging-time 300
```

14.22.16 deception mode strict

Function

The **deception mode strict** command enables the strict deception mode.

The **undo deception mode** command disables the strict deception mode.

By default, the strict deception mode is not used.

Format

deception mode strict

undo deception mode

Parameters

None

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

Fixed networking and stable servers are prerequisites for the strict deception mode. After the strict deception mode is set, the switch immediately lures the traffic destined for offline IP addresses or unopened TCP ports to the Decoy for further detection.

In non-strict mode, deception is performed only when the following conditions are met:

- The IP scanning or TCP port scanning frequency initiated by an IP address reaches the specified threshold.
- An offline IP address or unopened TCP port is scanned.

Example

Enable the strict deception mode.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception mode strict
```

14.22.17 deception syn-connect rate

Function

The **deception syn-connect rate** command sets a TCP port scanning threshold.

The **undo deception syn-connect rate** command restores the TCP port scanning threshold to the default value.

By default, the TCP port scanning threshold is 100 times per second.

Format

deception syn-connect rate *rate-number*

undo deception syn-connect rate

Parameters

Parameter	Description	Value
rate-number	Specifies a TCP port scanning threshold.	The value is an integer in the range from 1 to 20000, in **"times per second"**.

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

If the frequency of scanning a TCP port by a source IP address reaches the specified threshold, the switch considers the event to be a suspected attack. Once the switch detects that the scanned TCP port is unopened, it immediately lures the traffic to the Decoy for further detection.

Example

Set the TCP port scanning threshold to 200 times per second.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception syn-connect rate 200
```

14.22.18 deception whitelist

Function

The **deception whitelist** command sets a deception whitelist.

The **undo deception whitelist** command deletes a deception whitelist.

By default, there is no deception whitelist.

Format

deception whitelist id *id-number* { **destination** | **source** } *ip-address* [*mask*] [**vpn-instance** *vpn-instance-name*]

undo deception whitelist { **all** | **id** *id-number* }

Parameters

Parameter	Description	Value
id *id-number*	Specifies a whitelist ID.	The value is an integer in the range from 1 to 50.
destination	Indicates the destination IP address whitelist.	-
source	Indicates the source IP address whitelist.	-
ip-address [*mask*]	Adds a specified IP address or IP address segment to the deception whitelist. ● *ip-address* specifies an IP address. ● *mask* specifies the subnet mask of the IP address segment.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the VPN instance of the whitelisted IP address.	The VPN instance must be an existing one on the device.
all	Indicates all whitelists.	-

Views

Deception view

Default Level

2: Configuration level

Usage Guidelines

You can configure destination IP address whitelists and source IP address whitelists:

- Source IP address whitelist: If the source IP address of scanning packets is in the source IP address whitelist, the device does not lure the scanning packets sent from this IP address to the Decoy. The addresses of devices that proactively detect the network (such as the NMS) can be whitelisted to prevent deception.
- Destination IP address whitelist: If the destination IP address of scanning packets is in the destination IP address whitelist, the device does not lure the scanning packets sent to this IP address to the Decoy. The addresses of devices that do not respond to ARP requests or port connection requests (such as traditional printers) can be whitelisted to prevent deception.

Example

Add 10.1.1.10 to destination IP address whitelist.

```
<HUAWEI> system-view
[HUAWEI] deception
[HUAWEI-deception] deception whitelist id 1 destination 10.1.1.10
```

14.22.19 display deception aci

Function

The **display deception aci** command displays the ACI table.

Format

display deception aci [**source** *ip-address*]

Parameters

Parameter	Description	Value
source *ip-address*	Specifies the source IP address in an ACI entry.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The DecoySensor parses DNS reply packets and establishes mappings between the source addresses of DNS request packets and the IP addresses corresponding to the domain names in DNS reply packets (that is, the ACI table). Subsequent TCP SYN packets and ICMP ping packets will match the ACI table. Traffic that fails to match the table is deceived to the Decoy for in-depth interactive detection.

If the number of current entries approaches the upper limit, run the **deception aci timeout** command to set a shorter aging time for ACI entries.

Example

Display the ACI table.

```
<HUAWEI> display deception aci
 ------------------------------------------------------------------------------------------------------
 Current total number = 1
 ------------------------------------------------------------------------------------------------------
 source          destnation       time    vpn-instance
 ------------------------------------------------------------------------------------------------------
 192.168.1.1      172.16.2.1       192     public
```

Table 14-131 Description of the **display deception aci** command output

Item	Description
source	Source IP address initiating a DNS request
destnation	IP address corresponding to the domain name in the DNS reply packet
time	Remaining lifetime of the entry
vpn-instance	VPN instance to which the source IP address belongs

14.22.20 display deception arp-proxy

Function

The **display deception arp-proxy** command displays the interface IP address of the switch and the target IP addresses in the proxy ARP requests sent to the switch in the online IP address table.

Format

display deception arp-proxy

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The switch cannot scan its interface IP address and the target IP addresses in the proxy ARP requests sent to the switch. Therefore, the switch may lure the traffic destined for these IP addresses to a Decoy. To solve this problem, after the switch receives ARP requests destined for these IP addresses, the switch returns ARP reply packets, and the management plane instructs the deception module to add the target IP addresses in ARP requests to the online IP address table.

Example

Display the interface IP address of the switch and the target IP addresses in the proxy ARP requests sent to the switch in the online IP address table.

```
<HUAWEI> display deception arp-proxy
---------------------------------------------------------------------------------------------------------
```

```
Current total number = 1

-----------------------------------------------------------------------------------------------------------
ip-address       vlan   vpn-instance
10.1.1.1         10     default
-------------------------------------------------------------------------------
```

Table 14-132 Description of the **display deception arp-proxy** command output

Item	Description
Current total number	Number of entries.
ip-address	Interface IP address of the switch or the target IP address in the proxy ARP request sent to the switch.
vlan	VLAN ID corresponding to the IP address.
vpn-instance	VPN instance to which the IP address belongs.

14.22.21 display deception arp-request

Function

The **display deception arp-request** command displays the IP address scanning behavior detected by the switch.

Format

display deception arp-request [**source** *ip-address*]

Parameters

Parameter	Description	Value
source *ip-address*	Specifies the source IP address that initiates IP address scanning.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the IP address scanning behavior detected by the switch, so that you can configure a more accurate IP address canning threshold using the **deception arp-request rate** command. If an IP address is scanned at a lower frequency than the threshold specified by the **deception arp-**

request rate command but have been scanned for many times, the scanning behavior may be an attack.

Example

Display the IP address scanning behavior detected by the switch.

```
<HUAWEI> display deception arp-request
-------------------------------------------------------------------------------------------------
Current total number = 2

-------------------------------------------------------------------------------------------------
source          rate(num/10s)    number       vlan   vpn-instance
-------------------------------------------------------------------------------------------------
10.1.1.1        4                231          10     public
10.1.1.2        1                280          10     public
-------------------------------------------------------------------------------
```

Table 14-133 Description of the **display deception arp-request** command output

Item	Description
Current total number	Number of entries.
source	Source IP address that initiates IP scanning.
rate(num/10s)	IP address scanning frequency, in **"times per 10 seconds"**.
number	Number of IP address scanning times.
vlan	VLAN to which the source IP address belongs.
vpn-instance	VPN instance of the source IP address.

14.22.22 display deception config-flow

Function

The **display deception config-flow** command displays the configuration flow table.

Format

display deception config-flow [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When a detected network segment, bait network segment, or deception whitelist is configured, a configuration flow table is generated. If the preceding configuration is changed, the switch checks whether the deceived traffic meets the conditions of configuration flow tables and determines whether to lure the traffic to the Decoy.

Example

Display the configuration flow table.

```
<HUAWEI> display deception config-flow

Action          :1
Causeid         :16384
Vpn-instance    :
Destination IP  :10.10.10.22/255.255.255.255
```

Table 14-134 Description of the **display deception config-flow** command output

Item	Description
Slot	Slot ID.
CFG Flow ID *n* information	Information about configuration flow table *n*.
Priority	Priority of the configuration flow entry. The value is in the range from 0 to 10, and a smaller value indicates a higher priority. If a flow matches multiple configuration flow entries, the configuration flow entry with the highest priority takes effect.
Action	Action taken on the packets matching the configuration flow entry: ● 1: Deception check is not performed on the packets. ● 2: The packets are discarded. ● 4 and 8: Deception check is performed on the packets.
Causeid	Type of packets. The value in 2^i, in which i can be as follows: ● 0: packets matching the deception detected network segment ● 12: packets matching the bait network segment ● 14: packets matching the deception whitelist
Vpn-instance	VPN instance.
Destination IP	Destination IP address of traffic.
Destination Port	Destination TCP port number of traffic.
Source IP	Source IP address of traffic.

14.22.23 display deception decoy-network

Function

The **display deception decoy-network** command displays a bait network segment.

Format

display deception decoy-network [**id** *id-number*]

Parameters

Parameter	Description	Value
id *id-number*	Specifies the ID of a bait network segment.	The value is an integer in the range from 1 to 50.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring a bait network segment using the **deception decoy-network** command, you can run the **display deception decoy-network** command to check whether the bait network segment is correctly configured.

Example

Display all bait network segments.

```
<HUAWEI> display deception decoy-network
------------------------------------------------------------------------------------------------------------
Current total number = 1

------------------------------------------------------------------------------------------------------------
Decoy-network ID 1 information:
------------------------------------------------------------------------------------------------------------
source/mask              :any
destination/mask           :192.168.1.0/255.255.255.240
destination-port          :
vpn-instance             :
```

Table 14-135 Description of the **display deception decoy-network** command output

Item	Description
Current total number	Number of entries.

Item	Description
Decoy-network ID *i* information	Information about the bait network segment whose ID is *i*.
source/mask	Source IP address and subnet mask.
destination/mask	Destination IP address and subnet mask.
destination-port	Destination port number.
vpn-instance	VPN instance of the destination IP address.

14.22.24 display deception detect-network

Function

The **display deception detect-network** command displays the network segments detected for deception.

Format

display deception detect-network [**id** *id-number*]

Parameters

Parameter	Description	Value
id *id-number*	Specifies the ID of a detected network segment.	The value is an integer in the range from 1 to 50.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring a detected network segment using the **deception detect-network** command, you can run the **display deception detect-network** command to check whether the detected network segment is correctly configured.

Example

Display the network segments detected for deception.

```
<HUAWEI> display deception detect-network
-------------------------------------------------------------------------------------------------------
```

```
Current total number = 1

---------------------------------------------------------------------------------------------------
id   ip-address/mask(For both source and destination)        vpn-
instance
---------------------------------------------------------------------------------------------------
1    192.168.10.0/255.255.255.0
```

Table 14-136 Description of the **display deception detect-network** command output

Item	Description
Current total number	Number of entries.
id	ID of a detected network segment.
ip-address/mask	IP address and subnet mask of the detected network segment.
vpn-instance	VPN instance of the detected network segment.

14.22.25 display deception dns

Function

The **display deception dns** command displays the domain name scan status.

Format

display deception dns [**source** *ip-address*]

Parameters

Parameter	Description	Value
source *ip-address*	Specifies the source IP address initiating the domain name scan.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

By observing the domain name scan status, network administrators can set a more accurate domain name scan threshold using the **deception dns-request rate** command.

If the **rate** of a source address is low and does not reach the threshold but the **number** is large, a very patient hacker may be hidden behind this address.

Example

Display domain name scan status.

```
<HUAWEI> display deception dns
 -----------------------------------------------------------------------------
 Current total number = 2
 -----------------------------------------------------------------------------
 source           number    rate(num/s)    error-aci      vpn-instance
 -----------------------------------------------------------------------------
 192.168.1.1      4          231          0             public
 192.168.1.2      1          280          0             public
 -----------------------------------------------------------------------------
 recent request dns domain :
 www.huawei.com
 192.168.1.3.aci
```

Table 14-137 Description of the **display deception dns** command output

Item	Description
source	Source IP address initiating the domain name scan
number	Number of domain name scans
rate(num/s)	Rate of domain name scans, in scans per second
error-aci	Number of ACI suffix mismatches in DNS requests in ACI format
vpn-instance	VPN instance to which the source IP address belongs
recent request dns domain	Domain name in the latest request. A maximum of five domain names can be recorded

14.22.26 display deception flow

Function

The **display deception flow** command displays the deception flow table.

Format

display deception flow [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

In the deception flow table, you can view the traffic that meets certain conditions and will be sent to the deception module. The deception module then determines whether to lure the traffic to the Decoy based on the scanned IP address and TCP port.

Precautions

When a detected network segment, bait network segment, or deception whitelist is configured, a deception flow table is generated.

Example

Display the deception flow table.

```
<HUAWEI> display deception flow

Slot: 0
--------------------------------------------------------------------------------
Flow ID 1 information:
--------------------------------------------------------------------------------
Status          :Valid
Destination mac :0050-568c-1bbc
Vpn-instance    :
--------------------------------------------------------------------------------
Flow ID 2 information:
--------------------------------------------------------------------------------
Status          :Valid
Vpn-instance    :
Eth_type        :Arp
--------------------------------------------------------------------------------
Flow ID 4 information:
--------------------------------------------------------------------------------
Status          :Valid
Vpn-instance    :
Protocol        :Tcp
Tcp_flag        :Syn
--------------------------------------------------------------------------------
Flow ID 5 information:
--------------------------------------------------------------------------------
Status          :Valid
Vpn-instance    :
Protocol        :Tcp
Tcp_flag        :Syn | Ack
--------------------------------------------------------------------------------
Flow ID 6 information:
--------------------------------------------------------------------------------
Status          :Valid
Vpn-instance    :
Protocol        :Tcp
Tcp_flag        :Rst | Ack
```

Table 14-138 Description of the **display deception flow** command output

Item	Description
Slot	Slot ID.
Flow ID *n* information	Information about deception flow table *n*.
Status	Whether the deception flow entry is valid: ● Valid ● Invalid
Vpn-instance	VPN instance to which the inbound interface of the scanning packets belongs.
Destination mac	MAC address used by the switch to perform ARP spoofing on IP address scanning in a suspected attack.
Destination IP	Destination IP address of scanning packets.
Destination Port	Destination port number of scanning packets.
Source IP	Source IP address of scanning packets.
Protocol	Transport layer protocol type of scanning packets.
Eth_type	Layer 2 protocol type of scanning packets.
Tcp_flag	TCP flag.

14.22.27 display deception decoy status

Function

The **display deception decoy status** command displays the registration status of a DecoySensor on a Decoy.

Format

display deception decoy status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A DecoySensor initiates registration to a Decoy. If the registration succeeds:

- The registration status changes from **INIT** to **ALIVE**.
- The Decoy informs the DecoySensor of a port list for which the deception service is provided. Only the traffic whose destination ports in the list can be lured to the Decoy for further detection.
- The DecoySensor and Decoy send heartbeat packets to each other every 5 seconds. If the DecoySensor does not receive heartbeat packets from the Decoy within 60 seconds, its registration status changes to **INIT**. If the Decoy does not receive heartbeat packets from the DecoySensor within 60 seconds, it sends a deregistration packet to the DecoySensor. After the DecoySensor receives the packet, its registration status changes to **INIT**.

Example

Display the registration status of a DecoySensor on a Decoy.

```
<HUAWEI> display deception decoy status
 Decoy register status information:
   Register status                                   : alive
   Decoy select                                      : master
   Online time                                       : 37062(s)
   Send heartbeat timeout                                  : 0(s)
   Receive heartbeat timeout                               : 5(s)
 Decoy register port information:
   445      80       8080      443       22
   3389      21       3306      6379
```

Table 14-139 Description of the **display deception decoy status** command output

Item	Description
Decoy register status information	Registration status of a DecoySensor on a Decoy.
Register status	Registration status: ● init: Unregistered ● alive: Successfully registered
Decoy select	Currently connected Decoy ● master: Active ● backup: Standby
Online time	Duration of the connection to the Decoy.
Send heartbeat timeout	Period after the DecoySensor sent the last heartbeat packet, in seconds.
Receive Heartbeat timeout	Period after the DecoySensor received the last heartbeat packet, in seconds.
Decoy register port information	Port information of the deception service provided by the Decoy.

Item	Description
Decoy nonsupport port statistics	Port statistics not supported by the Decoy.

14.22.28 display deception instance

Function

The **display deception instance** command checks whether the deception process is normal.

Format

display deception instance

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

None

Example

Check whether the deception process is normal.

```
<HUAWEI> display deception instance
-------------------------------------------------------------------------------------------------------------

Instance        Slot      Cpu       State
-------------------------------------------------------------------------------------------------------------

decpt           *         *         normal
-------------------------------------------------------------------------------------------------------------

Current total number = 1
```

Table 14-140 Description of the **display deception instance** command output

Item	Description
Instance	Name of the deception process.

Item	Description
Slot	Slot ID.
Cpu	CPU ID.
State	Status: ● normal ● abnormal
Current total number	Total number of processes.

14.22.29 display deception interface

Function

The **display deception interface** command displays information about all deception-enabled interfaces.

Format

display deception interface

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view information about all deception-enabled interfaces, including the interface name, VLAN ID, and election status of interfaces for detecting IP address scanning. If a detected network segment has been configured using the **deception detect-network** command, the deception function can be configured only on the interfaces whose IP addresses are on the detected network segment.

Precautions

Interfaces whose IP addresses are not on the detected network segment cannot detect IP address scanning or participate in the election.

Example

Display information about all deception-enabled interfaces.

```
<HUAWEI> display deception interface
------------------------------------------------------------------------------------------------------
Current total number = 0
------------------------------------------------------------------------------------------------------
name                    ip-address         vlan   election-state   master-ip     vpn-instance
------------------------------------------------------------------------------------------------------
------------------------------------------------------------------------------------------------------
```

Table 14-141 Description of the **display deception interface** command output

Item	Description
name	Interface name.
ip-address	IP address of the interface.
vlan	VLAN to which the interface belongs.
election-state	Election status of the interface for detecting IP address scanning: ● master: If the device of the interface is elected as the active DecoySensor, it detects IP scanning on the network. ● slave: If the device of the interface is elected as a standby DecoySensor, it does not detect IP scanning on the network. ● init: Election is ongoing. ● --: The interface address is not in the detected network segment, so the interface does not participate in election.
master-ip	IP address of the active DecoySensor on the network segment.
vpn-instance	VPN instance of the interface.

14.22.30 display deception ip-redirect

Function

The **display deception ip-redirect** command displays information about deceived traffic due to the scanning of offline IP addresses.

Format

display deception ip-redirect [**source-ip** *ip-address*] [**destination-ip** *ip-address*] [**destination-port** *port*]

Parameters

Parameter	Description	Value
source-ip *ip-address*	Specifies the source IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-ip *ip-address*	Specifies the destination IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-port *port*	Specifies the destination port of the deceived traffic.	The value is an integer in the range from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

None

Example

Display information about deceived traffic due to the scanning of offline IP addresses.

```
<HUAWEI> display deception ip-redirect
--------------------------------------------------------------------------------
Current total number = 1
--------------------------------------------------------------------------------
source          destination     port  out-vlan  vpn-instance  left-time(s) packets
--------------------------------------------------------------------------------
10.1.1.1        10.1.1.2         *      10       public        432          0
--------------------------------------------------------------------------------
```

Table 14-142 Description of the **display deception ip-redirect** command output

Item	Description
Current total number	Number of entries.
source	Source IP address of the deceived traffic.
destination	Destination IP address of the deceived traffic.
port	Destination port number of the deceived traffic.

Item	Description
out-vlan	VLAN ID of the deceived traffic.
vpn-instance	VPN instance of the deceived traffic.
left-time(s)	Remaining time before an entry ages, in seconds. The aging time is 10 minutes. If no traffic matches the entry within the aging time, the entry is deleted. If traffic matches the entry within the aging time, the aging time is updated.
packets	Number of the deceived packets.

14.22.31 display deception ip-state

Function

The **display deception ip-state** command displays the online status of IP addresses scanned by the switch.

Format

display deception ip-state [*ip-address*] [**verbose**]

Parameters

Parameter	Description	Value
ip-address	Displays the online status of a specified IP address.	The value is in dotted decimal notation.
verbose	Displays the detailed online status of IP addresses.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A switch checks the online status of IP addresses every 30 minutes. If traffic destined for address A is deceived, the interval for checking the online status of address A is shortened to 10 to 110 seconds to minimize the adverse impact on network services. The interval depends on the number of the deceived source addresses. More source addresses result in a longer interval.

The **display deception ip-state** command output does not contain the IP address online status if the **deception detect-network** command is not used to set any detected network segment.

Precautions

The IP addresses scanned by the DecoySensor must be on the detected network segment, and the DecoySensor has an IP address belonging to this network segment.

The **reset deception ip-state** command clears the IP address online status and immediately initiates the check on the online status of IP addresses.

Example

Display the online status of IP addresses scanned by the switch.

```
<HUAWEI> display deception ip-state
----------------------------------------------------------------------------------------------------
Current total number = 0

----------------------------------------------------------------------------------------------------
ip-address       state     vlan    vpn-instance
----------------------------------------------------------------------------------------------------
```

Display the detailed online status of IP addresses scanned by the switch.

```
<HUAWEI> display deception ip-state verbose
----------------------------------------------------------------------------------------
10.1.1.1 information:
----------------------------------------------------------------------------------------
state               :online
vlan                :10
vpn-instance        :
proxy_flag          :1
on2off_flag         :0
redirect_num        :0
----------------------------------------------------------------------------------------
Total displayed = 1
```

Table 14-143 Description of the **display deception ip-state** command output

Item	Description
Current total number	Number of entries.
ip-address information	Detailed information about the IP address.
ip-address	IP address.
state	Online status of the IP address: ● online ● offline
vlan	VLAN to which the IP address belongs.
vpn-instance	VPN instance of the IP address.

Item	Description
proxy_flag	Whether the IP address is learned through proxy ARP: ● 0: No ● 1: Yes
on2off_flag	Whether the IP address changes from online to offline: ● 0: No ● 1: Yes
redirect_num	Number of the deceived source IP addresses that scanned this IP address.

14.22.32 display deception port-redirect

Function

The **display deception port-redirect** command displays information about deceived traffic due to the scanning of unopened TCP ports.

Format

display deception port-redirect [**source-ip** *ip-address*] [**destination-ip** *ip-address*] [**destination-port** *port*]

Parameters

Parameter	Description	Value
source-ip *ip-address*	Specifies the source IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-ip *ip-address*	Specifies the destination IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-port *port*	Specifies the destination port of the deceived traffic.	The value is an integer in the range from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If it is found that deceived traffic is normal service traffic, run the **reset deception port-redirect** command to delete the corresponding entry from the deception flow table to release the traffic.

Example

Display information about deceived traffic due to the scanning of unopened TCP ports.

```
<HUAWEI> display deception port-redirect
---------------------------------------------------------------------------------------------------
Current total number = 0

---------------------------------------------------------------------------------------------------
source          destination     port   out-vlan vpn-instance  packets  left-
time(s)
---------------------------------------------------------------------------------------------------
```

Table 14-144 Description of the **display deception port-redirect** command output

Item	Description
Current total number	Number of entries.
source	Source IP address of the deceived traffic.
destination	Destination IP address of the deceived traffic.
port	Destination TCP port of the deceived traffic.
out-vlan	VLAN of the deceived traffic.
vpn-instance	VPN instance of the deceived traffic.
packets	Number of the deceived packets
left-time(s)	Remaining time before an entry ages, in seconds. The aging time is 10 minutes. If no traffic matches the entry within the aging time, the entry is deleted. If traffic matches the entry within the aging time, the aging time is updated.

14.22.33 display deception port-state

Function

The **display deception port-state** command displays the port openness status of a service host.

Format

display deception port-state [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies an IP address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When a service host is busy, it responds with the RST-ACK packet even to normal TCP access. As a result, the DecoySensor incorrectly considers that the host port is not opened and deceives normal traffic. The DecoySensor records the port openness status based on the SYN-ACK packet returned by the service host and saves the record for 24 hours, until the record ages naturally or updated when a new SYN-ACK packet is generated. During this period, even if the DecoySensor receives the RST-ACK packet from the corresponding port, it does not deceive the traffic.

The DecoySensor records only the port openness status for TCP access requests whose destination IP addresses are in the detected network segment. The prerequisite for the DecoySensor to record the port openness status is that the in-depth interaction services must be supported by the Decoy.

The **reset deception port-state** command clears the current port openness status.

Examples

Display the port openness status of a service host.

```
<HUAWEI> display deception port-state
  --------------------------------------------------------------------------------
 Current total number = 2
--------------------------------------------------------------------------------
ip-address    :192.168.1.1
vpn-instance  :public port    state   time_out(h)
80      open    24
8080    open    24
445     open    24

ip-address    :192.168.1.2
vpn-instance  :public
port    state   time_out(h)
80      open    24
8080    open    24
445     open    2
```

Table 14-145 Description of the **display deception port-state** command output

Item	Description
ip-address	IP address of a service host
vpn-instance	VPN instance to which the IP address belongs
port	Port
state	Port openness status - open: Open
time_out(h)	Expiration time The new SYN-ACK packet will update the expiration time. If the expiration time is not updated within 24 hours, the service may have stopped working.

14.22.34 display deception statistics

Function

The **display deception statistics** command displays deception statistics.

Format

display deception statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To clear deception statistics, run the **reset deception statistics** command. Then, run the **display deception statistics** command to view deception statistics in this period.

Example

Display deception statistics.

```
<HUAWEI> display deception statistics
Dataplane normal statistics information:
  Receive local ip pkts                        : 9466
```

```
  Receive arp request pkts                    : 143087
  Receive arp reply pkts                    : 8671
  Receive don't need check pkts                   : 9471
  Receive from decoy pkts                    : 18605
  Receive from decoy reg acks                  : 14884
  Receive from decoy heartbeats                   : 3721
  Constructor arp request pkts                 : 8216
  Constructor arp reply pkts                  : 3860
  Send to decoy pkts                      : 14884
  Send to decoy regs                      : 14884
  Send channel success pkts                   : 12076
Dataplane discard statistics information:
  Send to decoy failed logs                  : 226
  VPN header illegal packets discarded                : 14884
Dataplane error statistics information:
```

Table 14-146 Description of the **display deception statistics** command output

Item	Description
Mgmtplane statistics information	Statistics about the management plane.
Rpc msg send success	Number of RPC messages that have been successfully sent.
Rpc msg recv success	Number of RPC messages that have been successfully received.
Rpc msg send instance not exist	Number of RPC messages that fail to be sent because the instance does not exist.
Rpc msg recv poll failed	Statistics about message query failures on the receiver.
Receive RPC msg	Number of received RPC messages.
Send RPC msg success	Number of RPC messages that have been successfully sent.
Dataplane normal statistics information	Statistics on normal packets
ReceiveRPCmsg	Number of received RPC messages
SendRPCmsgsuccess	Number of RPC messages that have been successfully sent
Receive total pkts	Number of received packets
Receive VLAN pkts	Number of received packets with VLAN tags
Receive local ip pkts	Number of packets destined for the local device or packets sent from the local device
Receive arp request pkts	Number of received ARP requests
Receive arp reply pkts	Number of received ARP replies

Item	Description
Receive offline ip icmp pkts	Number of received ICMP packets whose destination IP addresses are offline
Receive offline ip tcp pkts	Number of received TCP packets whose destination IP addresses are offline
Receive tcp syn pkts	Number of received SYN packets
Receive tcp syn ack pkts	Number of received SYN ACK packets
Receive tcp rst pkts	Number of received RST packets
Receive tcp decoy network pkts	Number of received packets that match the bait network segment
Receive don't need check pkts	Number of packets that do not need to be checked
Receive match acl	Number of packets that match ACLs
Receive from decoy pkts	Number of received packets from the Decoy
Receive arp consult pkts	Number of received ARP negotiation packets
Receive arp notify enable pkts	Number of received ARP notification enabling packets
Receive arp notify undo enable pkts	Number of received ARP notification disabling packets
Receive from decoy forward pkts	Number of received packets forwarded by the Decoy
Receive from decoy reg acks	Number of received registration reply packets from the Decoy
Receive from decoy update decoy ports	Number of packets received from the Decoy for updating the honeypot service port
Receive from decoy heartbeats	Number of received heartbeat packets from the Decoy
Receive total dns pkts	Number of received DNS packets
Receive dns request aci pkts	Number of received DNS packets with the ACI suffix
Receive aci syn pkts	Number of received SYN packets matching ACI entries
Constructor arp request pkts	Number of constructed ARP requests
Constructor arp reply pkts	Number of constructed ARP replies

Item	Description
Send to decoy pkts	Number of packets sent to the Decoy
Send to decoy forward pkts	Number of packets forwarded to the Decoy
Send to decoy regs	Number of registration packets sent to the Decoy
Send to decoy heartbeats	Number of heartbeat packets sent to the Decoy
Send to decoy logs	Number of log packets sent to the Decoy
Add ip state to decoy	Number of IP address status adding messages sent to the Decoy
Delete ip state to decoy	Number of IP address status deleting messages sent to the Decoy
Update ip state to decoy	Number of IP address status updating messages sent to the Decoy
Send to decoy iplist	Number of IP status packets sent to the Decoy
Send to decoy redirect	Number of packets redirected to the Decoy
Send scan reply to decoy	Number of scan response packets sent to the Decoy
Send channel success pkts	Number of packets successfully sent through the channel
Constructor icmp reply pkts	Number of constructed ICMP replies
Constructor tcp syn pkts	Number of constructed TCP SYN packets
Constructor arp consult pkts	Number of constructed ARP negotiation packets
Constructor arp notify enable pkts	Number of constructed ARP notification enabling packets
Constructor arp notify undo enable pkts	Number of constructed ARP notification disabling packets
Dns answer query pkts for aci	Number of DNS request packets responded using the ACI function
Dns answer respond pkts	Number of DNS reply packets modified using the ACI function
Aci forward syn pkts	Number of SYN packets forwarded using the ACI function
Aci decoy syn pkts	Number of SYN packets discarded or deceived using the ACI function

Item	Description
Send subnet	Number of times that subnet information is sent to the Decoy
Subnet add	Number of subnet information adding messages sent to the Decoy
Subnet del	Number of subnet information deleting messages sent to the Decoy
Dataplane discard statistics information	Statistics on discarded packets
Send RPC msg failed	Number of RPC messages that fail to be sent
Run RPC msg failed	Number of RPC message errors
Send channel failed pkts	Number of packets discarded due to transmission failures on the channel
Arp malloc node failed pkts	Number of packets discarded due to ARP table node application failures
Ip port table malloc node failed pkts	Number of packets discarded due to port table node application failures
Attack weight table malloc node failed pkts	Number of packets discarded due to attack weight table node application failures.
Arp redirect node exhaustion	Number of times when the ARP table node is full.
Get port info failed pkts	Number of packets discarded due to interface information obtaining failures
Hash length limit pkts	Number of packets discarded due to long hash table chains
Send to decoy failed pkts	Number of packets that fail to be sent to the Decoy
Send to decoy failed forward pkts	Number of packets that fail to be forwarded to the Decoy
Send to decoy failed regs	Number of registration packets that fail to be sent to the Decoy
Send to decoy failed heartbeats	Number of heartbeat packets that fail to be sent to the Decoy
Send to decoy failed logs	Number of log packets that fail to be sent to the Decoy
Send to decoy failed iplist	Number of IP status packets that fail to be sent to the Decoy

Item	Description
Send to decoy failed redirect	Number of packets that fail to be redirected to the Decoy
Send to attacker failed pkts	Number of packets that fail to be sent to the attacker
Smbuf malloc failed	Number of packets discarded due to Smbuf application failures
ARP header illegal packets discarded	Number of packets discarded due to invalid ARP headers
IP header illegal packets discarded	Number of packets discarded due to invalid IP headers
IP frag packets discarded	Number of discarded IP fragments
TCP header illegal packets discarded	Number of packets discarded due to invalid TCP headers
VPN header illegal packets discarded	Number of packets discarded due to invalid VPN headers
Arp extend type illegal packets discarded	Statistics of packets discarded due to invalid ARP extended types
Log cache num limit not merge	Number of logs that are not merged when the number of cached logs reaches the upper limit
Log cache num limit not send	Number of logs that are not sent when the number of cached logs reaches the upper limit
Aci node exhaustion	Number of ACI entry creation failures due to insufficient ACI cache resources
Aci source ip limit add fail	Number of ACI entry creation failures due to the limit on the number of source addresses that can be cached
Dns node exhaustion	Number of DNS entry creation failures due to insufficient DNS cache resources
Send subnet fai	Number of times that subnet information fails to be sent.
Smbuf pool exhaustion	Number of Smbuf resource application failures due to Smbuf resource exhaustion
Smbuf pool head null	Number of Smbuf resource application failures due to an empty Smbuf resource head
Smbuf pool bad safemask	Number of Smbuf resource application failures due to an incorrect header verification value of the Smbuf resource

Item	Description
Smbuf pool bad free flag	Number of Smbuf resource application failures due to an incorrect release verification value of the Smbuf resource
Dataplane error statistics information	Error statistics

14.22.35 display deception syn-connect

Function

The **display deception syn-connect** command displays the TCP port scanning behavior detected by the switch.

Format

display deception syn-connect [**source-ip** *ip-address*]

Parameters

Parameter	Description	Value
source-ip *ip-address*	Specifies the source IP address that initiates TCP port scanning.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the TCP port scanning behavior detected by the switch, so that you can configure a more accurate TCP port scanning threshold using the **deception syn-connect rate** command. If a TCP port is scanned at a lower frequency than the threshold specified by the **deception syn-connect rate** command but have been scanned for many times, the scanning behavior may be an attack.

Example

Display the TCP port scanning behavior detected by the switch.

```
<HUAWEI> display deception syn-connect
----------------------------------------------------------------------------------------------------
```

```
Current total number = 0

----------------------------------------------------------------------------------------------------
source           rate(num/s)number    vlan   vpn-instance
----------------------------------------------------------------------------------------------------
```

Table 14-147 Description of the **display deception syn-connect** command output

Item	Description
Current total number	Number of entries.
source	Source IP address that initiates TCP port scanning.
rate(num/s)	TCP port scanning frequency, in **"times per second"**.
number	Number of TCP port scanning times.
vlan	VLAN to which the source IP address belongs.
vpn-instance	VPN instance of the source IP address.

14.22.36 display deception version

Function

The **display deception version** command displays the DecoySensor version.

Format

display deception version

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The DecoySensor and Decoy need to be used together, and they can communicate with each only when their versions are the same.

Example

Display the DecoySensor version.

```
<HUAWEI> display deception version
Version 1.1.0
```

Table 14-148 Description of the **display deception version** command output

Item	Description
Version	DecoySensor version.

14.22.37 display deception whitelist

Function

The **display deception whitelist** command displays the deception whitelist.

Format

display deception whitelist [**id** *id-number*]

Parameters

Parameter	Description	Value
id *id-number*	Specifies a whitelist ID.	The value is an integer in the range from 1 to 50.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring a deception whitelist using the **deception whitelist** command, you can run the **display deception whitelist** command to check whether the deception whitelist is correctly configured.

Example

Display deception whitelists.

```
<HUAWEI> display deception whitelist
--------------------------------------------------------------------------------
Current total number = 1

--------------------------------------------------------------------------------
Whitelist ID 1 information:
--------------------------------------------------------------------------------
source/mask              :192.168.10.10/255.255.255.255
```

```
destination/mask         :any
vpn-instance             :
```

Table 14-149 Description of the **display deception whitelist** command output

Item	Description
Current total number	Number of entries.
Whitelist ID *i* information	Information about the whitelist whose ID is *i*.
source/mask	Source IP address and subnet mask.
destination/mask	Destination IP address and subnet mask.
vpn-instance	VPN instance of the IP address.

14.22.38 reset deception aci

Function

The **reset deception aci** command updates ACI entries.

Format

reset deception aci

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

After the ACI suffix is changed, you need to update the ACI entries. Otherwise, the old ACI suffix becomes invalid only after the ACI entries age.

After the ACI entries are updated, the access initiated by a terminal is deceived when the DNS record of the terminal does not age. Therefore, change the ACI suffix when no service traffic exists.

Example

Update ACI entries.

```
<HUAWEI> reset deception aci
  Warning:Reseting aci table will affect the normal service. Continue? [Y/N]:y
```

14.22.39 reset deception arp-proxy

Function

The **reset deception arp-proxy** command clears the interface IP address of the switch and the target IP addresses in the proxy ARP requests sent to the switch in the online IP address table.

Format

reset deception arp-proxy

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

None

Example

Clear the interface IP address of the switch and the target IP addresses in the proxy ARP requests sent to the switch in the online IP address table.

```
<HUAWEI> reset deception arp-proxy
```

14.22.40 reset deception ip-state

Function

The **reset deception ip-state** command updates the online status of IP addresses on the network where the switch is located.

Format

reset deception ip-state

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The **reset deception ip-state** command clears the IP address online status and immediately initiates the check on the online status of IP addresses. There are two exceptions:

- If traffic destined for address A is deceived, the online status of address A is not cleared.
- The online status of IP addresses learned through proxy ARP is not cleared.

Example

Update the online status of IP addresses on the network where the switch is located.

```
<HUAWEI> reset deception ip-state
```

14.22.41 reset deception port-redirect

Function

The **reset deception port-redirect** command clears information about deceived traffic that scanned unopened TCP ports and stops port deception.

Format

reset deception port-redirect [**source-ip** *ip-address*] [**destination-ip** *ip-address*] [**destination-port** *port*]

Parameters

Parameter	Description	Value
source-ip *ip-address*	Specifies the source IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-ip *ip-address*	Specifies the destination IP address of the deceived traffic.	The value is in dotted decimal notation.
destination-port *port*	Specifies the destination TCP port of the deceived traffic.	The value is an integer in the range from 1 to 65535.

Views

User view

Default Level

3: Management level

Usage Guidelines

If it is found that deceived traffic is normal service traffic based on the **display deception port-redirect** command, run the **reset deception port-redirect** command to delete the corresponding entry from the deception flow table to release the traffic.

Example

Clear information about deceived traffic that scanned unopened TCP ports and stop port deception.

```
<HUAWEI> reset deception port-redirect
```

14.22.42 reset deception port-state

Function

The **reset deception port-state** command updates the port openness status of a service host.

Format

reset deception port-state

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

The DecoySensor records the port openness status based on the SYN-ACK packet returned by the service host and saves the record for 24 hours, until the record ages naturally or updated when a new SYN-ACK packet is generated. During this period, even if the DecoySensor receives the RST-ACK packet from the corresponding port, it does not deceive the traffic.

If the service openness status of the service host is updated, update the record in a timely manner.

Examples

Update the port openness status of a service host.

```
<HUAWEI> reset deception port-state
```

14.22.43 reset deception statistics

Function

The **reset deception statistics** command clears deception statistics.

Format

reset deception statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

To clear deception statistics, run the **reset deception statistics** command. Then, run the **display deception statistics** command to view deception statistics in this period.

Example

Clear deception statistics.

```
<HUAWEI> reset deception statistics
```

14.23 Terminal Anti-Spoofing Configuration Commands

14.23.1 Command Support

Only the following models support terminal anti-spoofing:

S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

14.23.2 display terminal configuration

Function

The **display terminal configuration** command displays the manually entered terminal information.

Format

display terminal configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **terminal** command to manually enter terminal information, you can run the **display terminal configuration** command to check the manually entered terminal information.

Example

Display the manually entered terminal information.

```
<HUAWEI> display terminal configuration
-------------------------------------------------------------------------------------------
MAC Address     IP Address      Mask            Interface               Category
-------------------------------------------------------------------------------------------
00e0-fc11-1111  10.10.1.1       -               -                       printer
00e0-fc11-1112  10.10.1.2       255.255.255.0   -                       printer
-------------------------------------------------------------------------------------------
Total items displayed = 2
```

Table 14-150 Description of the **display terminal configuration** command output

Item	Description
MAC Address	MAC address of a terminal.
IP Address	IP address of a terminal.
Mask	Subnet mask of a terminal's IP address.
Interface	Access interface of a terminal.

Item	Description
Category	Type of a terminal.
Total items displayed	Total number of entries.

14.23.3 display terminal information

Function

The **display terminal information** command displays terminal entries.

Format

display terminal information { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays entry information about all terminals.	-
mac-address *mac-address*	Displays entry information about the terminal with a specified MAC address.	The value must be an existing terminal MAC address in the terminal table. The value is in H-H-H format. An H is a 4-digit hexadecimal number.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view terminal entries, including the MAC address, type, access interface, anomaly detection result, isolation status, and aging time of the terminal.

The device generates an entry for a terminal only when the terminal information manually entered using the **terminal** command matches the ARP packets sent by the terminal. Then you can run this command to view the terminal entry.

Example

Display entries of all terminals.

```
<HUAWEI> display terminal information all
Status: N - Normal,     F - Flow abnormal      U - Unknown
        IP - Ip abnormal, INT - Interface abnormal
        INTIP - Interface and ip abnormal
-------------------------------------------------------------------------------------------
MAC Address    Category  Ip Address     Interface           Status Isolation Inspect  Expire(minute)
-------------------------------------------------------------------------------------------
00e0-fc11-1111 Printer   10.1.10.1     GigabitEthernet0/0/1     N     No      Enable          30
00e0-fc22-2222 Ip-camera  10.1.20.1     GigabitEthernet0/0/2     N     No      Enable          24
-------------------------------------------------------------------------------------------
Total: 1, printed: 1
```

Table 14-151 Description of the **display terminal information** command output

Item	Description
MAC Address	MAC address of a terminal.
Category	Terminal type. The options are as follows: ● Printer: printer ● Ip-camera: IP camera ● Voip-phone: IP phone
Ip Address	IP address of a terminal.
Interface	Access interface of a terminal.
Status	Anomaly detection result of a terminal. The options are as follows: ● N: The terminal is normal. ● F: The traffic of the terminal is abnormal. ● U: No detection result is obtained after the terminal is de-isolated. ● IP: The IP address of the terminal is abnormal. ● INT: The access interface of the terminal is abnormal. ● INTIP: Both the access interface and IP address of the terminal are abnormal.
Isolation	Isolation status of a terminal. The options are as follows: ● Yes: The terminal is isolated. ● No: The terminal is not isolated.
Inspect	Whether terminal anomaly detection is enabled. The options are as follows: ● Enable: The function is enabled. ● Disable: The function is disabled.

Item	Description
Expire(minute)	● When the value of **Isolation** is **Yes**, this field indicates the remaining time of the isolation action, in minutes. When the remaining time is 0, the entry is deleted. ● When the value of Isolation is **No**, this field indicates the remaining time before a terminal entry is aged, in minutes. When the remaining time is 0, the entry is deleted.

14.23.4 display terminal-inspect abnormal-reason

Function

The **display terminal-inspect abnormal-reason** command displays the terminal anomaly cause.

Format

display terminal-inspect abnormal-reason { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays the anomaly causes of all terminals.	-
mac-address *mac-address*	Displays the anomaly cause of the terminal with a specified MAC address.	The value is in H-H-H format. An H is a 4-digit hexadecimal number. The value must be an existing terminal MAC address in the terminal table.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to check the anomaly cause of a terminal.

Prerequisites

The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.

Example

Display the anomaly causes of all terminals.

```
<HUAWEI> display terminal-inspect abnormal-reason all
---------------------------------
MAC            AbnormalReason
---------------------------------
00e0-fc11-1111 stream-model
00e0-fc11-1112 stream-model
---------------------------------
Total: 2, printed: 2
```

Table 14-152 Description of the **display terminal-inspect abnormal-reason** command output

Item	Description
MAC	MAC address of a terminal.
Abnormal-reason	Anomaly cause. ● stream-model: The actual traffic behavior of the terminal does not comply with the traffic behavior model of the terminal type.
Total	Total number of entries.
printed	Number of displayed entries.

14.23.5 display terminal-inspect cache-data

Function

The **display terminal-inspect cache-data** command displays terminal traffic data cached on the device.

Format

display terminal-inspect cache-data [**mac-address** *mac-address*]

Parameters

Parameter	Description	Value
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value must be the MAC address of an existing terminal. The value is in H-H-H format. An H is a 4-digit hexadecimal number.

Views

All view

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the **terminal-inspect cache-data** command is run to enable the traffic data caching function for a terminal, you can run the **display terminal-inspect cache-data** command to view the traffic data of the terminal.

Prerequisites

1. The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.
2. The **terminal-inspect cache-data** command has been run in the system view to enable the traffic data caching function for a terminal.

Precautions

A maximum of 128 terminal traffic data records can be displayed on the device, and the latest 128 records are saved in time sequence.

Example

Display terminal traffic data cached on the device.

```
<HUAWEI> display terminal-inspect cache-data
MAC: 00e0-fc11-1111
-------------------------------------------------------------------------------------
TimeStamp SrcMac         DstMac         SrcPort DstPort Protocol       Byte Packet
-------------------------------------------------------------------------------------
     8743 00e0-fc11-1111 00e0-fc22-2222       0    1000       17      34688    271
-------------------------------------------------------------------------------------
Total: 1, printed: 1
```

Table 14-153 Description of the **display terminal-inspect cache-data** command output

Item	Description
MAC	MAC address of a terminal.
TimeStamp	Time stamp of the first packet.
SrcMac	Source MAC address of packets.
DstMac	Destination MAC address of packets.
SrcPort	Source port number of packets.
DstPort	Destination port number of packets.
Protocol	5-tuple protocol identifier of traffic.
Byte	Total number of bytes.
Packet	Total number of packets.
Total	Total number of entries.
printed	Number of printed entries.

14.23.6 display terminal-inspect category

Function

The **display terminal-inspect category** command displays the types of terminals for which terminal anomaly detection is enabled.

Format

display terminal-inspect category

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the terminal anomaly detection function is enabled, you can run this command to view the terminal types.

Prerequisites

The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.

Example

Display the types of terminals for which terminal anomaly detection is enabled.

```
<HUAWEI> display terminal-inspect category
--------------------
Id Category
--------------------
 1 ip-camera
 2 voip-phone
--------------------
Total: 2
```

Table 14-154 Description of the **display terminal-inspect category** command output

Item	Description
Id	Terminal ID.
Category	Terminal type.
Total	Total number of terminal types.

14.23.7 display terminal-inspect result

Function

The **display terminal-inspect result** command displays the terminal anomaly detection result.

Format

display terminal-inspect result { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Displays anomaly detection results of all terminals.	-

Parameter	Description	Value
mac-address *mac-address*	Displays the anomaly detection result of the terminal with a specified MAC address.	The value must be an existing terminal MAC address in the terminal table. The value is in H-H-H format. An H is a 4-digit hexadecimal number.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view the comprehensive anomaly detection result of the traffic behavior model of a terminal, including the update time of the detection result, MAC address of the terminal, and detection result.

Example

Display the anomaly detection results of all terminals.

```
<HUAWEI> display terminal-inspect result all
--------------------------------------------
Mac-address    Time                Result
--------------------------------------------
00e0-fc11-1111 2021-04-29 13:10:07  abnormal
00e0-fc22-2222 2021-04-29 13:10:07  abnormal
--------------------------------------------
Total: 2, printed: 2
```

Table 14-155 Description of the **display terminal-inspect result** command output

Item	Description
Time	Time when the detection result is updated.
Mac-address	MAC address of a terminal.
Result	Anomaly detection result. The options are as follows: ● inspecting: Detection is in progress and no detection result is available. ● normal: The terminal is normal. ● abnormal: The terminal is abnormal. **NOTE** If a terminal has detection results, the result of the last detection is displayed when you perform the detection again.

Item	Description
Total	Total number of entries.

14.23.8 display terminal-inspect supervised abnormal-reason

Function

The **display terminal-inspect supervised abnormal-reason** command displays the anomaly degree of terminal detection indicators.

Format

display terminal-inspect supervised abnormal-reason { **all** | **mac-address** *mac-address* }

Parameters

Parameter	Description	Value
all	Specifies all terminals.	-
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value is in H-H-H format. An H is a 4-digit hexadecimal number. The value must be an existing terminal MAC address in the terminal table.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To locate terminal anomaly problems, you can run this command to check the anomaly degree of terminal detection indicators for further analysis. Exercise caution when running the **display terminal-inspect supervised abnormal-reason all** command. Excessive information output affects system performance.

Example

Display the anomaly degree of detection indicators for the terminal whose MAC address is 00e0-fc11-1111.

```
<HUAWEI> system-view
[HUAWEI] diagnose
[HUAWEI-diagnose] display terminal-inspect supervised abnormal-reason mac-address 00e0-fc11-1111
UpstreamTrafficRate: upstream traffic rate of a terminal
DownstreamTrafficRate: downstream traffic rate of a terminal
TotalTrafficRate: total traffic rate of a terminal
DestinationPort: destination port number in packets sent by a terminal
Ratio: ratio of the upstream traffic rate to the downstream traffic rate of a terminal
-------------------------------------------------------------------------------------------------------------------------
MAC              UpstreamTrafficRate     DownstreamTrafficRate      TotalTrafficRate      DestinationPort
Ratio
00e0-fc11-1111                 82%                      1%                   4%                  4%       9%
-------------------------------------------------------------------------------------------------------------------------
Total: 1, printed: 1
```

Table 14-156 Description of the **display terminal-inspect supervised abnormal-reason** command output

Item	Description
MAC	MAC address of a terminal.
UpstreamTrafficRate	Upstream traffic rate of a terminal.
DownstreamTrafficRate	Downstream traffic rate of a terminal.
TotalTrafficRate	Total traffic rate of a terminal.
DestinationPort	Number of the destination port to which packets are sent.
Ratio	Anomaly degree of the ratio of the upstream traffic rate to the downstream traffic rate for a terminal.
Total	Total number of MAC addresses.
printed	Number of printed entries.

14.23.9 display terminal-inspect terminal-list

Function

The **display terminal-inspect terminal-list** command displays the list of terminals under anomaly detection.

Format

display terminal-inspect [**category** *category-name*] **terminal-list**

Parameters

Parameter	Description	Value
category *category-name*	Specifies a terminal type.	The value is of the enumerated type: • ip-camera: IP camera • printer: printer • Voip-phone: IP phone

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command displays only the terminals that are enabled with anomaly detection and are not isolated.

Prerequisites

The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.

Example

Display the list of all terminals under anomaly detection.

```
<HUAWEI> display terminal-inspect terminal-list
------------------------------
MAC            Category
------------------------------
00e0-fc11-1111 ip-camera
00e0-fc22-2222 voip-phone
------------------------------
Total: 2, printed: 2
```

Table 14-157 Description of the **display terminal-inspect terminal-list** command output

Item	Description
MAC	MAC address of a terminal.
Category	Terminal type. The options are as follows: • printer: printer • ip-camera: IP camera • Voip-phone: IP phone

Item	Description
Total	Total number of entries.
printed	Number of displayed entries.

14.23.10 display terminal-isolate configuration

Function

The **display terminal-isolate configuration** command displays the configuration of a terminal isolation policy.

Format

display terminal-isolate { **apply** | **exclude** } **configuration**

Parameters

Parameter	Description	Value
apply	Displays the terminal isolation policy applied to the device.	-
exclude	Displays the whitelist configured in a terminal isolation policy. The device does not apply the isolation policy to whitelisted terminals.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a terminal isolation policy is configured, you can run this command to view the configuration of the terminal isolation policy.

Example

Display the terminal isolation policy applied to the device.

```
<HUAWEI> display terminal-isolate apply configuration
------------------------------------------------------------------------------------------
Category       MAC Address    Block         Period(minutes) Template Name
------------------------------------------------------------------------------------------
printer        00e0-fc11-1111 YES           35              test1
printer        00e0-fc22-2222 NO             20              test2
```

```
--------------------------------------------------------------------------------------------
Total items = 2
```

Display the whitelist configured in a terminal isolation policy.

```
<HUAWEI> display terminal-isolate exclude configuration
------------------------------
Category       MAC Address
------------------------------
printer        00e0-fc33-3333
------------------------------
Total items = 1
```

Table 14-158 Description of the **display terminal-isolate configuration** command output

Item	Description
Category	Terminal type.
MAC Address	MAC address of a terminal. If the MAC address of a terminal is not specified when you configure the terminal isolation policy, **NA** is displayed.
Block	Whether the isolation action of the terminal is block.
Period(minutes)	Aging time of the configured isolation action, in minutes. This parameter is configured using the **terminal-isolate period** command.
Template Name	Name of an isolation template.
Total items	Total number of entries.

14.23.11 reset terminal-inspect cache-data

Function

The **reset terminal-inspect cache-data** command clears the terminal traffic data cached on the device.

Format

reset terminal-inspect cache-data

Parameters

None

Views

User view

Usage Guidelines

Usage Scenario

To view the latest terminal traffic data, run the **reset terminal-inspect cache-data** command to clear the cached terminal traffic data. After a period of time, run the **display terminal-inspect cache-data** command to view the cached terminal traffic data.

Prerequisites

1. The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.
2. The **terminal-inspect cache-data** command has been run in the system view to enable the traffic data caching function for a terminal.

Example

Clear the terminal traffic data cached on the device.

```
<HUAWEI> reset terminal-inspect cache-data
```

14.23.12 terminal

Function

The **terminal** command allows you to manually enter terminal information.

The **undo terminal** command deletes the manually entered terminal information.

By default, no terminal information is manually entered on the device.

Format

terminal { **mac-address** *mac-address* [**ip-address** *ip-address* | **interface** *interface-type interface-number*] | **ip-address** *ip-address* { *mask* | *mask-length* } | **interface** { *interface-type interface-number* &<1-8> | *interface-type interface-number1* **to** *interface-number2* } } **category** { **printer** | **voip-phone** | **ip-camera** }

undo terminal { **mac-address** *mac-address* | **ip-address** *ip-address* { *mask* | *mask-length* } | **interface** { *interface-type interface-number* &<1-8> | *interface-type interface-number* **to** *interface-number* } }

undo terminal { **mac-address** | **ip-address** | **interface** } **all**

Parameters

Parameter	Description	Value
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value is in H-H-H format. H is a hexadecimal number of 4 digits, for example, 00e0 and fc01. If you enter less than four digits, 0s are prefixed to the input digits. For example, if you enter e0, the system changes e0 to 00e0. The MAC address cannot be FFFF-FFFF-FFFF, 0000-0000-0000, or a multicast MAC address.
ip-address *ip-address*	Specifies the IP address of a terminal.	The value is in dotted decimal notation.
mask	Specifies the subnet mask of an IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of an IP address.	The value is an integer ranging from 0 to 32, but the mask length of an IP address cannot be set to 0.
interface	Specifies the access interface of a terminal.	-
interface-type interface-number	Specifies the type and number of an interface.	The interface type cannot be set to Eth-Trunk.
interface-type interface-number1 **to** *interface-number2*	Specifies the type and number of an interface. *interface-number1* and *interface-number2* specify an interface range. *interface-number1* specifies the number of the first interface, and *interface-number2* specifies the number of the last interface. The value of *interface-number2* must be larger than that of *interface-number1*.	The interface type cannot be set to Eth-Trunk. In a stack, *interface-number1* and *interface-number2* cannot reside on different devices. That is, the slot IDs of the interfaces corresponding to *interface-number1* and *interface-number2* must be the same.

Parameter	Description	Value
category	Specifies a terminal type.	-
printer	Sets the terminal type to printer.	-
voip-phone	Sets the terminal type to IP phone.	-
ip-camera	Sets the terminal type to IP camera.	-
mac-address	Deletes all terminal MAC addresses.	-
ip-address	Deletes all terminal IP addresses.	-
interface	Deletes all terminal access interfaces.	-
all	Deletes all the manually entered terminal information.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to manually enter the MAC address, IP address, type, and access interface of a terminal.

Precautions

If different terminals have the same MAC address, their information cannot be recorded.

The device generates an entry for a terminal only when the terminal information manually entered using the **terminal** command matches the ARP packets sent by the terminal and terminal anomaly detection has been enabled globally using the **terminal-inspect flow enable** command. Then you can run the **display terminal information** command to view the terminal entry information.

You can run this command to manually enter the access interface information of a terminal only when the device is directly connected to the terminal. Otherwise, the terminal may be incorrectly identified.

Example

Manually enter the following terminal information: The terminal MAC address is 00e0-fc11-1111, the IP address is 10.1.1.1, and the terminal type is printer.

```
<HUAWEI> system-view
[HUAWEI] terminal mac-address 00e0-fc11-1111 ip-address 10.1.1.1 category printer
```

Delete all the manually entered terminal information.

```
<HUAWEI> system-view
[HUAWEI] undo terminal all
```

14.23.13 terminal-inspect cache-data

Function

The **terminal-inspect cache-data** command enables the traffic data caching function for a terminal.

The **undo terminal-inspect cache-data** command disables the traffic data caching function for a terminal.

By default, the traffic data caching function is disabled for a terminal.

Format

terminal-inspect cache-data mac-address *mac-address* [**max-num** *max-num*]

undo terminal-inspect cache-data mac-address *mac-address* [**max-num** *max-num*]

Parameters

Parameter	Description	Value
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value must be the MAC address of an existing terminal. The value is in H-H-H format. An H is a 4-digit hexadecimal number.
max-num *max-num*	Specifies the maximum number of traffic data entries that can be cached. If this parameter is not specified, a maximum of 128 entries can be cached.	The value is an integer ranging from 1 to 128.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the algorithm used for terminal anomaly detection is incorrect, engineers need to analyze the original traffic data to locate the problem. To view the traffic data of a terminal, run the **terminal-inspect cache-data** command to enable the traffic data caching function for the terminal. If you want to delete the cached traffic data of a terminal and disable the device from caching the traffic data of the terminal, run the **undo terminal-inspect cache-data** command to disable the traffic data caching function for the terminal.

Prerequisites

The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.

Follow-up Procedure

Run the **display terminal-inspect cache-data** command to view the terminal traffic data.

Precautions

If you run this command multiple times, only the latest configuration takes effect.

Example

Enable the traffic data caching function for the terminal whose MAC address is 00e0-fc12-3456.

```
<HUAWEI> system-view
[HUAWEI] terminal-inspect cache-data mac-address 00e0-fc12-3456
```

14.23.14 terminal-inspect category

Function

The **terminal-inspect category** command enables terminal anomaly detection for a specified type of terminal.

The **undo terminal-inspect category** command disables terminal anomaly detection for a specified type of terminal.

By default, anomaly detection is not directed at a specific type of terminal.

Format

terminal-inspect category { **printer** | **voip-phone** | **ip-camera** } [[**exclude**] **mac-address** *mac-address*]

undo terminal-inspect category { **printer** | **voip-phone** | **ip-camera** } [[**exclude**] **mac-address** *mac-address*]

Parameters

Parameter	Description	Value
printer	Sets the terminal type to printer.	-
voip-phone	Sets the terminal type to IP phone.	-
ip-camera	Sets the terminal type to IP camera.	-
exclude	Whitelist a terminal, for which terminal anomaly detection is not performed.	-
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value must be an existing terminal MAC address in the terminal table. The value is in H-H-H format. An H is a 4-digit hexadecimal number.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **terminal-inspect category** command to enable terminal anomaly detection for a specified type of terminal. After this command is configured, the device compares the traffic behavior model with the actual traffic behavior of the terminal to determine whether the traffic behavior of the terminal is abnormal.

The following uses printers as an example to describe how to use the **terminal-inspect category** command:

- Run the **terminal-inspect category printer** command to enable terminal anomaly detection for all printers.
- Run the **terminal-inspect category printer mac-address** *mac-address* command to enable terminal anomaly detection for the printer with a specified MAC address.
- After you run the **terminal-inspect category printer** command to enable terminal anomaly detection for all printers, run the **terminal-inspect category printer exclude mac-address** *mac-address* command to disable terminal anomaly detection for the printer with a specified MAC address.

Precautions

- The **terminal-inspect category** command takes effect only when the following conditions are met:
    a. The **terminal-inspect flow enable** command has been run in the system view to enable terminal anomaly detection globally.
    b. A terminal entry is generated on the device for the terminal to be detected. The device generates the corresponding terminal entry only when terminal anomaly detection is enabled globally and the terminal information manually entered using the **terminal** command matches the ARP packets sent by the terminal. You can run the **display terminal information** command to view the terminal entry information.
- Before running the **terminal-inspect category** { **printer** | **voip-phone** | **ip-camera** } **exclude mac-address** *mac-address* command, ensure that anomaly detection has been enabled for all terminals of the specified type.

  Using printers as an example, before running the **terminal-inspect category printer exclude mac-address** *mac-address* command, you must run the **terminal-inspect category printer** command.
- If anomaly detection has been enabled for all terminals of a certain type, you cannot run the **terminal-inspect category** { **printer** | **voip-phone** | **ip-camera** } **mac-address** *mac-address* command to enable this function for a terminal of this type with a specified MAC address.

  Using printers as an example, after the **terminal-inspect category printer** command is run, the **terminal-inspect category printer mac-address** *mac-address* command is not supported.
- When anomaly detection has been enabled for a terminal of a certain type with a specified MAC address and if you run the **terminal-inspect category** { **printer** | **voip-phone** | **ip-camera** } command to enable anomaly detection for all terminals of this type, the device deletes the configuration of enabling anomaly detection for the terminal of this type with the specified MAC address.

  Using printers as an example, if you run the **terminal-inspect category printer** command after the **terminal-inspect category printer mac-address** *mac-address* command, the device deletes the **terminal-inspect category printer mac-address** *mac-address* command configuration.

Example

Enable terminal anomaly detection for all printers.

```
<HUAWEI> system-view
[HUAWEI] terminal-inspect category printer
```

14.23.15 terminal-inspect flow enable

Function

The **terminal-inspect flow enable** command enables terminal anomaly detection globally.

The **undo terminal-inspect flow** disables terminal anomaly detection.

By default, terminal anomaly detection is disabled globally.

Format

terminal-inspect flow enable

undo terminal-inspect flow

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **terminal-inspect flow enable** command to enable terminal anomaly detection globally.

After terminal anomaly detection is enabled globally, the device sends the ARP packet received from a terminal to the CPU, and checks whether the IP address and access interface of the terminal are abnormal based on the terminal entry. The device generates an entry for a terminal only when the terminal information manually entered by the administrator matches the ARP packet sent by the terminal and the device sends the ARP packet to the CPU.

Precautions

- The **terminal-inspect flow enable** command is mutually exclusive with the following commands:
  - **s-ipfpm measure flow** (enables packet loss and delay measurement)
  - **s-ipfpm measure auto-detect** (enables automatic in-band flow measurement)
  - **ip netstream** (enables IPv4 traffic statistics collection on the inbound and outbound interfaces)
  - **ipv6 netstream** (enables IPv6 traffic statistics collection on the inbound and outbound interfaces)

  - **service-awareness enable** (enables service awareness)
  - **ec-analytics enable** (enables ECA)

Example

Enable terminal anomaly detection globally.

```
<HUAWEI> system-view
[HUAWEI] terminal-inspect flow enable
```

14.23.16 terminal-isolate category

Function

The **terminal-isolate category** command configures a terminal isolation policy for a specified type of terminal.

The **undo terminal-isolate category** command restores the default setting.

The **undo terminal-isolate all** command deletes all isolation policies and whitelists bound to all terminals.

By default, no terminal isolation policy is configured.

Format

terminal-isolate category { **printer** | **voip-phone** | **ip-camera** } { [**mac-address** *mac-address*] **apply template** *template-name* | **exclude mac-address** *mac-address* }

undo terminal-isolate category { **printer** | **voip-phone** | **ip-camera** } { [**mac-address** *mac-address*] **apply template** *template-name* | **exclude mac-address** *mac-address* }

undo terminal-isolate { **apply** | **exclude** } **all**

Parameters

Parameter	Description	Value
printer	Sets the terminal type to printer.	-
voip-phone	Sets the terminal type to IP phone.	-
ip-camera	Sets the terminal type to IP camera.	-

Parameter	Description	Value
mac-address *mac-address*	Specifies the MAC address of a terminal.	The value must be an existing terminal MAC address in the terminal table. The value is in H-H-H format. An H is a 4-digit hexadecimal number.
apply	Applies an isolation template to a terminal. If **apply** is specified but **mac-address** *mac-address* is not specified, the isolation template is applied to all terminals of the specified type.	-
template *template-name*	Specifies the name of an isolation template.	The value must be the name of an existing isolation template. The isolation template name is configured using the **terminal-isolate template** command.
exclude	Whitelists a terminal. The device does not apply the isolation policy to whitelisted terminals.	-
all	Deletes all isolation policies and whitelists bound to terminals.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement the terminal isolation action configured in a terminal isolation template for abnormal terminals of a specified type, run the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } [**mac-address** *mac-address*] **apply template** *template-name* command to apply the configured isolation template to all terminals of this type. Then if a terminal of this type does not need to be isolated, you can run the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } **exclude mac-address** *mac-address* command to add the terminal to the isolation whitelist.

Precautions

Before running the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } [**mac-address** *mac-address*] **apply template** *template-name* command, run the **terminal-isolate template** command to create a terminal isolation template. To make the terminal isolation template take effect, you must run the **terminal-isolate action** command in the terminal isolation template to configure a terminal isolation action.

Example

Apply the isolation template named **test** to all printers. In the isolation template, set the terminal isolation action to **block**.

```
<HUAWEI> system-view
[HUAWEI] terminal-isolate template test
[HUAWEI-terminal-isolate-test] terminal-isolate action block
[HUAWEI-terminal-isolate-test] quit
[HUAWEI] terminal-isolate category printer apply template test
```

Delete all isolation policies bound to terminals.

```
<HUAWEI> system-view
[HUAWEI] undo terminal-isolate apply all
```

14.23.17 terminal-isolate template

Function

The **terminal-isolate template** command creates a terminal isolation template and displays the terminal isolation template view.

The **undo terminal-isolate template** command deletes a terminal isolation template.

By default, no terminal isolation template is created.

Format

terminal-isolate template *template-name*

undo terminal-isolate template *template-name*

Parameters

Parameter	Description	Value
template-name	Specifies the name of a terminal isolation template.	The value is a string of 1 to 31 case-sensitive characters. It cannot contain spaces, question marks (?), or double quotation marks (").

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a terminal isolation policy, you need to create a terminal isolation template, configure a terminal isolation action and the aging time of the action in the terminal isolation template view, and run the **terminal-isolate category** command to bind the terminal isolation template to a specified type of terminal.

Follow-up Procedure

1. Run the **terminal-isolate action** command in the terminal isolation template view to configure a terminal isolation action.
2. (Optional) Run the **terminal-isolate period** command in the terminal isolation template view to set the aging time of the terminal isolation action.
3. Run the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } [**mac-address** *mac-address*] **apply template** *template-name* command in the system view to apply the terminal isolation template to a specified type of terminal.

Example

Create a terminal isolation template named **test**.

```
<HUAWEI> system-view
[HUAWEI] terminal-isolate template test
```

14.23.18 terminal-isolate action

Function

The **terminal-isolate action** command configures a terminal isolation action.

The **undo terminal-isolate action** command restores the default setting.

By default, no terminal isolation action is configured, meaning that the device does not isolate spoofed terminals.

Format

terminal-isolate action block

undo terminal-isolate action block

Parameters

Parameter	Description	Value
block	Specifies the terminal isolation action to **block**, that is, blocking packets.	-

Views

Terminal isolation template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a terminal isolation policy, you need to run the **terminal-isolate template** command to create a terminal isolation template, configure a terminal isolation action in the terminal isolation template view, and run the **terminal-isolate category** command to bind the terminal isolation template to a specified type of terminal.

When the terminal isolation action is set to block, the device discards packets from spoofed terminals identified by the device.

Follow-up Procedure

Run the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } [**mac-address** *mac-address*] **apply template** *template-name* command in the system view to apply the terminal isolation template to a specified type of terminal.

Example

In the isolation template named **test**, set the terminal isolation action to **block**.

```
<HUAWEI> system-view
[HUAWEI] terminal-isolate template test
[HUAWEI-terminal-isolate-test] terminal-isolate action block
```

14.23.19 terminal-isolate period

Function

The **terminal-isolate period** command sets the aging time of a terminal isolation action.

The **undo terminal-isolate period** command restores the default setting.

By default, the aging time is not configured for a terminal isolation action, meaning that a terminal isolation action does not age.

Format

terminal-isolate period *period-time*

undo terminal-isolate period

Parameters

Parameter	Description	Value
period-time	Specifies the aging time of a terminal isolation action.	The value is an integer ranging from 1 to 1440, in minutes.

Views

Terminal isolation template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a terminal isolation policy, you need to run the **terminal-isolate template** command to create a terminal isolation template, configure a terminal isolation action and the aging time of the action in the terminal isolation template view, and run the **terminal-isolate category** command to bind the terminal isolation template to a specified type of terminal.

By default, the aging time is not configured for a terminal isolation action, meaning that the device always implements the configured terminal isolation action for the identified spoofed terminals. To prevent abnormal terminals from being isolated after recovery, you can run the **terminal-isolate period** command to set the aging time of the terminal isolation action. When the aging time arrives, the device re-identifies whether the terminal is a spoofed terminal and determines whether to implement the configured terminal isolation action.

Prerequisites

The **terminal-isolate action** command has been run in the terminal isolation template view to configure a terminal isolation action.

Follow-up Procedure

Run the **terminal-isolate category** { **printer** | **voip-phone** | **ip-camera** } [**mac-address** *mac-address*] **apply template** *template-name* command in the system view to apply the terminal isolation template to a specified type of terminal.

Example

Configure an isolation template named **test**, set the terminal isolation action to **block**, and set the aging time of the terminal isolation action to 60 minutes. Apply the isolation template named **test** to all printers.

```
<HUAWEI> system-view
[HUAWEI] terminal-isolate template test
[HUAWEI-terminal-isolate-test] terminal-isolate action block
[HUAWEI-terminal-isolate-test] terminal-isolate period 60
[HUAWEI-terminal-isolate-test] quit
[HUAWEI] terminal-isolate category printer apply template test
```

14.24 Terminal Identification Configuration Commands

14.24.1 Command Support

Only the following models support terminal identify:

S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

14.24.2 display terminal identify result

Function

The **display terminal identify result** command displays the terminal identification result.

Format

display terminal identify result

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run this command to view the terminal identification result, including the update time of the identification result, MAC and IP addresses of the terminal, and identification result.

Example

Display the identification result of all terminals.

```
<HUAWEI> display terminal identify result
-------------------------------------------------------------------------------------------
IP            MAC             Category  Vendor    Model              Time
-------------------------------------------------------------------------------------------
1.1.1.1  xxxx-xxxx-xxx1 IP Camera xx1      M2220-In            2023-01-31:19-07-05
1.1.1.2  xxxx-xxxx-xxx2 IP Camera xx2      IPC-HDW1020C        2023-01-31:19-07-10
1.1.1.3  xxxx-xxxx-xxx3 IP Camera xx3      DS-2CD3386FWDV2-IS  2023-01-31:19-01-32
1.1.1.4  xxxx-xxxx-xxx4 IP Camera xx4      TL-IPC435H(P)-S2.8  2023-01-31:19-06-50
-------------------------------------------------------------------------------------------
Total: 4, printed: 4
-------------------------------------------------------------------------------------------
```

Table 14-159 Description of the **display terminal identify result** command output

Item	Description
IP	IP address of a terminal.
MAC	MAC address of a terminal.
Category	Terminal type.
Vendor	Vendor of a terminal.
Model	Terminal model.
Time	Time when the identification result is updated.

14.24.3 terminal-identify enable

Function

The **terminal-identify enable** command enables global terminal identification.

The **undo terminal-identify enable** command disables global terminal identification.

By default, global terminal identification is disabled.

Format

terminal-identify enable

undo terminal-identify enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **terminal-identify enable** command is used to enable global terminal identification. After global terminal identification is enabled, the device sends the ARP packets from the matching terminals to the CPU based on configurations of the **terminal-monitoring source-ip** command and scans the terminals. In addition, the device periodically scans terminals based on the network segment and detection interval configured using the **terminal-scan source-ip** command.

Example

Enable global terminal identification.

```
<HUAWEI> system-view
[HUAWEI] terminal-identify enable
```

14.24.4 terminal-monitoring source-ip

Function

The **terminal-monitoring source-ip** command enables terminal identification triggered when terminals in a specified domain go online.

The **undo terminal-monitoring source-ip** command disables terminal identification triggered when terminals in a specified domain go online.

By default, terminal identification triggered when terminals in a specified domain go online is disabled.

Format

terminal-monitoring source-ip *ip-address* { **vlan** *vlan-id* | **bridge-domain** *bd-id* | **monitor-ip** *ip-address* { *mask* | *mask-length* } } **vendor** { { *vendors* } * | **all** } **category** *ip-camera*

undo terminal-monitoring source-ip *ip-address* { **vlan** *vlan-id* | **bridge-domain** *bd-id* | **monitor-ip** *ip-address* { *mask* | *mask-length* } }

Parameters

Parameter	Description	Value
source-ip *ip-address*	Indicates the source IP address.	The value must be the IP address of the local host in dotted decimal notation.
vlan *vlan-id*	Indicates the VLAN ID.	The value is an integer that ranges from 1 to 4094.
bridge-domain *bd-id*	Indicates the bridge domain ID.	The value is an integer that ranges from 1 to 16777215.
monitor-ip *ip-address* { *mask* | *mask-length* }	Indicates the IP address range.	• *ip-address*: indicates an IP address, in dotted decimal notation. • *mask*: indicates the mask of an IP address, in dotted decimal notation. • *mask-length*: indicates the mask length, which is an integer that ranges from 0 to 32.
vendor { { *vendors* } ***** **|** *all* **}**	Indicates the device vendor.	The value is a character string.
category *ip-camera*	Indicates the terminal type.	The value is a character string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Using the **terminal-monitoring source-ip** command, you can enable terminal identification triggered when terminals in a specified domain go online. When a terminal goes online, the device identifies the terminal by performing proactive detection based on the configured domain, terminal vendor, and ARP packets sent by the terminal.

Take the cameras of vendor *xx* as an example. The **terminal-monitoring source-ip** command can be used in the following ways:

- Run the **terminal-monitoring source-ip** *ip-address* **vlan** *vlan-id* **vendor** *xx* **category** *ip-camera* command to enable the device (source IP address: **source-ip** *ip-address*) to detect the cameras of vendor *xx* in the specified VLAN (**vlan** *vlan-id*).
- Run the **terminal-monitoring source-ip** *ip-address* **bridge-domain** *bd-id* **vendor** *xx* **category** *ip-camera* command to enable the device (source IP address: **source-ip** *ip-address*) to detect the cameras of vendor *xx* in the specified bridge domain (*bd-id*).
- Run the **terminal-monitoring source-ip** *ip-address* **monitor-ip** *ip-address* { *mask* | *mask-length* } **vendor** *hikvision* **category** *ip-camera* command to enable the device (source IP address: **source-ip** *ip-address*) to detect the cameras of vendor *xx* on the specified IP network segment.

Prerequisites

1. Run the **terminal-identify enable** command in the system view to enable global terminal identification.
2. The specified source IP address, VLAN ID, and bridge domain ID exist on the local host.

Precautions

When you have run this command for multiple times, the latest configuration takes precedence if the source IP address, VLAN ID, and bridge domain ID are the same while different vendors are set.

Example

Enable the device with the source IP address **10.1.1.1** to perform terminal identification triggered when cameras of all vendors in VLAN 20 go online.

```
<HUAWEI> system-view
[HUAWEI] terminal-monitoring source-ip 2.2.2.1 vlan 20 vendor all category ip-camera
```

14.24.5 terminal-scan source-ip

Function

The **terminal-scan source-ip** command enables terminal identification for terminals in a specified domain.

The **undo terminal-scan source-ip** command disables terminal identification for terminals in a specified domain.

By default, terminal identification is disabled for terminals in any domain.

Format

terminal-scan source-ip *ip-address* { **vlan** *vlan-id* | **bridge-domain** *bd-id* } [**scan-ip** *ip-address* { *mask* | *mask-length* }] [**period** *period-time*] **vendor** { { *vendors* } * | **all** } **category** *ip-camera*

undo terminal-scan source-ip *ip-address* { **vlan** *vlan-id* | **bridge-domain** *bd-id* }

Parameters

Parameter	Description	Value
source-ip *ip-address*	Indicates the source IP address.	The value must be the IP address of the local host in dotted decimal notation.
vlan *vlan-id*	Indicates the VLAN ID.	The value is an integer that ranges from 1 to 4094.
bridge-domain *bd-id*	Indicates the bridge domain ID.	The value is an integer that ranges from 1 to 16777215.
scan-ip *ip-address* { *mask* | *mask-length* }	Indicates the IP address range.	● *ip-address*: indicates an IP address, in dotted decimal notation. ● *mask*: indicates the mask of an IP address, in dotted decimal notation. ● *mask-length*: indicates the mask length, which is an integer that ranges from 0 to 32.
period *period-time*	Indicates the detection interval.	The value is an integer that ranges from 1 to 65535, in minutes. The default value is 30.
vendor { { *vendors* } * | **all** }	Indicates the device vendor.	The value is a character string.
category *ip-camera*	Indicates the terminal type.	The value is a character string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **terminal-scan source-ip** command enables terminal identification for terminals in a specified domain. After this command is executed, the device periodically detects and identifies terminal information based on the configured network segment and terminal vendor.

Take the cameras of vendor *xx* as an example. The **terminal-scan source-ip** command can be used in the following ways:

- Run the **terminal-scan source-ip** *ip-address* **vlan** *vlan-id* **scan-ip** *ip-address mask* **period** *20* **vendor** *xx* **category** *ip-camera* command to enable the device (source IP address: **source-ip** *ip-address*) to detect the cameras of vendor *xx* in the specified VLAN (**vlan** *vlan-id*) at an interval of 20 minutes. Only cameras on the specified network segment (**scan-ip** *ip-address*) are identified.
- Run the **terminal-scan source-ip** *ip-address* **bridge-domain** *bd-id* **scan-ip** *ip-address mask* **period** *30* **vendor** *xx* **category** *ip-camera* command to enable the device (source IP address: **source-ip** *ip-address*) to detect the cameras of vendor *xx* in the specified bridge domain (*bd-id*) at an interval of 30 minutes.

Prerequisites

1. Run the **terminal-identify enable** command in the system view to enable global terminal identification.
2. The specified source IP address, VLAN ID, and bridge domain ID exist on the local host.

Precautions

When you have run this command for multiple times, the latest configuration takes precedence if the source IP address, VLAN ID, and bridge domain ID are the same while different IP address ranges, detection intervals, and vendors are set.

Example

Enable the device with the source IP address **10.1.1.1** to identify cameras of all vendors in VLAN 20 at an interval of 20 minutes.

```
<HUAWEI> system-view
[HUAWEI] terminal-scan source-ip 10.1.1.1 vlan 20 period 20 vendor all category ip-camera
```

14.25 WEAKEA Command Reference

14.25.1 ah authentication-algorithm

Function

The **ah authentication-algorithm** command specifies the authentication algorithm for AH protocol.

NOTE

All models support this command, except S200 and S1730S-S1.

Format

ah authentication-algorithm md5

Parameters

Parameter	Description	Value
md5	Specifies MD5 as the authentication algorithm.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPSec can use AH protocol to authenticate packets, preventing packets from being intercepted or modified, you can run the **ah authentication-algorithm** command to configure the authentication algorithm for AH protocol.

Prerequisite

The protocol of this IPSec proposal has been configured to AH using the **transform** command.

Precautions

The authentication algorithms on both IPSec peers must be identical.

Example

Configure the IPSec proposal **prop1** to use the AH protocol, and specify **MD5** as the authentication algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform ah
[HUAWEI-ipsec-proposal-prop1] ah authentication-algorithm md5
```

14.25.2 dh

Function

The **dh** command specifies a DH group used for IKE negotiation.

NOTE

All models support this command, except S200 and S1730S-S1.

Format

dh { **group1** | **group2** | **group5** }

Parameters

Parameter	Description	Value
group1	Uses the 768-bit DH group in IKE negotiation phase 1.	-
group2	Uses the 1024-bit DH group in IKE negotiation phase 1.	-
group5	Uses the 1536-bit DH group in IKE negotiation phase 1.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DH algorithm is a public key algorithm. Two communicating parties calculate a shared key based on data exchanged between them, without transmitting the key. A third party (such as a hacker) cannot calculate the actual key even if it obtains all exchanged data for key calculation.

Precautions

Both ends of an IPSec tunnel must be configured with the same DH group. Otherwise, the negotiation fails.

Example

Specify the **1024-bit DH group** in IKE negotiation phase 1.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] dh group2
```

14.25.3 esp authentication-algorithm

Function

The **esp authentication-algorithm** command configures the authentication algorithm for ESP protocol.

NOTE

All models support this command, except S200 and S1730S-S1.

Format

esp authentication-algorithm md5

Parameters

Parameter	Description	Value
md5	Specifies MD5 as the authentication algorithm.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPSec can use ESP protocol to authenticate and encrypt packets, preventing packets from being intercepted or modified, you can run the **esp authentication-algorithm** command to configure the authentication algorithm for ESP protocol.

Prerequisite

The protocol of this IPSec proposal has been configured to ESP using the **transform** command.

Precautions

The authentication algorithms on both IPSec peers must be identical.

The authentication algorithm and encryption algorithm for ESP protocol cannot be both set to **NULL**.

Example

Configure the IPSec proposal **prop1** to use the ESP protocol, and specify **MD5** as the authentication algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform esp
[HUAWEI-ipsec-proposal-prop1] esp authentication-algorithm md5
```

14.25.4 esp encryption-algorithm

Function

The **esp encryption-algorithm** command configures the encryption algorithm for ESP protocol.

NOTE

All models support this command, except S200 and S1730S-S1.

Format

esp encryption-algorithm des

Parameters

Parameter	Description	Value
des	Specifies DES as the encryption algorithm.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

IPSec can use ESP protocol to authenticate and encrypt packets, preventing packets from being intercepted or modified, you can run the **esp encryption-algorithm** command to configure the encryption algorithm for ESP protocol.

Prerequisite

The protocol of this IPSec proposal has been configured to ESP using the **transform** command.

Precautions

The encryption algorithms on both IPSec peers must be identical.

The authentication algorithm and encryption algorithm for ESP protocol cannot be both set to **NULL**.

Example

Configure the IPSec proposal **prop1** to use the AH protocol, and specify **DES** as the encryption algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform esp
[HUAWEI-ipsec-proposal-prop1] esp encryption-algorithm des
```

14.25.5 load-module weakea

Function

The **load-module weakea** command loads the WEAKEA plug-in from the system software.

Format

load-module weakea

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before installing the WEAKEA plug-in, run the **load-module weakea** command in the user view to load the WEAKEA plug-in (for example, *xxx***WEAKEA.mod**) from the system software to the plug-in installation directory **$_install_mod**.

Follow-up Procedure

Run the **install-module** *file-name* [**next-startup**] command in the user view to install the plug-in. *file-name* specifies the plug-in file name.

Precautions

If the WEAKEA plug-in exists in the plug-in installation directory **$_install_mod**, delete the original WEAKEA plug-in. Otherwise, this command cannot be executed successfully.

Example

Load the WEAKEA plug-in from the system software.

```
<HUAWEI> load-module weakea
```

14.25.6 pfs

Function

The **pfs** command enables PFS when the local end initiates IPSec tunnel negotiation.

NOTE

All models support this command, except S200 and S1730S-S1.

Format

pfs { **dh-group1** | **dh-group2** | **dh-group5** }

Parameters

Parameter	Description	Value
dh-group1	Uses the 768-bit DH group.	-
dh-group2	Uses the 1024-bit DH group.	-
dh-group5	Uses the 1536-bit DH group.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

When the local end initiates negotiation, there is an additional DH exchange in IKEv1 phase 2 or IKEv2 CREATE_CHILD_SA exchange. The additional DH exchange ensures security of the IPSec SA key and improves communication security.

Example

Enable PFS (using the **1024-bit DH group**) when the local end initiates IPSec tunnel negotiation.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] pfs dh-group2
```

14.25.7 pki export rsa-key-pair

Function

The **pki export rsa-key-pair** command exports the RSA key pair to the device flash memory and supports the export of the associated certificate.

Format

pki export rsa-key-pair *key-name* [**and-certificate** *certificate-name*] { **pem** *file-name* [**3des** | **des**] | **pkcs12** *file-name* } **password** *password*

Parameters

Parameter	Description	Value
key-name	Specifies the name of an RSA key pair on the device.	The value must be an existing RSA key pair name.
and-certificate *certificate-name*	Indicates that the certificate associated to the RSA key pair will be exported.	The value must be an existing certificate file name.
pem *file-name*	Indicates that the RSA key pair will be exported in PEM format and specifies the name of the file to be exported.	The value is a string of 1 to 64 case-insensitive characters. Spaces and question marks (?) are not supported. If the file path is included, the value is a string of 1 to 127 characters, for example, **flash:/8ab3/ab3.pem**.
pkcs12 *file-name*	Indicates that the RSA key pair will be exported in PKCS12 format and specifies the name of the file to be exported.	The value is a string of 1 to 64 case-insensitive characters without spaces and question marks (?). When the value contains a directory, it is a string of 1 to 127 characters, for example, flash:/8ab3/ab3.pem.
3des | **des**	Sets the encryption algorithm to DES or 3DES if the RSA key pair is exported in PEM format.	-

Parameter	Description	Value
password *password*	Specifies the encryption password for the RSA key pair file. This password protects the exported RSA key pair file and is required when you import the RSA key pair file.	The value is a string of 8 to 32 case-sensitive characters without question marks (?). For security purposes, a password must meet the minimum strength requirements, that is, the password needs to contain at least three types of the following characters: uppercase letters, lowercase letters, numerals, and special characters, such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before transferring or backing up an RSA key pair, run this command to enable the device to generate the PEM or PKCS12 file carrying this RSA key pair (which may include the certificate) in its flash memory.

Before using this command, run the **display pki rsa local-key-pair** command to view RSA key pair information on the device.

Prerequisites

The RSA key pair has been created and configured to be exportable using the **pki rsa local-key-pair create** command, or it has been imported to the device memory and configured to be exportable using the **pki import rsa-key-pair** command.

Precautions

The RSA key pair is sensitive information. Delete and destroy the exported RSA key pair on the device or storage device immediately after you do not need it.

Example

Export the RSA key pair **key1** to the file **aaa.pem** and set the encryption mode to DES.

```
<HUAWEI> system-view
[HUAWEI] pki rsa local-key-pair create key1 exportable
 Info: The name of the new key-pair will be: key1
 The size of the public key ranges from 512 to 4096.
 Input the bits in the modules:2048
 Generating key-pairs...
......+++
...................+++
[HUAWEI] pki export rsa-key-pair key1 pem aaa.pem DES password YsHsjx_202206
 Warning: Exporting the key pair impose security risks, are you sure you want to
 export it? [y/n]:y
 Info: Succeeded in exporting the RSA key pair in PEM format.
```

14.25.8 set cipher-suite

Function

The **set cipher-suite** command configures cipher suites for a customized SSL cipher suite policy.

Format

set cipher-suite { **tls12_ck_rsa_aes_256_cbc_sha256** | **tls1_ck_dhe_dss_with_aes_128_sha** | **tls1_ck_dhe_dss_with_aes_256_sha** | **tls1_ck_dhe_rsa_with_aes_128_sha** | **tls1_ck_dhe_rsa_with_aes_256_sha** | **tls1_ck_rsa_with_aes_128_sha** | **tls1_ck_rsa_with_aes_256_sha** }

Parameters

Parameter	Description	Value
tls12_ck_rsa_aes_256_cbc_sha256	Configures the TLS12_CK_RSA_AES_256_CBC_SHA256 cipher suite.	-
tls1_ck_dhe_dss_with_aes_128_sha	Configures the TLS1_CK_DHE_DSS_WITH_AES_128_SHA cipher suite.	-
tls1_ck_dhe_dss_with_aes_256_sha	Configures the TLS1_CK_DHE_DSS_WITH_AES_256_SHA cipher suite.	-
tls1_ck_dhe_rsa_with_aes_128_sha	Configures the TLS1_CK_DHE_RSA_WITH_AES_128_SHA cipher suite.	-

Parameter	Description	Value
tls1_ck_dhe_rsa_with_aes_256_sha	Configures the TLS1_CK_DHE_RSA_WITH_AES_256_SHA cipher suite.	-
tls1_ck_rsa_with_aes_128_sha	Configures the TLS1_CK_RSA_WITH_AES_128_SHA cipher suite.	-
tls1_ck_rsa_with_aes_256_sha	Configures the TLS1_CK_RSA_WITH_AES_256_SHA cipher suite.	-

Views

Customized SSL cipher suite policy view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To configure cipher suites for a customized SSL cipher suite policy, run the **set cipher-suite** command.

Precautions

If a customized SSL cipher suite policy is being referenced by an SSL policy, the cipher suites in the customized cipher suite policy can be added, modified, or partially deleted. Deleting all of the cipher suites is not allowed.

Example

Configure the **tls12_ck_rsa_aes_256_cbc_sha256** cipher suite for the customized SSL cipher suite policy named **cipher1**.

```
<HUAWEI> system-view
[HUAWEI] ssl cipher-suite-list cipher1
[HUAWEI-ssl-cipher-suite-cipher1] set cipher-suite tls12_ck_rsa_aes_256_cbc_sha256
```

14.25.9 ssh client cipher

Function

The **ssh client cipher** command configures an encryption algorithm list for an SSH client.

The **undo ssh client cipher** command restores the default encryption algorithm list of an SSH client.

By default, an SSH client supports all encryption algorithms.

Format

ssh client cipher { **des_cbc** | **3des_cbc** | **aes128_cbc** | **aes256_cbc** } *

undo ssh client cipher

Parameters

Parameter	Description	Value
des_cbc	Specifies the CBC DES encryption algorithm.	-
3des_cbc	Specifies the CBC 3DES encryption algorithm.	-
aes128_cbc	Specifies the CBC AES128 encryption algorithm.	-
aes256_cbc	Specifies the CBC AES256 encryption algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

An SSH server and a client need to negotiate an encryption algorithm for the packets exchanged between them. You can run the **ssh client cipher** command to configure an encryption algorithm list for the SSH client. After the SSH server receives a packet from the client, the server matches the encryption algorithm list of the client against its local list and selects the first matched encryption algorithm. If no encryption algorithm matches, the negotiation fails.

Example

Configure CBC encryption algorithms for an SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client cipher aes128_cbc aes256_cbc
```

14.25.10 ssh client hmac

Function

The **ssh client hmac** command configures an HMAC algorithm list for an SSH client.

The **undo ssh client hmac** command restores the default HMAC algorithm list of an SSH client.

By default, an SSH client supports all HMAC algorithms.

Format

ssh client hmac { **md5** | **md5_96** | **sha1** | **sha1_96** | **sha2_256_96** } *

undo ssh client hmac

Parameters

Parameter	Description	Value
md5	Specifies the HMAC MD5 algorithm.	-
md5_96	Specifies the HMAC MD5_96 algorithm.	-
sha1	Specifies the HMAC SHA1 algorithm.	-
sha1_96	Specifies the HMAC SHA1_96 algorithm.	-
sha2_256_96	Specifies the HMAC SHA2_256_96 algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

An SSH server and a client need to negotiate an HMAC algorithm for the packets exchanged between them. You can run the **ssh client hmac** command to configure an HMAC algorithm list for the SSH client. After the SSH server receives a packet from the client, the server matches the list of the client against its local list and selects the first matched HMAC algorithm. If no matched HMAC algorithms, the negotiation fails.

Example

Configure the HMAC **sha2_256_96** algorithm for an SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client hmac sha2_256_96
```

14.25.11 ssh client key-exchange

Function

The **ssh client key-exchange** command configures a key exchange algorithm list for an SSH client.

The **undo ssh client key-exchange** command restores the default configuration.

By default, an SSH client supports all key exchange algorithms.

Format

ssh client key-exchange { **dh_group14_sha1** | **dh_group1_sha1** | **dh_group_exchange_sha1** }*

undo ssh client key-exchange

Parameters

Parameter	Description	Value
dh_group14_sha1	Adds the Diffie-hellman-group14-sha1 algorithm to the key exchange algorithm list of an SSH client.	-
dh_group1_sha1	Adds the Diffie-hellman-group1-sha1 algorithm to the key exchange algorithm list of an SSH client.	-
dh_group_exchange_sha1	Adds the Diffie-hellman-group-exchange-sha1 algorithm to the key exchange algorithm list of an SSH client.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

The client and server negotiate the key exchange algorithm used for packet transmission. You can run the **ssh client key-exchange** command to configure a key exchange algorithm list for the SSH client. The SSH server compares the configured key exchange algorithm list with the counterpart sent by the client and then selects the first matched key exchange algorithm for packet transmission. If the key exchange algorithm list sent by the client does not match any algorithm in the key exchange algorithm list configured on the server, the negotiation fails.

Example

Configure key exchange algorithm lists **dh_group1_sha1** on the SSH client.

```
<HUAWEI> system-view
[HUAWEI] ssh client key-exchange dh_group1_sha1
```

14.25.12 ssh server cipher

Function

The **ssh server cipher** command configures an encryption algorithm list for an SSH server.

The **undo ssh server cipher** command restores the default encryption algorithm list of an SSH server.

By default, an SSH server supports all encryption algorithms.

Format

ssh server cipher { **des_cbc** | **3des_cbc** | **aes128_cbc** | **aes256_cbc** } *

undo ssh server cipher

Parameters

Parameter	Description	Value
des_cbc	Specifies the CBC DES encryption algorithm.	-
3des_cbc	Specifies the CBC 3DES encryption algorithm.	-
aes128_cbc	Specifies the CBC AES128 encryption algorithm.	-
aes256_cbc	Specifies the CBC AES256 encryption algorithm.	-

Views

System view

Usage Guidelines

An SSH server and a client need to negotiate an encryption algorithm for the packets exchanged between them. You can run the **ssh server cipher** command to configure an encryption algorithm list for the SSH server. After the SSH server receives a packet from the client, the server matches the encryption algorithm list of the client against its local list and selects the first matched encryption algorithm. If no matched encryption algorithms, the negotiation fails.

Example

Configure CBC encryption algorithms for an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server cipher aes256_cbc aes128_cbc
```

14.25.13 ssh server compatible-ssh1x enable

Function

The **ssh server compatible-ssh1x enable** command enables an SSH server to be compatible with earlier versions.

The **undo ssh server compatible-ssh1x enable** command disables an SSH server from being compatible with earlier versions.

By default, this function is disabled on unconfigured devices. After a device is upgraded, whether an SSH server is allowed to be compatible with earlier versions is determined by the configuration in the configuration file.

Format

ssh server compatible-ssh1x enable

undo ssh server compatible-ssh1x enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **ssh server compatible-ssh1x enable** command applies to scenarios where a client and a server negotiate with each other on a working version. After a TCP connection is set up between a client and a server, the client negotiates with the server on a version that both the client and server support.

The server compares its own version with that sent by the client and determines whether it can work with the client.

- If the protocol version on the client is earlier than 1.3 or later than 2.0, version negotiation fails and the server disconnects from the client.
- If the protocol version on the client is later than or equal to 1.3 and earlier than 1.99, the SSH1.5 server module is invoked, and the SSH1.X process is performed when the SSH1.X-compatible mode is configured. When the SSH1.X-incompatible mode is configured, version negotiation fails, and the server disconnects from the client.
- If the protocol version on the client is 1.99 or 2.0, the SSH2.0 server module is invoked, and the SSH2.0 process is performed.

Precautions

- If the SSH server is enabled to be compatible with earlier SSH versions, a device prompts a security risk.
- The device can only function as the SSH client of v2.0. When the device functions as the SSH server, it allows SSH clients of v1.x and v2.0 to log in.
- The configuration takes effect upon the next login.
- SSH2.0 has an extended structure and supports more authentication modes and key exchange methods than SSH1.X. SSH 2.0 can eliminate the security risks that SSH 1.X has. SSH 2.0 is more secure and therefore is recommended.
- If a device has empty configuration, the device delivers the **undo ssh server compatible-ssh1x enable** command to disable the SSH server's compatibility with earlier versions. If a device is upgraded, the SSH server's compatibility with earlier versions is the same as that in the configuration file.

NOTE

Currently, protocols support SSH versions as follows:

- STelnet: The device supports SSH v1.99. That is SSH1 (SSH1.x) and SSH2 (SSH2.0) are supported. By default, SSH2 (SSH2.0) is supported.
- SFTP: Only SSH2 (SSH2.0) is supported.
- SCP: Only SSH2 (SSH2.0) is supported.

Example

Enable an SSH server to be compatible with earlier versions.

```
<HUAWEI> system-view
[HUAWEI] ssh server compatible-ssh1x enable
Warning: SSHv1 is not a secure protocol, and it is recommended to use SSHv2.
```

14.25.14 sshd server

Function

The **sshd server** command configures the algorithms that can be used by a switch to establish a NETCONF session with a third-party controller.

The **undo sshd server** command deletes the algorithms that can be used by a switch to establish a NETCONF session with a third-party controller.

The algorithms that can be configured by this command have low security. By default, the switch does not support these algorithms when establishing a NETCONF session with a third-party controller.

NOTE

All models support this command, except S1720GW-E, S1720GWR-E, S200, and S1730S-S1.

Format

sshd server cipher { **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-gcm@openssh.com | aes256-gcm@opensscom** } *

sshd server hmac { **hmac-md5** | **hmac-md5-etm@openssh.com** | **hmac-sha1** | **hmac-sha1-etm@openssh.com** } *

sshd server hostkey *hostkey*

sshd server key-exchange { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** | **diffie-hellman-group1-sha1** | **diffie-hellman-group14-sha1** | **diffie-hellman-group-exchange-sha1** } *

sshd server hostkey-algorithms ssh-rsa

undo sshd server { **cipher** | **hmac** | **hostkey** | **key-exchange** | **hostkey-algorithms** }

Parameters

Parameter	Description	Value
cipher	Specifies an encryption algorithm.	-
aes128-cbc	Specifies the **aes128-cbc** algorithm.	-
aes192-cbc	Specifies the **aes192-cbc** algorithm.	-
aes256-cbc	Specifies the **aes256-cbc** algorithm.	-
aes128-gcm@openssh.com	Specifies the **aes128-gcm@openssh.com** algorithm.	-
aes256-gcm@openssh.com	Specifies the **aes256-gcm@openssh.com** algorithm.	-
hmac	Specifies an authentication algorithm.	-
hmac-md5	Specifies the **hmac-md5** algorithm.	-

Parameter	Description	Value
hmac-md5-etm@openssh.com	Specifies the **hmac-md5-etm@openssh.com** algorithm.	-
hmac-sha1	Specifies the **hmac-sha1** algorithm.	-
hmac-sha1-etm@openssh.com	Specifies the **hmac-sha1-etm@openssh.com** algorithm.	-
hostkey *hostkey*	Specifies a key file.	The key file must exist on the device.
key-exchange	Specifies a key exchange algorithm.	-
ecdh-sha2-nistp256	Specifies the **ecdh-sha2-nistp256** algorithm.	-
ecdh-sha2-nistp384	Specifies the **ecdh-sha2-nistp384** algorithm.	-
diffie-hellman-group1-sha1	Specifies the **diffie-hellman-group1-sha1** algorithm.	-
diffie-hellman-group14-sha1	Specifies the **diffie-hellman-group14-sha1** algorithm.	-
diffie-hellman-group-exchange-sha1	Specifies the **diffie-hellman-group-exchange-sha1** algorithm.	-
hostkey-algorithms	Specifies a key algorithm.	-

Usage Guidelines

The algorithms that can be configured by this command have low security. By default, the switch does not support these algorithms when establishing a

NETCONF session with a third-party controller. You are advised not to use these algorithms.

Example

Configure the **aes128-cbc** encryption algorithm that can be used by the switch to establish a NETCONF session with a third-party controller.

```
<HUAWEI> system-view
[HUAWEI] netconf
[HUAWEI-netconf] sshd server cipher aes128-cbc
Warning: Insecure encryption algorithms will be enabling and the SSH connection may be teared down. Continue? [Y/N]:y
```

14.25.15 ssh server hmac

Function

The **ssh server hmac** command configures an HMAC algorithm list for an SSH server.

The **undo ssh server hmac** command restores the default HMAC algorithm list of an SSH server.

By default, an SSH server supports all HMAC algorithms.

Format

ssh server hmac { **md5** | **md5_96** | **sha1** | **sha1_96** | **sha2_256_96** } *

undo ssh server hmac

Parameters

Parameter	Description	Value
md5	Specifies the HMAC MD5 algorithm.	-
md5_96	Specifies the HMAC MD5_96 algorithm.	-
sha1	Specifies the HMAC SHA1 algorithm.	-
sha1_96	Specifies the HMAC SHA1_96 algorithm.	-
sha2_256_96	Specifies the HMAC SHA2_256_96 algorithm.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

An SSH server and a client need to negotiate an HMAC algorithm for the packets exchanged between them. You can run the **ssh server hmac** command to configure an HMAC algorithm list for the SSH server. After the server receives a packet from the client, the server matches the list of the client against its local list and selects the first matched HMAC algorithm. If no matched HMAC algorithms, the negotiation fails.

Example

Configure the HMAC **sha2_256_96** algorithm for an SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server hmac sha2_256_96
```

14.25.16 ssh server key-exchange

Function

The **ssh server key-exchange** command configures a key exchange algorithm list on an SSH server.

The **undo ssh server key-exchange** command restores the default configuration.

By default, an SSH server supports all key exchange algorithms.

Format

ssh server key-exchange { **dh_group14_sha1** | **dh_group1_sha1** | **dh_group_exchange_sha1** }*

undo ssh server key-exchange

Parameters

Parameter	Description	Value
dh_group14_sha1	Adds the Diffie-hellman-group14-sha1 algorithm to the key exchange algorithm list of an SSH server.	-
dh_group1_sha1	Adds the Diffie-hellman-group1-sha1 algorithm to the key exchange algorithm list of an SSH server.	-
dh_group_exchange_sha1	Adds the Diffie-hellman-group-exchange-sha1 algorithm to the key exchange algorithm list of an SSH server.	-

Views

System view

Default Level

3: Management level

Usage Guidelines

An SSH server and a client need to negotiate a key exchange algorithm for the packets exchanged between them. You can run the **ssh server key-exchange** command to configure a key exchange algorithm list for the SSH server. After the server receives a packet from the client, the server matches the key exchange algorithm list of the client against its local list and selects the first matched key exchange algorithm. If no matched key exchange algorithms, the negotiation fails.

Example

Configure key exchange algorithm lists **dh_group1_sha1** on the SSH server.

```
<HUAWEI> system-view
[HUAWEI] ssh server key-exchange dh_group1_sha1
```

14.25.17 ssl minimum version

Function

The **ssl minimum version** command configures a minimum SSL version for an SSL policy.

Format

ssl minimum version tls1.0

Parameters

Parameter	Description	Value
tls1.0	Sets the minimum SSL version to TLS1.0 for an SSL policy.	-

Views

SSL policy view

Default Level

3: Management level

Usage Guidelines

To configure a minimum SSL version for an SSL policy, run the **ssl minimum version** command so that service modules can flexibly adopt the SSL policy.

Example

Configure the minimum SSL version for the SSL policy **ftp_server** to be TLS1.0.

```
<HUAWEI> system-view
[HUAWEI] ssl policy ftp_server
[HUAWEI-ssl-policy-ftp_server] ssl minimum version tls1.0
```

15 QoS Commands

15.1 MQC Configuration Commands

15.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.1.2 classifier behavior

Function

The **classifier behavior** command binds a traffic behavior to a traffic classifier in a traffic policy.

The **undo classifier** command unbinds a traffic behavior from a traffic classifier in a traffic policy.

By default, no traffic classifier or traffic behavior is bound to a traffic policy.

Format

classifier *classifier-name* **behavior** *behavior-name*

undo classifier *classifier-name*

Parameters

Parameter	Description	Value
classifier-name	Specifies the name of a traffic classifier.	The value must be the name of an existing traffic classifier.
behavior-name	Specifies the name of a traffic behavior.	The value must be the name of an existing traffic behavior.

Views

Traffic policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To take an action for packets of a certain type, use a traffic classifier to group the packets into one class and use a traffic behavior to define an action. Then associate the traffic classifier with the traffic behavior and bind them to a traffic policy.

Prerequisites

- A traffic classifier has been created using the **traffic classifier** command.
- A traffic behavior has been created using the **traffic behavior** command.
- A traffic policy has been created using the **traffic policy** command.

Precautions

You can dynamically add, modify, or delete the bound traffic classifiers, traffic behaviors, or binding of traffic classifiers and traffic behaviors in a traffic policy that has been applied to the system, a VLAN, or an interface.

NOTICE

Dynamically updating the traffic classifiers and traffic behaviors in a traffic policy makes the traffic policy ineffective for a short time. Confirm the operation before you use this command.

In a traffic policy, one traffic classifier can be bound to only one traffic behavior; each traffic policy supports a maximum of 256 pairs of traffic classifiers and traffic behaviors.

Example

Bind the traffic classifier **c1** to the traffic behavior **b1** in the traffic policy **p1**, and apply the traffic policy to GE0/0/1 in the inbound direction.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match any
[HUAWEI-classifier-c1] quit
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark 8021p 2
[HUAWEI-behavior-b1] quit
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-policy p1 inbound
[HUAWEI-GigabitEthernet0/0/1] quit
```

Bind the traffic classifier **c1** to the new traffic behavior **newb1** in the traffic policy **p1** that has been applied to GE0/0/1 in the inbound direction.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior newb1
[HUAWEI-trafficpolicy-p1] quit
```

15.1.3 display acl division

Function

The **display acl division** command displays division rules based on the VLAN ID range in a delivered traffic classification rule or port number range in a delivered ACL rule.

Format

display acl division *start-id* **to** *end-id*

Parameters

Parameter	Description	Value
start-id	Specifies the start VLAN ID or port number.	The value is an integer that ranges from 0 to 65535.

Parameter	Description	Value
to *end-id*	Specifies the end VLAN ID or port number.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the **if-match vlan-id** *start-vlan-id* [**to** *end-vlan-id*] [**cvlan-id** *cvlan-id*] command is used to configure a traffic classification rule defining a VLAN ID range, or the **rule (advanced ACL view)** or **rule (advanced ACL6 view)** command is used with the protocol as TCP or UDP and the port number range specified, run the **display acl resource** command to view occupied ACL resources. The system divides a rule into multiple rules. The **display acl division** command displays division rules based on the VLAN ID range or port number range.

Example

Display division rules based on VLAN 10 to VLAN 20 or PORT10 to PORT20.

```
<HUAWEI> display acl division 10 to 20
 Range: 10 to 20;  Total rules: 4
 ---------------------------------------------------------
  [ 1]:Value = 10     Mask = 0xfffe  Range[   10,   11]
  [ 2]:Value = 12     Mask = 0xfffc  Range[   12,   15]
  [ 3]:Value = 16     Mask = 0xfffc  Range[   16,   19]
  [ 4]:Value = 20     Mask = 0xffff  Range[   20,   20]
```

Table 15-1 Description of the **display acl division** command output

Item	Description
Range	Input VLAN ID range or port number range.
Total rules	Number of division rules based on the VLAN ID range or port number range.
[1]	ID of the division rule.
Value	Start VLAN ID of the division rule.
Mask	Mask of the VLAN ID in the division rule.
Range	Division rule range.

15.1.4 display traffic behavior

Function

The **display traffic behavior** command displays the traffic behavior configuration on the device.

Format

display traffic behavior user-defined [*behavior-name*]

Parameters

Parameter	Description	Value
user-defined [*behavior-name*]	Displays the configuration of a specified traffic behavior. If the name of a traffic behavior is not specified, the configuration of all traffic behaviors is displayed.	The value must be the name of an existing traffic behavior.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic behavior** command displays the configuration of a specified traffic behavior or all traffic behaviors. The command output helps you check the traffic behavior configuration and locate faults.

Precautions

If no traffic behavior is created, the system displays the following information after this command is executed:

```
Info: There is no behavior exists.
```

If the specified traffic behavior name is incorrect, the system displays the following information after this command is executed:

```
Info: The behavior does not exist.
```

Example

Display the configuration of all traffic behaviors.

```
<HUAWEI> display traffic behavior user-defined
  User Defined Behavior Information:
    Behavior: tb1
      Committed Access Rate:
        CIR 1000 (Kbps), CBS 125000 (Byte)
        PIR 1000 (Kbps), PBS 125000 (Byte)
        Green Action   : pass
        Yellow Action  : pass
        Red Action     : discard
      Remark:
        Remark 8021p 1
Total behavior number is 1
```

Table 15-2 Description of the **display traffic behavior user-defined** command output

Item	Description
Behavior	Traffic behavior name. To create a traffic behavior, run the **traffic behavior** command.
Committed Access Rate	CAR. To configure an action taken for packets whose rate exceeds the CAR, run the **car (traffic behavior view)** command.
CIR	Committed information rate (CIR). To set the CIR, run the **car (traffic behavior view)** command.
PIR	Peak information rate (PIR). To set the PIR, run the **car (traffic behavior view)** command.
CBS	Committed burst size (CBS). To set the CBS, run the **car (traffic behavior view)** command.
PBS	Peak burst size (PBS). To set the PBS, run the **car (traffic behavior view)** command.
Green Action	Action taken for green packets. To configure an action taken for green packets, run the **car (traffic behavior view)** command.
Yellow Action	Action taken for yellow packets. To configure an action taken for yellow packets, run the **car (traffic behavior view)** command.
Red Action	Action taken for red packets. To configure an action taken for red packets, run the **car (traffic behavior view)** command.
Remark	Re-marking action. To configure re-marking, run the **remark** command.
Total behavior number is 1	Total number of created traffic behaviors.

15.1.5 display traffic classifier

Function

The **display traffic classifier** command displays the traffic classifier configuration on the device.

Format

display traffic classifier user-defined [*classifier-name*]

Parameters

Parameter	Description	Value
user-defined [*classifier-name*]	Displays the configuration of a specified traffic classifier. If the name of a traffic classifier is not specified, the configuration of all traffic classifiers is displayed.	The value must be the name of an existing traffic classifier.

Views

Usage Guidelines

Usage Scenario

The **display traffic classifier** command displays the configuration of a specified traffic classifier or all traffic classifiers. The command output helps you check the traffic classifier configuration and locate faults.

Precautions

If no traffic classifier is created, the system displays the following information after this command is executed:

```
Info: There is no classifier exists.
```

If the specified traffic classifier name is incorrect, the system displays the following information after this command is executed:

```
Info: The classifier does not exist.
```

Example

Display the configuration of all traffic classifiers on the device.

```
<HUAWEI> display traffic classifier user-defined
  User Defined Classifier Information:
   Classifier: c1
    Operator: AND
    Rule(s) : if-match vlan-id 120

   Classifier: c2
    Operator: AND
    Rule(s) : if-match vlan-id 110

   Classifier: c3
    Operator: AND
    Rule(s) : if-match vlan-id 100

Total classifier number is 3
```

Table 15-3 Description of the **display traffic classifier user-defined** command output

Item	Description
Classifier	Traffic classifier name. To create a traffic classifier, run the **traffic classifier** command.
Operator	Relationship between rules in the traffic classifier. To configure the relationship between rules in a traffic classifier, run the **traffic classifier** command.
Rule(s)	Rule in a traffic classifier.
Total classifier number is	Total number of created traffic classifiers.

15.1.6 display traffic policy

Function

The **display traffic policy** command displays the traffic policy configuration on the device.

Format

display traffic policy { **interface** [*interface-type interface-number* [*.subinterface-number*]] | **vlan** [*vlan-id*] | **ssid-profile** [*ssid-profile-name*] | **global** } [**inbound** | **outbound**]

display traffic policy ap-group [*ap-group*] [**outbound**]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support sub-interfaces.

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support **ssid-profile** and **ap-group**.

Parameters

Parameter	Description	Value
interface [*interface-type interface-number* [.*subinterface-number*]]	Displays the traffic policy configuration on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* [.*subinterface-number*] specifies the interface or sub-interface number.	-
vlan [*vlan-id*]	Displays the traffic policy configuration in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
ssid-profile [*ssid-profile-name*]	Displays the traffic policy configuration in a specified SSID profile.	The value must be the name of an existing SSID profile.
ap-group [*ap-group*]	Displays the traffic policy configuration in a specified AP group.	The value must be the name of an existing AP group.
global	Displays the traffic policy configuration in the system.	-
inbound	Displays the traffic policy configuration in the inbound direction.	-
outbound	Displays the traffic policy configuration in the outbound direction.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic policy** command displays the configuration of a specified traffic policy or all traffic policies. The command output helps you check the traffic policy configuration and locate faults.

Example

Display the configuration of the traffic policy applied to GE0/0/1 .

```
<HUAWEI> display traffic policy interface gigabitethernet 0/0/1

 Interface: GigabitEthernet0/0/1

 Direction: Inbound

 Policy: p1
   Classifier: c1
    Operator: AND
    Rule(s) :
       if-match acl 5500
       if-match 8021p 6
       if-match acl 3001
   Behavior: b1
     Statistic enable

     Committed Access Rate:
       CIR 1000 (Kbps), CBS 125000 (Byte)
       PIR 1000 (Kbps), PBS 125000 (Byte)
       Green Action   : pass
       Yellow Action  : pass
       Red Action     : discard
```

Table 15-4 Description of the **display traffic policy interface** command output

Item	Description
Interface	Interface to which the traffic policy is applied.
Direction	Direction to which a traffic policy is applied. To apply a traffic policy, run the **traffic-policy (interface view)** command.
Policy	Traffic policy name. To create a traffic policy, run the **traffic policy** command.
Classifier	Traffic classifier in a traffic policy. To create a traffic classifier, run the **traffic classifier** command.
Operator	Relationship between rules in the traffic classifier. To configure the relationship between rules in a traffic classifier, run the **traffic classifier** command.
Rule(s)	Rule in a traffic classifier.
Behavior	Traffic behavior bound to the traffic classifier. To create a traffic behavior, run the **traffic behavior** command.

Item	Description
Committed Access Rate	CAR. To configure CAR, run the **car (traffic behavior view)** command.
CIR 100 (Kbps), CBS 9000 (Byte) PIR 40000 (Kbps), PBS 200000 (Byte)	Parameters in the QoS CAR profile, including the CIR, PIR, CBS, and PBS. To configure CAR parameters, run the **car (traffic behavior view)** command.
Green Action	Action taken for green packets. To configure an action taken for green packets, run the **car (traffic behavior view)** command.
Yellow Action	Action taken for yellow packets. To configure an action taken for yellow packets, run the **car (traffic behavior view)** command.
Red Action	Action taken for red packets. To configure an action taken for red packets, run the **car (traffic behavior view)** command.

Display the traffic policy in the SSID profile named test on the S5732-H.

```
<HUAWEI> display traffic policy ssid-profile test inbound
  Ssid-profile: test

  Direction: Inbound

  Policy: 1
    Classifier: 1
     Operator: AND
     Rule(s) :
        if-match vlan-id 100
    Behavior: 1
      Permit
```

Table 15-5 Description of the **display traffic policy ssid-profile** command output

Item	Description
Ssid-profile	SSID profile to which the traffic policy is applied.
Direction	Direction to which a traffic policy is applied. To apply a traffic policy, run the **traffic-policy (SSID profile view)** command.
Policy	Traffic policy name. To create a traffic policy, run the **traffic policy** command.
Classifier	Traffic classifier in a traffic policy. To create a traffic classifier, run the **traffic classifier** command.

Item	Description
Operator	Relationship between rules in the traffic classifier. To configure the relationship between rules in a traffic classifier, run the **traffic classifier** command.
Rule(s)	Rule in a traffic classifier.
Behavior	Traffic behavior bound to the traffic classifier. To create a traffic behavior, run the **traffic behavior** command.
Permit	Allows packets matching the rule in the traffic classifier to pass. To allow or disallow packets matching the rule in the traffic classifier to pass, run the **deny | permit** command.

15.1.7 display traffic policy statistics

Function

The **display traffic policy statistics** command displays packet statistics in the specified object or each object to which a traffic policy has been applied.

Format

display traffic policy statistics { **global** [**slot** *slot-id*] | **interface** *interface-type interface-number* [*.subinterface-number*] | **vlan** *vlan-id* | **ssid-profile** *ssid-profile-name* } { **inbound** | **outbound** } [**verbose** { **classifier-base** | **rule-base** } [**class** *classifier-name*]]

display traffic policy statistics ap-group *ap-group* **outbound** [**verbose** { **classifier-base** | **rule-base** } [**class** *classifier-name*]]

display traffic policy statistics policy-name *policy-name*

display traffic policy statistics all

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support sub-interfaces.

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support **ssid-profile** *ssid-profile-name* and **ap-group** *ap-group*.

Parameters

Parameter	Description	Value
global	Displays packet statistics in the system to which a traffic policy has been applied.	-
slot *slot-id*	Displays packet statistics on a specified device to which a traffic policy has been applied. *slot-id* specifies the slot ID of the device.	The value range depends on the device configuration.
interface *interface-type interface-number* [.*subinterface-number*]	Displays packet statistics on a specified interface to which a traffic policy has been applied. - *interface-type* specifies the interface type. - *interface-number* [.*subinterface-number*] specifies the interface or sub-interface number.	-
vlan *vlan-id*	Displays packet statistics in a specified VLAN to which a traffic policy has been applied. *vlan-id* specifies the ID of the VLAN.	The value is an integer that ranges from 1 to 4094.
ssid-profile *ssid-profile-name*	Displays packet statistics in a specified SSID profile to which a traffic policy has been applied. *ssid-profile-name* specifies the name of the SSID profile.	The value must be the name of an existing SSID profile.
ap-group *ap-group*	Displays packet statistics in a specified AP group to which a traffic policy has been applied. *ap-group* specifies the name of the AP group .	The value must be the name of an existing AP group.

Parameter	Description	Value
inbound	Displays packet statistics in the inbound direction to which a traffic policy has been applied.	-
outbound	Displays packet statistics in the outbound direction to which a traffic policy has been applied.	-
verbose	Displays detailed packet statistics.	-
classifier-base	Displays statistics on packets matching a specified traffic classifier. If this parameter is specified, statistics on packets matching all traffic classifiers in the traffic policy are displayed.	-
rule-base	Displays statistics on packets matching a rule. If this parameter is specified, statistics on packets matching all rules are displayed.	-
class *classifier-name*	Specifies the name of a traffic classifier. If this parameter is specified, statistics on packets matching the specified traffic classifier or rules in the specified traffic classifier are displayed. If this parameter is not specified, statistics on packets matching all traffic classifiers are displayed.	The value must be the name of an existing traffic classifier.
policy-name *policy-name*	Displays packet statistics in each object to which the specified traffic policy is applied.	The value must be the name of an existing traffic policy.

Parameter	Description	Value
all	Displays packet statistics in each object to which a traffic policy has been applied, including packet statistics in the inbound or outbound directions in the system, on each interface, in each VLAN, and in each SSID profile.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic policy statistics** command displays packet statistics in the specified object or each object to which a traffic policy has been applied. The command output helps you check statistics on forwarded and discarded packets and locate faults.

Precautions

If no traffic policy is applied, the system displays the following information after this command is executed:

```
Info: The Policy is not applied in this view.
```

If you do not run the **statistic enable (traffic behavior view)** command in the view of the traffic behavior in a traffic policy, the system displays the following information after this command is executed:

```
Info: Statistic has not been enabled.
```

If the **rule-base** parameter is specified in this command to display packet statistics matching a rule in a traffic classifier and ACL rules are modified or deleted at the same time, ACL rule statistics that are displayed in pagination mode are inaccurate. To obtain accurate ACL rule statistics, run this command after ACL rules are modified or deleted.

On the S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, S6720S-S, packetstatistics are collected only in the outbound direction of interfaces.

Example

Display packet statistics on GE0/0/1 in the inbound direction to which a traffic policy has been applied.

```
<HUAWEI> display traffic policy statistics interface gigabitethernet 0/0/1 inbound

 Interface: GigabitEthernet0/0/1
 Traffic policy inbound: p1
 Rule number: 1
 Current status: success
 Statistics interval: 300
---------------------------------------------------------------------
 Board : 0
---------------------------------------------------------------------
 Matched          |      Packets:                            0
                  |      Bytes:                              0
                  |      Rate(pps):                          0
                  |      Rate(bps):                          0
---------------------------------------------------------------------
   Passed         |      Packets:                            0
                  |      Bytes:                              0
                  |      Rate(pps):                          0
                  |      Rate(bps):                          0
---------------------------------------------------------------------
   Dropped        |      Packets:                            0
                  |      Bytes:                              0
                  |      Rate(pps):                          0
                  |      Rate(bps):                          0
---------------------------------------------------------------------
     Filter       |      Packets:                            0
                  |      Bytes:                              0
---------------------------------------------------------------------
     Car          |      Packets:                            0
                  |      Bytes:                              0
---------------------------------------------------------------------
```

Display statistics on incoming packets matching a rule after the traffic policy is applied to the system.

```
<HUAWEI> display traffic policy statistics global inbound verbose rule-base
 Global :
 Traffic policy inbound: p1
 Rule number: 1
 Current status: success
 Statistics interval: 300
---------------------------------------------------------------------
 Classifier: c1 operator and
 Behavior: b1
 if-match 8021p 5
 Board : 0
---------------------------------------------------------------------
 Passed           |      Packets:                            0
                  |      Bytes:                              0
                  |      Rate(pps):                          0
                  |      Rate(bps):                          0
---------------------------------------------------------------------
 Dropped          |      Packets:                            0

Table 15-6 Description of the **display traffic policy statistics** command output

Item	Description
Interface	Interface to which the traffic policy is applied.
Global	System to which the traffic policy is applied.
Vlan	VLAN to which the traffic policy is applied.
Ssid-profile	SSID profile to which the traffic policy is applied.
Ap-group	AP group to which the traffic policy is applied.
Traffic policy inbound	Applied traffic policy.
Rule number	Number of valid rules in the traffic classifier.
Current status	Traffic policy status.
Statistics interval	Interval for collecting traffic statistics. To set the interval for collecting traffic statistics, run the **traffic statistics interval** command.
Classifier	Relationship between rules in the traffic classifier. To configure the relationship between rules in a traffic classifier, run the **traffic classifier** command.
Behavior	Traffic behavior name. To create a traffic behavior, run the **traffic behavior** command.
Board	ID of the switch to which the traffic policy is applied. When you query the statistics on an Eth-Trunk, the system displays only the statistics on the switch where member interfaces in the Eth-Trunk are located.
Matched	Numbers of packets and bytes that match traffic classification rules. The data is originated from the packet statistics that have been collected since the original statistics were cleared last time.
Passed	Numbers of forwarded packets and bytes that match traffic classification rules. The data is originated from the packet statistics that have been collected since the original statistics were cleared last time.

Item	Description
Dropped	Numbers of discarded packets and bytes that match traffic classification rules. The data is originated from the packet statistics that have been collected since the original statistics were cleared last time. The discarded packets include the filtered packets and packets dropped by CAR.
Filter	Numbers of filtered packets and bytes that match traffic classification rules. The data is originated from the packet statistics that have been collected since the original statistics were cleared last time.
Car	Numbers of packets and bytes that match traffic classification rules and are discarded by CAR. The data is originated from the packet statistics that have been collected since the original statistics were cleared last time. To configure CAR, run the **car (traffic behavior view)** command.
Packets	Number of packets. If the information is displayed as -, the statistics on this item cannot be collected.
Bytes	Number of bytes. If the information is displayed as -, the statistics on this item cannot be collected.
Rate(pps)	Rate, in pps. If the information is displayed as -, the statistics on this item cannot be collected.
Rate(bps)	Rate, in bit/s. If the information is displayed as -, the statistics on this item cannot be collected.
match-counter 0	Number of times packets match ACL rules. **NOTE** FTP, TFTP, Telnet, SNMP, HTTP, routing, and multicast packets match software ACL rules, and the number of times packets match software ACL rules can be checked using a command. Other packets match hardware ACL rules, and the number of times packets match hardware ACL rules can be checked using other methods. For example, to view the number of times packets match ACL rules after a traffic policy is applied, run the **statistic enable (traffic behavior view)** command to enable traffic statistics in the traffic behavior and run the **display traffic policy statistics** command to check statistics.

15.1.8 display traffic policy user-defined

Function

The **display traffic policy user-defined** command displays the user-defined traffic policy configuration.

Format

display traffic policy user-defined [*policy-name* [**classifier** *classifier-name*]]

Parameters

Parameter	Description	Value
policy-name	Displays the configuration of a specified user-defined traffic policy. If this parameter is not specified, the configuration of all user-defined traffic policies is displayed.	The value must be the name of an existing traffic policy.
classifier *classifier-name*	Displays the configuration of a traffic behavior bound to a specified traffic classifier in a traffic policy. If this parameter is not specified, the traffic policy configuration is displayed.	The value must be the name of an existing traffic classifier.

Views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic policy user-defined** command displays the configuration of a specified traffic policy or all traffic policies. The command output helps you check the traffic policy configuration and locate faults.

Precautions

If no traffic policy is created, the system displays the following information after the **display traffic policy user-defined** command is executed:

```
Info: There is no policy exists.
```

If the specified traffic policy name is incorrect, the system displays the following information after the **display traffic policy user-defined** command is executed:

```
Info: The policy does not exist.
```

Example

Display the user-defined traffic policy configuration.

```
<HUAWEI> display traffic policy user-defined
  User Defined Traffic Policy Information:
  Policy: p1
   Classifier: c1
    Operator: AND
     Behavior: tb1
      Remark:
        Remark 8021p 0
      Committed Access Rate:
        CIR 10000 (Kbps), CBS 1250000 (Byte)
        PIR 10000 (Kbps), PBS 1250000 (Byte)
        Green Action   : pass
        Yellow Action  : pass
        Red Action     : discard

Total policy number is 1
```

Table 15-7 Description of the **display traffic policy user-defined** command output

Item	Description
User Defined Traffic Policy Information	User-defined traffic policy configuration.
Policy	Traffic policy name. To create a traffic policy, run the **traffic policy** command.
Classifier	Traffic classifier in a traffic policy. To create a traffic classifier, run the **traffic classifier** command.
Operator	Relationship between rules in the traffic classifier. To create a traffic classifier, run the **traffic classifier** command.
Behavior	Traffic behavior associated with the traffic classifier in the traffic policy. To create a traffic behavior, run the **traffic behavior** command.
Committed Access Rate	CAR. To configure the CAR, run the **car (traffic behavior view)** command.
Green Action	Action taken for green packets. To configure an action taken for green packets, run the **car (traffic behavior view)** command.

Item	Description
Yellow Action	Action taken for yellow packets. To configure an action taken for yellow packets, run the **car (traffic behavior view)** command.
Red Action	Action taken for red packets. To configure an action taken for red packets, run the **car (traffic behavior view)** command.
Remark	Re-marking action. To configure re-marking, run the **remark** command.
Total policy number is	Total number of created traffic policies.

15.1.9 display traffic-applied

Function

The **display traffic-applied** command displays information about ACL-based simplified and MQC-based traffic policies applied in various views.

Format

display traffic-applied [**interface** [*interface-type interface-number*] | **vlan** [*vlan-id*]] { **inbound** | **outbound** } [**verbose**]

display traffic-applied [**ssid-profile** [*ssid-profile-name*] | **traffic-profile** [*traffic-profile-name*]] { **inbound** | **outbound** }

display traffic-applied ap-group [*ap-group*] **outbound**

display traffic-applied brief

display traffic-applied record

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support **ssid-profile** and **ap-group**.

Parameters

Parameter	Description	Value
interface [*interface-type interface-number*]	Displays information about ACL-based simplified and MQC-based traffic policies applied to a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If this parameter is not specified, information about ACL-based simplified and MQC-based traffic policies applied to the system or a VLAN is displayed.	-
vlan [*vlan-id*]	Displays information about ACL-based simplified and MQC-based traffic policies applied to a specified VLAN. If this parameter is not specified, information about ACL-based simplified and MQC-based traffic policies applied to the system or an interface is displayed.	The value is an integer that ranges from 1 to 4094.
ssid-profile [*ssid-profile-name*]	Displays information about ACL-based simplified and MQC-based traffic policies applied to a specified SSID profile.	The value must be the name of an existing SSID profile.
ap-group [*ap-group*]	Displays information about ACL-based simplified and MQC-based traffic policies applied to a specified AP group.	The value must be the name of an existing AP group.

Parameter	Description	Value
traffic-profile [*traffic-profile-name*]	Displays information about ACL-based simplified and MQC-based traffic policies applied to a specified traffic profile.	The value must be the name of an existing traffic profile.
inbound	Displays information about ACL-based simplified and MQC-based traffic policies applied in the inbound direction.	-
outbound	Displays information about ACL-based simplified and MQC-based traffic policies applied in the outbound direction.	-
verbose	Displays detailed information about ACL-based simplified and MQC-based traffic policies applied to the system, a VLAN, or an interface.	-
brief	Displays brief information about ACL-based simplified and MQC-based traffic policies applied to the system, a VLAN, an interface, an SSID profile, or a traffic profile.	-
record	Displays information about all ACL-based simplified traffic policies applied to the device.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display traffic-applied** command displays information about ACL-based simplified and MQC-based traffic policies applied to the system, a VLAN, or an interface.

Example

Display information about globally applied ACL-based simplified and MQC-based traffic policies in the inbound direction.

```
<HUAWEI> display traffic-applied inbound
------------------------------------------------------------
Policy applied inbound global
  Policy:    p1
------------------------------------------------------------
```

Table 15-8 Description of the **display traffic-applied inbound** command output

Item	Description
Policy	Traffic policy name. To create a traffic policy, run the **traffic policy** command.

Display the configuration of all ACL-based simplified traffic policies on the device.

```
<HUAWEI> display traffic-applied record
---------------------------------------------------------------------------
*interface GigabitEthernet0/0/1
 traffic-filter inbound acl 3000
  slot 0: success

---------------------------------------------------------------------------
*system
 traffic-filter inbound acl 3001
  slot 0: success

 traffic-filter outbound acl 3002
  slot 0: success

---------------------------------------------------------------------------
```

Table 15-9 Description of the **display traffic-applied record** command output

Item	Description
interface GigabitEthernet0/0/1	Interface where the ACL-based simplified traffic policy has been applied.
traffic-filter inbound acl 3000	Configuration of the ACL-based simplified traffic policy that has been applied. For details, see **ACL-based Simplified Traffic Policy Commands**.

Item	Description
slot	Slot where the ACL-based simplified traffic policy has been applied. The value is 0 in a non-stack scenario. In a stack scenario, the value depends on the device configuration.
success	Status of the ACL-based simplified traffic policy that has been applied: ● success: The ACL-based simplified traffic policy has been applied successfully. ● fail: The ACL-based simplified traffic policy fails to be applied.
system	Configuration of the ACL-based simplified traffic policy that has been applied globally.

15.1.10 display traffic-policy applied-record

Function

The **display traffic-policy applied-record** command displays traffic policy records.

Format

display traffic-policy applied-record [*policy-name*]

Parameters

Parameter	Description	Value
policy-name	Displays the record of a specified traffic policy. If this parameter is not specified, records of all the applied traffic policies are displayed.	The value must be the name of an existing traffic policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic-policy applied-record** command displays a record of an applied traffic policy or records of all applied traffic policies, including the view, interface number, and direction that the traffic policy/policies is/are applied to, traffic policy status on an SSID profile, and number of times the traffic policy/policies is/are applied. The command output helps you check traffic policy records and locate faults.

Precautions

If no traffic policy is created, the system does not display any information after this command is executed.

If the specified traffic policy name is incorrect, the system displays the following information after this command is executed:

```
Info: Traffic policy does not exist.
```

Example

Display the record of the traffic policy **p1** in a non-stack scenario.

```
<HUAWEI> display traffic-policy applied-record p1
-------------------------------------------------
  Policy Name:   p1
  Policy Index:  0
     Classifier:c1     Behavior:b1
-------------------------------------------------
 *interface GigabitEthernet0/0/1
    traffic-policy p1 inbound
      slot 0    :  success (support sharing)
 *vlan 100
    traffic-policy p1 inbound
      slot 0    :  success
 *system
    traffic-policy p1 global inbound
      slot 0    :  success
 *ssid-profile test
    traffic-policy p1 inbound
      slot 0    :  success
 *ap-group test
    traffic-policy p1 outbound
      slot 0    :  success
-------------------------------------------------
  Policy total applied times: 5.
```

Display the record of the traffic policy **p1** in a stack scenario.

```
<HUAWEI> display traffic-policy applied-record p1
-------------------------------------------------
  Policy Name:   p1
  Policy Index:  1
     Classifier:c1     Behavior:b1
-------------------------------------------------
 *system
    traffic-policy p1 global inbound
      slot 2  :  success
      slot 1  :  success
      slot 0  :  success
 *system
    traffic-policy p1 global outbound
      slot 2  :  success
      slot 1  :  success
```

```
     slot 0  :  success
-------------------------------------------------
 Policy total applied times: 2.
```

Table 15-10 Description of the **display traffic-policy applied-record** command output

Item	Description
Policy Name	Traffic policy name. To configure a traffic policy, run the **traffic policy** command.
Policy Index	Traffic policy index.
Classifier	Traffic classifier name. To configure a traffic classifier, run the **traffic classifier** command.
Behavior	Traffic behavior name. To configure a traffic behavior, run the **traffic behavior** command.
interface GigabitEthernet0/0/1	Interface to which the traffic policy is applied. To apply a traffic policy to an interface, run the **traffic-policy (interface view)** command.
traffic-policy p1 inbound	Inbound direction to which the traffic policy **p1** is applied.
traffic-policy p1 outbound	Outbound direction to which the traffic policy **p1** is applied.
slot	Status of the traffic policy applied to the specified slot. ● success (support sharing): The traffic policy is applied successfully, and resources occupied by the traffic policy that is applied to the inbound direction of an interface can be shared by other interfaces to which the same traffic policy that is applied in the inbound direction in the slot. ● success: The traffic policy is applied successfully, but resources occupied by the traffic policy that is applied to an interface cannot be shared by other interfaces in the slot. ● fail: The traffic policy fails to be applied.
vlan	VLAN to which the traffic policy is applied. To apply a traffic policy to a VLAN, run the **traffic-policy (VLAN view)** command.
system	System to which the traffic policy is applied. To apply a traffic policy to the system, run the **traffic-policy global** command.

Item	Description
ssid-profile	SSID profile to which the traffic policy is applied. To apply a traffic policy to an SSID profile, run the **traffic-policy (SSID profile view)** command. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support SSID profiles.
ap-group	AP group to which the traffic policy is applied. To apply a traffic policy to an AP group, run the **traffic-policy (AP Group view)** command. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the AP group view.
Policy total applied times	Number of times the traffic policy is applied.

15.1.11 if-match 8021p

Function

The **if-match 8021p** command configures a matching rule based on the 802.1p priority of VLAN packets in a traffic classifier.

The **undo if-match 8021p** command deletes a matching rule based on the 802.1p priority of VLAN packets in a traffic classifier.

By default, a matching rule based on the 802.1p priority of VLAN packets is not configured in a traffic classifier.

Format

if-match 8021p *8021p-value* &<1-8>

undo if-match 8021p

Parameters

Parameter	Description	Value
8021p-value	Specifies the 802.1p priority of VLAN packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority in VLAN packets.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match 8021p** command to classify traffic based on the 802.1p priority in VLAN packets so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

For a Layer 2 network, run the **if-match 8021p** command; for a Layer 3 network, run the **if-match dscp** command.

After the **remark 8021p**, **add-tag vlan-id**, **remark cvlan-id**, and **remark vlan-id** commands are used, the system modifies VLAN tags of packets according to the re-marking configuration. These actions are called VLAN-based actions.

Regardless of whether the relationship between traffic classification rules is AND or OR, if you enter multiple values of 802.1p priorities, the packet that matches one 802.1p priority matches a rule.

If you run the **if-match 8021p** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the 802.1p priority of 1 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match 8021p 1
```

15.1.12 if-match acl

Function

The **if-match acl** command configures a matching rule based on an Access Control List (ACL) in a traffic classifier.

The **undo if-match acl** command deletes a matching rule based on an ACL.

By default, a matching rule based on an ACL is not configured in a traffic classifier.

Format

if-match [**ipv6**] **acl** { *acl-number* | *acl-name* }

undo if-match [**ipv6**] **acl** { *acl-number* | *acl-name* }

Parameters

Parameter	Description	Value
ipv6	Indicates that IPv6 ACLs are matched. If this parameter is not specified, IPv4 ACLs are matched.	-
acl-number	Specifies the number of an ACL.	The value is an integer that ranges from 2000 to 5999, and the value of an ACL6 ranges from 2000 to 3999. ● ACLs numbered 2000 to 2999 are basic ACLs, which are used to classify all packets. ● ACLs numbered 3000 to 3999 are advanced ACLs, which are used to classify packets based on Layer 3 information. ● ACLs numbered 4000 to 4999 are Layer 2 ACLs, which are used to classify packets based on the source MAC address, destination MAC address, and packet type. ● ACLs numbered 5000 to 5999 are user-defined ACLs.
acl-name	Specifies the name of an ACL.	The value must be the name of an existing ACL.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To classify packets based on the interface that receives packets, source IP address, destination IP address, protocol over IP, source and destination TCP port numbers, ICMP type and code, and source and destination MAC addresses, ARP packets, reference an ACL in a traffic classifier. You must first define an ACL and configure rules in the ACL, and then run the **if-match acl** command to configure a matching rule based on the ACL so that the device processes packets matching the same rule in the same manner.

Prerequisites

The following operations must have been performed:

- Create an ACL and configure rules in the ACL.
- Create a traffic classifier using the **traffic classifier** command.

Precautions

Regardless of whether the relationship between rules in a traffic classifier is AND or OR, if an ACL contains multiple rules, the packet that matches one ACL rule matches the ACL.

Only the S6720-EI, S6735-S, and S6720S-EI support traffic classifiers with advanced ACLs containing the **ttl-expired** field.

You can configure multiple ACL rules in a traffic classifier to match different types of packets.

If the **vpn-instance** parameter is specified in an ACL rule, a traffic policy that defines a traffic classifier matching this ACL rule does not take effect.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, and S500, S5735-S-I, S5735S-S, if a traffic policy is applied to the outbound direction and the relationship between rules in a traffic classifier is AND:

- Rules for matching the source IPv6 address and those for matching the destination IPv6 address cannot be configured in the same traffic classifier.
- Rules for matching IPv6 information (for example, **if-match protocol ipv6** and **if-match ipv6 acl**) and those for matching the source MAC address, destination MAC address, source IPv6 address, or destination IPv6 address of packets cannot be configured in the same traffic classifier. (ACL6 rules can be used to match the source or destination IPv6 address of packets.)
- Rules for matching IPv4 information (IP address and UDP port number) and those for matching some Layer 2 information (for example, **if-match source-mac**, **if-match destination-mac**, and **if-match l2-protocol** { **mpls** | **rarp** | *protocol-value* }) cannot be configured in the same traffic classifier.

On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, and S500, S5735-S-I, S5735S-S, if a traffic policy is applied to the outbound direction, and an ACL6 rule for matching the source IPv6 address of packets and an ACL6 rule for matching the destination IPv6 address of packets are respectively configured in two traffic classifiers:

- If the traffic behaviors corresponding to the two traffic classifiers do not conflict, the two traffic classifiers and their corresponding traffic behaviors take effect.
- If the traffic behaviors corresponding to the two traffic classifiers conflict, the traffic behavior and traffic classifier defining the ACL6 rule for matching the source IPv6 address of packets take effect.

MTU-exceeded UDP packets will be fragmented. Only the first fragmented packet contains UDP information, and the other fragmented packets cannot be matched against ACL rules based on UDP information. Therefore, a traffic policy that contains **if-match acl** for matching UDP information does not take effect on fragmented packets. For example, if traffic policing is configured for traffic that contains a large number of fragmented packets and these fragmented packets do not match the UDP port number in an ACL rule, traffic policing is not performed on the fragmented packets. As a result, the actual rate is higher than the rate limit.

For S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, on devices for which the resource mode of extended entry space cannot be configured, ACL6 rules can define only the protocol number, source port number, destination port number, source IPv6 address, and destination IPv6 address. Additionally, ACL6-based traffic policies that contain these ACL6 rules cannot be applied to sub-interfaces and VLANIF interfaces.

On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I, if the **first-fragment** parameter is specified in an ACL rule, a traffic policy defining this ACL rule can be applied only to the inbound direction.

Example

Configure a matching rule based on ACL 2046 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] acl 2046
[HUAWEI-acl-basic-2046] rule permit source any
[HUAWEI-acl-basic-2046] quit
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match acl 2046
```

15.1.13 if-match any

Function

The **if-match any** command configures a matching rule based on all data packets in a traffic classifier.

The **undo if-match any** command deletes a matching rule based on all data packets in a traffic classifier.

By default, a matching rule based on all data packets is not configured in a traffic classifier.

Format

if-match any

undo if-match any

Parameters

None

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To process all the data packets in the same manner, you can run the **if-match any** command to configure a matching rule based on all data packets in a traffic classifier.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

After the **if-match any** command is run, only the matching rule configured using this command takes effect, and the other matching rules in the same traffic classifier will become ineffective.

Example

Configure a matching rule based on all data packets in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match any
```

15.1.14 if-match cvlan-8021p

Function

The **if-match cvlan-8021p** command configures a matching rule based on the 802.1p priority in the inner tag of QinQ packets in a traffic classifier.

The **undo if-match cvlan-8021p** command deletes a matching rule based on the 802.1p priority in the inner tag of QinQ packets in a traffic classifier.

By default, a matching rule based on the 802.1p priority in the inner tag of QinQ packets is not configured in a traffic classifier.

NOTE

Only the S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

if-match cvlan-8021p *8021p-value* &<1-8>

undo if-match cvlan-8021p

Parameters

Parameter	Description	Value
8021p-value	Specifies the 802.1p priority in the inner tag of QinQ packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority of QinQ packets.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match cvlan-8021p** command to classify packets based on the 802.1p priority in the inner tag of QinQ packets so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

The **if-match cvlan-8021p** command is valid for only the double-tagged packets.

If you enter multiple 802.1p priorities in the inner tag of packets in the command, a packet matches a rule as long as it matches one of the 802.1p priorities in the inner tag of packets, regardless of whether the relationship between traffic classification rules is AND or OR.

If you run the **if-match cvlan-8021p** command multiple times in the same traffic classifier view, only the latest configuration takes effect.

Example

Configure a matching rule based on the inner 802.1p priority of 1 in QinQ packets in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match cvlan-8021p 1
```

15.1.15 if-match cvlan-id

Function

The **if-match cvlan-id** command configures a matching rule based on VLAN IDs in the inner and outer tags of QinQ packets in a traffic classifier. You can specify the VLAN ID range in the inner tag.

The **undo if-match cvlan-id** command deletes a matching rule based on VLAN IDs in the inner and outer tags of QinQ packets in a traffic classifier.

By default, a matching rule based on the VLAN ID in the inner and outer tags of QinQ packets is not configured in a traffic classifier.

NOTE

Only the S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

if-match cvlan-id *start-cvlan-id* [**to** *end-cvlan-id*] [**vlan-id** *vlan-id*]

undo if-match cvlan-id *start-cvlan-id* [**to** *end-cvlan-id*] [**vlan-id** *vlan-id*]

Parameters

Parameter	Description	Value
start-cvlan-id [**to** *end-cvlan-id*]	Specifies the VLAN ID in the inner tag of a QinQ packet.	• *start-cvlan-id* specifies the start VLAN ID in the inner tag. The value is an integer that ranges from 1 to 4094. • *end-cvlan-id* specifies the end VLAN ID in the inner tag. The value is an integer that ranges from 1 to 4094. The value of *end-cvlan-id* must be larger than the value of *start-cvlan-id*. If **to** *end-cvlan-id* is not specified, only the VLAN ID specified by *start-cvlan-id* is matched.
vlan-id *vlan-id*	Specifies the VLAN ID in the outer tag of a QinQ packet. If this parameter is not specified, only the VLAN ID in the inner tag of a QinQ packet is matched.	The value is an integer that ranges from 1 to 4094.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match cvlan-id** command to classify packets based on the VLAN ID in the inner tag of QinQ packets or VLAN IDs in inner and outer tags of QinQ packets so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

The **if-match cvlan-id** command is valid only for the double-tagged packets.

On the S6720-EI, if a traffic policy contains the traffic classifier defining the **if-match cvlan-id** *start-cvlan-id* [**to** *end-cvlan-id*] **vlan-id** *vlan-id* matching rule, IPv6 ACL resources are occupied. To display information about IPv6 ACL resources, run the **display acl resource** command.

Example

Configure a matching rule based on the VLAN ID of 100 in the inner tag of QinQ packets in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match cvlan-id 100
```

Configure a matching rule based on the inner VLAN ID in the range of 100 to 200 and outer VLAN ID 300 of QinQ packets in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match cvlan-id 100 to 200 vlan-id 300
```

15.1.16 if-match destination-mac

Function

The **if-match destination-mac** command configures a matching rule based on the destination MAC address in a traffic classifier.

The **undo if-match destination-mac** command deletes a matching rule based on the destination MAC address in a traffic classifier.

By default, a matching rule based on the destination MAC address is not configured in a traffic classifier.

Format

if-match destination-mac *mac-address* [*mac-address-mask*]

undo if-match destination-mac

Parameters

Parameter	Description	Value
mac-address	Specifies the destination MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
mac-address-mask	Specifies the mask of the destination MAC address. Similar to the mask of the IP address, the value F indicates that the destination MAC address is matched and the value 0 indicates that the destination MAC address is not matched. The mask of the MAC address determines a group of MAC addresses. The device can accurately match certain bits in the destination MAC address using the mask of the MAC address. In practice, you can set these bits to F in the mask of the destination MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The value cannot be 0-0-0.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match destination-mac** command to configure a matching rule based on the destination MAC address in a traffic classifier so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

If you run the **if-match destination-mac** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, and S500, S5735-S-I, S5735S-S, if a traffic policy is applied to the outbound direction and the relationship between rules in a traffic classifier is AND:

- Rules for matching the source IPv6 address and those for matching the destination IPv6 address cannot be configured in the same traffic classifier.
- Rules for matching IPv6 information (for example, **if-match protocol ipv6** and **if-match ipv6 acl**) and those for matching the source MAC address, destination MAC address, source IPv6 address, or destination IPv6 address of packets cannot be configured in the same traffic classifier. (ACL6 rules can be used to match the source or destination IPv6 address of packets.)
- Rules for matching IPv4 information (IP address and UDP port number) and those for matching some Layer 2 information (for example, **if-match source-mac**, **if-match destination-mac**, and **if-match l2-protocol** { **mpls** | **rarp** | *protocol-value* }) cannot be configured in the same traffic classifier.

Example

Configure a matching rule based on the destination MAC address of 00eo-fc12-3456 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match destination-mac 00eo-fc12-3456
```

Configure a matching rule based on the destination MAC address of XXeo-fXX2-3456 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match destination-mac 00eo-fc12-3456 00ff-f00f-ffff
```

15.1.17 if-match discard

Function

The **if-match discard** command configures a matching rule based on drop packets in a traffic classifier.

The **undo if-match discard** command deletes a matching rule based on drop packets in a traffic classifier.

By default, no matching rule based on drop packets is configured in a traffic classifier.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

if-match discard

undo if-match discard

Parameters

None

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After packets reach the device, invalid packets are discarded. You can run the **if-match discard** command to configure the device to match discarded packets, take action for the discarded packets such as traffic statistics collection and mirroring, and analyze them.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, both the traffic classifier defining **if-match discard** and traffic classifiers defining other matching rules (excluding **if-match application**) take effect. Examples are as follows:

- A packet matches two pairs of traffic classifiers and traffic behaviors defined in the same traffic policy, and only one traffic classifier contains **if-match discard**. (The other traffic classifier does not contain **if-match discard** or **if-match application**.) In this case, both pairs of traffic classifiers and traffic behaviors take effect for the packet.
- A packet matches two traffic policies, and a traffic classifier contains **if-match discard** in only one of the traffic policies. (The other traffic policy does not contain **if-match discard** or **if-match application**.) In this case, both traffic policies take effect for the packet.

Example

Configure a matching rule based on discarded packets in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match discard
```

15.1.18 if-match double-tag

Function

The **if-match double-tag** command configures a matching rule based on double tags of packets in a traffic classifier.

The **undo if-match double-tag** command deletes a matching rule based on double tags of packets in a traffic classifier.

By default, a matching rule based on double tags of packets is not configured in a traffic classifier.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

if-match double-tag

undo if-match double-tag

Parameters

None

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match double-tag** command to classify traffic based on double tags so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Example

Configure a matching rule based on double tags of packets in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match double-tag
```

15.1.19 if-match dscp

Function

The **if-match dscp** command configures a matching rule based on the Differentiated Services Code Point (DSCP) priority of packets in a traffic classifier.

The **undo if-match dscp** command deletes a matching rule based on the DSCP priority of packets in a traffic classifier.

By default, a matching rule based on the DSCP priority of packets is not configured in a traffic classifier.

Format

if-match dscp *dscp-value* &<1-8>

undo if-match dscp

Parameters

Parameter	Description	Value
dscp *dscp-value*	Specifies the DSCP priority.	The value can be a DiffServ code, an integer ranging from 0 to 63, or the name of the DSCP service type such as af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1-cs7, default, and ef. The values corresponding to service types are as follows: • af11: 10 • af12: 12 • af13: 14 • af21: 18 • af22: 20 • af23: 22 • af31: 26 • af32: 28 • af33: 30 • af41: 34 • af42: 36 • af43: 38 • cs1: 8 • cs2: 16 • cs3: 24 • cs4: 32 • cs5: 40 • cs6: 48 • cs7: 56 • default: 0 • ef: 46

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match dscp** command to classify packets based on the DSCP priority of packets so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

For a Layer 2 network, run the **if-match 8021p** command; for a Layer 3 network, run the **if-match dscp** command.

if-match dscp can match both IPv4 and IPv6 packets.

If you enter multiple DSCP priorities in the command, a packet matches a rule as longs as it matches one of the DSCP priorities, regardless of whether the relationship between traffic classification rules is AND or OR.

If the relationship between rules in a traffic classifier is AND, the **if-match dscp** and **if-match ip-precedence** commands cannot be used in the traffic classifier simultaneously.

In a version earlier than V200R009C00, if **if-match dscp** *dscp-value* is configured in the traffic classifier on the switch, the traffic classifier can only match IPv4 packets. After the switch is upgraded to V200R009C00 and later versions, the traffic classifier can match IPv4 and IPv6 packets.

If you run the **if-match dscp** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the DSCP priority of 1 in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match dscp 1
```

15.1.20 if-match flow-id

Function

The **if-match flow-id** command configures a matching rule based on the flow ID in a traffic classifier.

The **undo if-match flow-id** command deletes a matching rule based on the flow ID in a traffic classifier.

By default, no matching rule based on the flow ID is configured in a traffic classifier.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

if-match flow-id *flow-id*

undo if-match flow-id

Parameters

Parameter	Description	Value
flow-id	Specifies a flow ID.	The value is an integer that ranges from 1 to 15.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a traffic policy is applied to different interfaces or VLANs, to save ACL resources, you can run the **if-match flow-id** command to classify packets based on the flow ID so that the device processes packets matching the same flow ID in the same manner.

Assume that *M* ACLs are configured on the device to distinguish services, and each ACL contains *N* ACL rules. Traffic classifiers classify packets based on ACL rules, and the traffic policy containing the ACL rules is applied to *X* interfaces. If the actions of re-marking flow IDs and matching rules based on the flow IDs are not configured, applying the traffic policy occupies $M \times N \times X$ ACL resources. If the actions of re-marking flow IDs and matching rules based on flow IDs are configured, applying the traffic policy occupies only $M \times (N + X)$ ACL resources.

Prerequisites

The following operations must have been performed before this command is used:

- Run the **remark flow-id** command in the traffic behavior view to configure an action of re-marking the flow ID.
- Run the **traffic classifier** command in the system view to create a traffic classifier.

Precautions

It is recommended that the traffic classifier containing **if-match flow-id** and the traffic behavior containing **remark flow-id** be bound to different traffic policies.

The traffic policy containing **if-match flow-id** can be only applied to an interface, a VLAN, a VLANIF interface, or the system in the inbound direction.

If you run the **if-match flow-id** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the flow ID of 1 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match flow-id 1
```

15.1.21 if-match inbound-interface

Function

The **if-match inbound-interface** command configures a matching rule based on an inbound interface in a traffic classifier.

The **undo if-match inbound-interface** command deletes a matching rule based on an inbound interface in a traffic classifier.

By default, a matching rule based on an inbound interface is not configured in a traffic classifier.

Format

if-match inbound-interface *interface-type interface-number*

undo if-match inbound-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an inbound interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match inbound-interface** command to classify traffic based on an inbound interface so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

A traffic policy containing **if-match inbound-interface** cannot be applied to an interface.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the inbound interface in this command cannot be an Eth-Trunk member interface.

A traffic policy containing the **if-match inbound-interface** rule can only be applied to the inbound direction.

If you run the **if-match inbound-interface** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the inbound interface of GE0/0/1 in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match inbound-interface gigabitethernet 0/0/1
```

15.1.22 if-match ip-precedence

Function

The **if-match ip-precedence** command configures a matching rule based on the IP precedence of packets in a traffic classifier.

The **undo if-match ip-precedence** command deletes a matching rule based on the IP precedence of packets in a traffic classifier.

By default, a matching rule based on the IP precedence of packets is not configured in a traffic classifier.

Format

if-match ip-precedence *ip-precedence-value* &<1-8>

undo if-match ip-precedence

Parameters

Parameter	Description	Value
ip-precedence-value	Specifies the IP precedence.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority of packets.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match ip-precedence** command to classify packets based on the IP precedence so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

After the **if-match ip-precedence** command is run, IP precedences are listed in ascending order.

If you enter multiple IP precedences in the **if-match ip-precedence** command, a packet matches a rule as long as it matches one of the IP precedence values, regardless of whether the relationship between traffic classification rules is AND or OR.

In a traffic classifier where the relationship between rules is AND, the **if-match dscp** and **if-match ip-precedence** commands cannot be used simultaneously.

If you run the **if-match ip-precedence** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the IP precedence of 1 in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match ip-precedence 1
```

15.1.23 if-match l2-protocol

Function

The **if-match l2-protocol** command configures a matching rule based on the Layer 2 protocol type in a traffic classifier.

The **undo if-match l2-protocol** command deletes a matching rule based on the Layer 2 protocol type in a traffic classifier.

By default, a matching rule based on the Layer 2 protocol type is not configured in a traffic classifier.

Format

if-match l2-protocol { **arp** | **ip** | **mpls** | **rarp** | *protocol-value* }

undo if-match l2-protocol

Parameters

Parameter	Description	Value
arp	Indicates that ARP packets are classified.	The value of **arp** corresponds to 0x0806.
ip	Indicates that IP packets are classified.	The value of **ip** corresponds to 0x0800.
mpls	Indicates that MPLS packets are classified.	The value of **mpls** corresponds to 0x8847.

Parameter	Description	Value
rarp	Indicates that RARP packets are classified.	The value of **rarp** corresponds to 0x8035.
protocol-value	Specifies the value of a protocol type.	The value ranges from 0x0000 to 0xFFFF in hexadecimal notation and must start with 0x. If the value of *protocol-value* is smaller than 0x0600, the Destination Service Access Point (DSAP) and Source Service Access Point (SSAP) fields in the Logical Line Control (LLC) protocol packets are matched.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match l2-protocol** command to classify packets based on the Layer 2 protocol type so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

The device supports Layer 2 protocols including ARP, IP, MPLS, and RARP.

If you run the **if-match l2-protocol** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

If the relationship between rules in a traffic classifier is AND, and both the **if-match l2-protocol arp** and **if-match protocol** { **ip** | **ipv6** } commands are configured in this traffic classifier, of the two, only the **if-match l2-protocol arp** command takes effect.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, and S500, S5735-S-I, S5735S-S, if a traffic policy is applied to the outbound direction and the relationship between rules in a traffic classifier is AND:

- Rules for matching the source IPv6 address and those for matching the destination IPv6 address cannot be configured in the same traffic classifier.
- Rules for matching IPv6 information (for example, **if-match protocol ipv6** and **if-match ipv6 acl**) and those for matching the source MAC address, destination MAC address, source IPv6 address, or destination IPv6 address of packets cannot be configured in the same traffic classifier. (ACL6 rules can be used to match the source or destination IPv6 address of packets.)
- Rules for matching IPv4 information (IP address and UDP port number) and those for matching some Layer 2 information (for example, **if-match source-mac**, **if-match destination-mac**, and **if-match l2-protocol** { **mpls** | **rarp** | *protocol-value* }) cannot be configured in the same traffic classifier.

Example

Define a matching rule based on the protocol type of ARP in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match l2-protocol arp
```

15.1.24 if-match mpls-exp

Function

The **if-match mpls-exp** command configures a matching rule based on the EXP priority of MPLS packets in a traffic classifier.

The **undo if-match mpls-exp** command deletes a matching rule based on the EXP priority of MPLS packets in a traffic classifier.

By default, a matching rule based on the EXP priority of MPLS packets is not configured in a traffic classifier.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, and S6730-H support this command.

Format

if-match mpls-exp *exp-value* &<1-8>

undo if-match mpls-exp

Parameters

Parameter	Description	Value
exp-value	Specifies the EXP priority of MPLS packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority of MPLS packets.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match mpls-exp** command to classify MPLS packets based on the EXP priority so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

If you enter multiple values of EXP priorities in the command, a packet matches the traffic classifier as long as it matches one of the EXP priorities, regardless of whether the relationship between traffic classification rules is AND or OR.

If a traffic classifier in the traffic policy contains **if-match mpls-exp**, the traffic policy cannot be applied to the outbound direction on the S6720-EI and S6720S-EI.

If you run the **if-match mpls-exp** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the EXP priority of 1 or 4 in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match mpls-exp 1 4
```

15.1.25 if-match outbound-interface

Function

The **if-match outbound-interface** command configures a matching rule based on an outbound interface in a traffic classifier.

The **undo if-match outbound-interface** command deletes a matching rule based on an outbound interface in a traffic classifier.

By default, a matching rule based on an outbound interface is not configured in a traffic classifier.

NOTE

The S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S6720S-S, and S5735S-S do not support this command.

Format

if-match outbound-interface *interface-type interface-number*

undo if-match outbound-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an outbound interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match outbound-interface** command to classify packets based on an outbound interface so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

A traffic policy containing **if-match outbound-interface** cannot be applied to an interface.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the outbound interface in this command cannot be an Eth-Trunk member interface.

A traffic policy containing the **if-match outbound-interface** rule can only be applied to the outbound direction on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6730-H, S6730S-H, S6730-S, and S6730S-S.

If you run the **if-match outbound-interface** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the outbound interface of GE0/0/1 in the traffic classifier **class1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier class1
[HUAWEI-classifier-class1] if-match outbound-interface gigabitethernet 0/0/1
```

15.1.26 if-match protocol

Function

The **if-match protocol** command configures a matching rule based on a protocol in a traffic classifier.

The **undo if-match protocol** command deletes a matching rule based on a protocol in a traffic classifier.

By default, a matching rule based on a protocol is not configured in a traffic classifier.

Format

if-match protocol { **ip** | **ipv6** }

undo if-match protocol

Parameters

Parameter	Description	Value
ip	Specifies an IP protocol.	-
ipv6	Specifies an IPv6 protocol.	-

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match protocol** command to classify packets based on a protocol so that the device processes packets of the same protocol in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

Currently, the device supports IPv4 and IPv6.

If you run the **if-match protocol** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

If the relationship between rules in a traffic classifier is AND, and both the **if-match protocol** and **if-match l2-protocol arp** commands are configured in this traffic classifier, of the two, only the **if-match l2-protocol arp** command takes effect.

Example

Configure a matching rule based on the IP protocol in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match protocol ip
```

15.1.27 if-match source-mac

Function

The **if-match source-mac** command configures a matching rule based on the source MAC address in a traffic classifier.

The **undo if-match source-mac** command deletes a matching rule based on the source MAC address in a traffic classifier.

By default, a matching rule based on the source MAC address is not configured in a traffic classifier.

Format

if-match source-mac *mac-address* [*mac-address-mask*]

undo if-match source-mac

Parameters

Parameter	Description	Value
mac-address	Specifies the source MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.
mac-address-mask	Specifies the mask of the source MAC address. Similar to the mask of the IP address, the mask of the MAC address determines a group of MAC addresses. The device can accurately match certain bits in the source MAC address using the mask of the MAC address. In practice, you can set these bits to F in the mask of the source MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits. The value cannot be 0-0-0.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match source-mac** command to classify packets based on the source MAC address so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

If you run the **if-match source-mac** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, and S500, S5735-S-I, S5735S-S, if a traffic policy is applied to the outbound direction and the relationship between rules in a traffic classifier is AND:

- Rules for matching the source IPv6 address and those for matching the destination IPv6 address cannot be configured in the same traffic classifier.
- Rules for matching IPv6 information (for example, **if-match protocol ipv6** and **if-match ipv6 acl**) and those for matching the source MAC address, destination MAC address, source IPv6 address, or destination IPv6 address of packets cannot be configured in the same traffic classifier. (ACL6 rules can be used to match the source or destination IPv6 address of packets.)
- Rules for matching IPv4 information (IP address and UDP port number) and those for matching some Layer 2 information (for example, **if-match source-mac**, **if-match destination-mac**, and **if-match l2-protocol** { **mpls** | **rarp** | *protocol-value* }) cannot be configured in the same traffic classifier.

Example

Configure a matching rule based on the source MAC address of 00e0-fc12-3456 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match source-mac 00e0-fc12-3456
```

Configure a matching rule based on the source MAC address of XXe0-fXX2-3457 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match source-mac 00e0-fc12-3457 00ff-f00f-ffff
```

15.1.28 if-match tcp

Function

The **if-match tcp** command configures a matching rule based on the SYN Flag in the TCP packet header in a traffic classifier.

The **undo if-match tcp** command deletes a matching rule based on the SYN Flag in the TCP packet header in a traffic classifier.

By default, a matching rule based on the SYN Flag in the TCP packet header is not configured in a traffic classifier.

Format

if-match tcp syn-flag { *syn-flag-value* | **ack** | **fin** | **psh** | **rst** | **syn** | **urg** }

undo if-match tcp syn-flag

Parameters

Parameter	Description	Value
syn-flag	Specifies the SYN Flag in the TCP packet header.	-
syn-flag-value	Specifies the SYN Flag in the TCP packet header.	The value is an integer that ranges from 0 to 63.
ack	Indicates that the SYN Flag type in the TCP packet header is ACK.	-
fin	Indicates that the SYN Flag type in the TCP packet header is FIN.	-
psh	Indicates that the SYN Flag type in the TCP packet header is PSH.	-
rst	Indicates that the SYN Flag type in the TCP packet header is RST.	-
syn	Indicates that the SYN Flag type in the TCP packet header is SYN.	-
urg	Indicates that the SYN Flag type in the TCP packet header is URG.	-

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match tcp** command to classify packets based on the SYN Flag in the TCP packet header so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

If you run the **if-match tcp** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

Example

Configure a matching rule based on the SYN Flag of psh in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match tcp syn-flag psh
```

15.1.29 if-match vlan-id

Function

The **if-match vlan-id** command configures a matching rule based on the VLAN ID of packets in a traffic classifier.

The **undo if-match vlan-id** command deletes a matching rule based on the VLAN ID of packets in a traffic classifier.

By default, a matching rule based on the VLAN ID of packets is not configured in a traffic classifier.

Format

if-match vlan-id *start-vlan-id* [**to** *end-vlan-id*] [**cvlan-id** *cvlan-id*]

undo if-match vlan-id *start-vlan-id* [**to** *end-vlan-id*] [**cvlan-id** *cvlan-id*]

NOTE

Only the S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **cvlan-id** *cvlan-id* parameter.

Parameters

Parameter	Description	Value
start-vlan-id [**to** *end-vlan-id*]	Specifies the outer VLAN ID.	• *start-vlan-id* specifies the start outer VLAN ID. The value of *start-vlan-id* is an integer that ranges from 1 to 4094. • *end-vlan-id* specifies the end outer VLAN ID. The value of *end-vlan-id* is an integer that ranges from 1 to 4094. The value of *end-vlan-id* must be larger than the value of *start-vlan-id*. If **to** *end-vlan-id* is not specified, only the VLAN ID specified by *start-vlan-id* is matched.
cvlan-id *cvlan-id*	Specifies the inner VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match vlan-id** command to classify packets based on the VLAN ID so that the device processes packets matching the same traffic classifier in the same manner.

Prerequisites

A traffic classifier has been created using the **traffic classifier** command in the system view.

Precautions

On the S6720-EI, if a traffic policy contains the traffic classifier defining the **if-match vlan-id** *start-vlan-id* [**to** *end-vlan-id*] **cvlan-id** *cvlan-id* matching rule, IPv6 ACL resources are occupied. To display information about IPv6 ACL resources, run the **display acl resource** command.

Example

Configure a matching rule based on VLAN 2 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match vlan-id 2
```

15.1.30 if-match vxlan

Function

The **if-match vxlan** command configures a matching rule based on inner information of VXLAN packets in a traffic classifier.

The **undo if-match vxlan** command deletes a matching rule based on inner information of VXLAN packets from a traffic classifier.

By default, a matching rule based on inner information of VXLAN packets is not configured in a traffic classifier.

Format

if-match vxlan [**transit**] **vni** *vni-id*

undo if-match vxlan [**transit**] **vni** *vni-id*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command. On a VXLAN-incapable switch, the **transit** parameter must be set so that passerby packets can be transparently transmitted.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support VXLAN.

Parameters

Parameter	Description	Value
transit	Indicates that VXLAN packets on the transmission device are matched. If this parameter is not specified, a traffic policy containing this traffic classifier takes effect only on a VXLAN decapsulation device.	-

Parameter	Description	Value
vni *vni-id*	Specifies the VNI ID for matching VXLAN packets.	The value is an integer that ranges from 1 to 16777215.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A VNI is similar to a VLAN ID on a traditional network, and it identifies a VXLAN segment. You can use the **if-match vxlan** command to classify packets based on the inner information of VXLAN packets so that the device processes packets matching the same traffic classifier in the same manner.

Precautions

- A traffic policy containing this traffic classifier cannot be applied in the outbound direction.
- If a traffic classifier contains this matching rule, it supports only traffic behaviors of traffic policing, packet filtering, and traffic statistics.

Example

Configure a matching rule based on VNI 10 in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1] if-match vxlan transit vni 10
```

15.1.31 remark flow-id

Function

The **remark flow-id** command configures an action of re-marking the flow ID in a traffic behavior.

The **undo remark flow-id** command deletes the configuration.

By default, an action of re-marking the flow ID is not configured in a traffic behavior.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

remark flow-id *flow-id*

undo remark flow-id

Parameters

Parameter	Description	Value
flow-id	Specifies a flow ID.	The value is an integer that ranges from 1 to 15.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a traffic policy is applied to different interfaces or VLANs, to save ACL resources, you can run the **if-match flow-id** command to classify packets based on the flow ID so that the device processes packets matching the same flow ID in the same manner. Before the device classifies packets based on the flow ID, use the **remark flow-id** command to configure an action of re-marking the flow ID in a traffic behavior.

Assume that *M* ACLs are configured on the device to distinguish services, and each ACL contains *N* ACL rules. Traffic classifiers classify packets based on ACL rules, and the traffic policy containing the ACL rules is applied to *X* interfaces. If the actions of re-marking flow IDs and matching rules based on the flow IDs are not configured, applying the traffic policy occupies $M \times N \times X$ ACL resources. If the actions of re-marking flow IDs and matching rules based on flow IDs are configured, applying the traffic policy occupies only $M \times (N + X)$ ACL resources.

Follow-up Procedure

Run the **traffic classifier** command to configure a traffic classifier and run the **if-match flow-id** command in the traffic classifier view to create a matching rule based on the flow ID.

Precautions

It is recommended that the traffic classifier containing **if-match flow-id** and the traffic behavior containing **remark flow-id** be bound to different traffic policies.

The traffic policy containing **remark flow-id** can be only applied to an interface, a VLAN, or the system in the inbound direction.

remark flow-id, **statistic enable**, and **car** cannot be configured in the same traffic behavior.

If you run the **remark flow-id** command in the same traffic behavior view multiple times, only the latest configuration takes effect.

On the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, a traffic policy containing **remark flow-id** does not take effect for MPLS packets.

Example

Configure the device to re-mark the flow ID with 4 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark flow-id 4
```

15.1.32 reset traffic policy statistics

Function

The **reset traffic policy statistics** command clears statistics on packets matching a traffic policy that has been applied to the specified object or each object.

Format

reset traffic policy statistics { **global** [**slot** *slot-id*] | **interface** *interface-type interface-number* [*.subinterface-number*] | **vlan** *vlan-id* | **ssid-profile** *ssid-profile-name* } { **inbound** | **outbound** }

reset traffic policy statistic ap-group *ap-group* **outbound**

reset traffic policy statistics policy-name *policy-name*

reset traffic policy statistics all

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support sub-interfaces.

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support **ssid-profile** *ssid-profile-name* and **ap-group** *ap-group*.

Parameters

Parameter	Description	Value
global	Clears statistics on packets matching a traffic policy in the system.	-
slot *slot-id*	Clears statistics on packets matching a traffic policy on a specified device. *slot-id* specifies the slot ID of the device.	The value range depends on the device configuration.
interface *interface-type interface-number* [*.subinterface-number*]	Clears statistics on packets matching a traffic policy on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* [*.subinterface-number*] specifies the interface or sub-interface number.	-
vlan *vlan-id*	Clears statistics on packets matching a traffic policy in a specified VLAN. *vlan-id* specifies the ID of the VLAN.	The value is an integer that ranges from 1 to 4094.
ssid-profile *ssid-profile-name*	Clears statistics on packets matching a traffic policy in a specified SSID profile. *ssid-profile-name* specifies the name of the SSID profile.	The value must the name of an existing SSID profile.
ap-group *ap-group*	Clears statistics on packets matching a traffic policy in a specified AP group. *ap-group* specifies the name of the AP group .	The value must be the name of an existing AP group.
inbound	Clears traffic statistics in the inbound direction.	-

Parameter	Description	Value
outbound	Clears traffic statistics in the outbound direction.	-
policy-name *policy-name*	Clears statistics on packets matching the specified traffic policy in each object.	The value must be the name of an existing traffic policy.
all	Clears statistics on packets matching a traffic policy in each object, including statistics on packets in the inbound and outbound directions in the system, on each interface, in each VLAN, and in each SSID profile.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before re-collecting statistics on packets matching a traffic policy in the specified object or each object, run the **reset traffic policy statistics** command to clear existing packet statistics. Then run the **display traffic policy statistics** command to view packet statistics.

Precautions

The traffic policies that can be deleted from the device every second are limited. If many traffic policies are applied to the device, it may take a long time to delete the traffic policies.

The cleared traffic statistics cannot be restored. Exercise caution when you use the command.

If no traffic policy is applied, the system displays an error message after the **reset traffic policy statistics** command is executed:

```
Error: The Policy is not applied in this view.
```

If you do not run the **statistic enable (traffic behavior view)** command in the view of the traffic behavior in a traffic policy, the system displays an error message after the **reset traffic policy statistics** command is executed:

```
Info: Statistic has not been enabled.
```

Example

Clear traffic statistics on GE0/0/1 in the inbound direction to which a traffic policy has been applied.

```
<HUAWEI> reset traffic policy statistics interface gigabitethernet 0/0/1 inbound
```

15.1.33 rule-deny skip-action

Function

The **rule-deny skip-action** command creates an action for making the deny action in an ACL or ACL6 ineffective in a traffic behavior.

The **undo rule-deny skip-action** command cancels the configuration.

By default, no action for making the deny action in an ACL or ACL6 ineffective is created in a traffic behavior.

Format

rule-deny skip-action

undo rule-deny skip-action

Parameters

None

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a traffic classifier contains an ACL or ACL6 rule that defines the deny action, traffic matching the deny action is discarded.

To prevent such traffic from being discarded, run the **rule-deny skip-action** command in the traffic behavior view. The switch does not take other actions (except traffic statistics collection) defined in the traffic behavior for traffic matching the deny action.

Precautions

If both the **rule-deny skip-action** and **statistic enable** commands are configured in a traffic behavior, traffic matching the deny action in the ACL or ACL6 is forwarded based on the original forwarding path and statistics on the traffic are collected.

If the **rule-deny skip-action** command is configured in a traffic behavior and **logging** is specified in the ACL or ACL6 rule that defines the deny action, the following situations may occur:

- When the traffic policy is applied to the inbound direction on the S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6730-H, S6730S-H, or S6720S-EI, traffic matching the deny action in the ACL or ACL6 rule is forwarded based on the original forwarding path, and IP addresses of packets matching the rule are logged. On the other models, traffic matching the deny action in an ACL or ACL6 is discarded, and IP addresses of packets matching the rule are logged.
- When the traffic policy is applied to the outbound direction, traffic matching the deny action in the ACL or ACL6 is forwarded based on the original forwarding path, but IP addresses of packets matching the rule are not logged.

Example

Create an action for making the deny action in an ACL ineffective in traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule deny ip source 192.168.10.1 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match acl 3000
[HUAWEI-classifier-c1] quit
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] rule-deny skip-action
```

15.1.34 traffic behavior

Function

The **traffic behavior** command creates a traffic behavior and displays the traffic behavior view, or directly displays the view of an existing traffic behavior.

The **undo traffic behavior** command deletes a traffic behavior.

By default, no traffic behavior is created in the system.

Format

traffic behavior *behavior-name*

undo traffic behavior *behavior-name*

Parameters

Parameter	Description	Value
behavior-name	Specifies the name of a traffic behavior.	The value is a string of 1 to 64 case-sensitive characters, spaces and question marks (?) not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A traffic classifier is used to differentiate services and must be associated with a flow control or resource allocation action such as packet filtering, traffic policing, and re-marking. The actions constitute a traffic behavior. The **traffic behavior** command creates a traffic behavior.

Follow-up Procedure

Configure an action in the traffic behavior view. For example, run the **car (traffic behavior view)** command to configure the traffic policing action.

Precautions

To delete a traffic behavior, unbind the traffic policy containing the traffic behavior from the system, an interface, or a VLAN where the traffic policy is applied and unbind the traffic behavior from the traffic classifier. To modify only actions in a traffic behavior, you do not need to unbind the traffic policy containing the traffic behavior from the system, an interface, or a VLAN.

On the device, a maximum of 256 traffic behaviors can be created and multiple traffic actions can be configured in a traffic behavior.

Example

Create the traffic behavior **b1** and enter the traffic behavior view.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1]
```

15.1.35 traffic classifier

Function

The **traffic classifier** command creates a traffic classifier and displays the traffic classifier view, or directly displays the view of an existing traffic classifier.

The **undo traffic classifier** command deletes a traffic classifier.

By default, no traffic classifier is created in the system.

Format

traffic classifier *classifier-name* [**operator** { **and** | **or** }]

undo traffic classifier *classifier-name*

Parameters

Parameter	Description	Value
classifier-name	Specifies the name of a user-defined traffic classifier.	The value is a string of 1 to 64 case-sensitive characters, spaces and question marks (?) not supported. When double quotation marks are used around the string, spaces are allowed in the string.
operator	Specifies the relationship between rules in a traffic classifier. If this parameter is not specified, the relationship between rules is OR by default.	-

Parameter	Description	Value
and	Indicates that the relationship between rules is AND. After this parameter is specified, the following situations occur: - If a traffic classifier contains ACL rules, packets match the traffic classifier only when the packets match one ACL rule and all the non-ACL rules. - If a traffic classifier does not contain ACL rules, packets match the traffic classifier only when the packets match all the non-ACL rules.	-
or	Indicates that the relationship between rules is OR. After this parameter is specified, packets match a traffic classifier if the packets match one or more rules.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A traffic classifier classifies traffic of a certain type using matching rules. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior (see **traffic behavior**) to a traffic policy and apply the traffic policy.

A traffic classifier can be created based on Layer 2 information such as the 802.1p priority in the VLAN ID, 802.1p priority in the C-VLAN ID, VLAN ID, C-VLAN ID, or

Layer 2 protocol type, and Layer 3 information such as the DSCP priority or IP priority, or ACLs.

Follow-up Procedure

Define rules in the traffic classifier. For example, run the **if-match 8021p** command to define rules based on the 802.1p priority in the VLAN tag.

Precautions

To delete a traffic classifier, unbind the traffic policy containing the traffic classifier from the system, an interface, or a VLAN where the traffic policy is applied and unbind the traffic classifier from the traffic behavior.

A maximum of 512 traffic classifiers can be created on the device.

After the relationship between rules in a traffic classifier is changed, the system checks whether rules conflict. When the relationship between rules is changed from OR to AND and multiple rules are configured, for example, matching rules based on the 802.1p priority in the inner VLAN tag, DSCP priority, IP precedence, and VLAN ID, the rules may conflict and the traffic policy cannot take effect. If the relationship between rules is changed from AND to OR, the traffic policy still takes effect but services may be affected because more packets are matched. Exercise caution when you change the relationship between rules.

Example

Create a traffic classifier **c1** and enter the traffic classifier view.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1 operator and
[HUAWEI-classifier-c1]
```

15.1.36 traffic policy

Function

The **traffic policy** command creates a traffic policy and specifies the matching order of traffic classifiers in the traffic policy.

The **undo traffic policy** command deletes a traffic policy.

By default, no traffic policy is created in the system.

Format

traffic policy *policy-name* [**match-order** { **auto** | **config** }] [**atomic**]

undo traffic policy *policy-name*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **match-order** { **auto** | **config** }.

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a user-defined traffic policy.	The value is a string of 1 to 64 case-sensitive characters, spaces and question marks (?) not supported. When double quotation marks are used around the string, spaces are allowed in the string. The value cannot be f, fa, fas, fast, fast-, fast-m, fast-mo, fast-mod, or fast-mode.
match-order	Specifies the matching order of traffic classifiers in the traffic policy. By default, the matching order of traffic classifiers in a traffic policy is **config**.	-

Parameter	Description	Value
auto	Indicates that the matching order depends on priorities of traffic classifier types. For the S6735-S, S6720-EI and S6720S-EI: If a traffic policy is applied to the inbound direction, traffic classifiers based on the following information are matched in descending order of priority: Layer 2 and IPv4 Layer 3 information > advanced ACL6 > basic ACL6 > IPv4 Layer 3 information > Layer 2 information > user-defined ACL information. For other models: Traffic classifiers based on the following information are in descending order of priority: Layer 2 and IPv4 Layer 3 information > advanced ACL6 > basic ACL6 > Layer 2 information > IPv4 Layer 3 information > user-defined ACL information. If this parameter is specified, fewer ACL resources are consumed.	-
config	Indicates that the matching order depends on the sequence in which traffic classifiers were bound to traffic behaviors. If this parameter is specified, more ACL resources are consumed.	-

Parameter	Description	Value
atomic	Indicates the atomic attribute of a traffic policy. After this parameter is specified, if a traffic policy references an ACL and the ACL is applied to a specified object, dynamically updating the ACL does not interrupt services.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are obtained based on Layer 2 information, Layer 3 information, or ACLs. To implement differentiated services for service flows of packets, bind a traffic classifier and a traffic behavior to the created traffic policy and apply the traffic policy. You can use the **traffic policy** command to create a traffic policy. A maximum of 256 traffic policies can be created on the device.

Pre-configuration Tasks

A traffic classifier and a traffic behavior have been created.

Follow-up Procedure

- Run the **classifier behavior** command in the traffic policy view to associate the traffic policy with a traffic classifier and a traffic behavior.
- Run the **traffic-policy global**, **traffic-policy (interface view)**, **traffic-policy (VLAN view)**, or **traffic-policy (VLANIF interface view)** command to apply the traffic policy to the system, an interface, or a VLAN for the created traffic policy to take effect.

Precautions

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, no matter whether the traffic policy defines the **auto** or **config** matching order, traffic classifiers bound to the traffic policy always take effect in the **config** matching order.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, and S6720S-EI, when the traffic policy that defines the **config** matching order is applied to the inbound direction, traffic classifiers bound to the traffic policy take effect in the **config** matching order. When the traffic policy is applied to the outbound direction, even if the matching order is **config**, traffic classifiers bound to the traffic policy still take effect in the **auto** matching order.

For the S6735-S, S6720-EI and S6720S-EI, when any of the following actions is defined in a traffic action of a traffic policy, even if the matching order is **config**, traffic classifiers bound to the traffic policy still take effect in the **auto** matching order:

- **mac-address learning disable**
- **remark 8021p**
- **remark cvlan-id**
- **remark flow-id**

For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I, when any of the following actions is defined in a traffic behavior of a traffic policy, even if the matching order is **config**, traffic classifiers bound to the traffic policy still take effect in the **auto** matching order:

- **remark 8021p**
- **remark flow-id**
- **remark cvlan-id**
- **remark vlan-id**
- **redirect ip-nexthop**

You cannot directly modify the atomic attribute of a created traffic policy. To modify the atomic attribute, delete the traffic policy, and then recreate the traffic policy with the atomic attribute being specified or deleted.

The atomic attribute is valid for the traffic policy only containing the **permit** or **deny** action. If the traffic policy in which the atomic attribute is specified contains other actions in addition to **permit** or **deny**, applying the traffic policy will cause a failure to deliver the configuration.

For the traffic policy with specified atomic attribute, when the ACL configuration is being updated dynamically, ensure that the device has sufficient ACL resources. Otherwise, the updated ACL configuration will fail to be delivered.

If the atomic attribute is specified for a traffic policy and the device is downgraded from the current version to a version earlier than V200R011C10, the traffic policy configuration cannot be restored during device restart.

If the traffic policy that you want to delete has been applied to the system, an interface, or a VLAN, run the **undo traffic-policy** command to unbind the traffic policy in the corresponding view. Then run the **undo traffic policy** command in the system view to delete the traffic policy. The traffic policy that is not applied can be deleted directly.

When **rule** is configured in the traffic policy and **permit ip** is specified, many ARP Miss packets may be sent to the CPU. As a result, the device is disconnected.

Example

Create a traffic policy **p1**, and associate the traffic classifier **c1** with the traffic behavior **b1** in the traffic policy.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match any
[HUAWEI-classifier-c1] quit
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark 8021p 2
[HUAWEI-behavior-b1] quit
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
```

Delete the traffic policy **p1** that has been applied to the inbound indirection on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo traffic-policy p1 inbound
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] undo traffic policy p1
```

15.1.37 traffic statistics interval

Function

The **traffic statistics interval** command sets the interval at which the system measures the rates of forwarded and discarded packets in a queue.

The **undo traffic statistics interval** command restores the default interval.

By default, the system measures the rates of forwarded and discarded packets in a queue at intervals of 300s.

Format

traffic statistics interval *time-value*

undo traffic statistics interval [*time-value*]

Parameters

Parameter	Description	Value
time-value	Specifies the interval at which the system measures the rates of forwarded and discarded packets in a queue.	The value is an integer that ranges from 30 to 600, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device is managed by a network management system (NMS), the MIB module checks the rates of forwarded and discarded packets in each queue at intervals and sends the rates to the NMS. You can view the rates of forwarded and discarded packets in each queue to analyze network performance or locate faults. The MIB module calculates the average rates forwarded and discarded packets during an interval configured by this command.

Example

Set the interval at which the system measures the rates of forwarded and discarded packets in a queue to 100s.

```
<HUAWEI> system-view
[HUAWEI] traffic statistics interval 100
```

15.1.38 traffic statistics mode by-bytes

Function

The **traffic statistics mode by-bytes** command enables byte-based traffic statistics in a traffic policy.

The **undo traffic statistics mode by-bytes** command disables byte-based traffic statistics in a traffic policy.

By default, the byte-based traffic statistics function is not enabled in a traffic policy.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI support this command.

Format

traffic statistics mode by-bytes

undo traffic statistics mode by-bytes

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the traffic statistics function is defined in a traffic policy, the switch collects traffic statistics by packet by default. To collect traffic statistics by byte, run the **traffic statistics mode by-bytes** command. Then the **display traffic policy statistics** command displays the packet rate by byte.

Example

Enable byte-based traffic statistics in a traffic policy.

```
<HUAWEI> system-view
[HUAWEI] traffic statistics mode by-bytes
```

15.1.39 traffic-policy (interface view)

Function

The **traffic-policy** command applies a traffic policy to an interface.

The **undo traffic-policy** command deletes a traffic policy from an interface.

By default, no traffic policy is applied to an interface.

Format

traffic-policy *policy-name* { **inbound** | **outbound** }

undo traffic-policy [*policy-name*] { **inbound** | **outbound** }

NOTE

Traffic policies can be applied only to the inbound direction of sub-interfaces on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

NOTE

- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support Ethernet sub-interfaces.
- Only hybrid and trunk interfaces on the preceding switches support Layer 2 Ethernet sub-interface configuration.
- After you run the **undo portswitch** command to switch Layer 2 interfaces on the preceding series of switches into Layer 3 interfaces, you can configure Layer 3 Ethernet sub-interfaces on the interfaces.
- After an interface is added to an Eth-Trunk, sub-interfaces cannot be configured on the interface.
- VLAN termination sub-interfaces cannot be created on a VCMP client.

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a user-defined traffic policy.	The value must be the name of an existing traffic policy. When double quotation marks are used around the string, spaces are allowed in the string. The value cannot be f, fa, fas, fast, fast-, fast-m, fast-mo, fast-mod, or fast-mode.
inbound	Applies a traffic policy to the inbound direction.	-
outbound	Applies a traffic policy to the outbound direction.	-

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, MultiGE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view, port group view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy. You can use the **traffic-policy** command to apply a created traffic policy to an interface.

Prerequisites

A traffic policy has been created using the **traffic policy** command, and traffic classifiers and traffic behaviors have been bound to the traffic policy.

Precautions

If a traffic classifier in the traffic policy contains **if-match mpls-exp**, the traffic policy cannot be applied to the outbound direction on the S6735-S, S6720-EI and S6720S-EI.

Each direction on an interface can be configured with only one traffic policy. A single traffic policy can be applied to both directions on one or more interfaces.

After a traffic policy is applied to an interface, you cannot directly delete the traffic policy, the traffic classifier and traffic behavior bound to the traffic policy. In addition, you cannot modify the matching order of the rules in the traffic policy. However, you can modify the relationship between matching rules in the traffic classifier, matching rules in the traffic classifier, traffic action in the traffic behavior, and binding between the traffic classifier and the traffic behavior.

If the traffic policy that you want to delete has been applied to an interface, run the **undo traffic-policy** command to unbind the traffic policy from the interface. Then run the **undo traffic policy** command in the system view to delete the traffic policy.

Run the **undo traffic-policy** { **inbound** | **outbound** } command without *policy-name* specified to delete the traffic policy that has been applied to an interface and has the following names: i, in, inb, inbo, inbou, inboun, inbound, o, ou, out, outb, outbo, outbou, outboun, and outbound.

After setting the tunneling protocol of a tunnel interface to GRE, you can apply a traffic policy to the inbound direction of the tunnel interface. For details about how to configure GRE, see GRE Configuration in *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide - VPN*.

A traffic policy does not take effect on a Layer 2 VXLAN sub-interface, a Dot1q termination sub-interface, or a sub-interface in BGP AD mode. You are advised to configure a traffic policy that defines a traffic classifier containing a matching rule based on the flow ID on the main interface.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the inbound direction on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-policy p1 inbound
```

15.1.40 traffic-policy (AP group view)

Function

traffic-policy command applies a traffic policy to an AP group.

undo traffic-policy command deletes a traffic policy from an AP group.

By default, no traffic policy is applied to an AP group.

Format

traffic-policy *policy-name* **outbound**

undo traffic-policy [*policy-name*] **outbound**

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support this command.

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a user-defined traffic policy.	The value must be the name of an existing traffic policy.
outbound	Applies a traffic policy to the outbound direction of an AP group.	-

Views

AP group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy. You can use the **traffic-policy** command to apply a traffic policy to an AP group.

Prerequisites

A traffic policy has been created using the **traffic policy** command, and traffic classifiers and traffic behaviors have been bound to the traffic policy.

Precautions

The traffic policy applied to an AP group takes effect only for downstream broadcast, unknown-unicast, and multicast (BUM) traffic.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the outbound direction in the AP group named test.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] ap-group name test
[HUAWEI-wlan-ap-group-test] traffic-policy p1 outbound
```

15.1.41 traffic-policy (SSID profile view)

Function

traffic-policy command applies a traffic policy to an SSID profile.

undo traffic-policy command deletes a traffic policy from an SSID profile.

By default, no traffic policy is applied to an SSID profile.

Format

traffic-policy *policy-name* { **inbound** | **outbound** }

undo traffic-policy [*policy-name*] { **inbound** | **outbound** }

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support this command.

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a user-defined traffic policy.	The value must be the name of an existing traffic policy.
inbound	Applies a traffic policy to the inbound direction of an SSID profile.	-
outbound	Applies a traffic policy to the outbound direction of an SSID profile.	-

Views

SSID profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy. You can use the **traffic-policy** command to apply a traffic policy to an SSID profile.

Prerequisites

A traffic policy has been created using the **traffic policy** command, and traffic classifiers and traffic behaviors have been bound to the traffic policy.

Precautions

Only one traffic policy can be applied to each direction in an SSID profile, but a traffic policy can be applied to different directions in different SSID profiles.

NOTE

After a traffic policy is applied to an SSID profile, you cannot directly delete the traffic policy, the traffic classifier and traffic behavior bound to the traffic policy. In addition, you cannot modify the matching order of the rules in the traffic policy. However, you can modify the relationship between matching rules in the traffic classifier, matching rules in the traffic classifier, priority of the traffic classifier, traffic action in the traffic behavior, and binding between the traffic classifier and the traffic behavior.

If the traffic policy that you want to delete has been applied to an SSID profile, run the **undo traffic-policy** command to unbind the traffic policy from the SSID profile. Then run the **undo traffic policy** command in the system view to delete the traffic policy.

Run the **undo traffic-policy** { **inbound** | **outbound** } command without *policy-name* specified to delete the traffic policy that has been applied to an SSID profile and has the following names: i, in, inb, inbo, inbou, inboun, inbound, o, ou, out, outb, outbo, outbou, outboun, and outbound.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the inbound direction in the SSID profile named test.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] wlan
[HUAWEI-wlan-view] ssid-profile name test
[HUAWEI-wlan-ssid-prof-test] traffic-policy p1 inbound
```

15.1.42 traffic-policy (VLAN view)

Function

The **traffic-policy** command applies a traffic policy to a VLAN.

The **undo traffic-policy** command deletes a traffic policy from a VLAN.

By default, no traffic policy is applied to a VLAN.

Format

traffic-policy *policy-name* { **inbound** | **outbound** }

undo traffic-policy [*policy-name*] { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a traffic policy.	The value must be the name of an existing traffic policy.
inbound	Applies a traffic policy to the inbound direction of a VLAN.	-
outbound	Applies a traffic policy to the outbound direction of a VLAN.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy. You can use the **traffic-policy** command to apply a traffic policy to a VLAN.

Prerequisites

A traffic policy has been created using the **traffic policy** command.

Precautions

After a traffic policy is applied to a VLAN, the traffic policy takes effect for packets received and sent in the VLAN.

If a traffic classifier in the traffic policy contains **if-match mpls-exp**, the traffic policy cannot be applied to the outbound direction on the S6735-S, S6720-EI and S6720S-EI.

If a traffic policy has been applied to a VLAN, you are not allowed to delete the traffic policy or its traffic classifier and traffic behavior.

After a traffic policy is applied to a VLAN, you cannot directly delete the traffic policy, the traffic classifier and traffic behavior bound to the traffic policy. In addition, you cannot modify the matching order of the rules in the traffic policy. However, you can modify the relationship between matching rules in the traffic classifier, matching rules in the traffic classifier, traffic action in the traffic behavior, and binding between the traffic classifier and the traffic behavior.

To delete the traffic policy that has been applied, run the **undo traffic-policy** command in the corresponding view to unbind the traffic policy and then run the **undo traffic policy** command in the system view to delete the traffic policy.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the inbound direction in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] vlan 100
[HUAWEI-vlan100] traffic-policy p1 inbound
```

15.1.43 traffic-policy (VLANIF interface view)

Function

The **traffic-policy** command applies a traffic policy to a VLANIF interface.

The **undo traffic-policy** command deletes a traffic policy from a VLANIF interface.

By default, no traffic policy is applied to a VLANIF interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

traffic-policy *policy-name* { **inbound** | **outbound** }

undo traffic-policy [*policy-name*] { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a user-defined traffic policy.	The value must be the name of an existing traffic policy.
inbound	Applies a traffic policy to the inbound direction.	-
outbound	Applies a traffic policy to the outbound direction.	-

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy. You can use the **traffic-policy** command to apply a created traffic policy to a VLANIF interface.

Prerequisites

A traffic policy has been created using the **traffic policy** command, and traffic classifiers and traffic behaviors have been bound to the traffic policy.

Precautions

Each direction of a VLANIF interface can be configured with only one traffic policy. A single traffic policy can be applied to both directions on one or more VLANIF interfaces.

A traffic policy cannot be applied to a VLANIF interface corresponding to the super-VLAN or MUX VLAN.

On the S6720-EI, S6735-S, and S6720S-EI, a traffic policy applied to a VLANIF interface takes effect only for unicast packets and Layer 3 multicast packets on the VLANIF interface.

On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, a traffic policy applied to a VLANIF interface takes effect only for unicast packets on the VLANIF interface.

A traffic policy cannot be applied to the inbound direction of a VLANIF interface when the bound traffic behaviors define the following actions:

- **remark vlan-id**
- **remark cvlan-id**
- **remark 8021p**
- **remark flow-id**
- **mac-address learning disable**

A traffic policy cannot be applied to the outbound direction of a VLANIF interface when the bound traffic behaviors define the following actions:

- **remark flow-id**
- **mac-address learning disable**

After a traffic policy is applied to a VLANIF interface, you cannot directly delete the traffic policy, the traffic classifier and traffic behavior bound to the traffic policy. In addition, you cannot modify the matching order of the rules in the traffic policy. However, you can modify the relationship between matching rules in the traffic classifier, matching rules in the traffic classifier, traffic action in the traffic behavior, and binding between the traffic classifier and the traffic behavior.

If the traffic policy that you want to delete has been applied to a VLANIF interface, run the **undo traffic-policy** command to unbind the traffic policy from the VLANIF interface. Then run the **undo traffic policy** command in the system view to delete the traffic policy.

Run the **undo traffic-policy inbound** command without *policy-name* specified to delete the traffic policy that has been applied to a VLANIF interface and has the following names: i, in, inb, inbo, inbou, inboun, and inbound.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the inbound direction on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] traffic-policy p1 inbound
[HUAWEI-Vlanif100] quit
```

15.1.44 traffic-policy fast-mode enable

Function

The **traffic-policy fast-mode enable** command enables fast delivery of ACL rules.

The **undo traffic-policy fast-mode enable** command disables fast delivery of ACL rules.

By default, fast delivery of ACL rules is disabled.

Format

traffic-policy fast-mode enable

undo traffic-policy fast-mode enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If many ACL rules are applied in the system view, and then some of them are applied in the interface view, it takes a long time to deliver ACL rules. As a result, the ACL rules are slow to take effect, and the CPU usage is high. To speed up ACL delivery, run the **traffic-policy fast-mode enable** command.

Precautions

After the **traffic-policy fast-mode enable** command is run:

- ACL rules in effect may be invalid temporarily.
- The statistics on traffic policies are cleared.
- The device performance deteriorates.

Example

Enable fast delivery of ACL rules.

```
<HUAWEI> system-view
[HUAWEI] traffic-policy fast-mode enable
```

15.1.45 traffic-policy global

Function

The **traffic-policy global** command applies a traffic policy to the system.

The **undo traffic-policy global** command deletes a traffic policy that is applied to the system.

By default, no traffic policy is applied to the system.

Format

traffic-policy *policy-name* **global** { **inbound** | **outbound** } [**slot** *slot-id*]

undo traffic-policy [*policy-name*] **global** { **inbound** | **outbound** } [**slot** *slot-id*]

Parameters

Parameter	Description	Value
policy-name	Specifies the name of a traffic policy.	The value must be the name of an existing traffic policy.
inbound	Applies a traffic policy to the inbound direction.	-
outbound	Applies a traffic policy to the outbound direction.	-

Parameter	Description	Value
slot *slot-id*	On a stacked device, if *slot-id* is not specified, the traffic policy can be applied to all devices in the stack.	The value is fixed at 0 on a non-stacked device, and specifies the stack ID on a stacked device. **NOTE** If the value of *slot-id* is specified in the **undo traffic-policy** command, it must be the same as the ID of the specified slot to which the traffic policy is applied.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Packets are classified based on Layer 2 information, Layer 3 information, or ACLs. To provide differentiated services for service flows, bind a traffic classifier and a traffic behavior to a traffic policy and apply the traffic policy.

You can use the **traffic policy global** command to apply a traffic policy to the system.

Prerequisites

A traffic policy has been created using the **traffic policy** command.

Precautions

If a traffic policy has been applied, you cannot directly change the traffic policy or its traffic classifier and traffic behavior.

If a traffic classifier in the traffic policy contains **if-match mpls-exp**, the traffic policy cannot be applied to the outbound direction on the S6735-S, S6720-EI and S6720S-EI.

After a traffic policy is applied, you cannot directly delete the traffic policy or the traffic classifier and traffic behavior bound to the traffic policy. In addition, you cannot modify the matching order of the rules in the traffic policy. However, you can modify the relationship between matching rules in the traffic classifier, matching rules in the traffic classifier, traffic action in the traffic behavior, and binding between the traffic classifier and the traffic behavior.

Run the **undo traffic-policy global** { **inbound** | **outbound** } command without *policy-name* specified to delete the traffic policy that has been applied to an interface and has the following names: g, gl, glo, glob, globa, and global.

The traffic policy that has the following names cannot be applied to the system: f, fa, fas, fast, fast-, fast-m, fast-mo, fast-mod, and fast-mode.

Example

Create a traffic policy **p1**, bind the created traffic classifier **c1** and traffic behavior **b1** to the traffic policy, and apply the traffic policy to the inbound direction.

```
<HUAWEI> system-view
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] traffic-policy p1 global inbound
```

15.1.46 traffic rate statistics enable

Function

The **traffic rate statistics enable** command enables traffic rate statistics collection in a traffic policy.

The **undo traffic rate statistics enable** command disables traffic rate statistics collection in a traffic policy.

By default, traffic rate statistics collection is enabled in a traffic policy.

Format

traffic rate statistics enable

undo traffic rate statistics enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the traffic statistics function is configured in a traffic policy and more than 60K traffic classification rules are configured, memory resources may be insufficient. To release memory resources, run the **undo traffic rate statistics enable** command to disable traffic rate statistics collection in the traffic policy.

Precautions

After traffic rate statistics collection is disabled in a traffic policy, the **display traffic policy statistics** command can still display the number of packets and bytes, but traffic rates are all displayed as -.

This command is valid for traffic policies configured after traffic rate statistics collection is enabled or disabled, and traffic rate statistics collection is not disabled in traffic policies that have been configured before this command is executed.

Before you disable traffic rate statistics collection in a traffic policy, traffic statistics are displayed as follows:

```
<HUAWEI> display traffic policy statistics global slot 0 inbound
 Global :
 Traffic policy inbound: test
 Rule number: 0
 Current status: success
 Statistics interval: 300
---------------------------------------------------------------------
 Board : 0
---------------------------------------------------------------------
 Matched          |      Packets:                            0
                  |      Bytes:                          0
                  |      Rate(pps):                        0
                  |      Rate(bps):                        0
---------------------------------------------------------------------
   Passed         |      Packets:                          0
                  |      Bytes:                          0
                  |      Rate(pps):                        0
                  |      Rate(bps):                        0
---------------------------------------------------------------------
   Dropped        |      Packets:                          0
                  |      Bytes:                          0
                  |      Rate(pps):                        0
                  |      Rate(bps):                        0
---------------------------------------------------------------------
     Filter       |      Packets:                        0
                  |      Bytes:                          0
---------------------------------------------------------------------
     Car          |      Packets:                        0
                  |      Bytes:                          0
---------------------------------------------------------------------
```

After you disable traffic rate statistics collection in a traffic policy, traffic statistics are displayed as follows:

```
<HUAWEI> display traffic policy statistics global slot 0 inbound
 Global :
 Traffic policy inbound: testp
 Rule number: 1
 Current status: success
 Statistics interval: 300
---------------------------------------------------------------------
 Board : 0
---------------------------------------------------------------------
 Matched          |      Packets:                            0
                  |      Bytes:                          0
                  |      Rate(pps):                        -
                  |      Rate(bps):                        -
---------------------------------------------------------------------
   Passed         |      Packets:                          0
                  |      Bytes:                          0
                  |      Rate(pps):                        -
                  |      Rate(bps):                        -
---------------------------------------------------------------------
```

```
 Dropped        |      Packets:                          0
              |      Bytes:                          0
              |      Rate(pps):                          -
              |      Rate(bps):                          -
-------------------------------------------------------------------
    Filter      |      Packets:                          0
              |      Bytes:                          0
-------------------------------------------------------------------
    Car         |      Packets:                          0
              |      Bytes:                          0
-------------------------------------------------------------------
```

Example

Disable traffic rate statistics collection in a traffic policy.

```
<HUAWEI> system-view
[HUAWEI] undo traffic rate statistics enable
```

15.2 Priority Mapping Commands

15.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.2.2 8021p-inbound

Function

The **8021p-inbound** command maps the 802.1p priority of incoming VLAN packets in a DiffServ domain to the PHB and colors the packets.

The **undo 8021p-inbound** command restores the default mapping.

Table 15-11 lists the default mappings from the 802.1p priorities to PHBs and colors of incoming VLAN packets in a DiffServ domain.

Table 15-11 Mappings from 802.1p priorities to PHBs and colors of incoming packets in the DiffServ domain

802.1p Priority	PHB	Color
0	BE	green
1	AF1	green
2	AF2	green
3	AF3	green
4	AF4	green
5	EF	green

802.1p Priority	PHB	Color
6	CS6	green
7	CS7	green

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S:

8021p-inbound *8021p-value* **phb** *service-class* [**green** | **yellow** | **red**]

undo 8021p-inbound [*8021p-value*]

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

8021p-inbound *8021p-value* **phb** *service-class*

undo 8021p-inbound [*8021p-value*]

Parameters

Parameter	Description	Value
8021p-value	Specifies the 802.1p priority of VLAN packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
phb *service-class*	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7, each of which corresponds to queues 0 to 7 respectively.
green	Indicates that packets are colored green.	-
yellow	Indicates that packets are colored yellow.	-
red	Indicates that packets are colored red.	-

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

Scenario

To implement QoS scheduling on incoming VLAN packets, you can use the **8021p-inbound** command to map the 802.1p priorities of the packets to the PHBs and colors. After a DiffServ domain is bound to the inbound interface of packets, the device forwards the packets to queues based on PHBs of the packets. Congestion management is implemented. Packets are scheduled according to their colors after a discard template is configured, avoiding congestion.

Precautions

- The color is used to determine whether packets are discarded during flow control, and is independent of the mapping from internal priorities to queues.
- The CoS values of packets are mapped to the corresponding internal priorities and the packets are colored accordingly. If no mapping from 802.1p priorities to CoS values is specified, the device uses the default mappings of the system.
- If you do not specify the parameter *8021p-value* when running the **undo 8021p-inbound** command, all the mapping between 802.1p priorities and CoS values is restored.
- The DiffServ domain **default** exists by default. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.

Example

For devices excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In DiffServ domain **ds1**, map the 802.1p priority 2 of the incoming VLAN packets to PHB AF1 and mark the packets yellow.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] 8021p-inbound 2 phb af1 yellow
```

For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In the default DiffServ domain, map the 802.1p priority 2 of the incoming VLAN packets to PHB AF1.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain default
[HUAWEI-dsdomain-default] 8021p-inbound 2 phb af1
```

15.2.3 8021p-outbound

Function

The **8021p-outbound** command maps the PHB and color of outgoing VLAN packets in a DiffServ domain to the 802.1p priority.

The **undo 8021p-outbound** command restores the default mapping.

Table 15-12 lists the default mappings from the PHBs and colors to 802.1p priorities of outgoing VLAN packets in a DiffServ domain.

Table 15-12 Mappings from PHBs and colors to 802.1p priorities of outgoing VLAN packets in the DiffServ domain

PHB	Color	802.1p Priority
BE	green	0
BE	yellow	0
BE	red	0
AF1	green	1
AF1	yellow	1
AF1	red	1
AF2	green	2
AF2	yellow	2
AF2	red	2
AF3	green	3
AF3	yellow	3
AF3	red	3
AF4	green	4
AF4	yellow	4
AF4	red	4
EF	green	5
EF	yellow	5
EF	red	5
CS6	green	6
CS6	yellow	6
CS6	red	6

PHB	Color	802.1p Priority
CS7	green	7
CS7	yellow	7
CS7	red	7

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S:

8021p-outbound *service-class* { **green** | **yellow** | **red** } **map** *8021p-value*

undo 8021p-outbound [*service-class* { **green** | **yellow** | **red** }]

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

8021p-outbound *service-class* **map** *8021p-value*

undo 8021p-outbound [*service-class*]

Parameters

Parameter	Description	Value
service-class	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7, each of which corresponds to queues 0 to 7 respectively.
green	Indicates green packets.	-
yellow	Indicates yellow packets.	-
red	Indicates red packets.	-
map *8021p-value*	Specifies the 802.1p priority of VLAN packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

Scenario

After QoS scheduling is performed on VLAN packets, you can use the **8021p-outbound** command to map the PHB and color of the packets in a DiffServ domain to the 802.1p priority. After the DiffServ domain is bound to the outbound interface of the VLAN packets, the downstream device implements QoS scheduling according to the 802.1p priority.

Precautions

If you do not specify the parameters *service-class* and *color* when running the **undo 8021p-outbound** command, the default mappings from CoS values and colors to 802.1p priorities are restored.

The DiffServ domain **default** exists by default. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.

Example

For devices excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In DiffServ domain **ds1**, map PHB AF1 of the outgoing yellow VLAN packets to 802.1p priority 2.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] 8021p-outbound af1 yellow map 2
```

For devices excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In the default DiffServ domain, map PHB AF1 of the outgoing VLAN packets to 802.1p priority 2.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain default
[HUAWEI-dsdomain-default] 8021p-outbound af1 map 2
```

15.2.4 dei enable

Function

The **dei enable** command maps the drop eligible indicator (DEI) field in a VLAN tag to the drop priority.

The **undo dei enable** command cancels the configuration of the DEI field in a VLAN tag as the drop priority.

By default, the DEI field in a VLAN tag is not used as the drop priority.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

dei enable

undo dei enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, Eth-Trunk member interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Scenario

The DEI is also called the Canonical Format Indicator (CFI) field in a VLAN tag and its value is 0 or 1. The DEI field in a VLAN tag is used as the drop priority of packets in certain situations. When the rate of packets on certain devices exceeds the CIR value, the DEI field is set to 1. In this case, the drop priority of the packets is high. When congestion occurs, subsequent devices first discard the packets whose DEI field is 1.

Precautions

After the **dei enable** command is run, the DEI field in the VLAN tag is mapped to the drop priority:

- The DEI field in the VLAN tag is mapped to the drop priority (packet color) on the inbound interface as follows:
  - When the DEI field is 0, packets are colored green.
  - When the DEI field is 1, packets are colored yellow.
- The drop priority is mapped to the DEI field on the outbound interface as follows:
  - Green and yellow packets correspond to DEI 0.
  - Red packets correspond to DEI 1.

The **dei enable** command cannot be configured on both an Eth-Trunk and its member interfaces.

To configure the DEI field in a VLAN tag as the drop priority on multiple interfaces, perform the configuration on a port group to reduce the workload.

Example

Configure the DEI field in the VLAN tag as the drop priority on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dei enable
```

15.2.5 diffserv domain

Function

The **diffserv domain** command creates a DiffServ domain and displays the DiffServ domain view, or displays an existing DiffServ domain view.

The **undo diffserv domain** command deletes a specified DiffServ domain.

By default, the system defines a DiffServ mode named **default**.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

diffserv domain { **default** | *ds-domain-name* }

undo diffserv domain *ds-domain-name*

Parameters

Parameter	Description	Value
default	Indicates the default DiffServ domain preset in the system.	-

Parameter	Description	Value
ds-domain-name	Specifies the name of a DiffServ domain.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. The value cannot be n, no, non, or none. **NOTE** The value cannot be --. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the *ds-domain-name* parameter cannot be specified.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Scenario

A DiffServ domain defines the mapping between the packet priority and PHB/colors packets for managing and avoiding congestion. You can run the **display diffserv domain** command to view the mappings and packet colors defined in the DiffServ domain.

A DiffServ domain defines the mapping between the PHBs/colors and packet priorities (802.1p and DSCP). When binding a DiffServ domain to an interface, you can run the **trust** command to configure 802.1p or DSCP priority mapping on the interface.

Precautions

The DiffServ domain **default** exists by default. In addition to this domain, the device allows a maximum of 7 DiffServ domains. (On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.) You can only change the mapping for the DiffServ domain **default**, but cannot delete the domain.

Example

Create DiffServ domain **d1** and display the corresponding DiffServ domain view.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain d1
[HUAWEI-dsdomain-d1]
```

15.2.6 display diffserv domain

Function

The **display diffserv domain** command displays the DiffServ domain configuration.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S:

display diffserv domain [**all** | **name** *ds-domain-name*]

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

display diffserv domain name default

Parameters

Parameter	Description	Value
all	Displays configurations of all DiffServ domains.	-
name *ds-domain-name*	Displays the detailed configuration of a specified DiffServ domain.	The value must the name of an existing DiffServ domain. **NOTE** The DiffServ domain **default** exists by default. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.

1: Monitoring level

Usage Guidelines

Scenario

After creating a DiffServ domain and configuring the mappings in the DiffServ domain, you can use the **display diffserv domain** command to view the configuration of the DiffServ domain.

If no optional parameter is specified, this command displays configurations of all DiffServ domains on the device.

Example

Display the configuration of DiffServ domain **d1** (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S).

```
<HUAWEI> display diffserv domain name d1
diffserv domain name:d1

Table 15-13 Description of the **display diffserv domain name d1** command output

Item	Description
diffserv domain name	Name of the DiffServ domain. To create a DiffServ domain, run the **diffserv domain** command.
8021p-inbound	Mapping from the 802.1p priority of incoming VLAN packets in a DiffServ domain to the PHB and color. To configure the mapping, run the **8021p-inbound** command.
8021p-outbound	Mapping from the PHB and color of outgoing VLAN packets in a DiffServ domain to the 802.1p priority. To configure the mapping, run the **8021p-outbound** command.

Item	Description
ip-dscp-inbound	Mapping from the DSCP priority of incoming IP packets in a DiffServ domain to the PHB and color. To configure the mapping, run the **ip-dscp-inbound** command.
ip-dscp-outbound	Mapping from the PHB and color of outgoing IP packets in a DiffServ domain to the DSCP priority. To configure the mapping, run the **ip-dscp-outbound** command.
mpls-exp-inbound	Mapping from the EXP priority of incoming MPLS packets in a DiffServ domain to the PHB and color. To configure the mapping, run the **mpls-exp-inbound** command.
mpls-exp-outbound	Mapping from the PHB and color of outgoing MPLS packets in a DiffServ domain to the PHB and color. To configure the mapping, run the **mpls-exp-outbound** command.

Display configurations of all DiffServ domains on the device.

```
<HUAWEI> display diffserv domain
  index      DS name
 --------------------------------------
    0        default
    1        ds1
    2        ds2
 --------------------------------------
 Total 8, Used 3
```

Table 15-14 Description of the **display diffserv domain** command output

Item	Description
index	Index of the DiffServ domain.
DS name	Name of the DiffServ domain. To create a DiffServ domain, run the **diffserv domain** command.
Total	Total number of DiffServ domains supported by the device.
Used	Number of created DiffServ domains on the device.

15.2.7 display qos local-precedence-queue-map

Function

The **display qos local-precedence-queue-map** command displays the mapping between local precedences and queues.

Format

display qos local-precedence-queue-map

NOTE

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support this command.

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **qos local-precedence-queue-map** command, you can configure the mapping between local precedences and queues. Then you can run the **display qos local-precedence-queue-map** command to display the configuration.

Example

Display the mapping between local precedences and queues.

```
<HUAWEI> system-view
[HUAWEI] qos local-precedence-queue-map af3 2
[HUAWEI] display qos local-precedence-queue-map
 Current configurations of mapping between local-precedence and queue:
  local-precedence value: be     queue index: 0
  local-precedence value: af1    queue index: 1
  local-precedence value: af2    queue index: 2
  local-precedence value: af3    queue index: 2
  local-precedence value: af4    queue index: 4
  local-precedence value: ef     queue index: 5
  local-precedence value: cs6    queue index: 6
  local-precedence value: cs7    queue index: 7
```

Table 15-15 Description of the **display qos local-precedence-queue-map** command output

Item	Description
local-precedence value	Local priority.
queue index	Queue index mapping the local precedence. To configure the mapping between local precedences and queues, run the **qos local-precedence-queue-map** command.

15.2.8 display qos map-table

Function

The **display qos map-table** command displays the mapping between priorities.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S5736-S, and, S6720S-S support this command.

Format

display qos map-table [**dscp-dot1p** | **dscp-dp** | **dscp-dscp**]

Parameters

Parameter	Description	Value
dscp-dot1p	Specifies the name of the mapping table. That is, the mapping from DSCP priorities to 802.1p priorities.	-
dscp-dp	Specifies the name of the mapping table. That is, the mapping between the DSCP priority and the drop precedence is displayed.	-
dscp-dscp	Specifies the name of the mapping table. That is, the mapping between DSCP priorities.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before and after configuring the mapping between priorities, you can use the **display qos map-table** command to check whether the priority mapping is correct.

Example

Display the mapping between the current DSCP priorities and Dot1p priorities.

```
<HUAWEI> display qos map-table dscp-dot1p
Input DSCP       Dot1P
------------------------
0               0
1               0
2               0
3               0
4               0
5               0
6               0
7               0
......
```

Display all the mappings between the current priorities.

```
<HUAWEI> display qos map-table
Input DSCP       Dot1P   DP      DSCP
----------------------------------------
0               0       0       0
1               0       0       1
2               0       0       2
3               0       0       3
4               0       0       4
5               0       0       5
6               0       0       6
7               0       0       7
......
```

Table 15-16 Description of the **display qos map-table** command output

Item	Description
Input DSCP	Input DSCP priority. The value is an integer that ranges from 0 to 63. To set the input DSCP priority, run the **input (DSCP mapping table view)** command.
Dot1P	Output 802.1p priority. The value is an integer that ranges from 0 to 7. To set the output 802.1p priority, run the **input (DSCP mapping table view)** command.
DP	Output drop priority that corresponds to a color. The value is 0, 1, or 2. ● 0: green ● 1: yellow ● 2: red To set the output drop priority, run the **input (DSCP mapping table view)** command.
DSCP	Output DSCP priority. The value is an integer that ranges from 0 to 63. To set the output DSCP priority, run the **input (DSCP mapping table view)** command.

NOTE

A larger value indicates a higher priority.

15.2.9 input (DSCP mapping table view)

Function

The **input** command sets the mapping in a DSCP mapping table.

The **undo input** command restores the default mapping in a DSCP mapping table.

Table 15-17 lists the default mapping from DSCP priorities to 802.1p priorities and from DSCP priorities to drop priorities. The default mapping from DSCP priorities to DSCP priorities remains unchanged.

Table 15-17 Default mapping from DSCP priorities to 802.1p priorities and from DSCP priorities to drop priorities

Input DSCP	Output Dot1p	Output DP
0-7	0	0
8-15	1	0
16-23	2	0
24-31	3	0
32-39	4	0
40-47	5	0
48-55	6	0
56-63	7	0

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S5736-S, and, S6720S-S support this command.

Format

input { *input-value1* [**to** *input-value2*] } &<1-10> **output** *output-value*

undo input { **all** | { *input-value1* [**to** *input-value2*] } &<1-10> }

Parameters

Parameter	Description	Value
input-value1	Specifies the start DSCP priority that is entered.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
to *input-value2*	Specifies the end DSCP priority that is entered.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority. The value of *input-value2* must be greater than the value of *input-value1* and the two values determine the DSCP range.
output *output-value*	Specifies the output 802.1p priority, output drop precedence, or output DSCP value.	The current mapping table view determines the value of **output-value**. The value ranges are as follows: The value ranges from 0 to 7 in the dscp-dot1p view. The value ranges from 0 to 2 in the dscp-dp view. ● The drop priority 0 corresponds to green packets. ● The drop priority 1 corresponds to yellow packets. ● The drop priority 2 corresponds to red packets. The value ranges from 0 to 63 in the dscp-dscp view. A larger value indicates a higher priority.
all	Indicates all mappings in the DSCP mapping table.	-

Views

DSCP mapping table view

Default Level

2: Configuration level

Usage Guidelines

You must run the **qos map-table** command to enter the corresponding DSCP mapping table view before running the **input** command.

The **input** command modifies the mapping from DSCP priorities to Dot1p priorities, from DSCP priorities to drop priorities, and from DSCP priorities to DSCP priorities in the DSCP table.

After running the **input** command, you can run the **display qos map-table** command to view the current DSCP mapping.

Example

Set the mapping in the DSCP mapping table: Level 0 to level 7 in the DSCP mapping table are mapped to level 0 of 802.1p priority.

```
<HUAWEI> system-view
[HUAWEI] qos map-table dscp-dot1p
[HUAWEI-dscp-dot1p] input 0 to 7 output 0
```

15.2.10 ip-dscp-inbound

Function

The **ip-dscp-inbound** command maps the DSCP priority of incoming IP packets in a DiffServ domain to the PHB and colors the packets.

The **undo ip-dscp-inbound** command restores the default mapping.

Table 15-18 lists the default mappings from the DSCP priorities to PHBs and colors of incoming IP packets in a DiffServ domain.

Table 15-18 Mappings from DSCP priorities to PHBs and colors of incoming IP packets in the DiffServ domain

DSCP	PHB	Color	DSCP	PHB	Color
0	BE	green	32	AF4	green
1	BE	green	33	BE	green

30	AF3	red	62	BE	green
31	BE	green	63	BE	green

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S:

ip-dscp-inbound *dscp-value* **phb** *service-class* [**green** | **yellow** | **red**]

undo ip-dscp-inbound [*dscp-value*]

S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S:

ip-dscp-inbound *dscp-value* **phb** *service-class*

undo ip-dscp-inbound [*dscp-value*]

Parameters

Parameter	Description	Value
dscp-value	Specifies the DSCP priority of IP packets.	The value is an integer that ranges from 0 to 63.
phb *service-class*	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7, each of which corresponds to queues 0 to 7 respectively.
green	Indicates that packets are colored green.	-
yellow	Indicates that packets are colored yellow.	-
red	Indicates that packets are colored red.	-

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

Scenario

To implement QoS scheduling for incoming IP packets carrying DSCP priorities, use the **ip-dscp-inbound** command to configure mappings from DSCP priorities of packets to PHBs and color the packets. After a DiffServ domain is bound to the inbound interface of packets, the device forwards the packets to queues based on PHBs of the packets. Congestion management is implemented. Packets are scheduled according to their colors after a discard template is configured, avoiding congestion.

Precautions

- The color is used to determine whether packets are discarded during flow control, and is independent of the mapping from internal priorities to queues.
- The CoS values of packets are mapped to the corresponding internal priorities and the packets are colored accordingly. If no mapping from DSCP priorities to CoS values is specified, the device uses the default mappings of the system.
- If you do not specify the parameter *dscp-value* when running the **undo ip-dscp-inbound** command, all mappings from DSCP priorities to CoS values is restored.
- The DiffServ domain **default** exists by default. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.

Example

For devices excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In DiffServ domain **ds1**, map DSCP priority 8 of the incoming IP packets to PHB AF1 and mark the packets yellow.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] ip-dscp-inbound 8 phb af1 yellow
```

For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In the DiffServ domain, map DSCP priority 8 of the incoming IP packets to PHB AF1.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain default
[HUAWEI-dsdomain-default] ip-dscp-inbound 8 phb af1
```

15.2.11 ip-dscp-outbound

Function

The **ip-dscp-outbound** command maps the PHB and color of outgoing IP packets in a DiffServ domain to the DSCP priority.

The **undo ip-dscp-outbound** command restores the default mapping.

Table 15-19 lists the default mappings from the PHBs and colors to DSCP priorities of outgoing IP packets in a DiffServ domain.

Table 15-19 Mappings from PHBs and colors to DSCP priorities of outgoing IP packets in the DiffServ domain

PHB	Color	DSCP
BE	green	0
BE	yellow	0

PHB	Color	DSCP
BE	red	0
AF1	green	10
AF1	yellow	12
AF1	red	14
AF2	green	18
AF2	yellow	20
AF2	red	22
AF3	green	26
AF3	yellow	28
AF3	red	30
AF4	green	34
AF4	yellow	36
AF4	red	38
EF	green	46
EF	yellow	46
EF	red	46
CS6	green	48
CS6	yellow	48
CS6	red	48
CS7	green	56
CS7	yellow	56
CS7	red	56

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ip-dscp-outbound *service-class* { **green** | **yellow** | **red** } **map** *dscp-value*

undo ip-dscp-outbound [*service-class* { **green** | **yellow** | **red** }]

Parameters

Parameter	Description	Value
service-class	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7, each of which corresponds to queues 0 to 7 respectively.
green	Indicates green packets.	-
yellow	Indicates yellow packets.	-
red	Indicates red packets.	-
map *dscp-value*	Specifies the DSCP priority of IP packets.	The value is an integer that ranges from 0 to 63.

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

Scenario

After QoS scheduling is performed on the IP packets, you can use the **ip-dscp-outbound** command to map the PHB and color of IP packets in a DiffServ domain to the DSCP priority. After the DiffServ domain is bound to the outbound interface of the IP packets, the downstream device implements QoS scheduling according to the DSCP priority.

Precautions

If you do not specify the parameters *service-class* and colors when running the **undo ip-dscp-outbound** command, the default mappings from CoS values and colors to DSCP priorities are restored.

The DiffServ domain **default** exists by default. On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, only the DiffServ domain **default** is supported.

Example

For devices excluding the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In DiffServ domain **ds1**, map PHB AF1 of the outgoing yellow IP packets to DSCP priority 8.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] ip-dscp-outbound af1 yellow map 8
```

For the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S: In the DiffServ domain, map PHB AF1 of the outgoing yellow IP packets to DSCP priority 8.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain default
[HUAWEI-dsdomain-default] ip-dscp-outbound af1 yellow map 8
```

15.2.12 port priority

Function

The **port priority** command configures the priority for an interface.

The **undo port priority** command restores the default priority of an interface.

By default, the priority of an interface is 0.

Format

port priority *priority-value*

undo port priority

Parameters

Parameter	Description	Value
priority-value	Specifies the priority of an interface.	The value is an integer that ranges from 0 to 7. The default value is 0. A larger value indicates a higher priority of an interface.

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Scenario

The 802.1p priority is determined by the 3-bit priority 802.1p field contained in a VLAN tag. The 802.1p priority is used to ensure QoS in the DiffServ model.

If an interface receives untagged packets, the interface priority is added to packets during the internal forwarding.

If an interface is configured to trust the 802.1p priority using the **trust 8021p** command, the interface adds the 802.1p priority to the received untagged packets. The device then searches for the internal priority (represented by a PHB and color) mapping the 802.1p priority and marks packets with the internal priority.

Precautions

- The **port priority** command is invalid if the current interface is a member interface of an Eth-Trunk.
- If you run the **port priority** command multiple times in the same interface view, only the latest configuration takes effect.
- When an interface switches to Layer 3 mode through the **undo portswitch** command, you cannot configure a priority for the Ethernet interface. This Ethernet interface uses priority 0.

Example

Set the priority of GE0/0/1 to 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port priority 1
```

15.2.13 qos local-precedence-queue-map

Function

The **qos local-precedence-queue-map** command configures the default mappings between local precedences and queues.

The **undo qos local-precedence-queue-map** command restores the default mappings between local precedences and queues.

Table 15-20 lists the default mappings between local precedences and queues.

Table 15-20 Mappings between local precedences and queues

Local Precedence	Queue Index
BE	0
AF1	1
AF2	2
AF3	3
AF4	4
EF	5
CS6	6
CS7	7

Format

qos local-precedence-queue-map *local-precedence queue-index*

undo qos local-precedence-queue-map [*local-precedence*]

NOTE

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support the mapping configuration between local precedences and queues cannot be configured.

Parameters

Parameter	Description	Value
local-precedence	Specifies the name of the local precedence.	The value can be **af1**, **af2**, **af3**, **af4**, **be**, **cs6**, **cs7**, or **ef**.
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Scenario

The device sends packets to the specified queue according to the mapping between local precedences and queues.

To make traffic across the entire network achieve consistent QoS, ensure that all the stations keep consistent mapping between local precedences and queues.

Precautions

If you run the **qos local-precedence-queue-map** command multiple times in the system view, only the latest configuration takes effect.

Example

Map packets with local precedence AF3 to queue 2.

```
<HUAWEI> system-view
[HUAWEI] qos local-precedence-queue-map af3 2
```

15.2.14 qos map-table

Function

The **qos map-table** command displays the DSCP mapping table view.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S5736-S, and, S6720S-S support this command.

Format

qos map-table { **dscp-dot1p** | **dscp-dp** | **dscp-dscp** }

Parameters

Parameter	Description	Value
dscp-dot1p	Displays the dscp-dot1p view. The dscp-dot1p table contains the mapping between DSCP priorities and 802.1p priorities.	-
dscp-dp	Displays the dscp-dp view. The dscp-dp table contains the mapping between DSCP priorities and drop precedences.	-
dscp-dscp	Displays the dscp-dscp view. The dscp-dscp table contains the mapping between DSCP priorities and DSCP priorities.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before mapping received packets based on the DSCP priority, run the **qos map-table** command to enter the priority mapping table view.

Follow-up Procedure

Run the **input** (DSCP priority mapping table view) command to configure the mapping.

Example

Enter the dscp-dot1p view.

```
<HUAWEI> system-view
[HUAWEI] qos map-table dscp-dot1p
[HUAWEI-dscp-dot1p]
```

15.2.15 qos phb marking dscp enable (interface view)

Function

The **qos phb marking dscp enable** command enables PHB mapping for DSCP priorities in outgoing packets on an interface.

The **undo qos phb marking dscp enable** command disables PHB mapping for DSCP priorities in outgoing packets on an interface.

By default, PHB mapping is enabled for DSCP priorities in outgoing packets on an interface.

NOTE

This command is supported only on the following: S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, S6735-S, S6720-EI, and S6720S-EI.

Format

qos phb marking dscp enable

undo qos phb marking dscp enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **undo qos phb marking dscp enable** command is used on an interface of the edge node of the DiffServ domain, PHB mapping is disabled for DSCP priorities in outgoing packets on the interface connected to the device that does not belong to the DiffServ domain.

Precautions

The **trust upstream none** command disables PHB mapping on an interface. After this command is configured, the system does not perform PHB mapping for incoming and outgoing packets on the interface. Unlike the **trust upstream none** command, after the **undo qos phb marking dscp enable** command is used, the system does not perform PHB mapping for DSCP priorities in outgoing packets on the interface but performs PHB mapping for DSCP priorities in incoming packets on the interface.

The **undo qos phb marking dscp enable** and **trust upstream none** commands cannot be used simultaneously.

After the **undo qos phb marking dscp enable** command is used, DSCP priorities in packets are not mapped. However, 802.1p priorities in packets are still mapped. After the **undo qos phb marking enable** command is used, DSCP and 802.1p priorities in packets are not mapped.

If the **qos phb marking enable** command is configured on an interface and then the **trust dscp** or **qos phb marking dscp enable** command is configured on the interface, PHB mapping is performed for DSCP priorities in outgoing packets on the interface.

Example

Disable PHB mapping for DSCP priorities in outgoing packets on an interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo qos phb marking dscp enable
```

15.2.16 qos phb marking 8021p enable

Function

The **qos phb marking 8021p enable** command enables PHB mapping for 802.1p priorities in outgoing packets on an interface.

The **undo qos phb marking 8021p enable** command disables PHB mapping for 802.1p priorities in outgoing packets on an interface.

By default, PHB mapping for 802.1p priorities in outgoing packets is disabled on an interface, and outgoing packets are mapped based on the 802.1p priority (default configuration of the **trust** command).

NOTE

This command is supported only on the following: S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, S6735-S, S6720-EI, and S6720S-EI.

Format

qos phb marking 8021p enable

undo qos phb marking 8021p enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Typically, **undo qos phb marking 8021p enable** is configured on the device that functions as the edge node of the DiffServ domain to disable PHB mapping for 802.1p priorities in outgoing packets on an interface. If the downstream device needs to use the 802.1p priorities in packets, you can configure the **qos phb marking 8021p enable** command to perform PHB mapping for 802.1p priorities in outgoing packets on an interface.

Precautions

- The **trust upstream none** command is used to disable PHB mapping on an interface. After this command is configured, the system does not perform PHB mapping for incoming and outgoing packets on the interface.
- If the **undo qos phb marking enable** command is configured, the system does not perform PHB mapping for 802.1p priorities in outgoing packets on an interface.
- The **qos phb marking 8021p enable** command is mutually exclusive with the **trust upstream none** and **undo qos phb marking enable** commands.
- If the **qos phb marking enable** command is configured on an interface and then the **trust 8021p outer** or **qos phb marking 8021p enable** command is configured on the interface, the device performs PHB mapping for 802.1p priorities in outer VLAN tags of outgoing packets on the interface.

Example

Enable PHB mapping for 802.1p priorities in outgoing packets on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos phb marking 8021p enable
```

15.2.17 qos phb marking enable

Function

The **qos phb marking enable** command enables PHB mapping for outgoing packets on an interface.

The **undo qos phb marking enable** command disables PHB mapping for outgoing packets on an interface.

By default, PHB mapping is enabled for outgoing packets on an interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

qos phb marking enable

undo qos phb marking enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Scenario

After the **undo qos phb marking enable** command is executed on the interface of the edge node in a DiffServ domain, PHB mapping is disabled on the interface connected to a device that does not belong to the DiffServ domain.

Precautions

- The **trust upstream none** command is executed to disable PHB mapping on an interface. After the **trust upstream none** command is executed, the system does not perform PHB mapping for incoming and outgoing packets on the interface. Unlike the **trust upstream none** command, after the **undo qos phb marking enable** command is executed, the system does not perform PHB mapping for outgoing packets on the interface but performs PHB mapping for incoming packets on the interface.
- The **undo qos phb marking enable** and **trust upstream none** commands cannot be executed simultaneously.

Example

Disable PHB mapping for outgoing packets on GigabitEthernet0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo qos phb marking enable
```

15.2.18 remark 8021p

Function

The **remark 8021p** command configures an action of re-marking the 802.1p priority in VLAN packets in a traffic behavior.

The **undo remark 8021p** command deletes the configuration.

By default, no action of re-marking the 802.1p priority in VLAN packets is configured in a traffic behavior.

Format

remark 8021p [*8021p-value* | **inner-8021p**]

NOTE

inner-8021p is supported only on the following models: S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-S, S5735-S-IS6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

undo remark 8021p

Parameters

Parameter	Description	Value
8021p-value	Specifies the 802.1p priority of VLAN packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority in VLAN packets. If the value is not specified, the default value 0 is used.
inner-8021p	Inherits the 802.1p priority in the inner tag.	-

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To provide differentiated services based on the inner 802.1p priority in VLAN packets, run the **remark 8021p** command to configure the device to re-mark the inner 802.1p priority in VLAN packets in a traffic behavior.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing 802.1p priority re-marking.

Precautions

If a traffic policy containing **remark 8021p** is applied to the outbound direction on an interface, the device still processes outgoing packets based on the original priority but the downstream Layer 2 device processes the packets based on the re-marked priority.

A traffic policy containing **remark 8021p inner-8021p** can be applied only to the inbound direction, except for the following models: S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735-S-I, and S5735S-S. For the S6735-S, S6720-EI, and S6720S-EI, if a traffic policy contains **remark 8021p inner-8021p**, the PRI field (802.1p priority) in single-tagged packets is changed to 0. In this case, you can configure **if-match double-tag** in a traffic classifier to change the 802.1p priority only of double-tagged packets.

If a traffic policy containing **remark 8021p** is applied to the outbound direction on an interface, the VLAN of the interface must work in tag mode.

When a traffic classifier defines **if-match ipv6 acl** { *acl-number* | *acl-name* }, **remark 8021p** [*8021p-value* | **inner-8021p**] cannot be configured on the following models: S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

If selective QinQ, VLAN mapping, flow ID re-marking, 802.1p priority re-marking, or MAC address learning disabling is configured in a traffic behavior, the S5731-H, S5731-S, S5731S-H, S6730S-H, and S5731S-S do not support the following actions in the traffic behavior: traffic statistics collection, traffic mirroring, redirection, PBR, DSCP priority re-marking, internal priority re-marking, destination MAC address re-marking, traffic policing, and hierarchical traffic policing; the S5732-H, S6730-H, S6730-S, and S6730S-S do not support the following actions in the traffic behavior: traffic mirroring, redirection, PBR, DSCP priority re-marking, internal priority re-marking, destination MAC address re-marking, traffic policing, and hierarchical traffic policing.

On the S6720-EI, S6735-S, and S6720S-EI, if flow ID re-marking, re-marking of the inner VLAN tag in QinQ packets, MAC address learning disabling, or redirection of packets to a VPN instance is configured in a traffic behavior, the following actions cannot be defined in the traffic behavior: traffic statistics collection, traffic mirroring, redirection, PBR, DSCP priority re-marking, internal priority re-marking, destination MAC address re-marking, traffic policing, and hierarchical traffic policing.

If both the **trust 8021p** command and the traffic policy containing **remark 8021p** are used in the outbound direction on the interface of packets, the 802.1p priority specified by the **trust 8021p** command is the re-marked value. This is because the **remark 8021p** command takes precedence over the **trust 8021p** command.

On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735-S-I, and S5735S-S, if a traffic policy containing **remark 8021p** and a traffic policy containing **remark dscp** are applied to the inbound direction of an interface, and the **trust 8021p** or **trust dscp** command is configured in the outbound direction of the interface, the DSCP and 802.1p values of the packet are the values after re-marking.

The **remark 8021p** command configured on a Layer 3 routed sub-interface or termination sub-interface does not take effect.

The **remark 8021p** and **remark local-precedence** commands cannot be used in the same traffic behavior.

On the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, the **remark 8021p** and **remark dscp** commands cannot be used in the same traffic behavior.

If you run the **remark 8021p** command in the same traffic behavior view multiple times, only the latest configuration takes effect.

Example

Re-mark the 802.1p priority of VLAN packets with 4 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark 8021p 4
```

15.2.19 remark 8021p (QoS profile view)

Function

The **remark 8021p** command configures the device to re-mark 802.1p priorities in VLAN packets in a QoS profile.

The **undo remark 8021p** command cancels the configuration.

By default, the device does not re-mark 802.1p priorities in VLAN packets in a QoS profile.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

remark 8021p *8021p-value*

undo remark 8021p

Parameters

Parameter	Description	Value
8021p-value	Specifies the 802.1p priority of VLAN packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

QoS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device needs to provide differentiated services based on 802.1p priorities in VLAN packets, run the **remark 8021p** command to configure the device to re-mark 802.1p priorities in VLAN packets in a QoS profile.

Precautions

If you run the **remark 8021p** command in the same QoS profile view multiple times, only the latest configuration takes effect.

Example

Configure the device to re-mark the 802.1p priority in VLAN packets with 4 in the QoS profile **test**.

```
<HUAWEI> system-view
[HUAWEI] qos-profile name test
[HUAWEI-qos-test] remark 8021p 4
```

15.2.20 remark dscp

Function

The **remark dscp** command configures an action of re-marking the DSCP priority in IP packets in a traffic behavior.

The **undo remark dscp** command deletes the configuration.

By default, an action of re-marking the DSCP priority in IP packets is not configured in a traffic behavior.

Format

remark dscp { *dscp-name* | *dscp-value* }

undo remark dscp

Parameters

Parameter	Description	Value
dscp-name	Specifies the DSCP priority name in IP packets.	The value can be **ef**, **af11**, **af12**, **af13**, **af21**, **af22**, **af23**, **af31**, **af32**, **af33**, **af41**, **af42**, **af43**, **cs1**, **cs2**, **cs3**, **cs4**, **cs5**, **cs6**, **cs7**, or **default**.
dscp-value	Specifies the DSCP priority in IP packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To provide differentiated services based on the DSCP priority, run the **remark dscp** command to configure the device to re-mark the DSCP priority in IP packets in a traffic behavior.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing DSCP priority re-marking.

Precautions

If a traffic policy containing **remark dscp** is applied to the outbound direction on an interface, the device still processes outgoing packets based on the original priority but the downstream Layer 3 device or above processes the packets based on the re-marked priority.

If the traffic policy containing **remark dscp** and the **trust dscp** command are used in the outbound direction on the interface of packets, the **remark dscp** command changes DSCP priorities in packets because the **remark dscp** command takes precedence over the **trust dscp** command.

On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735-S-I, and S5735S-S, if a traffic policy containing

remark 8021p and a traffic policy containing **remark dscp** are applied to the inbound direction of an interface, and the **trust 8021p** or **trust dscp** command is configured in the outbound direction of the interface, the DSCP and 802.1p values of the packet are the values after re-marking.

The **remark dscp** and **remark ip-precedence** commands cannot be used in the same traffic behavior.

On the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, the **remark 8021p** and **remark dscp** commands cannot be used in the same traffic behavior.

If you run the **remark dscp** command in the same traffic behavior view multiple times, only the latest configuration takes effect.

After the **remark dscp** { *dscp-name* | *dscp-value* } command is configured in the traffic behavior view, the system maps the packet priority to a local priority based on the DSCP priority and sends the packet to a queue based on the mapped priority. If the **remark local-precedence** { *local-precedence-name* | *local-precedence-value* } command is also configured, the system sends packets to queues based on the priority configured using this command.

Example

Re-mark the DSCP priority in IP packets with 56 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark dscp 56
```

15.2.21 remark dscp (QoS profile view)

Function

The **remark dscp** command configures the device to re-mark DSCP priorities in IP packets in a QoS profile.

The **undo remark dscp** command cancels the configuration.

By default, the device does not re-mark DSCP priorities in IP packets in a QoS profile.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

remark dscp *dscp-value* { **inbound** | **outbound** }

undo remark dscp { **inbound** | **outbound** }

Parameters

Parameter	Description	Value
dscp-value	Specifies the DSCP priority in IP packets.	The value is an integer that ranges from 0 to 63. A larger value indicates a higher priority.
inbound	Specifies the DSCP priority in incoming IP packets.	-
outbound	Specifies the DSCP priority in outgoing IP packets.	-

Views

QoS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device needs to provide differentiated services based on DSCP priorities in IP packets, run the **remark dscp** command to configure the device to re-mark DSCP priorities in IP packets in a QoS profile.

Precautions

When the device processes IPv6 packets, or when the device uses the direct forwarding mode to process IPv4 packets, the **remark dscp** command cannot be used to re-mark DSCP priorities in these packets.

When packets match both outbound DSCP priority re-marking and outbound priority mapping that are configured on the device, only outbound priority mapping takes effect.

On the device that uses an earlier version of V200R011C10, the DSCP priority re-marking direction cannot be specified. When the device that uses an earlier version of V200R011C10 is upgraded to V200R011C10, the device re-marks DSCP priorities of incoming packets by default.

If you run the **remark dscp** command in the same QoS profile view multiple times, only the latest configuration takes effect.

Example

Configure the device to re-mark the DSCP priority in incoming IP packets with 56 in the QoS profile **test**.

```
<HUAWEI> system-view
[HUAWEI] qos-profile name test
[HUAWEI-qos-test] remark dscp 56 inbound
```

15.2.22 remark ip-precedence

Function

The **remark ip-precedence** command configures an action of re-marking the IP precedence in IP packets in a traffic behavior.

The **undo remark ip-precedence** command deletes the configuration.

By default, an action of re-marking the IP precedence in IP packets is not configured in a traffic behavior.

Format

remark ip-precedence *ip-precedence*

undo remark ip-precedence

Parameters

Parameter	Description	Value
ip-precedence	Specifies the IP precedence.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the downstream device needs to provide differentiated services based on the IP precedence, run the **remark ip precedence** command to configure the device to re-mark the IP precedence in IP packets in a traffic behavior.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing IP precedence re-marking.

Precautions

After the re-marking action is configured, the device still processes outgoing packets based on the original priority but the downstream Layer 3 device or above processes the packets based on the re-marked priority.

A traffic policy containing the **remark ip-precedence** action can be only used in the inbound direction.

The **remark dscp** and **remark ip-precedence** commands cannot be used in the same traffic behavior.

If you run the **remark ip-precedence** command in the same traffic behavior view multiple times, only the latest configuration takes effect.

Example

Re-mark the IP precedence in IP packets with 6 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark ip-precedence 6
```

15.2.23 remark local-precedence

Function

The **remark local-precedence** command configures an action of re-marking the internal priority in packets in a traffic behavior.

The **undo remark local-precedence** command deletes the configuration.

By default, an action of re-marking the internal priority in packets is not configured in a traffic behavior.

Format

remark local-precedence { *local-precedence-name* | *local-precedence-value* } [**green** | **yellow** | **red**]

undo remark local-precedence

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **green**, **yellow**, and **red**.

Parameters

Parameter	Description	Value
local-precedence-name	Specifies the internal priority name.	The value can be **af1**, **af2**, **af3**, **af4**, **be**, **cs6**, **cs7**, or **ef**.

Parameter	Description	Value
local-precedence-value	Specifies the internal priority value.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
green	Indicates that the green color corresponds to an internal priority.	-
yellow	Indicates that the yellow color corresponds to an internal priority.	-
red	Indicates that the red color corresponds to an internal priority.	-

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To provide differentiated services based on the internal priority of packets, run the **remark local-precedence** command to configure the device to re-mark the internal priority of packets so that the device can provide QoS based on the re-marked priority.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing internal priority re-marking.

Precautions

Re-marking the internal priority only affects QoS processing of packets on the device.

The **remark 8021p** and **remark local-precedence** commands cannot be used in the same traffic behavior.

A traffic policy containing the **remark local-precedence** action can be only used in the inbound direction.

If you run the **remark local-precedence** command in the same traffic behavior view multiple times, only the latest configuration takes effect.

Example

Re-mark the internal priority of packets with 2 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] remark local-precedence 2
```

15.2.24 trust

Function

The **trust** command specifies the priority to be mapped for packets.

The **undo trust** command cancels the configuration.

By default:

- The S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI process packets based on the mapping of the 802.1p priority.
- The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S process packets based on the mapping of the outer 802.1p priority.

Format

trust { **8021p** | **dscp** } (S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI)

undo trust { **8021p** | **dscp** } (S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI)

trust { **8021p** { **inner** | **outer** } | **dscp** } (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S)

undo trust (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
8021p	Maps packets based on the 802.1p priority.	-
inner	Maps packets based on the inner 802.1p priority.	-

Parameter	Description	Value
outer	Maps packets based on the outer 802.1p priority.	-
dscp	Maps packets based on the DSCP priority.	-

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, Eth-Trunk member interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a device does not trust any packet priority, packets enter queue 0 and 802.1p priorities in the packets are set to 0. Differentiated services cannot be provided. After the **trust** command is used, the device searches for the mapping table based on the priority in packets, re-marks the inner priority in packets, and sends packets to queues.

To set the same priority to be trusted on multiple interfaces, you can perform the configuration on a port group to reduce the workload.

Precautions

By default, the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, and S5720-LI in a version earlier than V200R013C00 do not trust priorities of packets. If the **trust** command is not executed to change the switches to trust 802.1p or DSCP priority of packets, the switches will process packets based on the mapping of the 802.1p priority after they are updated to V200R013C00 and later versions.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI, when the **trust dscp** and **trust 8021p** commands are configured on the same interface:

- The interface trusts DSCP priorities if IPv4 packets are received.
- The interface trusts 802.1p priorities if VLAN packets are received.

If both a traffic policy containing **remark 8021p** or **remark dscp** and the **trust 8021p** or **trust dscp** command are configured in the outbound interface of packets, only the traffic policy containing **remark 8021p** or **remark dscp** takes effect, and the **trust 8021p** or **trust dscp** command does not take effect.

On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if you run the **trust 8021p inner**, **trust 8021p outer**, and **trust dscp** commands multiple times on the same interface, only the latest configuration takes effect.

The **trust** command cannot be configured on both an Eth-Trunk and its member interfaces.

This command can be delivered in Layer 3 mode.

Example

Configure GE0/0/1 to trust DSCP priorities.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] trust dscp
```

15.2.25 trust upstream

Function

The **trust upstream** { **default** | *ds-domain-name* } command applies a DiffServ domain to an interface.

The **trust upstream none** command disables the priority mapping on an interface.

The **undo trust upstream** command restores the default settings.

By default, no DiffServ domain is bound to an interface. The priority mappings on the interface are the same as those of the DiffServ domain **default**.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

trust upstream { **default** | *ds-domain-name* | **none** }

undo trust upstream

Parameters

Parameter	Description	Value
default	Indicates the default DiffServ domain preset in the system.	-
ds-domain-name	Specifies the name of a DiffServ domain applied to an interface.	The value must the name of an existing DiffServ domain.

Parameter	Description	Value
none	Indicates that none DiffServ domain is applied to an interface, and the priorities in packets are not trusted.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, Eth-Trunk member interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To map priorities of the packets sent from the upstream device to PHBs according to the mappings defined in a DiffServ domain, run the **trust upstream** command to apply the DiffServ domain to the inbound interface of the packets. The system then maps priorities of packets to PHBs according to the mappings defined in the DiffServ domain.

To map PHBs of the packets sent to the downstream device to priorities according to the mappings defined in a DiffServ domain, run the **trust upstream** command to apply the DiffServ domain to the outbound interface of the packets. The system then maps PHBs of packets to the priorities according to the mappings defined in the DiffServ domain.

Prerequisites

A DiffServ domain has been created.

Precautions

- After the **trust upstream** command is executed on an interface, the system maps the priorities of packets on the interface to the following values according to the mappings defined in the DiffServ domain:
  - PHB
  - Packet color

  For default mappings from 802.1p priorities to PHBs and colors, from PHBs and colors to 802.1p priorities, from EXP priorities to PHBs and colors, from PHBs and colors to EXP priorities, from DSCP priorities to PHBs and colors, and from PHBs and colors to DSCP priorities, see the **8021p-inbound**, **8021p-outbound**, , **mpls-exp-inbound**, **mpls-exp-outbound**, **ip-dscp-inbound**, and **ip-dscp-outbound** commands.

- After the **trust upstream none** command is executed, the system performs no priority mapping on packets passing the interface.
- To change the DiffServ domain bound to an interface, run the **undo trust upstream** command to unbind the original DiffServ domain from the interface, and then run the **trust upstream** command to apply the new DiffServ domain to the interface.
- If you run the **trust upstream** command multiple times in the same interface view, only the latest configuration takes effect.
- The **trust upstream** command cannot be configured on both an Eth-Trunk and its member interfaces.
- To apply a DiffServ domain to multiple interfaces, you can perform the configuration on the port group to reduce the workload.

Example

Apply DiffServ domain **ds1** to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] trust upstream ds1
```

15.3 Traffic Policing, Traffic Shaping, and Interface-based Rate Limiting Commands

15.3.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.3.2 assign car-resource

Function

The **assign car-resource** command configures the CAR resource allocation mode.

The **undo assign car-resource** command restores the default CAR resource allocation mode.

By default, the **enhanced** CAR resource allocation mode is used, where CAR resources are allocated in a contiguous manner.

NOTE

This command is supported only on the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I.

Format

assign car-resource { **enhanced** | **normal** } [**slot** *slot-id*]

undo assign car-resource [**slot** *slot-id*]

Parameters

Parameter	Description	Value
enhanced	Sets the CAR resource allocation mode to **enhanced**.	-
normal	Sets the CAR resource allocation mode to **normal**. In this mode, CAR resources are allocated in a non-contiguous manner.	-
slot *slot-id*	● Specifies the slot ID if stacking is not configured. ● Specifies the stack ID if stacking is configured. If *slot-id* is not specified, the CAR resource allocation mode of all stacked switches is displayed.	The value must be set according to the device configuration.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When the **car (traffic behavior view)** command is used to configure a traffic policing policy, CAR resources are occupied. By default, the device uses the **enhanced** CAR resource allocation mode, where CAR resources are allocated in a contiguous manner. However, in some scenarios, for example, scenarios with heavy traffic, traffic may be rate-limited inaccurately. In this case, you can change the CAR resource allocation mode to **normal**, where CAR resources are allocated in a non-contiguous manner.

Precautions

- After configuring the CAR resource allocation mode, save the configuration, and restart the device for the configuration to take effect.
- After the CAR resource allocation mode is changed from **enhanced** to **normal**, the number of available CAR resources is halved.

Example

Change the CAR resource allocation mode to **enhanced**.

```
<HUAWEI> system-view
[HUAWEI] assign car-resource enhanced
```

15.3.3 car (traffic behavior view)

Function

The **car** command configures traffic policing in a traffic behavior.

The **undo car** command deletes traffic policing from a traffic behavior.

By default, traffic policing is not configured in a traffic behavior.

Format

car [**aggregation**] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**share**] [**mode** { **color-blind** | **color-aware** }] [**green pass**] [**yellow** { **discard** | **pass** [**remark-dscp** *dscp-value* | **remark-8021p** *8021p-value*] }] [**red** { **discard** | **pass** [**remark-dscp** *dscp-value* | **remark-8021p** *8021p-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, and S5720S-LI)

car [**aggregation**] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**share**] [**coupling-flag** *flag-value*] [**mode** { **color-blind** | **color-aware** }] [**green pass**] [**yellow** { **discard** | **pass** [**remark-dscp** *dscp-value* | **remark-8021p** *8021p-value*] }] [**red** { **discard** | **pass** [**remark-dscp** *dscp-value* | **remark-8021p** *8021p-value*] }] (S5735S-H, S5735-S, S5735S-S, S6720S-S, and S5736-S)

undo car

Parameters

Parameter	Description	Value
aggregation	Indicates aggregated CAR. Aggregated CAR can be applied to multiple interfaces, and traffic on the interfaces is restricted by aggregated CAR.	-
cir *cir-value*	Specifies the committed information rate (CIR), which is the allowed rate at which traffic can pass through.	The value is an integer that ranges from 8 to 4294967295, in kbit/s. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the minimum CIR is 16 kbit/s.
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate at which traffic can pass through.	The value is an integer that ranges from 8 to 4294967295, in kbit/s. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the minimum PIR is 16 kbit/s. The PIR must be greater than or equal to the CIR. By default, the PIR is equal to the CIR.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. By default, the CBS is 125 times the CIR. **NOTE** If the default CBS is smaller than 4000 because the CIR is small, the device uses the CBS of 4000. If the default CBS is larger than 4294967295 because the CIR is large, the device uses the CBS of 4294967295.

Parameter	Description	Value
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. If the PIR is not set, the default PBS is 125 times the CIR. If the PIR is set, the default PBS is 125 times the PIR. **NOTE** If the default PBS is smaller than 4000 because the CIR or PIR is small, the device uses the PBS of 4000. If the default PBS is larger than 4294967295 because the CIR or PIR is large, the device uses the PBS of 4294967295.
share	Indicates level-1 aggregated CAR. If level-1 aggregated CAR is defined in a traffic behavior, and a traffic classifier defining multiple matching rules is bound to this traffic behavior, traffic matching the traffic classifier shares the rate limit.	-
coupling-flag *flag-value*	Specifies the MEF meter algorithm. The following models support both the MEF0 and MEF1 algorithms: S6720S-S, S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-H, S6730-S, S6730S-S, S6730S-H, S5735S-H, and S5736-S. The following models support only the MEF0 algorithm: S6735-S, S6720-EI, and S6720S-EI.	The value is 0 for the S6735-S, S6720-EI, and S6720S-EI and can be 0 or 1 for the other models.
mode	Specifies the color mode for traffic policing.	-

Parameter	Description	Value
color-blind	Specifies the color-blind mode. In color-blind mode, the original packet color does not affect the traffic policing action.	-
color-aware	Specifies the color-aware mode. In color-aware mode, the original packet color affects the traffic policing action.	-
green **yellow** **red**	Specifies the packet color. The packet color is determined by the CBS and PBS. By default, green packets and yellow packets are allowed to pass through, and red packets are discarded.	-
discard	Discards packets.	If the action specified for green packets is **discard**, the action specified for yellow and red packets must be **discard**. If the action specified for yellow packets is **discard**, the action specified for red packets must be **discard**.
pass	Allows packets to pass through.	-
remark-8021p *8021p-value*	Re-marks the 802.1p priorities of packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
remark-dscp *dscp-value*	Re-marks the DSCP priority of packets.	The value is an integer that ranges from 0 to 63.
service-class *class*	Specifies the class of service (CoS).	The value can be **af1**, **af2**, **af3**, **af4**, **be**, **cs6**, **cs7**, or **ef**.
color *color*	Specifies the color corresponding to the CoS.	The value can be **green**, yellow, or **red**.

2: Configuration level

Usage Guidelines

Usage Scenario

Flow-based traffic policing controls traffic that matches traffic classification rules and discards the excess traffic to limit traffic within a proper range and to protect network resources.

When data is sent from a high-speed link to a low-speed link, the bandwidth on the interface of the low-speed link is insufficient. As a result, a large number of packets are discarded. To solve this problem, configure traffic policing for outgoing traffic on the interface of the high-speed link. The interface then discards the packets whose rate exceeds the traffic policing rate so that the outgoing traffic rate is limited within a proper range. You can also configure traffic policing for incoming traffic on the interface of the low-speed link. The interface then discards the received packets whose rate exceeds the traffic policing rate.

Traffic policing based on traffic policies controls rates of packets of different types.

The packet color is determined by the CBS and PBS:

- When the size of a packet is smaller than the CBS, the packet is colored green.
- When the size of a packet is greater than or equal to the CBS but smaller than the PBS, the packet is colored yellow.
- When the size of a packet is greater than or equal to the PBS, the packet is colored red.

After traffic policing is configured, the device counts forwarded and discarded packets.

If level-1 aggregated CAR is defined in a traffic behavior, and a traffic classifier defining multiple matching rules is bound to this traffic behavior, traffic matching the traffic classifier shares the rate limit. If level-1 aggregated CAR is not configured in a traffic behavior, the device limits the rate of traffic based on rules.

Prerequisites

A traffic behavior has been created using the **traffic behavior** command.

Precautions

When a traffic policy containing traffic policing actions is applied to an interface, you must use the **undo traffic-policy** command to unbind the traffic policy if you need to change traffic policing parameters.

If a traffic behavior defines the **car** command with **remark-8021p** *8021p-value* or **remark-dscp** *dscp-value* specified on the S6720S-S, S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, and S5736-S, a traffic policy containing this traffic behavior can only be applied in the inbound direction.

For the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S, S6720S-S: If aggregated CAR is configured by specifying the **aggregation** parameter, a traffic policy containing this traffic behavior can only be applied in the inbound direction.

If a traffic behavior defines the **car** command with **share** specified, a traffic policy containing this traffic behavior can only be applied in the inbound direction.

The **aggregation** and **share** parameters cannot be specified simultaneously in one traffic behavior.

For the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S, S6720S-S: If a traffic policy defining aggregated CAR and traffic statistics collection is applied to multiple interfaces, the system collects traffic statistics on all these interfaces. Traffic statistics on any one of the interfaces are the sum traffic statistics of all these interfaces.

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

When you use a traffic policy for rate limiting and apply the traffic policy in the Eth-Trunk interface view, if the Eth-Trunk interface contains several member interfaces, these member interfaces share the bandwidth specified by the rate limit.

On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if traffic policing and traffic statistics collection are configured in the same traffic behavior, only the following statistics are correct: numbers of packets and bytes that match the bound traffic classifier and on the packet rate, namely, values of **Packets**, **Bytes**, **Rate(pps)**, and **Rate(bps)** in **matched** in the **display traffic policy statistics** command output.

For the S6735-S, S6720-EI, S6720S-EI, the **car** command containing **remark-dscp** *dscp-value* and the **remark dscp** command cannot be configured in the same traffic behavior.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if the **car** command containing **remark-dscp** *dscp-value* and the **remark dscp** command are configured in the same traffic behavior, only the **car** command takes effect after the corresponding traffic policy is applied. The re-marked DSCP priority of a packet depends on the **car** command configuration.

Example

Configure traffic policing in the traffic behavior **b1** as follows: Set the CIR to 1000 kbit/s, permit green and yellow packets to pass through, re-mark the 802.1p priority of green packets with 7, re-mark the DSCP priority of yellow packets with 20, and discard red packets.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] car cir 1000 green pass remark-8021p 7 yellow pass remark-dscp 20 red discard
```

Configure level-1 aggregated CAR in the traffic behavior **b2** as follows: Set the CIR to 100 kbit/s for incoming data flows with destination IP addresses in 192.168.1.0/24 and 192.168.2.0/24 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl number 4999
[HUAWEI-acl-L2-4999] rule 5 permit destination 192.168.1.0 0.0.0.255
[HUAWEI-acl-L2-4999] rule 10 permit destination 192.168.2.168 0
[HUAWEI-acl-L2-4999] rule 15 permit destination 192.168.2.0 0.0.0.255
[HUAWEI-acl-L2-4999] quit
[HUAWEI] traffic classifier c2 operator or
[HUAWEI-classifier-c2] if-match acl 4999
[HUAWEI-classifier-c2] quit
[HUAWEI] traffic behavior b2
[HUAWEI-behavior-b2] car cir 100 pir 100 cbs 18800 pbs 31300 share green pass yellow pass red discard
[HUAWEI-behavior-b2] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-policy p2 inbound
```

If level-1 aggregated CAR is not configured, configure the traffic behavior **b2** in the preceding example as follows: Limit the rate of incoming data flows destined for 192.168.2.168 on GE0/0/1 to 100 kbit/s, and limit the total rate of incoming data flows destined for 192.168.1.0/24 and 192.168.2.0/24 (excluding 192.168.2.168) to 100 kbit/s, respectively.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b2
[HUAWEI-behavior-b2] car cir 100 pir 100 cbs 18800 pbs 31300 green pass yellow pass red discard
```

15.3.4 car (QoS profile view)

Function

The **car** command configures traffic policing in a QoS profile.

The **undo car** command deletes the traffic policing configuration from the QoS profile.

By default, traffic policing is not configured in a QoS profile.

Format

car cir *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] { **inbound** | **outbound** }

undo car { **inbound** | **outbound** }

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

The S6720-EI, S6735-S, and S6720S-EI do not support inbound traffic policing.

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the guaranteed average transmission rate.	The value is an integer that ranges from 64 to 4294967295, in kbit/s.
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate of traffic that can pass through an interface.	The value is an integer that ranges from 64 to 4294967295, in kbit/s. The PIR must be greater than or equal to the CIR. The default PIR is equal to the CIR.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. If the PIR is not set, the default CBS is 188 times the CIR. If the PIR is set, the default CBS is 125 times the CIR.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. If the PIR is not set, the default PBS is 313 times the CIR. If the PIR is set, the default PBS is 125 times the PIR.
inbound	Indicates inbound traffic policing.	-
outbound	Indicates outbound traffic policing.	-

Views

QoS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traffic policing discards excess traffic to limit traffic within a proper range and to protect network resources.

The **car** command configures traffic policing in a QoS profile.

Follow-up Procedure

Apply the QoS profile in the AAA domain view.

Precautions

When the traffic policing rate is larger than the maximum bandwidth of an interface, traffic policing does not take effect on the interface. Set the CIR and PIR to be smaller than the rate of an interface.

When the CBS is smaller than the number of bytes in a packet, the device directly discards the packet.

Example

Create a QoS profile named **huawei** in which the CIR is set to 10000 kbit/s, the CBS is set to 10240 bytes, and the PBS is set to 10240 bytes.

```
<HUAWEI> system-view
[HUAWEI] qos-profile name huawei
[HUAWEI-qos-huawei] car cir 10000 cbs 10240 pbs 10240 inbound
```

15.3.5 car share

Function

The **car share** command configures aggregated CAR in a traffic behavior.

The **undo car share** command cancels aggregated CAR in a traffic behavior.

By default, aggregated CAR is not configured in a traffic behavior.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

car *car-name* **share**

undo car [*car-name*] **share**

Parameters

Parameter	Description	Value
car-name	Specifies the name of a CAR profile.	The value must the name of an existing CAR profile.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple traffic classifiers are defined in a traffic policy and traffic behaviors associated with the traffic classifiers define CAR (using the **car cir** command) and aggregated CAR, the system limits the rates of flows using the configured CAR, aggregates the flows, and limits the rate of the aggregated traffic using the aggregated CAR in sequence. This process is called hierarchical traffic policing.

Hierarchical traffic policing multiplexes traffic statistics and controls services in a fine-granular manner. For example, hierarchical traffic policing limits the service traffic of level-1 and level-2 users or traffic of level-1 and level-2 user groups.

Prerequisites

A QoS CAR profile has been configured using the **qos car** command.

Precautions

The traffic policy defining the aggregated CAR action can only be used in the inbound direction.

After aggregated CAR is configured, all the rules in the traffic classifiers bound to the same traffic behavior share the CAR index. The system aggregates all the flows matching these traffic classifiers and uses CAR to limit the rate of the flows. If the traffic classifiers define both Layer 2 and Layer 3 information, the aggregated CAR configuration is invalid.

A traffic policy limits the traffic rate using the aggregated CAR only in the current applied object. For example, when the traffic policy **p1** defining the aggregated CAR is applied to **interface1** and **interface2**, the aggregated CAR applies to traffic on **interface1** and **interface2** respectively, without affecting each other.

Example

Configure aggregated CAR in the traffic behavior **tb1**.

```
<HUAWEI> system-view
[HUAWEI] qos car qoscar1 cir 2000
[HUAWEI] traffic behavior tb1
[HUAWEI-behavior-tb1] car cir 1000 pir 123456
[HUAWEI-behavior-tb1] car qoscar1 share
```

15.3.6 display car-resource configuration

Function

The **display car-resource configuration** command displays the CAR resource allocation mode.

NOTE

This command is supported only on the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, and S5735-S-I.

Format

display car-resource configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the CAR resource allocation mode that is used currently and to be used after the next startup of the device.

Example

Display the CAR resource allocation mode on a device.

```
<HUAWEI> display car-resource configuration
Slot      Current Mode    Next Mode
- - - - - - - - - - - - - - - - - - - - - - -
0         enhanced        enhanced
1         enhanced        enhanced
-------------------------------------------------------------------------------
```

Table 15-21 Description of the **display car-resource configuration** command output

Item	Description
Slot	Slot ID.
Current Mode	CAR resource allocation mode that is used currently.
Next Mode	CAR resource allocation mode to be used after the next startup of the device. To configure the CAR resource allocation mode, run the **assign car-resource** command.

15.3.7 display qos-profile

Function

The **display qos-profile** command displays the configured QoS profile information.

Format

display qos-profile [**name** *profile-name* | **all**]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a QoS profile.	The value must the name of an existing QoS profile.
all	Indicates all QoS profiles.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display qos-profile** command displays the configuration of a specified QoS profile or all QoS profiles. The command output helps you check the QoS profile configuration and locate QoS faults.

Example

Display the configurations of all QoS profiles.

```
<HUAWEI> display qos-profile all
Qos-profile[0]: huawei
---------------------------------------------
IcarConfiged      :      0
IcarCir           :      0
IcarPir           :      0
IcarCbs           :      0
IcarPbs           :      0
```

```
EcarConfiged       :        0
EcarCir            :        0
EcarPir            :        0
EcarCbs            :        0
EcarPbs            :        0
StatisticEn        :        0
Remark8021p        :        0
8021pValue         :        0
RemarkDscp inbound  :        0
DscpValue inbound   :        0
RemarkDscp outbound :        0
DscpValue outbound  :        0
---------------------------------------------
```

NOTE

The **display qos-profile** command on the S6735-S, S6720-EI and S6720S-EI does not display **Remark8021p**, **8021pValue**, **RemarkDscp**, or **DscpValue**.

Table 15-22 Description of the **display qos-profile all** command output

Item	Description
Qos-profile[0]	Name of a QoS profile. The number in bracket is the index that the system assigns to the QoS profile. To create a QoS profile, run the **qos-profile** command.
IcarConfiged	Whether inbound traffic policing is configured: ● 0: Inbound traffic policing is not configured. ● 1: Inbound traffic policing is configured. To configure inbound traffic policing in a QoS profile, run the **car (QoS profile view)** command.
IcarCir	CIR in the inbound direction. To change the value, run the **car (QoS profile view)** command.
IcarPir	PIR in the inbound direction. To change the value, run the **car (QoS profile view)** command.
IcarCbs	CBS in the inbound direction. To change the value, run the **car (QoS profile view)** command.
IcarPbs	PBS in the inbound direction. To change the value, run the **car (QoS profile view)** command.

Item	Description
EcarConfiged	Whether outbound traffic policing is configured: ● 0: Outbound traffic policing is not configured. ● 1: Outbound traffic policing is configured. To configure outbound traffic policing in a QoS profile, run the **car (QoS profile view)** command.

EcarCbs	CBS in the outbound direction. To change the value, run the **car (QoS profile view)** command.
EcarPbs	PBS in the outbound direction. To change the value, run the **car (QoS profile view)** command.
StatisticEn	Whether the traffic statistics function is configured: ● 0: The traffic statistics function is not configured. ● 1: The traffic statistics function is configured. To configure the traffic statistics function in a QoS profile, run the **statistic enable (QoS profile view)** command.
Remark8021p	Whether 802.1p priority re-marking is configured: ● 0: 802.1p priority re-marking is not configured. ● 1: 802.1p priority re-marking is configured. To configure 802.1p priority re-marking in a QoS profile, run the **remark 8021p (QoS profile view)** command.

Item	Description
8021pValue	Re-marked 802.1p priority. To change the value, run the **remark 8021p (QoS profile view)** command.
RemarkDscp inbound	Whether to re-mark the DSCP priority of incoming packets: - 0: DSCP priority re-marking is not configured. - 1: DSCP priority re-marking is configured. To configure DSCP priority re-marking in a QoS profile, run the **remark dscp (QoS profile view)** command.
DscpValue inbound	Re-marked DSCP priority of incoming packets. To change the value, run the **remark dscp (QoS profile view)** command.
RemarkDscp outbound	Whether to re-mark the DSCP priority of outgoing packets: - 0: DSCP priority re-marking is not configured. - 1: DSCP priority re-marking is configured. To configure DSCP priority re-marking in a QoS profile, run the **remark dscp (QoS profile view)** command.
DscpValue outbound	Re-marked DSCP priority of outgoing packets. To change the value, run the **remark dscp (QoS profile view)** command.

Display the summary configurations of all QoS profiles.

```
<HUAWEI> display qos-profile
       index                  qos-profile name
-------------------------------------------------------------------
       0                      huawei
-------------------------------------------------------------------
 Total   64     Used   1
```

Table 15-23 Description of the **display qos-profile** command output

Item	Description
index	Index that the system assigns to a QoS profile.

Item	Description
qos-profile name	Name of a QoS profile.
Total	Maximum number of QoS profiles that can be configured.
Used	Number of used QoS profiles.

15.3.8 display qos car

Function

The **display qos car** command displays the QoS CAR profile configuration.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display qos car { **all** | **name** *car-name* }

Parameters

Parameter	Description	Value
all	Displays the configurations of all QoS CAR profiles.	-
name *car-name*	Displays the configuration of a specified QoS CAR profile.	The value must the name of an existing QoS CAR profile.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display qos car** command displays the configurations of all QoS CAR profiles or a specified QoS CAR profile. The command output helps you check the QoS CAR profile configuration and locate QoS faults.

Precautions

If you do not use the **qos car** command to create a QoS CAR profile, no information is displayed after the **display qos car** command is executed.

Example

Display the configurations of all QoS CAR profiles.

```
<HUAWEI> display qos car all
  ----------------------------------------------------------------
   CAR Name     : qoscar1
   CAR Index    : 0
    car cir 8000 (Kbps) pir 10000 (Kbps) cbs 1000000 (byte) pbs 1250000 (byte)
  ----------------------------------------------------------------
   CAR Name     : qoscar2
   CAR Index    : 1
    car cir 5000 (Kbps) pir 8000 (Kbps) cbs 625000 (byte) pbs 1000000 (byte)
  ----------------------------------------------------------------
   CAR Name     : car1
   CAR Index    : 2
    car cir 1000 (Kbps) cbs 188000 (byte)
```

Display the configuration of the QoS CAR profile named **car1**.

```
<HUAWEI> display qos car name car1
  ----------------------------------------------------------------
   CAR Name     : car1
   CAR Index    : 2
    car cir 1000 (Kbps) cbs 188000 (byte)
```

Table 15-24 Description of the **display qos car** command output

Item	Description
CAR Name	QoS CAR profile name. To configure a QoS CAR profile, run the **qos car** command.
CAR Index	Index of the QoS CAR profile.
car cir 8000 (Kbps) pir 10000 (Kbps) cbs 1000000 (byte) pbs 1250000 (byte)	Parameters of the QoS CAR profile, including the CIR, PIR, CBS, and PBS. To set parameters in a QoS CAR profile, run the **qos car** command.

15.3.9 display qos configuration

Function

The **display qos configuration** command displays the QoS configuration on an interface.

Format

display qos configuration interface [*interface-type interface-number*]

Parameters

Parameter	Description	Value
interface [*interface-type interface-number*]	Displays the QoS configuration on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If no interface is specified, the QoS configurations on all the interfaces are displayed.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display qos configuration** command displays QoS configurations on a specified interface or all interfaces. The command output helps you check the QoS configuration and locate QoS faults.

Example

Display the QoS configuration on GE0/0/1 of the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, or S5720-LI.

```
<HUAWEI> display qos configuration interface gigabitethernet 0/0/1
 interface GigabitEthernet0/0/1
 ------------------------------------------------------------------------
 Trust flag            | 8021p
 Port priority         | 0
 Schedule-profile        |
 Tail-drop-profile       |
 Port lr             | outbound, cir = , cbs =
 Port lr             | inbound, cir = , cbs =
 ------------------------------------------------------------------------
 queue-index | configuration |
 ------------------------------------------------------------------------
```

```
0           | shaping       | cir = , cbs =
            |               | pir = , pbs =
            | schedule      | wrr, weight = 1
----------------------------------------------------------------------------
1           | shaping       | cir = , cbs =
            |               | pir = , pbs =
            | schedule      | wrr, weight = 1
----------------------------------------------------------------------------
2           | shaping       | cir = , cbs =
            |               | pir = , pbs =

------------------------------------------------------------------------------
```

Table 15-25 Description of the **display qos configuration** command output

Item	Description
Trust flag	Type of the external priority (802.1p priority, DSCP priority, or IP precedence) mapped to the internal priority (DiffServ level and color). To change the value, run the **trust** command.
DS name	DiffServ domain name. To create a DiffServ domain, run the **diffserv domain** command.
DEI enable	Whether the function that DEI field in a VLAN tag is mapped to the drop priority is enabled. ● enable: The function is enabled. ● disable: The function is disabled. To set the function that DEI field in a VLAN tag is mapped to the drop priority, run the **dei enable** command.
PHB marking	Whether PHB mapping is enabled for outgoing packets on the interface. ● enable: PHB mapping is enabled for outgoing packets on the interface. ● disable: PHB mapping is disabled for outgoing packets on the interface. To set PHB mapping, run the **qos phb marking enable** command.
Port priority	Default 802.1p priority added to untagged packets by the interface. To change the value, run the **port priority** command.
Port wred	Name of the WRED drop profile applied to the interface. To apply a WRED drop profile to an interface, run the **qos wred** command.
Schedule-profile	Name of the scheduling profile applied to the interface. To apply a scheduling profile to an interface, run the **qos schedule-profile (interface view)** command.
Tail-drop-profile	Name of the tail drop profile applied to the interface. To apply a tail drop profile to an interface, run the **qos tail-drop-profile (interface view)** command.

Item	Description
Port lr	Traffic shaping rate on the interface. To configure traffic shaping rate on an interface, run the **qos lr outbound** or **qos lr inbound** command.
TM enable	Whether the traffic manager (TM) is enabled to buffer and schedule packets. ● enable: The TM is enabled to buffer and schedule packets. ● disable: The TM is disabled from buffering and scheduling packets. To enable the TM, run the **qos traffic-manage enable** command.
queue-index	Interface queue index.
configuration	Interface queue configuration.
shaping	Traffic shaping configuration of the interface queue. To configure traffic shaping on an interface, run the **qos queue shaping** command.
cir	Committed information rate (CIR). To change the value, run the **qos queue shaping** command.
cbs	Committed burst size (CBS). To change the value, run the **qos queue shaping** command.
pir	Peak information rate (PIR). To change the value, run the **qos queue shaping** command.
pbs	Peak burst size (PBS). To change the value, run the **qos queue shaping** command.
schedule	Scheduling mode of the interface queue. To set the scheduling mode of interface queues, run the **qos { pq | wrr | drr }** command.
wred	WRED drop profile bound to an interface queue. To bind a WRED drop profile to an interface queue, run the **qos queue wred** command.
weight	Scheduling weight of a queue. To set the scheduling weight of a queue, run the **qos queue drr** or **qos queue wrr** command.
length	Interface queue length. This field cannot be modified on the switch and is empty in the command output.

15.3.10 display qos lr

Function

The **display qos lr** command displays the rate limit configuration on an interface.

Format

display qos lr { **inbound** | **outbound** } **interface** *interface-type interface-number*

Parameters

Parameter	Description	Value
inbound	Displays the rate limit configuration in the inbound direction on an interface.	-
outbound	Displays the rate limit configuration in the outbound direction on an interface.	-
interface-type interface-number	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display qos lr** command displays the rate limit configuration on a specified interface. The command output helps you check the rate limit on an interface and locate faults.

Precautions

If you do not use the **qos lr inbound** or **qos lr outbound** command to configure the rate limit on an interface, no information is displayed after the **display qos lr** command is executed.

Example

Set the CIR of data packets to be sent from the GE0/0/1 to 20000 kbit/s and the CBS to 375000 bytes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos lr outbound cir 20000 cbs 375000
[HUAWEI-GigabitEthernet0/0/1] quit
```

Display the rate limit configuration on the GE0/0/1.

```
<HUAWEI> display qos lr outbound interface gigabitethernet 0/0/1
GigabitEthernet0/0/1 lr outbound:
  cir: 20000 Kbps, cbs: 375000 Byte
```

Table 15-26 Description of the **display qos lr** command output

Item	Description
cir	Committed information rate (CIR). To set the CIR, run the **qos lr inbound** or **qos lr outbound** command.
cbs	Committed burst size (CBS). To set the CBS, run the **qos lr inbound** or **qos lr outbound** command.

15.3.11 display qos statistics

Function

The **display qos statistics** command displays traffic statistics on an interface where rate limiting is performed in the inbound direction.

Format

display qos statistics interface *interface-type interface-number* **inbound**

display qos statistics inbound all [**nonzero**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays traffic statistics on a specified interface where rate limiting is performed. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
inbound	Displays traffic statistics in the inbound direction.	-
all	Displays traffic statistics on all interfaces where rate limiting is performed.	-
nonzero	Displays traffic statistics on all interfaces where rate limiting is performed and the statistics are not 0.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display qos statistics** command to view statistics on forwarded and discarded packets and check whether rate limiting takes effect. The command output helps you locate faults.

Prerequisites

The **qos lr inbound** command has been executed to configure rate limiting in the inbound direction on an interface.

Precautions

If the **qos lr inbound** command is not used, the system displays the following message after the **display qos statistics interface** *interface-type interface-number* **inbound** command is executed:

```
Info: There is no rate limited configuration inbound in the interface.
```

Example

Display traffic statistics on GE0/0/1 where rate limiting is performed in the inbound direction. (S5732-H)

```
<HUAWEI> display qos statistics interface gigabitethernet 0/0/1 inbound
------------------------------------------------------------
 Item                                     Value
------------------------------------------------------------
 Passed packets                             0
 Passed bytes                              0
 Dropped packets                             0
 Dropped bytes                              0
------------------------------------------------------------
```

Display traffic statistics on GE0/0/1 where rate limiting is performed in the inbound direction. (S5735-S)

```
<HUAWEI> display qos statistics interface gigabitethernet 0/0/1 inbound
------------------------------------------------------------
 It has not reached the threshold of ingress bandwidth.
------------------------------------------------------------
```

Table 15-27 Description of the **display qos statistics** command output

Item	Description
Passed packets	Number of forwarded packets.
Passed bytes	Number of forwarded bytes.
Dropped packets	Number of discarded packets.
Dropped bytes	Number of discarded bytes.
It has not reached the threshold of ingress bandwidth.	On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the following information may be displayed in the **display qos statistics** command output: ● The rate limit is not reached: It has not reached the threshold of ingress bandwidth. ● The rate limit is reached: It has reached the threshold of ingress bandwidth.

15.3.12 qos car

Function

The **qos car** command creates a QoS CAR profile and sets parameters in the QoS CAR profile.

The **undo qos car** command deletes a QoS CAR profile.

By default, no QoS CAR profile is created.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

qos car *car-name* **cir** *cir-value* [**cbs** *cbs-value* [**pbs** *pbs-value*] | **pir** *pir-value* [**cbs** *cbs-value* **pbs** *pbs-value*]]

undo qos car *car-name*

Parameters

Parameter	Description	Value
car-name	Specifies the name of a QoS CAR profile.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. The value cannot be c, ci, or cir.
cir *cir-value*	Specifies the committed information rate (CIR), which is the average rate of traffic that can pass through an interface.	The value is an integer that ranges from 64 to 4294967295, in kbit/s.
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate of traffic that can pass through an interface.	The value is an integer that ranges from 64 to 4294967295, in kbit/s. The PIR must be greater than or equal to the CIR. By default, the PIR is equal to the CIR.

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. By default, the CBS is 188 times the CIR if the PIR is not set and is 125 times the CIR if the PIR is set.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. By default, the PBS is 125 times the PIR.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traffic policing controls traffic by monitoring the rate of traffic, and discards excess traffic to limit traffic within a proper range and to protect network resources.

When data is sent from a high-speed link to a low-speed link, the bandwidth on the interface of the low-speed link is insufficient. As a result, a large number of packets are discarded. To solve this problem, configure traffic policing for outgoing traffic on the interface of the high-speed link. The interface then discards the packets whose rate exceeds the traffic policing rate so that the outgoing traffic rate is limited within a proper range. You can also configure traffic policing for incoming traffic on the interface of the low-speed link. The interface then discards the received packets whose rate exceeds the traffic policing rate.

The packet color is determined by **cbs** *cbs-value* and **pbs** *pbs-value* of this command:

- When the size of a packet is smaller than the CBS, the packet is colored green.
- When the size of a packet is greater than or equal to the CBS but smaller than the PBS, the packet is colored yellow.
- When the size of a packet is greater than or equal to the PBS, the packet is colored red.

Precautions

A maximum of 512 QoS CAR profiles can be created on the switch.

When the traffic shaping rate is greater than the maximum rate of an interface, traffic policing is not performed on the interface. You need to set the CIR or PIR to be smaller than the maximum rate of the interface.

When the CBS is smaller than the number of bytes in a packet, packets of this type are discarded.

To prevent a device failure to identify the packet color, you are advised to set the PBS to be larger than the CBS.

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

The granularity of traffic policing may increase with the CBS. For the S6735-S, S6720-EI and S6720S-EI, if the CIR is far smaller than the CBS (for example, the CIR is set to 1000 kbit/s and CBS is set to 1000000 bytes), rate limiting may be inaccurate.

Example

Create a QoS CAR profile named **qoscar1**, and set the CIR to 10000 kbit/s and the CBS to 10240 bytes.

```
<HUAWEI> system-view
[HUAWEI] qos car qoscar1 cir 10000 cbs 10240
```

15.3.13 qos-car exclude-interframe

Function

The **qos-car exclude-interframe** command configures the device not to count the inter-frame gap and preamble of packets when the device calculates the traffic policing rate or rate limit.

The **undo qos-car exclude-interframe** command configures the device to count the inter-frame gap and preamble of packets when the device calculates the traffic policing rate or rate limit.

By default, the device calculates the inter-frame gap and preamble of packets when the device calculates the traffic policing rate or rate limit.

Format

qos-car exclude-interframe

undo qos-car exclude-interframe

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When traffic policing or rate limiting is configured on an interface, the device calculates the inter-frame gap and preamble of packets for the traffic policing rate or rate limit. As a result, the rate is inaccurate. After the **qos-car exclude-interframe** command is used, the device does not count the inter-frame gap and preamble of packets for the traffic policing rate or rate limit.

The **qos-car exclude-interframe** command affects calculation of the traffic policing rate and inbound rate limit. When the **car (traffic behavior view)** and **qos lr inbound** commands are used to configure traffic policing and inbound rate limiting, the device does not count the inter-frame gap and preamble for the traffic policing rate or rate limit.

Precautions

Before this command is used, the following formula is used to calculate the traffic policing rate or rate limit:

Traffic policing rate/Rate limit = (Original packet length + Inter-frame gap + Preamble) x Number of packets forwarded per second

The inter-frame gap and preamble occupy 20 bytes.

After this command is used, the following formula is used to calculate the traffic policing rate or rate limit:

Traffic policing rate/Rate limit = Original packet length x Number of packets forwarded per second

Example

Configure the device not to count the inter-frame gap and preamble of packets when the device calculates the traffic policing rate.

```
<HUAWEI> system-view
[HUAWEI] qos-car exclude-interframe
```

15.3.14 qos-profile

Function

The **qos-profile** command creates a QoS profile and displays its view, or directly displays the view of an existing QoS profile.

The **undo qos-profile** command deletes a QoS profile.

By default, no QoS profile is configured on the device.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

qos-profile name *profile-name*

undo qos-profile { **all** | **name** *profile-name* }

Parameters

Parameter	Description	Value
name *profile-name*	Specifies the name of a QoS profile.	The value is a string of 1 to 64 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. The value cannot be --.
all	Indicates all QoS profiles.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can define QoS configurations in a QoS profile to implement such functions as traffic policing, priority re-marking, and traffic statistics.

Follow-up Procedure

- Define parameters in the QoS profile, including parameters of traffic policing, priority re-marking, and traffic statistics.
- Apply the QoS profile in the specified view.

Precautions

The **undo qos-profile all** command only deletes the QoS profiles that are not applied.

The switch supports a maximum of 64 QoS profiles.

Example

Create a QoS profile named **huawei** and enter the QoS profile view.

```
<HUAWEI> system-view
[HUAWEI] qos-profile name huawei
[HUAWEI-qos-huawei]
```

15.3.15 qos-shaping exclude-interframe

Function

The **qos-shaping exclude-interframe** command configures the device not to count the inter-frame gap and preamble of packets when the device calculates the traffic shaping rate.

The **undo qos-shaping exclude-interframe** command configures the device to count the inter-frame gap and preamble of packets when the device calculates the traffic shaping rate.

By default, the device counts the inter-frame gap and preamble of packets when the device calculates the traffic shaping rate.

Format

qos-shaping exclude-interframe

undo qos-shaping exclude-interframe

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After traffic shaping is configured on an interface, the device counts the inter-frame gap and preamble of packets for the traffic shaping rate. As a result, the rate is inaccurate. After the **qos-shaping exclude-interframe** command is used, the device does not calculate the inter-frame gap and preamble of packets for the traffic shaping rate.

The **qos-shaping exclude-interframe** command affects calculation of the traffic shaping rate and outbound rate limit. When the **qos queue shaping** and **qos lr outbound** commands are used to configure traffic shaping and outbound rate limiting, the device does not count the inter-frame gap and preamble for the traffic shaping rate.

Precautions

Before this command is used, the following formula is used to calculate the traffic shaping rate:

Traffic shaping rate = (Original packet length + Inter-frame gap + Preamble) x Number of packets forwarded per second

The inter-frame gap and preamble occupy 20 bytes.

After this command is used, the following formula is used to calculate the traffic shaping rate:

Traffic shaping rate = Original packet length x Number of packets forwarded per second

Example

Configure the device not to count the inter-frame gap and preamble of packets when the device calculates the traffic shaping rate.

```
<HUAWEI> system-view
[HUAWEI] qos-shaping exclude-interframe
```

15.3.16 qos lr inbound

Function

The **qos lr inbound** command configures traffic policing in the inbound direction on an interface.

The **undo qos lr inbound** command cancels traffic policing in the inbound direction on an interface.

By default, traffic policing is not configured in the inbound direction on an interface.

Format

qos lr inbound cir *cir-value* [**cbs** *cbs-value*]

undo qos lr inbound

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR).	The value is an integer. The value range differs depending on the interface type: - Interfaces in a port group: 64 to 100000000 - Other interfaces: 64 to X, where X indicates the maximum rate supported by the interface Unit: kbit/s

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS).	The value is an integer that ranges from 4000 to 4294967295, in bytes. If this parameter is not specified, the CBS is 125 times the CIR by default. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, CloudEngine S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the maximum CBS is 65535 bytes. On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI, the maximum value of the CBS is 65535 granularities. Each granularity depends on the CIR: ● When the CIR is in the range of 64 kbit/s to 1023 kbit/s, each granularity is 1 byte. ● When the CIR is in the range of 1024 kbit/s to 10230 kbit/s, each granularity is 8 bytes. ● When the CIR is in the range of 10231 kbit/s to 102300 kbit/s, each granularity is 64 bytes. ● When the CIR is in the range of 102301 kbit/s to 1023000 kbit/s, each granularity is 512 bytes. ● When the CIR is in the range of 1023001 kbit/s to 10000000 kbit/s, each granularity is 4096 bytes.

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When data is sent from a high-speed link to a low-speed link, the bandwidth on the interface of the low-speed link is insufficient. As a result, a large number of packets are discarded. In this case, the data traffic rate needs to be limited. After the traffic policing rate for incoming packets on an interface is set by using the **qos lr inbound** command, if the rate of packets received by the interface is larger than the traffic policing rate and the queue buffer is full, the packets exceeding the rate limit are discarded.

Precautions

When interface-based 802.1X authentication is configured and the RADIUS server delivers the rate limit, the interface does not support the rate limit.

If both the IPSG function and inbound interface-based rate limiting are configured on an interface of the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI, both IPSG and interface-based rate-limiting configurations take effect as long as the configurations do not conflict. Otherwise, only the IPSG configuration takes effect.

The **traffic-limit (interface view)** command limits the rate of packets matching an ACL, whereas the **qos lr inbound** command limits the rate of all packets on an interface. If both of them are configured:

- On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI, the **qos lr inbound** command takes effect.
- On the S6735-S, S6720-EI, and S6720S-EI, rate limiting is inaccurate.
- On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, the actual rate limit is the smaller CIR between CIR values configured using the two commands.

Configuring the **qos lr inbound** command occupies system resources. If system resources are insufficient, the configuration fails.

If you run the **qos lr inbound** command multiple times on the same interface, only the latest configuration takes effect.

If you need to set the same traffic policing rate on multiple interfaces, you can perform the configuration on a port group to reduce the workload.

The granularity of traffic shaping may increase with the CBS. For the S6735-S, S6720-EI and S6720S-EI, if the CIR is far smaller than the CBS (for example, the CIR is set to 1000 kbit/s and CBS is set to 1000000 bytes), rate limiting may be inaccurate.

If the rate range configured in a version earlier than V200R019C10 exceeds the maximum rate supported by an interface, the corresponding command in the configuration file of the source version can still be delivered after the version is upgraded to V200R019C10 or a later version. However, the maximum rate supported by the interface takes effect.

Example

Set the CIR of data packets received by the GE0/0/1 to 20000 kbit/s and the CBS to 375000 bytes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos lr inbound cir 20000 cbs 375000
[HUAWEI-GigabitEthernet0/0/1] quit
```

15.3.17 qos lr inbound whitelist protocol

Function

The **qos lr inbound whitelist protocol** command adds protocol packets to the whitelist for inbound interface-based rate limiting.

The **undo qos lr inbound whitelist protocol** command cancels the configuration.

By default, no protocol packet is added to the whitelist for inbound interface-based rate limiting.

NOTE

Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S support this command.

Format

qos lr inbound whitelist protocol { **arp-request** | **bpdu** | **dhcp** | **igmp** | **rip** }*

undo qos lr inbound whitelist protocol { **arp-request** | **bpdu** | **dhcp** | **igmp** | **rip** }*

Parameters

Parameter	Description	Value
arp-request	Indicates ARP request packets and Neighbor Solicitation (NS) messages.	-
bpdu	Indicates BPDUs.	-

Parameter	Description	Value
dhcp	Indicates DHCP and DHCPv6 packets.	-
igmp	Indicates IGMP packets, including IPv4 IGMP, IPv6 MLDv1, IPv6 MLDv2, and PIM packets.	-
rip	Indicates RIP and OSPF packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the traffic policing rate for incoming packets on an interface is set by using the **qos lr inbound** command, if the rate of packets received by the interface is larger than the traffic policing rate and the queue buffer is full, the packets exceeding the rate limit are discarded. To make the **qos lr inbound** command ineffective to one or more types of protocol packets (for example, DHCP packets, ARP request packets, and NS messages), you can run the **qos lr inbound whitelist protocol** command to add the protocol packets to the whitelist for inbound interface-based rate limiting. Then, the switch will not rate-limit incoming packets of these protocols on all interfaces.

Precautions

After the **qos lr inbound whitelist protocol** command is run to add protocol packets to the whitelist for inbound interface-based rate limiting, incoming packets of these protocols are exempted from traffic suppression and storm control.

Example

Add DHCP and DHCPv6 packets to the whitelist for inbound interface-based rate limiting.

```
<HUAWEI> system-view
[HUAWEI] qos lr inbound whitelist protocol dhcp
```

15.3.18 qos lr outbound

Function

The **qos lr outbound** command configures traffic shaping in the outbound direction on an interface.

The **undo qos lr outbound** command cancels traffic shaping in the outbound direction on an interface.

By default, traffic shaping is not configured in the outbound direction on an interface.

Format

qos lr outbound cir *cir-value* [**cbs** *cbs-value*]

undo qos lr outbound

NOTE

cbs *cbs-value* is not supported on the S5731-H, S5731-S, S5731S-H, and S5731S-S.

Parameters

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR).	The value is an integer, in kbit/s. The value range differs depending on the interface type: ● Interfaces in a port group: 64 to 100000000 ● Other interfaces: 64 to X, where X indicates the maximum rate supported by the interface

Parameter	Description	Value
cbs *cbs-value*	Specifies the committed burst size (CBS).	The value is an integer that ranges from 4000 to 4294967295, in bytes. If this parameter is not specified, the CBS is 125 times the CIR by default. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, CloudEngine S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the maximum CBS is 65535 bytes.

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a large amount of data flows are sent from the upstream device to its downstream device, to prevent congestion or packet loss, run the **qos lr outbound** command to configure traffic shaping on the outbound interface of the device to limit the traffic and burst traffic transmitted over a connection so that packets are sent at an even rate.

Similar to traffic policing, traffic shaping limits the traffic rate. When traffic policing is used, the system directly discards the packets whose rate is larger than the traffic policing rate. Traffic shaping, however, buffers the packets whose rate is larger than the traffic shaping rate. When there are sufficient tokens in the token bucket, the device forwards buffered packets at an even rate. Traffic shaping increases the delay, whereas traffic policing does not.

Precautions

When interface-based NAC authentication is configured and the RADIUS server delivers the rate limit, the interface does not support the rate limit.

If you need to set the same traffic shaping rate on multiple interfaces, you can perform the configuration on a port group to reduce the workload.

If both traffic shaping and queue shaping (configured by using the **qos queue shaping** command) are configured on an interface, the CIR of traffic shaping cannot be lower than the sum of CIR values of all the queues on the interface; otherwise, the traffic shaping result may be incorrect. For example, the queue with a lower priority may occupy the bandwidth of the queue with a higher priority.

Traffic shaping uses the buffer mechanism, thereby increasing the delay.

If you run the **qos lr outbound** command multiple times on the same interface, only the latest configuration takes effect.

After traffic shaping is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

On the S6720S-S, S5735S-H, and S5736-S, the **cbs** *cbs-value* parameter specified in the **qos lr outbound** command does not take effect and has a fixed value of 132000, in bytes.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, and S5720-LI, the maximum value of **cbs** *cbs-value* specified in the **qos lr outbound** command is 16380000, in bytes, even if the specified value is greater than 16380000.

The granularity of traffic policing may increase with the CBS. For the S6735-S, S6720-EI and S6720S-EI, if the CIR is far smaller than the CBS (for example, the CIR is set to 1000 kbit/s and CBS is set to 1000000 bytes), rate limiting may be inaccurate.

If the rate range configured in a version earlier than V200R019C10 exceeds the maximum rate supported by an interface, the corresponding command in the configuration file of the source version can still be delivered after the version is upgraded to V200R019C10 or a later version. However, the maximum rate supported by the interface takes effect.

Example

Set the CIR of data packets sent by the GE0/0/1 to 20000 kbit/s and the CBS to 375000 bytes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos lr outbound cir 20000 cbs 375000
[HUAWEI-GigabitEthernet0/0/1] quit
```

15.3.19 qos lr pps

Function

The **qos lr pps** command rate-limits incoming traffic on a management network interface.

The **undo qos lr pps** command disables rate limiting for incoming traffic on a management network interface.

By default, the rate limit on the management interface is 1000 pps.

NOTE

Only switches with management network interfaces support this command.

Format

qos lr pps *packets*

undo qos lr

Parameters

Parameter	Description	Value
packets	Specifies the maximum number of packets that are allowed to pass per second.	• S6720S-S, S5736-S, and S5735S-H: The value is an integer that ranges from 1 to 2500, in pps. • Other models: The value is an integer that ranges from 1 to 3000, in pps.

Views

MEth interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If there is heavy traffic on the management interface caused by malicious attacks or network exceptions, the CPU is overloaded and services are interrupted. To prevent this problem, run the **qos lr pps** command to rate-limit incoming traffic on a management network interface.

Configuration Impact

If a small rate limit is used, FTP and Telnet functions may be affected.

If you run the **qos lr pps** command multiple times on the same interface, only the latest configuration takes effect.

In a stack, only the management interface of the master switch can reach the value specified by the **qos lr pps** command.

Example

Set the rate limit of MEth0/0/1 to 100 pps.

```
<HUAWEI> system-view
[HUAWEI] interface meth 0/0/1
[HUAWEI-MEth0/0/1] qos lr pps 100
```

15.3.20 qos queue shaping

Function

The **qos queue shaping** command enables traffic shaping for a queue on a specified interface and sets traffic shaping parameters.

The **undo qos queue shaping** command restores the default scheduling parameters of each queue on an interface.

The following table describes the default scheduling parameters on an interface.

Format

qos queue *queue-index* **shaping cir** *cir-value* **pir** *pir-value* [**cbs** *cbs-value* **pbs** *pbs-value*]

undo qos queue *queue-index* **shaping**

NOTE

For the S5731-H, S5731-S, S5731S-H, and S5731S-S, only **pir** *pir-value* takes effect.

Parameters

Parameter	Description	Value
queue-index	Specifies the queue index.	The value is an integer that ranges from 0 to 7.
cir *cir-value*	Specifies the committed information rate (CIR) of a queue.	The value is an integer, in kbit/s. The value range differs depending on the interface type: ● Interfaces in a port group: 0 to 10000000 ● Other interfaces: 0 to X (the actual maximum rate supported by such an interface) The default value is the maximum bandwidth of an interface.

Parameter	Description	Value
pir *pir-value*	Specifies the peak information rate (PIR) of a queue.	The value is an integer, in kbit/s. The value range differs depending on the interface type: ● Interfaces in a port group: 64 to 10000000 ● Other interfaces: 64 to X (the actual maximum rate supported by such an interface) The default value is the maximum bandwidth of an interface. The PIR must be greater than or equal to the CIR. The default PIR is equal to the CIR.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, CloudEngine S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the maximum CBS is 65535 bytes.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. **NOTE** On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, the maximum PBS is 65535 bytes.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the traffic rate of an interface on a downstream device is lower than that of the connected interface on the upstream device, traffic congestion may occur on the interface of the downstream device. You can configure traffic shaping for queues on the outbound interface of the upstream device and adjust the transmit rate of the interface.

The **qos queue shaping** command configures traffic shaping on packets of a specific service on an interface.

Prerequisites

Priority mapping based on simple traffic classification has been configured to map packet priorities to PHBs and colors, or internal priority re-marking based on complex traffic classification has been configured so that packets of different services enter different queues.

Precautions

If traffic shaping is configured both on an interface queue and an interface (using the **qos lr outbound** command), the CIR of the interface cannot be lower than the sum of CIR values of all the queues on the interface; otherwise, traffic shaping result may be incorrect. For example, the queue with a lower priority may occupy the bandwidth of the queue with a higher priority.

It is recommended that the CBS be 120 times the CIR.

After traffic shaping is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

When interface queue shaping is configured on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, only *pir* and *pbs* take effect, and the maximum value of *pbs* is 16380000.

If you run the **qos queue shaping** command multiple times on the same interface, only the latest configuration takes effect.

On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, after traffic shaping is configured, statistics on the number of discarded packets in the **display qos queue statistics** command output may be incorrect upon heavy traffic bursts.

If the rate range configured in a version earlier than V200R019C10 exceeds the maximum rate supported by an interface, the corresponding command in the configuration file of the source version can still be delivered after the version is upgraded to V200R019C10 or a later version. However, the maximum rate supported by the interface takes effect.

Example

Set the CIR of queue 4 on the GE0/0/1 to 10000 kbit/s and the PIR to 20000 kbit/s.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos queue 4 shaping cir 10000 pir 20000
[HUAWEI-GigabitEthernet0/0/1] quit
```

15.3.21 reset qos statistics

Function

The **reset qos statistics** command clears traffic statistics on an interface where rate limiting is performed in the inbound direction.

Format

reset qos statistics interface *interface-type interface-number* **inbound**

reset qos statistics inbound all

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears traffic statistics on a specified interface where rate limiting is performed. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
inbound	Clears traffic statistics in the inbound direction.	-
all	Clears traffic statistics on all interfaces where rate limiting is performed.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before re-collecting traffic statistics on an interface where rate limiting is performed in the inbound direction, run the **reset qos statistics** command to clear existing traffic statistics. Then run the **display qos statistics** command to view the traffic statistics.

Prerequisites

The **qos lr inbound** command has been executed to configure rate limiting in the inbound direction on an interface.

Precautions

If the **qos lr inbound** command is not used, the system displays the following error message when you run the **reset qos statistics interface** *interface-type interface-number* **inbound** command:

```
Error: There is no rate limited configuration inbound in the interface.
```

The cleared statistics cannot be restored. Exercise caution when you use this command.

Example

Clear traffic statistics on GE0/0/1 where rate limiting is performed in the inbound direction.

```
<HUAWEI> reset qos statistics interface gigabitethernet 0/0/1 inbound
```

15.4 Congestion Avoidance and Congestion Management Commands

15.4.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.4.2 color

Function

The **color** command sets parameters of a WRED drop file, including the upper drop threshold, lower drop threshold, and maximum drop probability.

The **undo color** command restores the default settings of a WRED drop profile.

By default, the upper drop threshold, lower drop threshold, and maximum drop probability of a WRED drop profile are all 100.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

color { **green** | **non-tcp** | **red** | **yellow** } **low-limit** *low-limit-percentage* **high-limit** *high-limit-percentage* **discard-percentage** *discard-percentage*

undo color { **green** | **non-tcp** | **red** | **yellow** }

NOTE

Only the S6735-S, S6720-EI, and S6720S-EI support the **non-tcp** parameter.

Parameters

Parameter	Description	Value
green	Sets WRED parameters for green packets.	-
non-tcp	Sets WRED parameters for non-TCP packets.	-
red	Sets WRED parameters for red packets.	-
yellow	Sets WRED parameters for yellow packets.	-
low-limit *low-limit-percentage*	Specifies the lower drop threshold. When the percentage of the packet count in a queue to the queue length reaches this value, the switch starts to discard packets.	The value is an integer that ranges from 0 to 100, in percentage. The default value is 100.
high-limit *high-limit-percentage*	Specifies the upper drop threshold. When the percentage of the packet count in a queue to the queue length reaches this value, the switch discards all subsequent packets.	The value is an integer that ranges from *low-limit-percentage* to 100, in percentage. The default value is 100.
discard-percentage *discard-percentage*	Specifies the maximum drop probability.	The value is an integer that ranges from 1 to 100, in percentage. The default value is 100.

Views

Drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When packets enter a switch, the switch colors packets based on the mappings defined in a DiffServ domain. The system processes the packets of different colors based on the WRED configuration:

- When the queue length reaches the lower drop threshold, the switch discards some packets.
- When the queue length reaches the upper drop threshold, the switch discards all subsequent packets in the queue.

When congestion occurs, the switch first discards packets with the highest drop probability.

Precautions

If multiple interfaces are congested and packets cannot be forwarded at the line rate on some interfaces on the S5731-H, S5731-S, S5731S-H, and S5731S-S, you can run the **display qos queue statistics** command to check queues in which packets are discarded on the congested interfaces and run the **color** command to decrease the upper drop threshold, lower drop threshold, and maximum drop probability. This ensures that packets can be properly forwarded at the line rate on all interfaces.

If you run the **color** command multiple times in the same drop profile view, only the latest configuration takes effect.

Example

Configure WRED drop profile **wred1** in which the lower drop threshold, upper drop threshold, and maximum drop probability of green packets are set to 80, 100, and 10 for green packets, to 60, 80, and 20 for yellow packets, and to 40, 60, and 40 for red packets.

```
<HUAWEI> system-view
[HUAWEI] drop-profile wred1
[HUAWEI-drop-wred1] color green low-limit 80 high-limit 100 discard-percentage 10
[HUAWEI-drop-wred1] color yellow low-limit 60 high-limit 80 discard-percentage 20
[HUAWEI-drop-wred1] color red low-limit 40 high-limit 60 discard-percentage 40
```

15.4.3 display drop-profile

Function

The **display drop-profile** command displays the WRED drop profile configuration.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display drop-profile [**all** | **name** *drop-profile-name*]

Parameters

Parameter	Description	Value
all	Displays detailed information about all WRED drop profiles.	-
name *drop-profile-name*	Displays detailed information about a WRED drop profile with the specified name.	The value must be the name of an existing WRED drop profile.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use the **display drop-profile** command to view the number of configured WRED drop profiles and all configuration of a specified WRED drop profile.

Precautions

If the **all** and **name** *drop-profile-name* parameters are not specified, brief information about all WRED drop profiles is displayed.

Example

Display brief information about all WRED drop profiles on the switch.

```
<HUAWEI> display drop-profile
        index                   drop-profile name
-------------------------------------------------------------------
        0                     default
        1                     dp1
-------------------------------------------------------------------
 Total   64     Used   2
```

Display detailed information about the WRED drop profile named **dp1**.

```
<HUAWEI> display drop-profile name dp1
Drop-profile[1]: dp1
Queue depth    : default
Color     Low-limit   High-limit  Discard-percentage
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Green     60          90          20
Yellow    100         100         100
Red       100         100         100
Non-tcp   100         100         100
-------------------------------------------------------------------
```

Display detailed information about all WRED drop profiles on the switch.

```
<HUAWEI> display drop-profile all
Drop-profile[0]: default
Queue depth    : default
Color     Low-limit   High-limit  Discard-percentage
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Green     100         100         100
Yellow    100         100         100
Red       100         100         100
Non-tcp   100         100         100
-------------------------------------------------------------------
Drop-profile[1]: dp1
Queue depth    : default
Color     Low-limit   High-limit  Discard-percentage
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Green     60          90          20
Yellow    100         100         100
Red       100         100         100
Non-tcp   100         100         100
-------------------------------------------------------------------
```

Table 15-28 Description of the **display drop-profile** command output

Item	Description
index	WRED drop profile index.
drop-profile name	WRED drop profile name. To configure a WRED drop profile, run the **drop-profile** command.
Queue depth	Length of a queue. To configure the length of a queue, run the **queue-depth (WRED drop profile view)** command. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this field.
Total	Total number of WRED drop profiles that can be configured on the switch.
Used	Number of configured WRED drop profiles.
Drop-profile[1]	WRED drop profile name in which 1 indicates the drop profile index.

Item	Description
Color	Color of packets: ● Green ● Yellow ● Red ● Non-tcp To set the color of packets, run the **color** command.
Low-limit	Lower drop threshold, in percentage. To set the lower drop threshold, run the **color** command.
High-limit	Upper drop threshold, in percentage. To set the upper drop threshold, run the **color** command.
Discard-percentage	Maximum drop probability, in percentage. To set the maximum drop probability, run the **color** command.

15.4.4 display qos micro-burst peak-buffer verbose interface

Function

The **display qos micro-burst peak-buffer verbose interface** command displays the peak buffer usage and the buffer usage of queues on an interface.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display qos micro-burst peak-buffer verbose interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Displays buffer information on a specified interface. - *interface-type* specifies an interface type. - *interface-number* specifies an interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display qos micro-burst peak-buffer verbose interface** *interface-type interface-number* command displays the peak buffer usage and the buffer usage of queues on an interface.

Prerequisites

1. The microburst detection function has been enabled on the switch by running the **qos micro-burst detection** [**enhanced**] **enable slot** *slot-id* command in the system view.
2. The microburst detection function has been enabled on an interface by running the **qos micro-burst detection enable** command in the interface view.

Example

In default microburst detection mode, display the peak buffer usage and the buffer usage of queues on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] qos micro-burst detection enable slot 0
[HUAWEI] interface gigabitEthernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos micro-burst detection enable
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] quit
<HUAWEI> display qos micro-burst peak-buffer verbose interface GigabitEthernet 0/0/1
--------------------------------------------------------------------------------------------------------------
P-Buffer     Queue0    Queue1    Queue2    Queue3    Queue4    Queue5    Queue6    Queue7
DateTime
(KB)           (KB)      (KB)      (KB)      (KB)      (KB)      (KB)      (KB)      (KB)
```

```
---------------------------------------------------------------------------------------------------------------
4099            0        0        0        0      4099        0        0        0  2019-08-27 08:43:17
---------------------------------------------------------------------------------------------------------------
```

Table 15-29 Description of the **display qos micro-burst peak-buffer verbose interface** command output

Item	Description
P-Buffer(KB)	Peak value of the buffer usage on the interface.
Queue0(KB)	Buffer usage of queue 0.
Queue1(KB)	Buffer usage of queue 1.
Queue2(KB)	Buffer usage of queue 2.
Queue3(KB)	Buffer usage of queue 3.
Queue4(KB)	Buffer usage of queue 4.
Queue5(KB)	Buffer usage of queue 5.
Queue6(KB)	Buffer usage of queue 6.
Queue7(KB)	Buffer usage of queue 7.
DateTime	Time when the device recorded the entry.

15.4.5 display qos micro-burst statistics interface

Function

The **display qos micro-burst statistics interface** command displays statistics about microburst detection on an interface.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display qos micro-burst statistics interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Displays statistics on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

In default microburst detection mode, the packet sampling interval is 5 ms. In enhanced microburst detection mode, the packet sampling interval is 1 ms.

The microburst detection period is 5 minutes. That is, key performance indicators of an interface are collected every 5 minutes and related entries are generated. You can run the **display qos micro-burst statistics interface** *interface-type interface-number* command to view statistics collected within the most recent 300 minutes after microburst detection is enabled on an interface, including the average rate of burst traffic, maximum rate of burst traffic, number of discarded packets, average buffer usage on the interface, peak buffer usage on the interface, and entry generation time.

Prerequisites

1. The microburst detection function has been enabled on the device by running the **qos micro-burst detection** [**enhanced**] **enable slot** *slot-id* command in the system view.
2. The microburst detection function has been enabled on an interface by running the **qos micro-burst detection enable** command in the interface view.

Precautions

The average buffer usage and peak buffer usage on an interface cannot be checked on the S5731-H, S5731-S, S5731S-S, and S5731S-H.

Example

In default microburst detection mode, display microburst detection statistics on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] qos micro-burst detection enable slot 0
[HUAWEI] interface gigabitEthernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos micro-burst detection enable
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] quit
<HUAWEI> display qos micro-burst statistics interface GigabitEthernet 0/0/1
----------------------------------------------------------------------------------------------------
A-Rate          P-Rate          Discard         A-Buffer        P-Buffer              DateTime
(bps)           (bps)          Packets            (KB)            (KB)
----------------------------------------------------------------------------------------------------
840385600       845712000         29956755            2503            2507      2019-09-28 14:54:43
840561600       845712000         13524346            2503            2507      2019-09-28 14:49:43
----------------------------------------------------------------------------------------------------
```

Table 15-30 Description of the **display qos micro-burst statistics interface** command output

Item	Description
A-Rate(bps)	Average rate of packets forwarded to an interface from any other interfaces on the same device, in bit/s.
P-Rate(bps)	Peak rate of packets forwarded to an interface from any other interfaces on the same device, in bit/s.
Discard Packets	Number of discarded packets.
A-Buffer(KB)	Average buffer usage, in kilobytes.
P-Buffer(KB)	Peak buffer usage, in kilobytes.
DateTime	Time when an entry is generated.

15.4.6 display qos micro-burst status all

Function

The **display qos micro-burst status all** command displays information about all interfaces enabled with microburst detection and packet loss information on the interfaces.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display qos micro-burst status all [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display qos micro-burst status all** [**slot** *slot-id*] command to view information about all interfaces enabled with microburst detection and packet loss information on the interfaces.

Prerequisites

1. The microburst detection function has been enabled on the switch by running the **qos micro-burst detection** [**enhanced**] **enable slot** *slot-id* command in the system view.
2. The microburst detection function has been enabled on an interface by running the **qos micro-burst detection enable** command in the interface view.

Example

In default microburst detection mode, display all interfaces enabled with microburst detection and packet loss information on the interfaces.

```
<HUAWEI> system-view
[HUAWEI] qos micro-burst detection enable slot 0
[HUAWEI] interface gigabitEthernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos micro-burst detection enable
[HUAWEI-GigabitEthernet0/0/1] quit
<HUAWEI> display qos micro-burst status all
Slot 0                  Mode:default(5ms)
------------------------------------------
Interface               Discard(Packets)
------------------------------------------
GigabitEthernet0/0/1                 0
```

Table 15-31 Description of the **display qos micro-burst status all** command output

Item	Description
Slot	ID of a slot enabled with microburst detection.
Mode	Microburst detection mode: - default(5ms): In default mode, the packet sampling interval is 5 ms. - enhanced(1ms): In enhanced mode, the packet sampling interval is 1 ms.
Interface	Interface enabled with microburst detection.
Discard(Packets)	Number of discarded packets.

15.4.7 display qos queue statistics

Function

The **display qos queue statistics** command displays queue-based traffic statistics on an interface.

Format

display qos queue statistics interface *interface-type interface-number* [**queue** *queue-index*]

display qos queue statistics all

Parameters

Parameter	Description	Value
queue *queue-index*	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
interface *interface-type interface-number*	Displays queue-based traffic statistics on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
all	Displays queue-based traffic statistics on all interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check whether packets in each queue on an interface are forwarded or discarded due to congestion, run this command to check statistics on each queue on the interface.

To collect queue-based statistics within a certain period, first run the **reset qos queue statistics** command to clear the existing statistics.

The function of displaying queue-based traffic statistics is unavailable to stack ports.

Example

Display queue-based traffic statistics on the GE0/0/1 on the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

```
<HUAWEI> display qos queue statistics interface gigabitethernet 0/0/1
--------------------------------------------------------
 Queue ID          : 0
 CIR(kbps)         : 0

15.4.8 drop-profile

Function

The **drop-profile** command creates a WRED drop profile and displays the WRED drop profile view, or displays the existing WRED drop profile view.

The **undo drop-profile** command deletes a WRED drop profile.

By default, the system provides a WRED drop profile named **default**.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

drop-profile *drop-profile-name*

undo drop-profile *drop-profile-name*

Parameters

Parameter	Description	Value
drop-profile-name	Specifies the name of a WRED drop profile.	The value is a string of 1 to 31 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A WRED drop profile defines WRED parameters for packets of different priorities. After the WRED drop profile is applied to an interface or queues on an interface, congestion avoidance is implemented. The **drop-profile** command creates a WRED drop profile or displays the WRED drop profile view.

Precautions

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support a maximum of 16 WRED drop profiles, and other switches support a maximum of 64 WRED drop profiles, including the default drop profile. The default drop profile can be modified but cannot be deleted.

Follow-up Procedure

1. Set parameters for the WRED drop profile.

   Run the **color** command in the WRED drop profile view to set WRED parameters for packets of different priorities.
2. Apply the WRED drop profile to an interface or queues on an interface.

Example

Create a WRED drop profile named **drop1** and enter the WRED drop profile view.

```
<HUAWEI> system-view
[HUAWEI] drop-profile drop1
[HUAWEI-drop-drop1]
```

15.4.9 qos burst-mode (interface view)

Function

The **qos burst-mode** command configures a burst traffic buffer mode on an interface.

The **undo qos burst-mode** command restores the default burst traffic buffer mode on an interface.

By default, an interface uses the standard mode.

NOTE

Only the S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

qos burst-mode { **enhanced** | **extreme** }

undo qos burst-mode { **enhanced** | **extreme** }

Parameters

Parameter	Description	Value
enhanced	Indicates the enhanced burst traffic buffer mode.	-
extreme	Indicates the extreme burst traffic buffer mode.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Scenario

The buffer size on an interface is small, and traffic on the live network is not always stable. When the traffic rate on an interface reaches 50% to 60% of the interface bandwidth, packet loss may occur. The burst traffic buffer mode enables an interface to occupy more available buffer space in the system to process burst traffic, improving a switch's packet processing performance.

The device buffer is allocated in static and dynamic modes. By default, each interface is allocated some static buffer space for the basic buffer requirement. The remaining buffer space is used as the dynamic buffer for a switch.

In standard mode, an interface can occupy only some dynamic buffer space on the switch.

In enhanced mode, an interface can occupy only some dynamic buffer space on the switch, and more dynamic buffer space than that in standard mode.

In extreme mode, an interface occupies the dynamic buffer space as well as static buffer space on interfaces in non-extreme mode.

Precautions

The **qos burst-mode (interface view)** and **qos queue buffer shared-ratio** commands cannot be used on the same interface.

When the enhanced mode is used, the **qos burst-mode (interface view)** and **qos burst-mode (system view)** commands cannot be used together.

The **extreme** mode is not recommended because forwarding of other interfaces may be affected and QoS results such as scheduling and shaping results may be incorrect.

The **extreme** mode is used only when the switch uses one or two interfaces. This mode takes effect only when it is configured globally and on an interface. If the **extreme** mode is configured globally but is not configured on an interface, traffic forwarding may be abnormal and multicast packets may fail to be obtained. If the **extreme** mode is configured on an interface but is not configured globally, the **extreme** mode does not take effect.

When the **extreme** mode is configured globally, the interface where the **extreme** mode is not configured cannot be used as a service interface.

Example

Configure the enhanced burst traffic buffer mode on the GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos burst-mode enhanced
```

15.4.10 qos burst-mode (system view)

Function

The **qos burst-mode** command configures a burst traffic buffer mode on a switch.

The **undo qos burst-mode** command restores the default burst traffic buffer mode on a switch.

By default, the switch uses the standard mode.

NOTE

Only the S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

qos burst-mode { **enhanced** | **extreme** } **slot** *slot-id*

undo qos burst-mode { **enhanced** | **extreme** } **slot** *slot-id*

Parameters

Parameter	Description	Value
enhanced	Indicates the enhanced burst traffic buffer mode.	-
extreme	Indicates the extreme burst traffic buffer mode.	-
slot *slot-id*	The default value of *slot-id* is 0 on a non-stacked switch. *slot-id* specifies the stack ID.	-

Views

System view

2: Configuration level

Usage Guidelines

Scenario

By default, the buffer size on an interface is small. When the traffic rate on an interface reaches 50% to 60% of the interface bandwidth, packet loss occurs on the interface. After the burst traffic buffer mode is configured on a switch, all interfaces on the switch can occupy more buffer space in the system to process burst traffic, improving a switch's packet processing performance.

The device buffer is allocated in static and dynamic modes. By default, each interface is allocated some static buffer space for the basic buffer requirement. The remaining buffer space is used as the dynamic buffer for a switch.

In standard mode, an interface can occupy only some dynamic buffer space on the switch.

In enhanced mode, an interface can occupy only some dynamic buffer space on the switch, and more dynamic buffer space than that in standard mode.

In extreme mode, an interface occupies the dynamic buffer space as well as static buffer space on interfaces in non-extreme mode.

Precautions

The **qos burst-mode (system view)** and **qos queue buffer shared-ratio** commands cannot be used on the switch simultaneously.

The **extreme** mode is not recommended because forwarding of other interfaces may be affected and QoS results such as scheduling and shaping results may be incorrect.

The **extreme** mode is used only when the switch uses one or two interfaces. This mode takes effect only when it is configured globally and on an interface. If the **extreme** mode is configured globally but is not configured on an interface, traffic forwarding may be abnormal and multicast packets may fail to be obtained. If the **extreme** mode is configured on an interface but is not configured globally, the **extreme** mode does not take effect.

When the **extreme** mode is configured globally, the interface where the **extreme** mode is not configured cannot be used as a service interface.

Example

Configure the enhanced burst traffic buffer mode in slot 0.

```
<HUAWEI> system-view
[HUAWEI] qos burst-mode enhanced slot 0
```

15.4.11 qos dynamic-buffer enable

Function

The **qos dynamic-buffer enable** command enables dynamic queue buffer adjustment.

The **undo qos dynamic-buffer enable** command disables dynamic queue buffer adjustment.

By default, the device does not dynamically adjust the queue buffer.

NOTE

This command is available only on the following switch models:

S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S

Format

qos dynamic-buffer enable

undo qos dynamic-buffer enable

Parameters

None

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If congestion occurs, the switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos dynamic-buffer enable** command to enable dynamic queue buffer adjustment. This ensures that a queue has sufficient buffer space, preventing packets from being discarded. To configure the interval for dynamically adjusting the queue buffer, run the **qos dynamic-buffer interval** command; to configure the maximum buffer size of a queue for which dynamic buffer adjustment is enabled, run the **qos dynamic-buffer maximum** command.

Precautions

This command takes effect only when multicast entries exist.

Example

Enable the dynamic queue buffer adjustment function.

```
<HUAWEI> system-view
[HUAWEI] qos dynamic-buffer enable
```

15.4.12 qos dynamic-buffer interval

Function

The **qos dynamic-buffer interval** command configures the interval for dynamically adjusting the queue buffer.

The **undo qos dynamic-buffer interval** command restores the default interval for dynamically adjusting the queue buffer.

By default, the device dynamically adjusts the queue buffer at an interval of 100 ms.

NOTE

This command is available only on the following switch models:

S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S

Format

qos dynamic-buffer interval *interval-value*

undo qos dynamic-buffer interval

Parameters

Parameter	Description	Value
interval-value	Specifies the interval for dynamically adjusting the queue buffer.	The value is an integer in the range from 1 to 10000, in milliseconds.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If congestion occurs, the switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos dynamic-buffer enable** command to enable dynamic queue buffer adjustment. This ensures that a queue has sufficient buffer space, preventing packets from being discarded. You can run the **qos dynamic-buffer interval** command to configure the interval for dynamically adjusting the queue buffer. A shorter interval indicates that the device performs dynamic adjustment of the queue buffer more frequently.

Precautions

This command takes effect only after the **qos dynamic-buffer enable** command is run to enable dynamic queue buffer adjustment.

Example

Set the interval for dynamically adjusting the queue buffer to 1000 ms.

```
<HUAWEI> system-view
[HUAWEI] qos dynamic-buffer interval 1000
```

15.4.13 qos dynamic-buffer maximum

Function

The **qos dynamic-buffer maximum** command configures the maximum buffer size of a queue for which dynamic buffer adjustment is enabled.

The **undo qos dynamic-buffer maximum** command restores the default maximum buffer size of a queue for which dynamic buffer adjustment is enabled.

By default, the maximum buffer size of a queue for which dynamic buffer adjustment is enabled is 320 cells. The size of a cell is 128 bytes.

NOTE

This command is available only on the following switch models:

S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S

Format

qos dynamic-buffer maximum *maximum*

undo qos dynamic-buffer maximum

Parameters

Parameter	Description	Value
maximum	Specifies the maximum buffer size of a queue for which dynamic buffer adjustment is enabled.	The value is an integer in the range from 10 to 3500, in cells. The size of a cell is 128 bytes.

Views

System view

Usage Scenario

If congestion occurs, the switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos dynamic-buffer enable** command to enable dynamic queue buffer adjustment. This ensures that a queue has sufficient buffer space, preventing packets from being discarded. You can run the **qos dynamic-buffer maximum** command to configure the maximum buffer size of a queue for which dynamic buffer adjustment is enabled.

Precautions

This command takes effect only after the **qos dynamic-buffer enable** command is run to enable dynamic queue buffer adjustment.

Example

Set the maximum buffer size of a queue for which dynamic buffer adjustment is enabled to 100, in cells.

```
<HUAWEI> system-view
[HUAWEI] qos dynamic-buffer maximum 100
```

15.4.14 qos micro-burst detection enable

Function

The **qos micro-burst detection enable** command enables microburst detection.

The **undo qos micro-burst detection enable** command disables microburst detection.

By default, microburst detection is disabled on a switch and interfaces.

NOTE

Only the S5731-H, S5731-S, S5731S-S, S5731S-H, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

System view:

qos micro-burst detection [**enhanced**] **enable slot** *slot-id*

undo qos micro-burst detection [**enhanced**] **enable slot** *slot-id*

Interface view:

qos micro-burst detection enable

undo qos micro-burst detection enable

Parameters

Parameter	Description	Value
enhanced	Enables microburst detection in enhanced mode. If this parameter is not specified, microburst detection in default mode is enabled.	-
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Views

System view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To detect microbursts on an outbound interface, you must enable microburst detection on a switch and interfaces. This helps locate packet loss caused by microbursts.

In default microburst detection mode, the packet sampling interval is 5 ms. In enhanced microburst detection mode, the packet sampling interval is 1 ms.

Precautions

Before enabling microburst detection on an interface, you must enable this function on the slot where the interface resides.

In default microburst detection mode, microburst detection can be enabled on multiple interfaces on a switch. In enhanced microburst detection mode, microburst detection can be enabled on only one interface on a switch.

To change the mode of microburst detection, you must delete the existing microburst detection configuration from the switch.

Example

Enable microburst detection in default mode in slot 0 on the switch, and enable microburst detection on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] qos micro-burst detection enable slot 0
[HUAWEI] interface GigabitEthernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos micro-burst detection enable
```

15.4.15 qos { pq | wrr | drr }

Function

The **qos** { **pq** | **wrr** | **drr** } command configures a scheduling mode for queues on an interface.

The **undo qos** { **pq** | **wrr** | **drr** } command restores the default scheduling mode of queues on an interface.

By default, the scheduling mode of queues on an interface of the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S is WDRR, and the scheduling mode of queues on an interface of other models is WRR.

Format

qos { **pq** | **wrr** | **drr** }

undo qos { **pq** | **wrr** | **drr** }

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command in interface mode.

Only the S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI support this command using a schedule template.

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support **wrr**.

Parameters

Parameter	Description	Value
pq	Indicates the PQ scheduling mode.	-
wrr	Indicates the WRR scheduling mode.	-
drr	Indicates the WDRR scheduling mode.	-

Views

GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Scheduling profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When congestion occurs on a network, configure a combination of queue scheduling modes to adjust the delay and jitter of various service packets as follows:

- Packets of delay-sensitive services, such as the voice and video services, are processed preferentially.
- Among the delay-insensitive services, such as the email service, the packets with the same priority are processed equally and the packets with different priorities are processed based on their weights.

The switch supports PQ+WRR and PQ+WDRR. When a combination of queue scheduling modes is used, the switch first schedules the packets in queues using PQ scheduling. When all packets in the queues using PQ scheduling are sent out, the switch schedules the packets in queues using WRR or WDRR scheduling. Packets from the queues using PQ scheduling are scheduled based on packet priorities.

Precautions

- Before configuring a queue scheduling mode, map packet priorities to PHBs and colors or re-mark local priorities of packets. The packets of different priorities enter different queues.
- To set the same queue scheduling mode on multiple interfaces, perform the configuration on a port group to reduce the workload.
- When the scheduling mode of queues on an interface is set to PQ+WRR or PQ +WDRR, a queue can use only one scheduling mode. If you set multiple scheduling modes for a queue, only the latest configuration takes effect.
- If the queue scheduling mode is set to WDRR or WRR on an interface on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735-S-I, and S5735S-S, other interfaces on the switch use the same queue scheduling mode as this interface.
- On the S6720S-S, S5735S-H, and S5736-S, the WRR scheduling changed from WDRR scheduling takes effect only after the switch runs for a period with traffic transmitted.
- For GE interfaces (including XGE interfaces configured with GE optical modules) on the S5731-H, S5731-S, S5731S-H, and S5731S-S, if severe congestions occur, queue scheduling is inaccurate on these interfaces, and traffic forwarding may even be interrupted in some low-priority queues. To prevent this, you are advised to configure congestion avoidance.

Example

Set the scheduling mode of queues on GE0/0/1 of the S5732-H to PQ.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos pq
```

Set the scheduling mode of queues on GE0/0/1 of the S5720-LI to WDRR.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
[HUAWEI-qos-schedule-profile-test] qos drr
[HUAWEI-qos-schedule-profile-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos schedule-profile test
```

15.4.16 qos queue buffer shared-ratio

Function

The **qos queue buffer shared-ratio** command sets the maximum ratio of the dynamic buffer occupied by a queue on an interface.

The **undo qos queue buffer shared-ratio** command restores the default maximum ratio of the dynamic buffer occupied by a queue on an interface.

By default, the maximum ratio of the dynamic buffer occupied by a queue on an interface of the S6735-S, S6720-EI and S6720S-EI is 20%.

NOTE

Only the S6735-S, S6720-EI and S6720S-EI support this command.

Format

qos queue *queue-index* **buffer shared-ratio** *ratio-value*

undo qos queue *queue-index* **buffer shared-ratio**

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
ratio-value	Specifies the maximum ratio of the dynamic buffer occupied by a queue on an interface, in percentage.	The value is an integer that ranges from 1 to 90.

Views

GE interface view, XGE interface view, 40GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the buffer of an interface is small. When the traffic rate on an interface reaches 50% to 60% of the interface bandwidth, packets are lost on the interface. The switch uses static and dynamic modes to allocate the buffer. The switch allocates specified static buffer to each interface, and the remaining buffer is used as the dynamic buffer. When there is heavy burst traffic in a queue on an interface, you can run the **qos queue buffer shared-ratio** command to increase the maximum ratio of the dynamic buffer occupied by the queue. The switch allocates larger dynamic buffer to the queue to reduce packet loss on the queue.

Precautions

The available dynamic buffer on each interface is limited. When a queue on an interface occupies more dynamic buffer, there is less dynamic buffer that can be occupied by other queues on the interface. As a result, the queues' capability to forward burst traffic is lowered.

The **qos queue buffer shared-ratio** and **qos burst-mode (system view)** commands cannot be configured on the switch simultaneously.

The **qos queue buffer shared-ratio** and **qos burst-mode (interface view)** commands cannot be configured on the same interface simultaneously.

Example

Set the maximum ratio of the dynamic buffer occupied by queue 3 on the GE0/0/1 to 35%.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos queue 3 buffer shared-ratio 35
```

15.4.17 qos queue drr

Function

The **qos queue drr** command sets the WDRR weight of queues that participate in WDRR scheduling.

The **undo qos queue drr** command restores the default WDRR weight of queues that participate in WDRR scheduling.

By default, the WDRR weight of queues that participate in WDRR scheduling is 1.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command in interface mode.

Format

qos queue *queue-index* **drr weight** *weight*

undo qos queue *queue-index* **drr**

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
weight *weight*	Specifies a WDRR weight.	The value is an integer that ranges from 0 to 127.

Views

GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, port group view, Scheduling profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WDRR schedules packets based on the packet length used as the weight. If the packet length is too long, WDRR allows the negative weight value so that long packets can be scheduled. In the next round, the queue with the negative weight value is not scheduled until its weight value becomes positive.

WDRR offsets the disadvantages of PQ scheduling and WRR scheduling. In PQ scheduling, packets in queues with lower priorities cannot be scheduled for a long time if congestion occurs. In WRR scheduling, bandwidth is allocated improperly when the packet length of each queue is different or variable.

When WDRR scheduling is used, set the weight for each queue. The switch schedules queues in turn according to the weights.

Precautions

When WDRR scheduling is applied and the weight of a queue is set to 0, the queue uses PQ scheduling and the scheduling mode is PQ+WDRR.

For the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI:

- When configuring the PQ+WDRR scheduling mode, ensure that queues with weight 0 (queues using PQ scheduling) are consecutively configured, without being interrupted by the configuration of the queues using WDRR scheduling.
- If PQ+WDRR scheduling is used and the numbers of the queues using PQ scheduling are consecutive (for example, queue 0, queues 0 and 1, and queues 0 to 2), the device schedules packets in queues using PQ scheduling after scheduling for the packets in queues using WDRR scheduling is completed.

On the S6735-S, S6720-EI and S6720S-EI, if the queue scheduling mode is changed or the weight is changed during queue scheduling, packet loss occurs within 20 ms.

To set the same WDRR weight on multiple interfaces, perform the configuration on a port group to reduce the workload.

Example

Set the WDRR weight of queue 4 on GE0/0/1 of the S5732-H to 9.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos drr
[HUAWEI-GigabitEthernet0/0/1] qos queue 4 drr weight 9
```

Set the WDRR weight of queue 4 on GE0/0/1 of the S5720-LI to 9.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
[HUAWEI-qos-schedule-profile-test] qos drr
[HUAWEI-qos-schedule-profile-test] qos queue 4 drr weight 9
[HUAWEI-qos-schedule-profile-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos schedule-profile test
```

15.4.18 qos queue low-limit high-limit

Function

The **qos queue low-limit high-limit** command sets the upper and lower limits for buffering packets in a queue.

The **undo qos queue low-limit high-limit** command restores the default values of the upper and lower limits for buffering packets in a queue.

By default, the upper and lower limits for buffering packets in a queue are 78 and 68 buffer units, respectively. Each buffer unit is 360 bytes.

NOTE

Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S support this command.

Format

qos queue *queue-index* **low-limit** *low-limit-pages* **high-limit** *high-limit-pages*

undo qos queue *queue-index* [**low-limit** *low-limit-pages* **high-limit** *high-limit-pages*]

Parameters

Parameter	Description	Value
queue *queue-index*	Specifies the index of a queue.	The value is an integer in the range from 0 to 7.
low-limit *low-limit-pages*	Specifies the lower limit for buffering packets in a queue.	The value is an integer in the range from 1 to 5000. Each buffer unit is 360 bytes.
high-limit *high-limit-pages*	Specifies the upper limit for buffering packets in a queue.	The value is an integer in the range from the value of **low-limit** *low-limit-pages* to 5000. Each buffer unit is 360 bytes.

Views

Tail drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When congestion occurs, a switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos queue low-limit high-limit** command to set the upper limit and lower limit for buffering packets in a specified queue on an interface so that the queue has sufficient buffer, preventing packet loss.

When the size of packets in the queue buffer is always lower than or equal to the lower limit (**low-limit** *low-limit-pages*), the switch does not discard any packet. When the size of packets in the buffer increases and is greater than the lower limit:

- If the size of packets in the queue buffer is always less than or equal to the upper limit (**high-limit** *high-limit-pages*), the switch does not discard any packet.
- If the size of packets in the buffer increases gradually or even exceeds the upper limit, the switch discards the packets in the buffer until the size of packets in the queue does not exceed the lower limit.

Prerequisites

A tail drop profile has been created using the **qos tail-drop-profile (system view)** command. Only one tail drop profile can be created on the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S.

Example

Create a global tail drop profile named **test**, and set the lower limit and upper limit to 100 and 120 buffer units, respectively, for queue 0.

```
<HUAWEI> system-view
[HUAWEI] qos tail-drop-profile test
[HUAWEI-tail-drop-profile-test] qos queue 0 low-limit 100 high-limit 120
```

15.4.19 qos queue max-buffer

Function

The **qos queue max-buffer** command sets the maximum number of bytes in all packets to be cached in a queue.

The **undo qos queue max-buffer** command restores the default maximum number of bytes in all packets to be cached in a queue.

The **qos queue green max-buffer** command sets the maximum number of bytes in green packets to be cached in a queue.

The **undo qos queue green max-buffer** command restores the default maximum number of bytes in green packets to be cached in a queue.

By default, the maximum buffer size of all packets in a queue is 24 and the maximum buffer size of green packets in a queue is 12, in cells. The size of a cell is 128 bytes.

NOTE

Only the S1720GW-E, S1720GWR-E, S300, S500, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S6720S-S, and S5736-S support this command.

Format

qos queue *queue-index* **max-buffer** *cell-number* [**green max-buffer** *cell-number*]

undo qos queue *queue-index* **max-buffer** [*cell-number* **green max-buffer** *cell-number* | **green max-buffer**]

qos queue *queue-index* **green max-buffer** *cell-number*

undo qos queue *queue-index* **green max-buffer**

Parameters

Parameter	Description	Value
queue *queue-index*	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
max-buffer *cell-number*	Specifies the maximum number of bytes in all packets to be cached in a queue.	The value is an integer, in cells. The value range is as follows: ● S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, and S5720-LI: from 1 to 5444. ● S5735S-H, S6720S-S, and S5736-S from 1 to 10000. The size of a cell is 128 bytes.
green max-buffer *cell-number*	Specifies the maximum number of bytes in green packets to be cached in a queue.	The value is an integer, in cells. The value range is as follows: ● S5735S-H, S6720S-S, and S5736-S: from 1 to 10000. ● Other models except the S5735S-H, S6720S-S, and S5736-S: from 1 to 5444. The size of a cell is 128 bytes.

Views

Tail drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When congestion occurs, the switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos queue max-buffer** command to set the maximum number of bytes in all packets or green packets to be cached in a queue so that the queue has sufficient buffer, preventing packet loss.

Prerequisites

A tail drop profile has been created using the **qos tail-drop-profile (system view)** command.

Precautions

You can also use the **qos queue max-length** command to set the maximum number of packets to be cached in a queue. If the maximum number of bytes or packets is reached, the device considers that congestion occurs and will discard subsequent packets.

Example

Create a global tail drop profile named **test**, and then set the maximum buffer size of all packets in a BE queue for the global tail drop profile to 100, in cells.

```
<HUAWEI> system-view
[HUAWEI] qos tail-drop-profile test
[HUAWEI-tail-drop-profile-test] qos queue 0 max-buffer 100
```

15.4.20 qos queue max-length

Function

The **qos queue max-length** command sets the maximum number of packets allowed in a queue.

The **undo qos queue max-length** command restores the default maximum number of packets allowed in a queue.

The **qos queue green max-length** command sets the maximum number of green packets allowed in a queue.

The **undo qos queue green max-length** command restores the default maximum number of green packets allowed in a queue.

By default, the maximum buffer size of all packets in a queue is 22 and the maximum buffer size of green packets in a queue is 11, in packets.

NOTE

Only the S1720GW-E, S1720GWR-E, S300, S500, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S6720S-S, and S5736-S support this command.

Format

qos queue *queue-index* **max-length** *packet-number* [**green max-length** *packet-number*]

undo qos queue *queue-index* **max-length** [*packet-number* **green max-length** *packet-number* | **green max-length**]

qos queue *queue-index* **green max-length** *packet-number*

undo qos queue *queue-index* **green max-length**

Parameters

Parameter	Description	Value
queue *queue-index*	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
max-length *packet-number*	Specifies the maximum number of packets allowed in a queue.	The value is an integer, in packets. The value range is as follows: ● S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, and S5720-LI: from 1 to 5134. ● S5735S-H, S6720S-S, and S5736-S from 1 to 10000.
green max-length *packet-number*	Specifies the maximum number of green packets to be cached in a queue.	The value is an integer, in packets. The value range is as follows: ● S5735S-H, S6720S-S, and S5736-S: from 1 to 10000. ● Other models except the S5735S-H, S6720S-S, and S5736-S: from 1 to 5134.

Views

Tail drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When congestion occurs, the switch uses the tail drop method. When the queue length reaches the upper limit, excess packets (buffered at the queue tail) are discarded until congestion is removed. You can run the **qos queue max-length** command to set the maximum number of packets to be cached in a specified queue on an interface so that the queue has sufficient buffer, preventing packet loss.

Prerequisites

A tail drop profile has been created using the **qos tail-drop-profile (system view)** command.

Precautions

You can also run the **qos queue max-buffer** command to set the maximum number of bytes in all packets to be cached in a queue. If the maximum number of bytes or packets is reached, the device considers that congestion occurs and will discard subsequent packets.

Example

Create a global tail drop template named **test** and set the maximum number of packets to be cached in queue 0 for the global tail drop template to 200.

```
<HUAWEI> system-view
[HUAWEI] qos tail-drop-profile test
[HUAWEI-tail-drop-profile-test] qos queue 0 max-length 200
```

15.4.21 qos queue statistics interval

Function

The **qos queue statistics interval** command sets the interval for checking the rate of discarded packets in a queue.

The **undo qos queue statistics interval** command restores the default interval.

By default, the rate of discarded packets in a queue is checked every 300 seconds.

Format

qos queue statistics interval *interval-value*

undo qos queue statistics interval

Parameters

Parameter	Description	Value
interval-value	Specifies the interval for checking the rate of discarded packets in a queue.	The value is an integer that ranges from 60 to 600, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch is managed by a network management system (NMS), the MIB module checks the rate of discarded packets in each queue at intervals and sends the rate to the NMS. You can view the rate of discarded packets in each queue to analyze network performance or locate faults. The **qos queue statistics interval** command sets the interval. The MIB module calculates the average rate at which packets in a queue are discarded at an interval.

Example

Set the interval for checking the rate of discarded packets in a queue to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] qos queue statistics interval 100
```

15.4.22 qos queue wred

Function

The **qos queue wred** command applies a Weighted Random Early Detection (WRED) drop profile to the system or an interface queue.

The **undo qos queue wred** command deletes a WRED drop profile from the system or an interface queue.

By default, no WRED drop profile is applied to the system or an interface queue.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

A WRED drop profile cannot be applied to interfaces 1 to 12 on the S5732-H48S6Q, S5732-H48UM2CC, S5732-H48XUM2CC, and S6730-H48X6C.

Format

qos queue *queue-index* **wred** *drop-profile-name*

undo qos queue *queue-index* **wred**

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
drop-profile-name	Specifies the name of a WRED drop profile.	The value must be the name of an existing WRED drop profile.

Views

System view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Tail drop technology processes all packets in the same manner without classifying the packets. When the queue length reaches its maximum value, the packets that were added last (at the tail of the queue) are discarded. This packet drop policy may cause global TCP synchronization. As a result, TCP connections cannot be set up.

Random Early Detection (RED) and WRED are used to avoid global TCP synchronization.

RED and WRED randomly discard packets to prevent global TCP synchronization. When packets of a TCP connection are discarded, packets of other TCP connections can still be sent at a high rate, ensuring bandwidth use efficiency.

Prerequisites

A WRED drop profile has been created using the **drop-profile** command.

Precautions

On the switch, you can apply a WRED drop profile to an interface, the system, or a queue on an interface.

If a WRED drop profile is applied to the system and an interface simultaneously, the WRED drop profile applied to the interface takes effect. After a WRED drop profile is applied to the system, it takes effect on all the interfaces.

If you apply a WRED drop profile to an interface and a queue on an interface simultaneously, the system matches the packets with the profiles applied to the queue and interface in sequence. Then the switch performs congestion avoidance on the packets that match the WRED drop profile.

To apply the same WRED drop profile to queues with the same index on multiple interfaces, perform the configuration on a port group to reduce the workload.

Example

Create a WRED drop profile named **wred1** and apply it to queue 1 on the GE0/0/1.

```
<HUAWEI> system view
[HUAWEI] drop-profile wred1
[HUAWEI-drop-wred1] color green low-limit 80 high-limit 100 discard-percentage 10
[HUAWEI-drop-wred1] color yellow low-limit 60 high-limit 80 discard-percentage 20
[HUAWEI-drop-wred1] color red low-limit 40 high-limit 60 discard-percentage 40
[HUAWEI-drop-wred1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos queue 1 wred wred1
```

15.4.23 qos queue wrr

Function

The **qos queue wrr** command sets the WRR weight of queues that participate in WRR scheduling.

The **undo qos queue wrr** command restores the default WRR weight of queues that participate in WRR scheduling.

By default, the WRR weight of queues that participate in WRR scheduling is 1.

Format

qos queue *queue-index* **wrr weight** *weight*

undo qos queue *queue-index* **wrr**

NOTE

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support this command.

Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, and S6720S-EI support this command in interface mode.

Only the S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI support this command using a schedule template.

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.

Parameter	Description	Value
weight *weight*	Specifies a WRR weight.	The value is an integer that ranges from 0 to 127.

Views

GE interface view, XGE interface view, 40GE interface view, 100GE interface view, port group view, Scheduling profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Weighted Round Robin (WRR) ensures that packets in all the queues are scheduled in turn.

When using WRR scheduling, set the weight for each queue. The switch schedules queues in turn according to the weights.

Precautions

When WRR scheduling is applied and the weight of a queue is set to 0, the queue uses PQ scheduling and the scheduling mode is PQ+WRR.

For the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI:

- When configuring the PQ+WRR scheduling mode, ensure that queues with weight 0 (queues using PQ scheduling) are consecutively configured, without being interrupted by the configuration of the queues using WRR scheduling.
- If PQ+WRR scheduling is used and the numbers of the queues using PQ scheduling are consecutive (for example, queue 0, queues 0 and 1, and queues 0 to 2), the device schedules packets in queues using PQ scheduling after scheduling for the packets in queues using WRR scheduling is completed.

On the S6735-S, S6720-EI and S6720S-EI, if the queue scheduling mode is changed or the weight is changed during queue scheduling, packet loss occurs within 20 ms.

To set the same WRR weight on multiple interfaces, perform the configuration on a port group to reduce the workload.

Example

Set the WRR weight of queue 4 on GE0/0/1 of the S5720-LI to 9.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
```

```
[HUAWEI-qos-schedule-profile-test] qos wrr
[HUAWEI-qos-schedule-profile-test] qos queue 4 wrr weight 9
[HUAWEI-qos-schedule-profile-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos schedule-profile test
[HUAWEI-GigabitEthernet0/0/1] quit
```

15.4.24 qos schedule-profile (interface view)

Function

The **qos schedule-profile** command applies a global scheduling profile to an interface.

The **undo qos schedule-profile** command deletes a global scheduling profile from an interface.

By default, no global scheduling profile is applied to an interface.

NOTE

Only the S1720GW-E, S1720GWR-E, S300, S500, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S6720S-S, and S5736-S support this command.

Format

qos schedule-profile *profile-name*

undo qos schedule-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a scheduling profile.	The value must be the name of an existing scheduling profile.

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 40GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

After running the **qos schedule-profile (system view)** command to create a global scheduling profile, you can run the **qos schedule-profile** command in the interface view to apply the global scheduling profile to an interface to perform queue scheduling.

Example

Create a global scheduling profile named **test**, set the queue scheduling mode to PQ, and then apply the global scheduling profile to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
[HUAWEI-qos-schedule-profile-test] qos pq
[HUAWEI-qos-schedule-profile-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos schedule-profile test
```

15.4.25 qos schedule-profile (system view)

Function

The **qos schedule-profile** command creates a global scheduling profile and displays the scheduling profile view.

The **undo qos schedule-profile** command deletes a created global scheduling profile.

By default, no global scheduling profile is created.

NOTE

Only the S1720GW-E, S1720GWR-E, S300, S500, S5720I-SI, S5720-LI, S5720S-LI, S5735S-H, S6720S-S, and S5736-S support this command.

Format

qos schedule-profile *profile-name*

undo qos schedule-profile *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a scheduling profile.	The value is a string of 1 to 31 case-insensitive characters without spaces. **NOTE** A maximum of six scheduling profiles are allowed; otherwise, the system displays an error message.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After running the **qos schedule-profile** command in the system view to create a global scheduling profile, you can run the **qos { pq | wrr | drr }** command in the scheduling profile view to configure a queue scheduling mode. You can apply a global scheduling profile to a physical interface to perform queue scheduling.

Example

Create a global scheduling profile named **test**.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
[HUAWEI-qos-schedule-profile-test]
```

15.4.26 qos tail-drop-profile (interface view)

Function

The **qos tail-drop-profile** command applies a tail drop profile to an interface.

The **undo qos tail-drop-profile** command deletes a tail drop profile from an interface.

By default, no tail drop profile is applied to an interface.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S support this command.

Format

qos tail-drop-profile *profile-name*

undo qos tail-drop-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a tail drop profile.	The value must be the name of an existing tail drop profile.

Views

Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 40GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

After running the **qos tail-drop-profile (system view)** command to create a global tail drop profile, run the **qos tail-drop-profile** command in the interface view to apply the global tail drop profile to an interface to drop packets at the end of a queue.

Example

Create a global tail drop profile named **test**, set the maximum length of green packets in queue 1 for the global tail drop profile to 10, and then apply the global tail drop profile to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] qos tail-drop-profile test
[HUAWEI-tail-drop-profile-test] qos queue 1 green max-length 10
[HUAWEI-tail-drop-profile-test] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos tail-drop-profile test
```

15.4.27 qos tail-drop-profile (system view)

Function

The **qos tail-drop-profile** command creates a global tail drop profile and displays the tail drop profile view.

The **undo qos tail-drop-profile** command deletes a global tail drop profile.

By default, no global tail drop profile is created.

NOTE

Only the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S6720S-S, S5735S-S, S5735-S-I, S5735S-H, and S5736-S support this command.

Format

qos tail-drop-profile *profile-name*

undo qos tail-drop-profile *profile-name*

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a tail drop profile.	The value is a string of 1 to 16 case-insensitive characters, without spaces. **NOTE** - For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, CloudEngine S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, a maximum of one tail drop profile is allowed; otherwise, the system displays an error message. - For other models, a maximum of six tail drop profiles are allowed; otherwise, the system displays an error message.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After running the **qos tail-drop-profile** command in the system view to create a tail drop profile, you can run the **qos queue max-length** or **qos queue max-buffer** command in the tail drop profile view to configure a queue. You can apply a global tail drop profile to a physical interface to drop packets at the end of a queue.

Example

Create a global tail drop profile named **test**.

```
<HUAWEI> system-view
[HUAWEI] qos tail-drop-profile test
[HUAWEI-tail-drop-profile-test]
```

15.4.28 qos traffic-manage enable

Function

The **qos traffic-manage enable** command enables the traffic manager (TM) to buffer and schedule packets.

The **undo qos traffic-manage enable** command disables the TM from buffering and scheduling packets.

By default, the TM is enabled to buffer and schedule packets.

NOTE

Only the S5731-S, S5731S-S, S5731-H, and S5731S-H support this command.

Format

qos traffic-manage enable

undo qos traffic-manage enable

Parameters

None

Views

GE interface view, XGE interface view, 25GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the TM is enabled to buffer and schedule packets. When heavy traffic needs to be forwarded on all interfaces, the device cannot ensure lossless forwarding. You can run the **undo qos traffic-manage enable** command to disable the TM from buffering and scheduling packets.

Configuration Note

After the **undo qos traffic-manage enable** command is executed, the switch does not support HQoS.

After the **undo qos traffic-manage enable** command is executed, the buffer of the device is greatly reduced.

Example

Configure the TM not to buffer and schedule packets on the GE0/0/1.

```
<HUAWEI> system view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo qos traffic-manage enable
```

15.4.29 qos wred

Function

The **qos wred** command applies a WRED drop profile to an interface.

The **undo qos wred** command deletes a WRED drop profile from an interface.

By default, no WRED drop profile is applied to an interface.

NOTE

Only the S6735-S, S6720-EI and S6720S-EI support this command.

Format

qos wred *drop-profile-name*

undo qos wred

Parameters

Parameter	Description	Value
drop-profile-name	Specifies the name of a WRED drop profile.	The value must be the name of an existing WRED drop profile.

Views

GE interface view, XGE interface view, 40GE interface view, 100GE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a WRED drop profile is applied to an interface, congestion avoidance is implemented on the interface.

Prerequisites

Before applying a WRED drop profile, run the **drop-profile** command to create a WRED drop profile.

Precautions

A WRED drop profile can be applied to an interface or a queue.

If you apply WRED drop profiles to an interface and to a queue on the interface, the system first matches the packets with the profiles applied to the queue and interface in sequence. The system performs congestion avoidance for the packets that match the WRED drop profiles.

To configure the same WRED drop profile on multiple interfaces, perform the configuration on a port group to reduce the workload.

Example

Create a WRED drop profile named **wred1** and apply it to the GE0/0/1.

```
<HUAWEI> system view
[HUAWEI] drop-profile wred1
[HUAWEI-drop-wred1] color green low-limit 80 high-limit 100 discard-percentage 10
[HUAWEI-drop-wred1] color yellow low-limit 60 high-limit 80 discard-percentage 20
[HUAWEI-drop-wred1] color red low-limit 40 high-limit 60 discard-percentage 40
[HUAWEI-drop-wred1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] qos wred wred1
[HUAWEI-GigabitEthernet0/0/1] quit
```

15.4.30 qos wred high-limit

Function

The **qos wred high-limit** command configures the Weighted Random Early Detection (WRED) threshold for all port queues.

The **undo qos wred high-limit** command cancels the configuration.

By default, the WRED threshold for all port queues is 100.

NOTE

This command is available only on the S5731-H, S5731-S, S5731S-H, and S5731S-S.

Format

qos wred slot *slot-id* **high-limit** *high-limit-percentage*

undo qos wred slot *slot-id* **high-limit**

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies a slot ID.	The value must be set according to the device configuration.

Parameter	Description	Value
high-limit-percentage	Specifies the WRED threshold. When the percentage of the packet count in a queue to the queue length reaches this value, the switch discards all subsequent packets.	The value is an integer in the range from 1 to 100, in percentage.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

WRED randomly discards packets based on drop parameters. When packets enter a switch, the switch marks the packets with corresponding colors based on the mappings defined in the DiffServ domain. Then the switch processes the packets of different colors according to the WRED configuration.

To avoid congestion, you can configure WRED and set the same threshold for packets of different colors in all port queues. This simplifies configuration.

Precautions

If the WRED threshold is set and the WRED drop profile is also applied to a port queue, the WRED drop profile applied to the port queue takes effect.

Example

Set the WRED threshold to 90 for all port queues in slot 0.

```
<HUAWEI> system view
[HUAWEI] qos wred slot 0 high-limit 90
```

15.4.31 queue-depth (WRED drop profile view)

Function

The **queue-depth** command sets the length of a queue.

The **undo queue-depth** command restores the default length of a queue.

By default, the system uniformly manages the lengths of queues.

Format

queue-depth *queue-depth-value*

undo queue-depth

📖 **NOTE**

Only the S5731-S, S5731S-S, S5731-H, and S5731S-H support this command.

Parameters

Parameter	Description	Value
queue-depth-value	Specifies the queue length.	The value is an integer that ranges from 1024 to 805306368, in bytes.

Views

Drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When packets entering interface queues are processed based on parameters in a WRED drop profile, the percentage of the packet length to the queue length needs to be calculated. When the percentage reaches the lower drop threshold, the switch discards packets based on the drop probability. When the percentage reaches the upper drop threshold, the switch discards all subsequent packets. You can adjust the queue length to optimize the congestion avoidance effect.

Prerequisites

A WRED drop profile has been created and the WRED drop profile view has been displayed.

Precautions

When a small queue length is used, the delay of packets passing a queue is shortened but the queue buffer capability is lowered. When a large queue length is used, the queue buffer capability is improved but the delay of packets passing a queue is extended. In addition, when congestion occurs in a queue, many buffer resources are occupied. In this case, packets in other queues may be discarded due to insufficient buffer resources.

Example

Configure WRED drop profile **wred1** and set the queue length to 2000 bytes.

```
<HUAWEI> system-view
[HUAWEI] drop-profile wred1
[HUAWEI-drop-wred1] queue-depth 2000
```

15.4.32 reset qos queue statistics

Function

The **reset qos queue statistics** command clears queue-based traffic statistics on an interface.

Format

reset qos queue statistics interface *interface-type interface-number*

reset qos queue statistics all

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears queue-based traffic statistics on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
all	Clears queue-based traffic statistics on all interfaces.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To collect queue-based statistics within a certain period, first run the **reset qos queue statistics** command to clear the existing statistics.

Precautions

The cleared queue-based statistics cannot be restored. Therefore, exercise caution when you run the command.

Example

Clear queue-based traffic statistics on the GE0/0/1.

```
<HUAWEI> reset qos queue statistics interface gigabitethernet 0/0/1
```

15.4.33 stack-port qos { pq | wrr | drr }

Function

The **stack-port qos** { **pq** | **wrr** | **drr** } command configures a scheduling mode of queues on an interface of the stack.

The **undo stack-port qos** { **pq** | **wrr** | **drr** } command restores the default scheduling mode of queues on an interface of the stack.

By default, the queue scheduling mode of queues is priority queuing (PQ).

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

stack-port qos { **pq** | **wrr** | **drr** }

undo stack-port qos { **pq** | **wrr** | **drr** }

NOTE

The S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not support WRR scheduling mode.

Parameters

Parameter	Description	Value
pq	Indicates the PQ scheduling mode.	-
wrr	Indicates the Weighted Round Robin (WRR) scheduling mode.	-
drr	Indicates the Weighted Deficit Round Robin (WDRR) scheduling mode.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the stack is configured, stack protocol packets and packets between chassis are exchanged on the stack interface. If a large number of packets are exchanged, congestion may occur on the stack interface. As a result, core services such as video and voice services cannot be processed in a timely manner. You can set the scheduling mode on the stack interface so that services with the same priority are processed in the same manner and services with different priorities are processed based on weights.

Precautions

Before setting the scheduling mode of queues, configure priority mapping based on simple traffic classification to map packet priorities to per-hop behaviors (PHBs) and colors or configure internal priority re-marking based on complex traffic classification so that packets of different services enter different queues.

Example

Set the queue scheduling mode on the stack interface to WDRR.

```
<HUAWEI> system view
[HUAWEI] stack-port qos drr
```

15.4.34 stack-port qos queue

Function

The **stack-port qos queue** command configures the WRR or WDRR weight for queues on an interface of the stack.

The **undo stack-port qos queue** command restores the default WRR or WDRR weight for queues on a stack interface.

By default, the WRR or WDRR weight for queues on an interface of the stack is 1.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

stack-port qos queue *queue-index* { **wrr** | **drr** } **weight** *weight*

undo stack-port qos queue *queue-index* { **wrr** | **drr** } [**weight** *weight*]

NOTE

The WRR weight of queues cannot be set on the stack interface of the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Parameters

Parameter	Description	Value
queue *queue-index*	Specifies the index of a queue.	The value is an integer that ranges from 0 to 7.
wrr	Indicates the WRR weight.	-
drr	Indicates the WDRR weight.	-
weight *weight*	Specifies the WRR or WDRR weight.	The value is an integer. The value range is 0 to 127.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When using WRR or WDRR scheduling, you can set the weight for each queue. Then the switch schedules queues in turn based on the weights. If the weight of a queue is set to 0, the queue uses PQ scheduling. In this case, PQ+WRR or PQ +WDRR is used.

Prerequisites

The **stack-port qos** { **pq** | **wrr** | **drr** } command has been executed to configure the WRR or WDRR scheduling mode of queues on a stack interface.

Example

Set the WDRR weight for queue 1 on the stack interface to 30.

```
<HUAWEI> system view
[HUAWEI] stack-port qos queue 1 drr weight 30
```

15.4.35 stack-port qos schedule-profile

Function

The **stack-port qos schedule-profile** command applies a scheduling profile to a stack interface.

The **undo stack-port qos schedule-profile** command deletes a scheduling profile from a stack interface.

NOTE

The following switches support this command:

- S5720I-SI (excluding the S5720I-10X-PWH-SI-AC and S5720I-6X-PWH-SI-AC), S5720-LI, and S5720S-LI
- S5735S-H, S5736-S, S6720S-S
- S5735-S, S5735S-S

Format

stack-port qos schedule-profile *profile-name*

undo stack-port qos schedule-profile [*profile-name*]

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a scheduling profile.	The value must be the name of an existing scheduling profile.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After the **qos schedule-profile** *profile-name* command is used to create a scheduling profile globally, run this command to apply the scheduling profile. Then the switch schedules traffic on the stack interface based on the scheduling mode defined in the scheduling profile.

Example

Create a scheduling profile named **test** globally, set the queue scheduling mode to PQ, and apply the scheduling profile to the system.

```
<HUAWEI> system-view
[HUAWEI] qos schedule-profile test
[HUAWEI-qos-schedule-profile-test] qos pq
[HUAWEI-qos-schedule-profile-test] quit
[HUAWEI] stack-port qos schedule-profile test
```

15.5 Filtering Configuration Commands

15.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.5.2 deny | permit

Function

The **deny** | **permit** command configures access control for service packets based on traffic classifiers.

- The **deny** command prevents service flows that match a specified rule from passing through.
- The **permit** command forwards packets matching traffic classification rules according to the original policy.

The **undo** { **deny** | **permit** } command cancels access control for service packets based on traffic classifiers.

By default, a switch does not control service packets based on traffic classifiers.

Format

deny | **permit**

undo { **deny** | **permit** }

Parameters

None

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device implements access control using a traffic policy. That is, you can use a traffic policy containing **deny** | **permit** on the device so that the device provides the firewall function to filter out specified types of packets. The **deny** | **permit** command only filters data packets, but does not process control packets such as STP BPDUs sent to the CPU.

Precautions

When you specify a packet filtering action for packets matching an ACL, if the ACL rule defines **permit**, the device processes packets according to the action (**deny** or **permit**) in the traffic behavior. If the ACL rule defines **deny**, the device discards packets regardless of whether **deny** or **permit** is configured in the traffic behavior.

When you specify the packet filtering action for packets matching an ACL to **deny** or **permit**, if the ACL rule contains the **logging** field, logs are recorded when packets are discarded or forwarded.

If a traffic policy in which the **deny** behavior is defined is applied to the outbound direction on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, control packets of ICMP, OSPF, BGP, RIP, SNMP, and Telnet sent by the CPU are discarded. This affects relevant protocol functions.

In the same traffic behavior, the deny action cannot be used with other traffic actions. Before adding other traffic actions such as re-marking to a traffic behavior, ensure that the traffic behavior does not contain the deny action. If the traffic behavior contains the deny action, configure the permit action before configuring other traffic actions.

Example

Configure a traffic policy **p1** to prevent the packets from VLAN 2 to pass through GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match vlan-id 2
[HUAWEI-classifier-c1] quit
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] deny
[HUAWEI-behavior-b1] quit
[HUAWEI] traffic policy p1
[HUAWEI-trafficpolicy-p1] classifier c1 behavior b1
[HUAWEI-trafficpolicy-p1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-policy p1 inbound
```

15.6 Redirection Configuration Commands

15.6.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.6.2 redirect cpu

Function

The **redirect cpu** command configures an action of redirecting packets to the CPU in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, an action of redirecting packets to the CPU is not configured in a traffic behavior.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

redirect cpu

undo redirect

Parameters

None

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to the CPU.

Precautions

The traffic policy that contains the redirection action can only be applied to the system, an interface, or a VLAN.

NOTICE

After the traffic policy containing **redirect cpu** is used, the traffic matching the traffic classification rule is redirected to the CPU, causing CPU performance to deteriorate. Exercise caution when you run the **redirect cpu** command.

Example

Redirect packets to the CPU in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect cpu
```

15.6.3 redirect interface

Function

The **redirect interface** command configures an action of redirecting packets to an interface in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, no action of redirecting packets to an interface is configured in a traffic behavior.

Format

redirect interface *interface-type interface-number* [**forced**]

undo redirect

NOTE

Tunnel interfaces do not support **forced**.

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the action of redirecting packets to a tunnel interface.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the interface to which packets are redirected. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
forced	Directly discards packets when the interface is in Down state.	-

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **redirect interface** command configures an action of redirecting packets to an interface in a traffic behavior. For example, packets can be redirected to a firewall for security check.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to an interface.

Precautions

The traffic policy that contains the redirection action can only be applied to the system, an interface, or a VLAN in the inbound direction.

For the S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, packets can be redirected to physical interfaces and Eth-Trunk interfaces in Layer 2 or Layer 3 mode. For other models, packets can be redirected only to physical interfaces and Eth-Trunk interfaces in Layer 2 mode.

The packets that are redirected to an interface will be discarded if the VLAN of the packets on the interface is not allowed.

Example

Redirect packets to GE0/0/1 in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect interface gigabitethernet 0/0/1
```

15.6.4 redirect vpn-instance

Function

The **redirect vpn-instance** command configures an action of redirecting packets to a VPN instance in a traffic behavior.

The **undo redirect** command deletes the redirection configuration.

By default, no action of redirecting packets to a VPN instance is configured in a traffic behavior.

NOTE

The S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735-S, S500, S5735-S-I, S5735S-L, S5735S-L1, S5735S-S, and S5735S-L-M do not support this command.

Format

redirect vpn-instance *vpn-instance-name*

undo redirect

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the VPN instance to which packets are redirected.	The value must be an existing VPN instance name.

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **redirect vpn-instance** command configures an action of redirecting packets to a VPN instance in a traffic behavior.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing redirection to an interface.

Precautions

The traffic policy that contains the redirection action can only be applied to the system, an interface, or a VLAN in the inbound direction.

Example

Redirect packets to the VPN instance named **vpn1** in the traffic behavior **b1**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior b1
[HUAWEI-behavior-b1] redirect vpn-instance vpn1
```

15.7 Statistics Configuration Commands

15.7.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.7.2 statistic enable (traffic behavior view)

Function

The **statistic enable** command enables the traffic statistics function in a traffic behavior.

The **undo statistic enable** command disables the traffic statistics function in a traffic behavior.

By default, the traffic statistics function in a traffic behavior is disabled.

Format

statistic enable

undo statistic enable

Parameters

None

Views

Traffic behavior view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view the statistics on packets matching a traffic policy, you can use the **statistic enable** command to enable the statistics function. After the statistics function is enabled, you can use the **display traffic policy statistics** command to view the statistics.

Precautions

If only **statistic enable** is configured in a traffic behavior, the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI support packet-based traffic statistics but not byte-based traffic statistics. After the **traffic statistics mode by-bytes** command is configured in the system view and traffic statistics is configured in a traffic policy, the switches support byte-based traffic statistics.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, if a traffic policy defining traffic statistics is applied to an Eth-Trunk in the outbound direction, traffic statistics does not take effect for the packets sent by the CPU. In this case, you can configure traffic statistics or port mirroring in the inbound direction on the interface connected to the Eth-Trunk.

Follow-up Procedure

Run the **traffic policy** command to create a traffic policy and run the **classifier behavior** command in the traffic policy view to bind the traffic classifier to the traffic behavior containing the traffic statistics collection function.

Example

Enable the statistics function in traffic behavior **test**.

```
<HUAWEI> system-view
[HUAWEI] traffic behavior test
[HUAWEI-behavior-test] statistic enable
```

15.7.3 statistic enable (QoS profile view)

Function

The **statistic enable** command enables traffic statistics in a QoS profile.

The **undo statistic enable** command disables traffic statistics in a QoS profile.

By default, the traffic statistics function is disabled in a QoS profile.

Format

statistic enable

undo statistic enable

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

QoS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **statistic enable** command collects traffic statistics of successfully authenticated online users.

Precautions

When users connected to the device through an Eth-Trunk go online through Portal authentication, the S6720-EI, S6735-S, and S6720S-EI cannot provide traffic statistics for the users.

Example

Enable traffic statistics in the QoS profile **test**

```
<HUAWEI> system-view
[HUAWEI] qos-profile name test
[HUAWEI-qos-test] statistic enable
```

15.8 ACL-based Simplified Traffic Policy Commands

15.8.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

15.8.2 display traffic-statistics

Function

The **display traffic-statistics** command displays ACL-based traffic statistics.

Format

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound** [**acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*]] [**secure**]

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound acl** *user-acl* [**rule** *rule-id*]

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **outbound** [**acl** { *bas-acl* | *adv-acl* | *user-acl* } [**rule** *rule-id*]]

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound** [**acl** { *acl-name* | *l2-acl* } [**rule** *rule-id*] [**acl** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]] [**secure**]

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **outbound** [**acl** { *acl-name* | *l2-acl* } [**rule** *rule-id*] [**acl** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]]

display traffic-statistics interface inbound [**secure**]

display traffic-statistics interface outbound

display traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] { **inbound** | **outbound** } [**acl ipv6** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays ACL-based traffic statistics in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Displays ACL-based traffic statistics on a specified interface. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number. If *interface-type interface-number* is not specified, ACL-based traffic statistics on all interfaces are displayed.	-
inbound	Displays ACL-based traffic statistics in the inbound direction.	-
outbound	Displays ACL-based traffic statistics in the outbound direction.	-
acl { *bas-acl* | *adv-acl* | *user-acl* }	Displays traffic statistics on packets matching a specified ACL. • *bas-acl* specifies a basic ACL. • *adv-acl* specifies an advanced ACL. • *user-acl* specifies a user-defined ACL.	The value is an integer. The value ranges are as follows: • The value of *bas-acl* ranges from 2000 to 2999. • The value of *adv-acl* ranges from 3000 to 3999. • The value of *user-acl* ranges from 5000 to 5999.
acl { *acl-name* | *l2-acl* }	Displays traffic statistics on packets matching a specified ACL. • *acl-name* specifies the name of an ACL. • *l2-acl* specifies the number of a Layer 2 ACL.	• The value of *acl-name* must be the name of an existing ACL. • The value of *l2-acl* is an integer that ranges from 4000 to 4999.

Parameter	Description	Value
acl ipv6	Displays traffic statistics based on the IPv6 ACL.	-
rule *rule-id*	Displays traffic statistics on packets matching a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
secure	Displays traffic statistics on packets based on packet filtering policies configured through the **traffic-secure (interface view)** or **traffic-secure (system view)** command.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic-statistics** command displays ACL-based traffic statistics on an interface or in a VLAN. The command output helps you learn about forwarded and discarded packets matching the ACL and locate faults.

Prerequisites

The traffic statistics function has been enabled using the **traffic-statistic (interface view)** or **traffic-statistic (system view)** command.

Precautions

Before running the **display traffic-statistics** command to display traffic statistics on packets based on packet filtering policies configured through the **traffic-secure (interface view)** command, you must specify the **secure** parameter in the **traffic-statistic (interface view)** command.

Before running the **display traffic-statistics** command to display traffic statistics on packets based on packet filtering policies configured through the **traffic-secure (system view)** command, you must specify the **secure** parameter in the **traffic-statistic (system view)** command.

On the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if traffic policing and traffic statistics collection based on the same ACL are configured, only statistics on the number of packets matching an ACL, namely, value of **matched** in the **display traffic-statistics** command output, are correct.

Example

Display statistics on packets matching ACL 3009 in the inbound direction on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl 3009
[HUAWEI-acl-adv-3009] rule 1 permit ip
[HUAWEI-acl-adv-3009] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-statistic inbound acl 3009
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] display traffic-statistics interface gigabitethernet 0/0/1 inbound acl 3009
--------------------------------------------------------------------------------
Interface GigabitEthernet0/0/1
 ACL:3009 Rule:1
     matched:0 packets, passed:0 packets, dropped:0 packets
```

Table 15-34 Description of the **display traffic-statistics** command output

Item	Description
ACL	ACL number.
Rule	ACL rule ID.
matched	Number of packets matching the ACL.
passed	Number of forwarded packets.
dropped	Number of discarded packets.

15.8.3 reset traffic-statistics

Function

The **reset traffic-statistics** command clears ACL-based traffic statistics.

Format

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound** [**acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*]] [**secure**]

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound acl** *user-acl* [**rule** *rule-id*]

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **outbound** [**acl** { *bas-acl* | *adv-acl* | *user-acl* } [**rule** *rule-id*]]

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **inbound** [**acl** { *acl-name* | *l2-acl* } [**rule** *rule-id*] [**acl** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]] [**secure**]

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] **outbound** [**acl** { *acl-name* | *l2-acl* } [**rule** *rule-id*] [**acl** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]]

reset traffic-statistics { **interface** | **vlan** } **inbound** [**secure**]

reset traffic-statistics { **interface** | **vlan** } **outbound**

reset traffic-statistics [**vlan** *vlan-id* | **interface** *interface-type interface-number*] { **inbound** | **outbound** } [**acl ipv6** { *bas-acl* | *adv-acl* | *acl-name* } [**rule** *rule-id*]]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Clears ACL-based traffic statistics in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface *interface-type interface-number*	Clears ACL-based traffic statistics on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. If *interface-type interface-number* is not specified, ACL-based traffic statistics on all interfaces are cleared.	-
inbound	Clears ACL-based traffic statistics in the inbound direction.	-
outbound	Clears ACL-based traffic statistics in the outbound direction.	-

Parameter	Description	Value
acl { *bas-acl* | *adv-acl* | *user-acl* }	Clears traffic statistics on packets matching a specified ACL. ● *bas-acl* specifies a basic ACL. ● *adv-acl* specifies an advanced ACL. ● *user-acl* specifies a user-defined ACL.	The value is an integer. The value ranges are as follows: ● The value of *bas-acl* ranges from 2000 to 2999. ● The value of *adv-acl* ranges from 3000 to 3999. ● The value of *user-acl* ranges from 5000 to 5999.
acl { *acl-name* | *l2-acl* }	Clears traffic statistics on packets matching a specified ACL. ● *acl-name* specifies the name of an ACL. ● *l2-acl* specifies the number of a Layer 2 ACL.	● The value of *acl-name* must be the name of an existing ACL. ● The value of *l2-acl* is an integer that ranges from 4000 to 4999.
acl ipv6	Clears traffic statistics based on the IPv6 ACL.	-
rule *rule-id*	Clears traffic statistics on packets matching a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
secure	Clears traffic statistics on packets based on packet filtering policies configured through the **traffic-secure (interface view)** or **traffic-secure (system view)** command.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before re-collecting ACL-based traffic statistics, run the **reset traffic-statistics** command to clear existing statistics. Then run the **display traffic-statistics** command to view ACL-based traffic statistics.

Precautions

After the **reset traffic-statistics** command is executed, statistics are cleared and cannot be restored. Exercise caution when you use this command.

Example

Clear statistics about incoming packets that match rule 5 in the ACL named **test** on GE0/0/1.

```
<HUAWEI> reset traffic-statistics interface gigabitethernet 0/0/1 inbound acl test rule 5
```

15.8.4 traffic-delete fast-mode enable

Function

The **traffic-delete fast-mode enable** command enables the device to rapidly delete ACL-based simplified traffic policies.

The **undo traffic-delete fast-mode enable** command disables the device from rapidly deleting ACL-based simplified traffic policies.

By default, the device is disabled from rapidly deleting ACL-based simplified traffic policies.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

traffic-delete fast-mode enable

undo traffic-delete fast-mode enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple ACL-based simplified traffic policies are configured and the ACL contains a large number of rules, it takes a long time for the device to delete the traffic policies. To solve the problem, run the **traffic-delete fast-mode enable** command to enable the device to rapidly delete ACL-based simplified traffic policies.

Precautions

After the **traffic-delete fast-mode enable** command is executed, the traffic policy statistics are cleared.

After the **traffic-delete fast-mode enable** command is used, if you configure a new ACL-based simplified traffic policy, the original ACL-based simplified traffic policy becomes invalid temporarily and takes effect only when the new ACL-based simplified traffic policy is applied successfully.

Example

Enable the device to rapidly delete ACL-based simplified traffic policies.

```
<HUAWEI> system-view
[HUAWEI] traffic-delete fast-mode enable
```

15.8.5 traffic-filter (interface view)

Function

The **traffic-filter** command applies an ACL to an interface to filter packets on the interface.

The **undo traffic-filter** command cancels the configuration.

By default, no ACL is applied to an interface to filter packets on the interface.

Format

Use the following command in the inbound direction on an interface:

traffic-filter inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

undo traffic-filter inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

Use the following command in the inbound direction on a tunnel interface:

traffic-filter inbound acl { *adv-acl* | *ucl-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-filter inbound acl { *adv-acl* | *ucl-acl* | **name** *acl-name* } [**rule** *rule-id*]

NOTE

ACL-based packet filtering can be configured on the tunnel interface in the inbound direction only on the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Use the following command in the outbound direction on an interface:

traffic-filter outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

undo traffic-filter outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-filter { **inbound** | **outbound** } **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-filter { **inbound** | **outbound** } **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-filter { **inbound** | **outbound** } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-filter { **inbound** | **outbound** } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
inbound	Configures ACL-based packet filtering in the inbound direction on an interface.	-
outbound	Configures ACL-based packet filtering in the outbound direction on an interface.	-
acl	Filters packets based on the IPv4 ACL.	-
ipv6	Filters packets based on the IPv6 ACL.	-
bas-acl	Filters packets based on a specified basic ACL.	The value is an integer in the range from 2000 to 2999.
adv-acl	Filters packets based on a specified advanced ACL.	The value is an integer in the range from 3000 to 3999.
l2-acl	Filters packets based on a specified Layer 2 ACL.	The value is an integer in the range from 4000 to 4999.
user-acl	Filters packets based on a specified user-defined ACL.	The value is an integer in the range from 5000 to 5999.

Parameter	Description	Value
ucl-acl	Filters packets based on a specified user ACL.	The value is an integer in the range from 6000 to 9999.
name *acl-name*	Filters packets based on a specified named ACL. *acl-name* specifies the name of an ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Filters packets based on a specified ACL rule.	The value is an integer in the range from 0 to 4294967294.

Views

VLANIF interface view, Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Tunnel interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-filter** command is executed on an interface, the device filters packets matching ACL rules:

- If the action in an ACL rule is **deny**, the device discards packets matching the rule.
- If the action in an ACL rule is **permit**, the device forwards packets matching the rule.
- If no rule is matched, packets are allowed to pass through.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

If the **traffic-filter (system view)** and **traffic-filter (interface view)** commands are used simultaneously, and the associated ACLs are non-user-defined ACLs, the **traffic-filter (interface view)** command takes effect.

When the deny action is defined in the ACL rule associated with the **traffic-filter** command, the ACL rule can only be associated with the **traffic-mirror (interface view)**, **traffic-mirror (system view)**, **traffic-statistic (interface view)**, or **traffic-statistic (system view)** command. If the ACL rule is associated with other simplified traffic policies, the simplified traffic policies may not take effect.

When the permit action is defined in the ACL rule associated with the **traffic-filter** command, the ACL rule can be associated with other simplified traffic policies.

When the ACL rule containing the **logging** field is associated with the **traffic-filter** command, logs are recorded when packets are discarded or forwarded.

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

Outbound ACL-based packet filtering on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based packet filtering is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based packet filtering.

If an ACL rule defines **deny** and **traffic-filter** based on the ACL is applied to the outbound direction on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, when packets match the ACL rule, control packets of ICMP, OSPF, BGP, RIP, SNMP, and Telnet sent by the CPU are discarded. This affects relevant protocol functions.

Example

On the GE0/0/1, configure packet filtering based on the ACL that rejects packets with source IP address 192.168.0.2/32.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 deny ip source 192.168.0.2 0
```

```
[HUAWEI-acl-adv-3000] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-filter inbound acl 3000
```

15.8.6 traffic-filter (system view)

Function

The **traffic-filter** command configures ACL-based packet filtering globally or in a VLAN.

The **undo traffic-filter** command cancels ACL-based packet filtering globally or in a VLAN.

By default, ACL-based packet filtering is not configured globally or in a VLAN.

NOTE

When ACL-based packet filtering is implemented in the system or in a VLAN, the ACL number is in the range of 2000 to 5999. When ACL-based packet filtering is implemented for user access control on the NAC network, the ACL number is in the range of 6000 to 9999. See **traffic-filter acl**.

Format

To configure ACL-based packet filtering in the inbound direction on a switch, use the following command:

traffic-filter [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

undo traffic-filter [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

traffic-filter inbound acl [**ipv6**] *ucl-acl*

undo traffic-filter inbound acl [**ipv6**] *ucl-acl*

To configure ACL-based packet filtering in the outbound direction on a switch, use the following command:

traffic-filter [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] {*bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

undo traffic-filter [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-filter [**vlan** *vlan-id*] { **inbound** | **outbound** } **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-filter [**vlan** *vlan-id*] { **inbound** | **outbound** } **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-filter [**vlan** *vlan-id*] { **inbound** | **outbound** } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-filter [**vlan** *vlan-id*] { **inbound** | **outbound** } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Configures ACL-based packet filtering in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
inbound	Configures ACL-based packet filtering in the inbound direction.	-
outbound	Configures ACL-based packet filtering in the outbound direction. **NOTE** Packet filtering based on the user-defined ACL cannot be applied to the outbound direction.	-
acl	Filters packets based on the IPv4 ACL.	-
ipv6	Filters packets based on the IPv6 ACL.	-
bas-acl	Filters packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Filters packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Filters packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Filters packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Specifies the name of an ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Filters packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.

Usage Guidelines

Usage Scenario

After the **traffic-filter** command is executed on the device, the device filters packets matching an ACL rule:

- If the action in the ACL rule is **deny**, the device discards packets matching the rule.
- If the action in the ACL rule is **permit**, the device forwards packets matching the rule.
- If no rule is matched, packets are allowed to pass through.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If the **traffic-filter (system view)** and **traffic-filter (interface view)** commands are used simultaneously, and the associated ACLs are non-user-defined ACL, the **traffic-filter (interface view)** command takes effect.

When the deny action is defined in the ACL rule associated with the **traffic-filter** command, the ACL rule can only be associated with the **traffic-mirror (interface view)**, **traffic-mirror (system view)**, **traffic-statistic (interface view)**, or **traffic-statistic (system view)** command. If the ACL rule is associated with other simplified traffic policies, the simplified traffic policies may not take effect.

When the permit action is defined in the ACL rule associated with the **traffic-filter** command, the ACL rule can be associated with other simplified traffic policies.

When the ACL rule containing the **logging** field is associated with the **traffic-filter** command, logs are recorded when packets are discarded or forwarded.

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

Outbound ACL-based packet filtering on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based packet filtering is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based packet filtering.

If an ACL rule defines **deny** and **traffic-filter** based on the ACL is applied to the outbound direction on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, when packets match the ACL rule, control packets of ICMP, OSPF, BGP, RIP, SNMP, and Telnet sent by the CPU are discarded. This affects relevant protocol functions.

Example

Configure ACL-based packet filtering in VLAN 100. The ACL rejects packets with source IP address 192.168.0.2/32.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] acl name test 3000
[HUAWEI-acl-adv-test] rule 5 deny ip source 192.168.0.2 0
[HUAWEI-acl-adv-test] quit
[HUAWEI] traffic-filter vlan 100 inbound acl name test
```

15.8.7 traffic-limit (interface view)

Function

The **traffic-limit** command configures ACL-based traffic policing on an interface.

The **undo traffic-limit** command cancels ACL-based traffic policing on an interface.

By default, ACL-based traffic policing is not configured on an interface.

Format

Use the following command in the inbound direction on a switch interface:

traffic-limit inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

Use the following command in the outbound direction on a switch interface:

traffic-limit outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }]] (S6735-S, S6720-EI, S6720S-EI)

traffic-limit outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S)

traffic-limit outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow pass**] [**red** { **drop** | **pass** }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and traffic policing is used in the inbound direction on a switch interface, use the following command:

traffic-limit inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-*

value **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

traffic-limit inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-limit inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and traffic policing is used in the outbound direction on a switch interface, use the following command:

traffic-limit outbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit outbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit outbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo traffic-limit outbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
inbound	Performs traffic policing for packets in the inbound direction of an interface.	-
outbound	Performs traffic policing for packets in the outbound direction of an interface.	-
acl	Performs traffic policing for packets based on the IPv4 ACL.	-
ipv6	Performs traffic policing for packets based on the IPv6 ACL.	-
bas-acl	Performs traffic policing for packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Performs traffic policing for packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Performs traffic policing for packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Performs traffic policing for packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.

Parameter	Description	Value
name *acl-name*	Performs traffic policing for packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Performs traffic policing for packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
cir *cir-value*	Specifies the committed information rate (CIR), which is the guaranteed average transmission rate.	The value is an integer that ranges from 8 to 4294967295, in kbit/s.
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate at which traffic can pass through.	The value is an integer that ranges from 8 to 4294967295, in kbit/s. The PIR must be greater than or equal to the CIR. The default PIR is equal to the CIR.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. The default CBS is 125 times the CIR. If the CIR multiplied by 125 is smaller than 4000, the default CBS is 4000.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. If the PIR is not set, the default PBS is 125 times the CIR. If the PIR is set, the default PBS is 125 times the PIR. If the CIR or PIR multiplied by 125 is smaller than 4000, the default PBS is 4000.
green	Performs traffic policing for green packets. By default, green packets are allowed to pass through.	-

Parameter	Description	Value
yellow	Performs traffic policing for yellow packets. By default, yellow packets are allowed to pass through.	-
red	Performs traffic policing for red packets. By default, red packets are discarded.	-
remark-8021p *8021p-value*	Re-marks the 802.1p priority in packets.	The value is an integer that ranges from 0 to 7.
remark-dscp *dscp-value*	Re-marks the DSCP priority in packets.	The value is an integer that ranges from 0 to 63.
drop	Indicates that packets are discarded.	-
pass	Indicates that packets are allowed to pass through.	-

Views

VLANIF interface view, Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Tunnel interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-limit** command is executed on an interface, the device limits the rate and remarks the 802.1p or DSCP priority of packets matching an ACL.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

If the **traffic-limit (system view)** and **traffic-limit (interface view)** commands are used simultaneously, the **traffic-limit (interface view)** command takes effect.

When the **traffic-limit (interface view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used simultaneously, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, the traffic rate is limited.

If the **traffic-limit** command with the same ACL rule specified is executed two or more times in the interface view, the system displays the following information:

```
Error:Sacl does not support config the same acl or rule repeatedly.
```

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

Outbound ACL-based traffic policing on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based traffic policing is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based traffic policing.

Example

Configure ACL-based traffic policing in the inbound direction on GE0/0/1, set the CIR to 10000 kbit/s for packets matching ACL 3000, configure GE0/0/1 to allow green packets, yellow packets, and red packets to pass through, and re-mark the DSCP priority of red packets with 5.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-limit inbound acl 3000 cir 10000 green pass yellow pass red
pass remark-dscp 5
```

15.8.8 traffic-limit (system view)

Function

The **traffic-limit** command configures ACL-based traffic policing globally or in a VLAN.

The **undo traffic-limit** command cancels ACL-based traffic policing globally or in a VLAN.

By default, ACL-based traffic policing is not configured globally or in a VLAN.

Format

To configure ACL-based traffic policing in the inbound direction on a switch, use the following command:

traffic-limit [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

To configure ACL-based traffic policing in the outbound direction on a switch, use the following command:

traffic-limit [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }]] (S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp**

dscp-value] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow pass**] [**red** { **drop** | **pass** }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and traffic policing is used in the inbound direction on a switch, use the following command:

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

traffic-limit [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-*

value] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-8021p** *8021p-value* | **remark-dscp** *dscp-value*] }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-limit [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and traffic policing is used in the outbound direction on a switch, use the following command:

traffic-limit [**vlan** *vlan-id*] **outbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**yellow** { **drop** | **pass** [**remark-dscp** *dscp-value*] }] [**red** { **drop** | **pass** [**remark-dscp** *dscp-value*] }]] (S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [[**green** { **drop** | **pass** }] [**yellow** { **drop** | **pass** }] [**red** { **drop** | **pass** }]] (S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

traffic-limit [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **cir** *cir-value* [**pir** *pir-value*] [**cbs** *cbs-value* **pbs** *pbs-value*] [**green pass**] [**yellow pass**] [**red** { **drop** | **pass** }] (S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI)

undo traffic-limit [**vlan** *vlan-id*] **outbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-limit [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.
inbound	Performs traffic policing for packets in the inbound direction.	-
outbound	Performs traffic policing for packets in the outbound direction.	-
acl	Performs traffic policing for packets based on the IPv4 ACL.	-
ipv6	Performs traffic policing for packets based on the IPv6 ACL.	-
bas-acl	Performs traffic policing for packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Performs traffic policing for packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Performs traffic policing for packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Performs traffic policing for packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Performs traffic policing for packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Performs traffic policing for packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.

Parameter	Description	Value
cir *cir-value*	Specifies the committed information rate (CIR), which is the guaranteed average transmission rate.	The value is an integer that ranges from 8 to 4294967295, in kbit/s.
pir *pir-value*	Specifies the peak information rate (PIR), which is the maximum rate at which traffic can pass through.	The value is an integer that ranges from 8 to 4294967295, in kbit/s. The PIR must be greater than or equal to the CIR. The default PIR is equal to the CIR.
cbs *cbs-value*	Specifies the committed burst size (CBS), which is the average volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. The default CBS is 125 times the CIR. If the CIR multiplied by 125 is smaller than 4000, the default CBS is 4000.
pbs *pbs-value*	Specifies the peak burst size (PBS), which is the maximum volume of burst traffic that can pass through an interface.	The value is an integer that ranges from 4000 to 4294967295, in bytes. If the PIR is not set, the default PBS is 125 times the CIR. If the PIR is set, the default PBS is 125 times the PIR. If the CIR or PIR multiplied by 125 is smaller than 4000, the default PBS is 4000.
green	Performs traffic policing for green packets. By default, green packets are allowed to pass through.	-
yellow	Performs traffic policing for yellow packets. By default, yellow packets are allowed to pass through.	-
red	Performs traffic policing for red packets. By default, red packets are discarded.	-

Parameter	Description	Value
remark-8021p *8021p-value*	Re-marks the 802.1p priority in packets.	The value is an integer that ranges from 0 to 7.
remark-dscp *dscp-value*	Re-marks the DSCP priority in packets.	The value is an integer that ranges from 0 to 63.
drop	Indicates that packets are discarded.	-
pass	Indicates that packets are allowed to pass through.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-limit** command is executed on the device, the device limits the rate and remarks the 802.1p or DSCP priority of packets matching an ACL.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If the **traffic-limit (interface view)** and **traffic-limit (system view)** commands are used simultaneously, the **traffic-limit (interface view)** command takes effect.

When the **traffic-limit (system view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used simultaneously, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, the traffic rate is limited.

After traffic policing is configured on an interface, the number of packets that can be forwarded on the interface every second is relevant to the packet length calculation method. By default, the device calculates the 20-byte inter-frame gap and preamble. That is, the device calculates the actual packet length plus 20-byte inter-frame gap and preamble.

Outbound ACL-based traffic policing on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based traffic policing is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based traffic policing.

Example

In the inbound direction in VLAN 100, configure traffic policing based on ACL 3000, set the CIR to 10000 kbit/s, and configure the device to permit green and yellow packets to pass through and to discard red packets.

```
<HUAWEI> system-view
[HUAWEI] traffic-limit vlan 100 inbound acl 3000 cir 10000 green pass yellow pass red drop
```

15.8.9 traffic-mirror (interface view)

Function

The **traffic-mirror** command configures ACL-based flow mirroring on an interface.

The **undo traffic-mirror** command cancels ACL-based flow mirroring on an interface.

By default, ACL-based flow mirroring is not configured on an interface.

Format

To configure a single ACL, use the following command:

traffic-mirror inbound { **acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror inbound { **acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-mirror inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-mirror inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-mirror inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
inbound	Mirrors packets in the inbound direction on an interface.	-
acl	Mirrors packets based on the IPv4 ACL.	-
ipv6	Mirrors packets based on the IPv6 ACL.	-
bas-acl	Mirrors packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Mirrors packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Mirrors packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Mirrors packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Mirrors packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Mirrors packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.

Parameter	Description	Value
to observe-port *o-index*	Specifies the index of the observing port to which packets are mirrored.	The value is an integer and the value range depends on the product model: - S1720GW-E, S1720GWR-E, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, and S5720-LI: 1 - S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S: 1 to 8

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the **traffic-mirror** command is configured, the device can perform flow mirroring or remote flow mirroring, without affecting traffic forwarding.

Prerequisites

An observing port has been created through the **observe-port (local mirroring)** or **observe-port (remote mirroring)** command.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

If the **traffic-mirror (system view)** and **traffic-mirror (interface view)** commands are used simultaneously, the **traffic-mirror (interface view)** command takes effect.

Example

Configure ACL-based flow mirroring in the inbound direction on GE0/0/1, and mirror the packets matching ACL 3000 to the observing port with the index of 1.

```
<HUAWEI> system-view
[HUAWEI] observe-port 1 interface gigabitethernet 0/0/1
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-mirror inbound acl 3000 to observe-port 1
```

15.8.10 traffic-mirror (system view)

Function

The **traffic-mirror** command configures ACL-based flow mirroring globally or in a VLAN.

The **undo traffic-mirror** command cancels ACL-based flow mirroring globally or in a VLAN.

By default, ACL-based flow mirroring is not configured globally or in a VLAN.

Format

To configure a single ACL, use the following command:

traffic-mirror [**vlan** *vlan-id*] **inbound** { **acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror [**vlan** *vlan-id*] **inbound** { **acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-mirror [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-mirror [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-mirror [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **to observe-port** *o-index*

undo traffic-mirror [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.
inbound	Mirrors packets in the inbound direction.	-
acl	Mirrors packets based on the IPv4 ACL.	-
ipv6	Mirrors packets based on the IPv6 ACL.	-
bas-acl	Mirrors packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Mirrors packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Mirrors packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Mirrors packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Mirrors packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.

Parameter	Description	Value
rule *rule-id*	Mirrors packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
to observe-port *o-index*	Specifies the index of the observing port to which packets are mirrored.	The value is an integer and the value range depends on the product model: • S1720GW-E, S1720GWR-E, S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S, and S5720-LI: 1 • S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S: 1 to 8

Usage Guidelines

Usage Scenario

After the **traffic-mirror** command is configured, the device can perform flow mirroring or remote flow mirroring, without affecting traffic forwarding.

Prerequisites

An observing port has been created through the **observe-port (local mirroring)** or **observe-port (remote mirroring)** command.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If the **traffic-mirror (interface view)** and **traffic-mirror (system view)** commands are used simultaneously, the **traffic-mirror (interface view)** command takes effect.

Example

Configure ACL-based flow mirroring in the inbound direction in VLAN 100, and mirror the packets matching ACL 3000 to the observing port with the index of 1.

```
<HUAWEI> system-view
[HUAWEI] observe-port 1 interface gigabitethernet 0/0/1
[HUAWEI] traffic-mirror vlan 100 inbound acl 3000 to observe-port 1
```

15.8.11 traffic-redirect (interface view)

Function

The **traffic-redirect** command configures ACL-based redirection on an interface.

The **undo traffic-redirect** command cancels ACL-based redirection on an interface.

By default, ACL-based redirection is not configured on an interface.

Format

To configure a single ACL, use the following command:

traffic-redirect inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

Use the following command on a tunnel interface:

traffic-redirect inbound acl { *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **interface tunnel** *interface-number* [**force**]

undo traffic-redirect inbound acl { *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-redirect inbound acl *ucl-acl* **interface tunnel** *interface-number* [**force**]

undo traffic-redirect inbound acl *ucl-acl*

NOTE

ACL-based redirection can be configured in the inbound direction of a tunnel interface only on the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S.

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-redirect inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-redirect inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-redirect inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vpn-instance** *vpn-instance-name*.

Parameters

Parameter	Description	Value
inbound	Redirects packets in the inbound direction on an interface.	-

Parameter	Description	Value
acl	Redirects packets based on the IPv4 ACL.	-
ipv6	Redirects packets based on the IPv6 ACL.	-
bas-acl	Redirects packets based on a specified basic ACL.	The value is an integer in the range from 2000 to 2999.
adv-acl	Redirects packets based on a specified advanced ACL.	The value is an integer in the range from 3000 to 3999.
l2-acl	Redirects packets based on a specified Layer 2 ACL.	The value is an integer in the range from 4000 to 4999.
user-acl	Redirects packets based on a specified user-defined ACL.	The value is an integer in the range from 5000 to 5999.
ucl-acl	Redirects packets based on a user ACL.	The value is an integer in the range from 6000 to 9999.
name *acl-name*	Redirects packets based on a specified named ACL. *acl-name* specifies the name of an ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Redirects packets based on a specified ACL rule.	The value is an integer in the range from 0 to 4294967294.
cpu	Redirects packets to the CPU.	-
interface *interface-type interface-number*	Redirects packets to a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
remote	Redirects packets to a remote next hop.	-
vpn-instance *vpn-instance-name*	Redirects packets to a VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
ip-nexthop *ip-nexthop*	Redirects packets to a next-hop IPv4 address.	The value is in dotted decimal notation.
ipv6-nexthop *ipv6-nexthop*	Redirects packets to a next-hop IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
ipv6-nexthop link-local *link-local-address* **interface** *interface-type interface-number*	Redirects packets to the IPv6 link-local address of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. When the link-local address is configured, the IPv6 address prefix should match FE80::/10.	The link-local address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Usage Guidelines

Usage Scenario

After the **traffic-redirect** command is executed on an interface, the device redirects packets matching an ACL to the CPU, a specified interface, or a specified next-hop address.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

If the **traffic-redirect (system view)** and **traffic-redirect (interface view)** commands are used simultaneously, the **traffic-redirect (interface view)** command takes effect.

When the **traffic-redirect (interface view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used simultaneously, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, traffic is redirected.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, if traffic matching **traffic-redirect (interface view)** also matches **traffic-secure (interface view)** or **traffic-secure (system view)**, **traffic-redirect (interface view)** takes effect. On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the ACL defines the permit action, **traffic-secure (interface view)** or **traffic-secure (system view)** and **traffic-redirect (interface view)** take effect.

Before redirecting packets to an IPv6 address using this command, run the **ipv6 neighbor** command to configure a static neighbor.

Redirection to a next hop only takes effect on L3 traffic for the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735-S-I, and S5735S-S.

NOTICE

If packets are redirected to the CPU, a large number of packets will be sent to the CPU, affecting normal services. Exercise caution when you configure redirection to the CPU.

Example

Configure ACL-based redirection in the inbound direction on GE0/0/1, and redirect packets matching ACL 3000 to GE0/0/2.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-redirect inbound acl 3000 interface gigabitethernet 0/0/2
```

15.8.12 traffic-redirect (system view)

Function

The **traffic-redirect** command configures ACL-based redirection globally or in a VLAN.

The **undo traffic-redirect** command cancels ACL-based redirection globally or in a VLAN.

By default, ACL-based redirection is not configured globally or in a VLAN.

NOTE

When ACL-based redirection is implemented in the system or in a VLAN, the ACL number is in the range of 2000 to 5999. When ACL-based redirection is implemented on the NAC network, the ACL number is in the range of 6000 to 9999. See **traffic-redirect acl**.

Format

To configure a single ACL, use the following command:

traffic-redirect [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-redirect [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-redirect [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-redirect [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **cpu** | **interface** *interface-type interface-number* | { [**remote**] { [**vpn-instance** *vpn-instance-name*] **ip-nexthop** *ip-nexthop* | **ipv6-nexthop** *ipv6-nexthop* } } }

traffic-redirect [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } **ipv6-nexthop link-local** *link-local-address* **interface** *interface-type interface-number*

undo traffic-redirect [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **vpn-instance** *vpn-instance-name*.

Parameters

Parameter	Description	Value
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.
inbound	Redirects packets to the inbound direction.	-
acl	Redirects packets based on the IPv4 ACL.	-
ipv6	Redirects packets based on the IPv6 ACL.	-
bas-acl	Redirects packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Redirects packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Redirects packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Redirects packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.

Parameter	Description	Value
name *acl-name*	Redirects packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Redirects packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
cpu	Redirects packets to the CPU.	-
interface *interface-type interface-number*	Redirects packets to a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
remote	Redirects packets to a remote next hop.	-
vpn-instance *vpn-instance-name*	Redirects packets to a VPN instance.	The value must be an existing VPN instance name.
ip-nexthop *ip-nexthop*	Redirects packets to a next-hop IPv4 address.	The value is in dotted decimal notation.
ipv6-nexthop *ipv6-nexthop*	Redirects packets to a next-hop IPv6 address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-nexthop link-local *link-local-address* **interface** *interface-type interface-number*	Redirects packets to the IPv6 link-local address of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number. When the link-local address is configured, the IPv6 address prefix should match FE80::/10.	The link-local address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-redirect** command is executed on the device, the device redirects packets matching an ACL to the CPU, a specified interface, or a specified next hop address.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If the **traffic-redirect (interface view)** and **traffic-redirect (system view)** commands are used simultaneously, the **traffic-redirect (interface view)** command takes effect.

When the **traffic-redirect (system view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used simultaneously, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, traffic is redirected.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, if traffic matching **traffic-redirect (system view)** also matches **traffic-secure (interface view)** or **traffic-secure (system view)**, **traffic-redirect (system view)** takes effect. On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the ACL defines the permit action, **traffic-secure (interface view)** or **traffic-secure (system view)** and **traffic-redirect (system view)** take effect.

Before redirecting packets to an IPv6 address using this command, run the **ipv6 neighbor** command to configure a static neighbor.

Redirection to a next hop only takes effect on L3 traffic for the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735-S-I, and S5735S-S.

NOTICE

If packets are redirected to the CPU, a large number of packets will be sent to the CPU, affecting normal services. Exercise caution when you configure redirection to the CPU.

Example

Configure ACL-based redirection in the inbound direction in VLAN 100, and redirect packets matching ACL 3000 to GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] traffic-redirect vlan 100 inbound acl 3000 interface gigabitethernet 0/0/1
```

15.8.13 traffic-remark (interface view)

Function

The **traffic-remark** command configures ACL-based re-marking on an interface.

The **undo traffic-remark** command cancels ACL-based re-marking on an interface.

By default, ACL-based re-marking is not configured on an interface.

Format

To configure ACL-based re-marking in the inbound direction on a switch interface, use the following command:

traffic-remark inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark inbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

To configure ACL-based re-marking in the outbound direction on a switch interface, use the following command:

traffic-remark outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

If both Layer 2 and Layer 3 ACLs are configured and re-marking is used in the inbound direction on a switch interface, use the following command:

traffic-remark inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

traffic-remark inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

traffic-remark inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

If both Layer 2 and Layer 3 ACLs are configured and re-marking is used in the outbound direction on a switch interface, use the following command:

traffic-remark outbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark outbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

traffic-remark outbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark outbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

traffic-remark outbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark outbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

Parameters

Parameter	Description	Value
inbound	Re-marks packets in the inbound direction.	-
outbound	Re-marks packets in the outbound direction.	-

Parameter	Description	Value
acl	Re-marks packets based on the IPv4 ACL.	-
ipv6	Re-marks packets based on the IPv6 ACL.	-
bas-acl	Re-marks packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Re-marks packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Re-marks packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
user-acl	Re-marks packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Re-marks packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Re-marks packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
8021p *8021p-value*	Re-marks the 802.1p priority in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
cvlan-id *cvlan-id*	Re-marks the inner VLAN tag in QinQ packets. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **cvlan-id** *cvlan-id*.	The value is an integer that ranges from 1 to 4094.
destination-mac *mac-address*	Re-marks the destination MAC address in packets. **NOTE** Only the S6735-S, S6720-EI and S6720S-EI support **destination-mac** *mac-address*.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
dscp { *dscp-name* | *dscp-value* }	Re-marks the DSCP service type in packets.	The value can be an integer in the range of 0 to 63, or DSCP service name, for example, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values corresponding to DSCP service names are as follows: • af11: 10 • af12: 12 • af13: 14 • af21: 18 • af22: 20 • af23: 22 • af31: 26 • af32: 28 • af33: 30 • af41: 34 • af42: 36 • af43: 38 • cs1: 8 • cs2: 16 • cs3: 24 • cs4: 32 • cs5: 40 • cs6: 48 • cs7: 56 • default: 0 • ef: 46 By default, the *dscp-value* is 0.
local-precedence *local-precedence-value*	Re-marks the local IP precedence in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
ip-precedence *ip-precedence-value*	Re-marks the IP precedence in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
vlan-id *vlan-id*	Re-marks the VLAN ID in packets.	The value is an integer that ranges from 1 to 4094.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-remark** command is executed on an interface, the device re-marks packets matching an ACL, for example, 802.1p priority, inner VLAN tag in QinQ packets, destination MAC address, DSCP service type, local IP precedence, IP precedence, and VLAN ID.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied

to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

- The destination MAC address and VLAN ID in packets cannot be re-marked.

If the **traffic-remark (system view)** and **traffic-remark (interface view)** commands are used simultaneously, the **traffic-remark (interface view)** command takes effect.

When the **traffic-remark (interface view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used simultaneously, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, traffic is re-marked.

Outbound ACL-based re-marking on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based re-marking is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based re-marking.

Example

Configure ACL-based re-marking in the inbound direction on GE0/0/1, and re-mark the VLAN ID in packets from source MAC address 0-0-1 with 100.

```
<HUAWEI> system-view
[HUAWEI] acl 4001
[HUAWEI-acl-L2-4001] rule 5 permit source-mac 0-0-1
[HUAWEI-acl-L2-4001] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-remark inbound acl 4001 rule 5 vlan-id 100
```

15.8.14 traffic-remark (system view)

Function

The **traffic-remark** command configures ACL-based re-marking globally or in a VLAN.

The **undo traffic-remark** command cancels ACL-based re-marking globally or in a VLAN.

By default, ACL-based re-marking is not configured globally or in a VLAN.

Format

To configure ACL-based re-marking in the inbound direction on a switch, use the following command:

traffic-remark [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-**

mac *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **inbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

traffic-remark inbound acl { **name** *acl-name* | *ucl-acl* } **local-precedence** *local-precedence-value*

NOTE

The function of re-marking the internal priority of packets based on a user ACL is available only on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S.

To configure ACL-based re-marking in the outbound direction on a switch, use the following command:

traffic-remark [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

If both Layer 2 and Layer 3 ACLs are configured and re-marking is used in the inbound direction on a switch, use the following command:

traffic-remark [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

traffic-remark [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

traffic-remark [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **destination-mac** *mac-address* | **dscp** { *dscp-name* | *dscp-value* } | **ip-precedence** *ip-precedence-value* | **local-precedence** *local-precedence-value* | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **destination-mac** | **dscp** | **ip-precedence** | **local-precedence** | **vlan-id** }

If both Layer 2 and Layer 3 ACLs are configured and re-marking is used in the outbound direction on a switch, use the following command:

traffic-remark [**vlan** *vlan-id*] **outbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **outbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

traffic-remark [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

traffic-remark [**vlan** *vlan-id*] **outbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** *8021p-value* | **cvlan-id** *cvlan-id* | **dscp** { *dscp-name* | *dscp-value* } | **vlan-id** *vlan-id* }

undo traffic-remark [**vlan** *vlan-id*] **outbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] { **8021p** | **cvlan-id** | **dscp** | **vlan-id** }

Parameters

Parameter	Description	Value
vlan *vlan-id*	Configures ACL-based re-marking in a specified VLAN.	The value is an integer in the range from 1 to 4094.
inbound	Re-marks packets in the inbound direction.	-
outbound	Re-marks packets in the outbound direction.	-
acl	Re-marks packets based on the IPv4 ACL.	-
ipv6	Re-marks packets based on the IPv6 ACL.	-
bas-acl	Re-marks packets based on a specified basic ACL.	The value is an integer in the range from 2000 to 2999.
adv-acl	Re-marks packets based on a specified advanced ACL.	The value is an integer in the range from 3000 to 3999.
l2-acl	Re-marks packets based on a specified Layer 2 ACL.	The value is an integer in the range from 4000 to 4999.

Parameter	Description	Value
user-acl	Re-marks packets based on a specified user-defined ACL.	The value is an integer in the range from 5000 to 5999.
ucl-acl	Specifies the user ACL for re-marking packets based on a user ACL.	The value is an integer in the range from 6000 to 9999.
name *acl-name*	Re-marks packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Re-marks packets based on a specified ACL rule.	The value is an integer in the range from 0 to 4294967294.
8021p *8021p-value*	Re-marks the 802.1p priority in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
cvlan-id *cvlan-id*	Re-marks the inner VLAN tag in QinQ packets. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **cvlan-id** *cvlan-id*.	The value is an integer in the range from 1 to 4094.
destination-mac *mac-address*	Re-marks the destination MAC address in packets. **NOTE** Only the S6735-S, S6720-EI and S6720S-EI support **destination-mac** *mac-address*.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
dscp { *dscp-name* | *dscp-value* }	Re-marks the DSCP priority in packets.	The value can be an integer in the range of 0 to 63, or DSCP service name, for example, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cs1 to cs7, default, or ef. The values corresponding to DSCP service names are as follows: ● af11: 10 ● af12: 12 ● af13: 14 ● af21: 18 ● af22: 20 ● af23: 22 ● af31: 26 ● af32: 28 ● af33: 30 ● af41: 34 ● af42: 36 ● af43: 38 ● cs1: 8 ● cs2: 16 ● cs3: 24 ● cs4: 32 ● cs5: 40 ● cs6: 48 ● cs7: 56 ● default: 0 ● ef: 46 By default, the *dscp-value* is 0.
local-precedence *local-precedence-value*	Re-marks the local IP precedence in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.

Parameter	Description	Value
ip-precedence *ip-precedence-value*	Re-marks the IP precedence in packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
vlan-id *vlan-id*	Re-marks the VLAN ID in packets.	The value is an integer in the range from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-remark** command is executed on a device, the device re-marks packets matching an ACL rule, for example, 802.1p priority, inner VLAN tag in QinQ packets, destination MAC address, DSCP service type, local precedence, IP precedence, and VLAN ID.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If both the **traffic-remark (interface view)** and **traffic-remark (system view)** commands are used, the **traffic-remark (interface view)** command takes effect.

When both the **traffic-remark (system view)** command and the **traffic-filter (interface view)** command or the **traffic-filter (system view)** command are used, and the two commands are associated with the same ACL rule:

- If the deny action is configured in the ACL rule, traffic is discarded.
- If the permit action is configured in the ACL rule, traffic is re-marked.

Outbound ACL-based re-marking on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based re-marking is configured, and the ACL is based on VLAN IDs.

- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based re-marking.

Example

Configure ACL-based re-marking in the inbound direction in VLAN 100, and re-mark the VLAN ID in packets from source MAC address 0-0-1 with 101.

```
<HUAWEI> system-view
[HUAWEI] acl 4001
[HUAWEI-acl-L2-4001] rule 5 permit source-mac 0-0-1
[HUAWEI-acl-L2-4001] quit
[HUAWEI] traffic-remark vlan 100 inbound acl 4001 rule 5 vlan-id 101
```

15.8.15 traffic-secure (interface view)

Function

The **traffic-secure** command configures ACL-based packet filtering on an interface.

The **undo traffic-secure** command cancels ACL-based packet filtering on an interface.

By default, ACL-based packet filtering is not configured on an interface.

Format

To configure a single ACL, use the following command:

traffic-secure inbound acl { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-secure inbound acl { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-secure inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-secure inbound acl { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
inbound	Filters packets in the inbound direction.	-
acl	Filters packets based on the IPv4 ACL.	-
bas-acl	Filters packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.

Parameter	Description	Value
adv-acl	Filters packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Filters packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
name *acl-name*	Filters packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Filters packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.

Views

VLANIF interface view, Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Tunnel interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-secure** command is executed on an interface, the device filters packets matching ACL rules:

- If the action in an ACL rule is **deny**, the device discards packets matching the rule.
- If the action in an ACL rule is **permit**, the device forwards packets matching the rule.
- If no rule is matched, packets are allowed to pass through.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, if traffic matching **traffic-secure (interface view)** also matches **traffic-redirect (interface view)** or **traffic-redirect (system view)**, **traffic-redirect (interface view)** or **traffic-redirect (system view)** takes effect. On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the ACL defines the permit action, **traffic-redirect (interface view)** or **traffic-redirect (system view)** and **traffic-secure (interface view)** take effect.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, **traffic-secure** takes precedence over other ACL-based simplified traffic policy commands except **traffic-redirect (interface view)** and **traffic-redirect (system view)**.

On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, **traffic-secure** takes precedence over other ACL-based simplified traffic policy commands.

If both **traffic-secure** and other ACL-based simplified traffic policy commands need to be configured on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, and the ACL is based on the inner 802.1p priority, inner VLAN ID, or port range, configure the **traffic-secure** command, and then configure other ACL-based simplified traffic policy commands.

Example

Configure the traffic filtering action on GE0/0/1 to discard the packets with source address 192.168.0.2 and mirror the packets with destination address 192.168.1.3 to the observing interface with the index of 1.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 deny ip source 192.168.0.2 0

[HUAWEI-GigabitEthernet0/0/1] traffic-mirror inbound acl 3001 to observe-port 1
```

15.8.16 traffic-secure (system view)

Function

The **traffic-secure** command configures ACL-based packet filtering globally or in a VLAN.

The **undo traffic-secure** command cancels ACL-based packet filtering globally or in a VLAN.

By default, ACL-based packet filtering is not configured globally or in a VLAN.

Format

To configure a single ACL, use the following command:

traffic-secure [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-secure [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

If both Layer 2 ACLs and Layer 3 ACLs are configured, use the following command:

traffic-secure [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-secure [**vlan** *vlan-id*] **inbound acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Configures ACL-based packet filtering in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
inbound	Filters packets in the inbound direction.	-
acl	Filters packets based on the IPv4 ACL.	-
bas-acl	Filters packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Filters packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.

Parameter	Description	Value
l2-acl	Filters packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.
name *acl-name*	Filters packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Filters packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-secure** command is executed on the device, the device filters packets matching ACL rules:

- If the action in an ACL rule is **deny**, the device discards packets matching the rule.
- If the action in an ACL rule is **permit**, the device forwards packets matching the rule.
- If no rule is matched, packets are allowed to pass through.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, if traffic matching **traffic-secure (system view)** also matches **traffic-redirect (interface view)** or **traffic-redirect (system view)**, **traffic-redirect (interface view)** or **traffic-redirect (system view)** takes effect. On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, if the ACL defines the permit action, **traffic-redirect (interface view)** or **traffic-redirect (system view)** and **traffic-secure (system view)** take effect.

On the S1720GW-E, S1720GWR-E, S5720I-SI, S5720S-LI, S5735S-H, S5736-S, S6720S-S, and S5720-LI, **traffic-secure** takes precedence over other ACL-based simplified traffic policy commands except **traffic-redirect (interface view)** and **traffic-redirect (system view)**.

On the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, **traffic-secure** takes precedence over other ACL-based simplified traffic policy commands.

If both **traffic-secure** and other ACL-based simplified traffic policy commands need to be configured on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S, and the ACL is based on the inner 802.1p priority, inner VLAN ID, or port range, configure the **traffic-secure** command, and then configure other ACL-based simplified traffic policy commands.

Example

Configure the traffic filtering action globally to discard the packets with source address 192.168.0.2 and mirror the packets with destination address 192.168.1.3 to the observing interface with the index of 1.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 deny ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] acl name test 3001
[HUAWEI-acl-adv-test] rule 5 permit ip destination 192.168.1.3 0
[HUAWEI-acl-adv-test] quit
[HUAWEI] traffic-secure inbound acl 3000
[HUAWEI] traffic-mirror inbound acl 3001 to observe-port 1
```

15.8.17 traffic-statistic (interface view)

Function

The **traffic-statistic** command configures ACL-based traffic statistics on an interface.

The **undo traffic-statistic** command cancels ACL-based traffic statistics on an interface.

By default, the ACL-based traffic statistics function is not configured on an interface.

Format

Use the following command in the inbound direction on an interface:

traffic-statistic inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* | *l2-acl* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic inbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* | *l2-acl* } [**rule** *rule-id*] [**secure**]

traffic-statistic inbound acl { **ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* } | *user-acl* } [**rule** *rule-id*] [**by-bytes**]

undo traffic-statistic inbound acl { **ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* } | *user-acl* } [**rule** *rule-id*]

Use the following command in the inbound direction on a tunnel interface:

traffic-statistic inbound acl { *adv-acl* | *ucl-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**]

undo traffic-statistic inbound acl { *adv-acl* | *ucl-acl* | **name** *acl-name* } [**rule** *rule-id*]

NOTE

ACL-based traffic statistics collection can be configured in the inbound direction of a tunnel interface only on the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Use the following command in the outbound direction on an interface:

traffic-statistic outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

undo traffic-statistic outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and the ACL-based traffic statistics collection function is used in the inbound direction on an interface, use the following command:

traffic-statistic inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic inbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

traffic-statistic inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic inbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

traffic-statistic inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic inbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

If both Layer 2 and Layer 3 ACLs are configured and the ACL-based traffic statistics collection function is used in the outbound direction on an interface, use the following command:

traffic-statistic outbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic outbound acl *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-statistic outbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic outbound acl { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-statistic outbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic outbound acl name *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
inbound	Collects statistics on packets in the inbound direction.	-
outbound	Collects statistics on packets in the outbound direction.	-
acl	Collects statistics on packets based on the IPv4 ACL.	-
ipv6	Collects statistics on packets based on the IPv6 ACL.	-
bas-acl	Collects statistics on packets based on a specified basic ACL.	The value is an integer in the range from 2000 to 2999.
adv-acl	Collects statistics on packets based on a specified advanced ACL.	The value is an integer in the range from 3000 to 3999.
l2-acl	Collects statistics on packets based on a specified Layer 2 ACL.	The value is an integer in the range from 4000 to 4999.
user-acl	Collects statistics on packets based on a specified user-defined ACL.	The value is an integer in the range from 5000 to 5999.
ucl-acl	Collects statistics on packets based on a specified user ACL.	The value is an integer in the range from 6000 to 9999.

Parameter	Description	Value
name *acl-name*	Collects statistics on packets based on a specified named ACL. *acl-name* specifies the name of an ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Collects statistics on packets based on a specified ACL rule.	The value is an integer in the range from 0 to 4294967294.
by-bytes	Collects statistics on packets based on the number of bytes. **NOTE** By default, traffic statistics are collected based on the number of packets. After **by-bytes** is specified, traffic statistics are collected based on the number of bytes.	-
secure	Collects statistics on packets based on packet filtering policies configured through the **traffic-secure (interface view)** command.	-

Views

VLANIF interface view, Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Tunnel interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-statistic** command is executed on an interface, the device collects statistics on packets matching an ACL. After the statistics collection function is configured, you can use the **display traffic-statistics** command to view the statistics.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support ACL-based simplified traffic policy configuration on a VLANIF interface.

- The VLAN corresponding to the VLANIF interface cannot be a Super-VLAN or MUX VLAN.
- For the S6735-S, S6720-EI and S6720S-EI, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets and Layer 3 multicast packets on the VLANIF interface.
- For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, an ACL-based simplified traffic policy that is applied to a VLANIF interface is only valid for unicast packets on the VLANIF interface.

If the **traffic-statistic (system view)** and **traffic-statistic (interface view)** commands are used simultaneously, the **traffic-statistic (interface view)** command takes effect.

When the action in an ACL rule is **permit** or **deny**, the ACL can be associated with the **traffic-statistic** command, but **deny** does not take effect. That is, only traffic statistics are collected.

Outbound ACL-based traffic statistics collection on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based traffic statistics collection is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based traffic statistics collection.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, ifIf **traffic-statistic** is applied to an Eth-Trunk in the outbound direction, traffic statistics does not take effect for the packets sent by the CPU. In this case, you can configure traffic statistics or port mirroring in the inbound direction on the interface connected to the Eth-Trunk.

Example

Configure the ACL-based traffic statistics function in the inbound direction on GE0/0/1 to collect statistics on packets matching rule 1 in ACL 3000.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-statistic inbound acl 3000 rule 1
```

15.8.18 traffic-statistic (system view)

Function

The **traffic-statistic** command configures ACL-based traffic statistics globally or in a VLAN.

The **undo traffic-statistic** command cancels ACL-based traffic statistics globally or in a VLAN

By default, the ACL-based traffic statistics function is not configured globally or in a VLAN.

Format

Use the following command in the inbound direction on a switch:

traffic-statistic [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* | *l2-acl* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* | **name** *acl-name* | *l2-acl* } [**rule** *rule-id*] [**secure**]

traffic-statistic [**vlan** *vlan-id*] **inbound acl** { **ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* } | *user-acl* } [**rule** *rule-id*] [**by-bytes**]

undo traffic-statistic [**vlan** *vlan-id*] **inbound acl** { **ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* } | *user-acl* } [**rule** *rule-id*]

Use the following command in the outbound direction on a switch:

traffic-statistic [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

undo traffic-statistic [**vlan** *vlan-id*] **outbound acl** { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } | *l2-acl* | *user-acl* } [**rule** *rule-id*]

If both Layer 2 and Layer 3 ACLs are configured and the ACL-based traffic statistics function is used in the inbound direction on a switch, use the following command:

traffic-statistic [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic [**vlan** *vlan-id*] **inbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

traffic-statistic [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic [**vlan** *vlan-id*] **inbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

traffic-statistic [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**by-bytes**] [**secure**]

undo traffic-statistic [**vlan** *vlan-id*] **inbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*] [**secure**]

If both Layer 2 and Layer 3 ACLs are configured and the ACL-based traffic statistics function is used in the outbound direction on a switch, use the following command:

traffic-statistic [**vlan** *vlan-id*] **outbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic [**vlan** *vlan-id*] **outbound acl** *l2-acl* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-statistic [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic [**vlan** *vlan-id*] **outbound acl** { *bas-acl* | *adv-acl* } [**rule** *rule-id*] **acl** { *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

traffic-statistic [**vlan** *vlan-id*] **outbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

undo traffic-statistic [**vlan** *vlan-id*] **outbound acl name** *acl-name* [**rule** *rule-id*] **acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* } [**rule** *rule-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Configures ACL-based packet statistics in a specified VLAN.	The value is an integer that ranges from 1 to 4094.
inbound	Collects statistics on packets in the inbound direction.	-
outbound	Collects statistics on packets in the outbound direction.	-
acl	Collects statistics on packets based on the IPv4 ACL.	-
ipv6	Collects statistics on packets based on the IPv6 ACL.	-
bas-acl	Collects statistics on packets based on a specified basic ACL.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Collects statistics on packets based on a specified advanced ACL.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Collects statistics on packets based on a specified Layer 2 ACL.	The value is an integer that ranges from 4000 to 4999.

Parameter	Description	Value
user-acl	Collects statistics on packets based on a specified user-defined ACL.	The value is an integer that ranges from 5000 to 5999.
name *acl-name*	Collects statistics on packets based on a specified named ACL. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
rule *rule-id*	Collects statistics on packets based on a specified ACL rule.	The value is an integer that ranges from 0 to 4294967294.
by-bytes	Indicates that traffic statistics are collected based on the number of bytes. **NOTE** By default, traffic statistics are collected based on the number of packets. After **by-bytes** is specified, traffic statistics are collected based on the number of bytes.	-
secure	Collects statistics on packets based on packet filtering policies configured through the **traffic-secure (system view)** command.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **traffic-statistic** command is executed on the device, the device collects statistics on packets matching an ACL. After the statistics function is configured, you can use the **display traffic-statistics** command to view the statistics.

Precautions

If **name** *acl-name* is specified in the command, you need to run the **acl name** or **acl ipv6 name** command to create the corresponding ACL. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If **rule** *rule-id* is specified in the command, you need to create an ACL and configure the corresponding rule. Otherwise, the ACL-based simplified traffic policy fails to be configured.

If the **traffic-statistic (interface view)** and **traffic-statistic (system view)** commands are used simultaneously, the **traffic-statistic (interface view)** command takes effect.

When the action in an ACL rule is **permit** or **deny**, the ACL can be associated with the **traffic-statistic** command, but **deny** does not take effect. That is, only traffic statistics are collected.

Outbound ACL-based traffic statistics collection on an interface does not take effect on the S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S5735S-H, S5736-S, S6720S-S, and S5720S-LI if:

- Outbound ACL-based traffic statistics collection is configured, and the ACL is based on VLAN IDs.
- VLAN mapping is also configured on the interface, and the mapped VLAN ID is the same as the VLAN ID in ACL-based traffic statistics collection.

Example

Configure the ACL-based traffic statistics function in the inbound direction in VLAN 100 to collect statistics on packets matching rule 1 in ACL 3000.

```
<HUAWEI> system-view
[HUAWEI] traffic-statistic vlan 100 inbound acl 3000 rule 1
```

15.9 HQoS Commands

15.9.1 Command Support

Only the following switch model supports HQoS:

S5731-S, S5731S-S, S5731-H, S5731S-H

15.9.2 color (flow queue WRED drop profile view)

Function

The **color** command configures upper and lower drop thresholds and maximum drop probability in a flow queue WRED drop profile based on the packet color.

The **undo color** command restores default parameters in a flow queue WRED drop profile.

By default, the upper and lower drop thresholds and maximum drop probability for green, yellow, and red packets are 100.

Format

color { **green** | **yellow** | **red** } **low-limit** *low-limit-percentage* **high-limit** *high-limit-percentage* **discard-percentage** *discard-percentage*

undo color { **green** | **yellow** | **red** }

Parameters

Parameter	Description	Value
green	Indicates WRED parameters for green packets.	-
yellow	Indicates WRED parameters for yellow packets.	-
red	Indicates WRED parameters for red packets.	-
low-limit *low-limit-percentage*	Specifies the lower drop threshold, in percentage. When the percentage of the packet length to the queue length reaches this value, the device discards packets based on the drop probability.	The value is an integer that ranges from 0 to 100. The default value is 100.
high-limit *high-limit-percentage*	Specifies the upper drop threshold, in percentage. When the percentage of the packet length to the queue length reaches this value, the device starts to discard all subsequent packets.	The value is an integer that ranges from *low-limit-percentage* to 100. The default value is 100.
discard-percentage *discard-percentage*	Specifies the maximum drop probability.	The value is an integer that ranges from 1 to 100. The default value is 100.

Flow queue WRED drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When packets enter queues, the device colors packets based on the mapping defined in a DiffServ domain. The device processes packets entering flow queues based on parameters in a flow queue WRED drop profile. When the percentage of the packet length to the queue length reaches the lower drop threshold, the device discards packets based on the drop probability. When the percentage of the packet length to the queue length reaches the upper drop threshold, the device discards all subsequent packets.

Prerequisites

A flow queue WRED drop profile has been created and the flow queue WRED drop profile view has been displayed.

Example

Configure flow queue WRED drop profile **wred1**, set the lower drop threshold, upper drop threshold, and maximum drop probability for green packets to 80%, 100%, and 10%, set the lower drop threshold, upper drop threshold, and maximum drop probability for yellow packets to 60%, 80%, and 20%, and set the lower drop threshold, upper drop threshold, and maximum drop probability for red packets to 40%, 60%, and 40%.

```
<HUAWEI> system-view
[HUAWEI] flow-wred-profile wred1
[HUAWEI-flow-wred-wred1] color green low-limit 80 high-limit 100 discard-percentage 10
[HUAWEI-flow-wred-wred1] color yellow low-limit 60 high-limit 80 discard-percentage 20
[HUAWEI-flow-wred-wred1] color red low-limit 40 high-limit 60 discard-percentage 40
```

15.9.3 display flow-queue-profile

Function

The **display flow-queue-profile** command displays the flow queue profile configuration.

Format

display flow-queue-profile [**name** *flow-queue-profile-name* | **all**]

Parameters

Parameter	Description	Value
name *flow-queue-profile-name*	Displays detailed information about a specified flow queue profile.	The value must be the name of an existing flow queue profile.
all	Displays detailed information about all flow queue profiles.	-

Usage Guidelines

Usage Scenario

You can use the **display flow-queue-profile** command to view the number of configured flow queue profiles and all the configuration of the specified flow queue profile.

Precautions

If **all** and **name** *flow-queue-profile* are not specified, brief information about all flow queue profiles is displayed.

Example

Display brief information about all flow queue profiles.

```
<HUAWEI> display flow-queue-profile
       index                  flow-queue-profile name
--------------------------------------------------------------------
       0                     default
       1                     flow1
--------------------------------------------------------------------
 Total   128     Used   2
```

Display detailed information about flow queue profile **flow1**.

```
<HUAWEI> display flow-queue-profile name flow1
Flow-queue-profile[1]: flow1
Queue Schedule(Weight) Shaping        flow-wred-profile
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
0     WFQ(50)          50%            wred1
1     PQ               None           default
2     PQ               None           default
3     PQ               None           default
4     PQ               None           default
5     PQ               None           default
6     PQ               None           default
7     PQ               None           default
---------------------------------------------------------------------------
```

Display detailed information about all flow queue profiles.

```
<HUAWEI> display flow-queue-profile all
Flow-queue-profile[0]: default
Queue Schedule(Weight) Shaping        flow-wred-profile
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
0     PQ               None           default
1     PQ               None           default
2     PQ               None           default
3     PQ               None           default
4     PQ               None           default
5     PQ               None           default
6     PQ               None           default
7     PQ               None           default
---------------------------------------------------------------------------
```

```
Flow-queue-profile[1]: flow1

------------------------------------------------------------------------
```

Table 15-35 Description of the **display flow-queue-profile** command output

Item	Description
index	Index of the flow queue profile.
flow-queue-profile name	Name of the flow queue profile. To create a flow queue profile, run the **flow-queue-profile** command.
Total	Total number of flow queue profiles.
Used	Number of configured flow queue profiles.
Flow-queue-profile[1]	Name of the flow queue profile. The value 1 is the index of the flow queue profile. To create a flow queue profile, run the **flow-queue-profile** command.
Queue	Index of the flow queue, which corresponds to the local priority of packets.
Schedule(Weight)	Scheduling mode or weight of the flow queue. To set the scheduling mode and weight of a flow queue, run the **qos queue (flow queue profile view)** command.
Shaping	Traffic shaping rate or percentage of the flow queue. To set the traffic shaping and percentage of a flow queue, run the **qos queue (flow queue profile view)** command.
flow-wred-profile	Name of the WRED drop profile bound to the flow queue. To bind a WRED drop profile to a flow queue, run the **qos queue (flow queue profile view)** command.

15.9.4 display flow-wred-profile

Function

The **display flow-wred-profile** command displays the configuration of flow queue WRED drop profiles.

Format

display flow-wred-profile [**name** *flow-wred-profile-name* | **all**]

Parameters

Parameter	Description	Value
name *flow-wred-profile-name*	Displays detailed information about a specified flow queue WRED drop profile.	The value must be the name of an existing flow queue WRED drop profile.
all	Displays detailed information about all flow queue WRED drop profiles.	-

Views

Usage Guidelines

Usage Scenario

You can use the **display flow-wred-profile** command to view the number of configured flow queue WRED drop profiles and all the configuration of the specified flow queue WRED drop profile.

Precautions

If **all** and **name** *flow-wred-profile-name* are not specified, brief information about all flow queue WRED drop profiles is displayed.

Example

Display brief information about all flow queue WRED drop profiles.

```
<HUAWEI> display flow-wred-profile
        index                    flow-wred-profile name
----------------------------------------------------------------
```

```
      0                    default
      1                    wred1
----------------------------------------------------------------------
 Total   128     Used    2
```

Display detailed information about flow queue WRED drop profile **wred1**.

```
<HUAWEI> display flow-wred-profile name wred1
Flow-wred-profile[1]: wred1
Queue depth         : 1048576
Color     Low-limit   High-limit  Discard-percentage
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Green     80          100         10
Yellow    60          80          20
Red       40          60          40
----------------------------------------------------------------------
```

Display detailed information about all flow queue WRED drop profiles.

```
<HUAWEI> display flow-wred-profile all
Flow-wred-profile[0]: default
Queue depth         : 1048576
Color     Low-limit   High-limit  Discard-percentage
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
Green     100         100         100
Yellow    100         100         100
Red       100         100         100
----------------------------------------------------------------------
Flow-wred-profile[1]: wred1

```

Table 15-36 Description of the display flow-wred-profile command output

Item	Description
index	Index of the flow queue WRED drop profile.
flow-wred-profile name	Name of the flow queue WRED drop profile. To create a flow queue WRED drop profile, run the **flow-wred-profile** command.
Total	Total number of flow queue WRED drop profiles.
Used	Number of configured flow queue WRED drop profiles.
Flow-wred-profile[1]	Name of the flow queue WRED drop profile. The value 1 is the index of the flow queue WRED drop profile. To create a flow queue WRED drop profile, run the **flow-wred-profile** command.

Item	Description
Queue depth	Queue length. To set the queue length, run the **queue-depth (flow queue WRED drop profile view)** command.
Color	Packet color. To set the packet color, run the **color (flow queue WRED drop profile view)** command.
Low-limit	Lower drop threshold in the flow queue WRED drop profile, in percentage. To set the lower drop threshold in a flow queue WRED drop profile, run the **color (flow queue WRED drop profile view)** command.
High-limit	Upper drop threshold in the flow queue WRED drop profile, in percentage. To set the upper drop threshold in a flow queue WRED drop profile, run the **color (flow queue WRED drop profile view)** command.
Discard-percentage	Maximum drop probability in the flow queue WRED drop profile, in percentage. To set the maximum drop probability in a flow queue WRED drop profile, run the **color (flow queue WRED drop profile view)** command.

15.9.5 display traffic-user-queue statistics

Function

The **display traffic-user-queue statistics** command displays traffic statistics on subscriber queues.

Format

display traffic-user-queue statistics interface *interface-type interface-number* **outbound acl** { *bas-acl* | *adv-acl* } [**acl** { *l2-acl* | **name** *acl-name* }]

display traffic-user-queue statistics interface *interface-type interface-number* **outbound acl** *l2-acl* [**acl** { *bas-acl* | *adv-acl* | **name** *acl-name* }]

display traffic-user-queue statistics interface *interface-type interface-number* **outbound acl name** *acl-name* [**acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* }]

display traffic-user-queue statistics interface *interface-type interface-number* **outbound acl ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* }

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays traffic statistics on subscriber queues on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
outbound	Displays traffic statistics on subscriber queues in the outbound direction on an interface.	-
acl	Displays traffic statistics on subscriber queues based on IPv4 ACLs.	-
ipv6	Displays traffic statistics on subscriber queues based on IPv6 ACLs.	-
bas-acl	Displays traffic statistics on subscriber queues based on basic ACLs.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Displays traffic statistics on subscriber queues based on advanced ACLs.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Displays traffic statistics on subscriber queues based on Layer 2 ACLs.	The value is an integer that ranges from 4000 to 4999.
name *acl-name*	Displays traffic statistics on subscriber queues based on named ACLs. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display traffic-user-queue statistics** command displays traffic statistics on subscriber queues based on ACLs on an interface. The command output helps you learn about forwarded and discarded packets matching ACLs and locate faults.

Prerequisites

The **traffic-user-queue** command has been executed to create a subscriber queue based on ACLs to implement HQoS.

Example

Display traffic statistics on subscriber queues based on ACL 3009 in the outbound direction on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl 3009
[HUAWEI-acl-adv-3009] rule 1 permit ip
[HUAWEI-acl-adv-3009] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-user-queue outbound acl 3009 pir 2000
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] display traffic-user-queue statistics interface gigabitethernet 0/0/1 outbound acl 3009
-------------------------------------------------------------------------------
 Interface: GigabitEthernet0/0/1
-------------------------------------------------------------------------------
    Queue ID     |                   Statistics information

                |                  drop:                        0
-------------------------------------------------------------------------------
```

Table 15-37 Description of the **display traffic-user-queue statistics** command output

Item	Description
Queue ID	Index of the flow queue.
packets	Number of collected packets. pass indicates the number of forwarded packets, and drop indicates the number of discarded packets.
bytes	Number of collected bytes. pass indicates the number of forwarded bytes, and drop indicates the number of discarded bytes.

15.9.6 flow-queue-profile

Function

The **flow-queue-profile** command creates a flow queue profile or displays the view of an existing flow queue profile.

The **undo flow-queue-profile** command deletes the created flow queue profile.

By default, the system predefines a flow queue profile **default**.

Format

flow-queue-profile *flow-queue-profile-name*

undo flow-queue-profile *flow-queue-profile-name*

Parameters

Parameter	Description	Value
flow-queue-profile-name	Specifies the name of a flow queue profile.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring congestion management and traffic shaping parameters of a flow queue, you can run the **flow-queue-profile** *flow-queue-profile-name* command to create a flow queue profile and define parameters in the profile. To set the same scheduling mode and weight for different flow queues, reference the same flow queue profile.

Precautions

The flow queue profile **default** cannot be modified or deleted.

Follow-up Procedure

Configure congestion management and traffic shaping parameters of a flow queue and reference the flow queue WRED drop profile in the flow queue profile view.

Example

Create flow queue profile **test**.

```
<HUAWEI> system-view
[HUAWEI] flow-queue-profile test
[HUAWEI-flow-queue-test]
```

15.9.7 flow-wred-profile

Function

The **flow-wred-profile** command creates a flow queue WRED drop profile or displays the view of an existing flow queue WRED drop profile.

The **undo flow-wred-profile** command deletes the created flow queue WRED drop profile.

By default, the system predefines a flow queue WRED drop profile **default**.

Format

flow-wred-profile *flow-wred-profile-name*

undo flow-wred-profile *flow-wred-profile-name*

Parameters

Parameter	Description	Value
flow-wred-profile-name	Specifies the name of a flow queue WRED drop profile.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring WRED parameters of a flow queue, you can run the **flow-wred-profile** *flow-wred-profile-name* command to create a flow queue WRED drop profile and define parameters in the profile. To use the same upper and lower drop thresholds and maximum drop probability for different flow queues, reference the same flow queue WRED drop profile.

Precautions

The flow queue WRED drop profile **default** cannot be modified or deleted.

Follow-up Procedure

Configure WRED parameters of the flow queue and queue length in the flow queue WRED drop profile view.

Example

Create flow queue WRED drop profile **test**.

```
<HUAWEI> system-view
[HUAWEI] flow-wred-profile test
[HUAWEI-flow-wred-test]
```

15.9.8 qos queue (flow queue profile view)

Function

The **qos queue** command sets the scheduling mode, traffic shaping rate, and referenced flow queue WRED drop profile.

The **undo qos queue** command restores the default scheduling mode, traffic shaping rate, and referenced flow queue WRED drop profile.

By default, a flow queue uses PQ scheduling, PIR of a subscriber queue as the traffic shaping rate, and flow queue WRED drop profile **default**.

Format

qos queue *queue-index* { { **pq** | **wfq weight** *weight-value* } | { **shaping** { *shaping-value* | **shaping-percentage** *shaping-percentage-value* } } | { **flow-wred-profile** *flow-wred-profile-name* } } *

undo qos queue *queue-index* { { **pq** | **wfq** } | **shaping** | **flow-wred-profile** } *

Parameters

Parameter	Description	Value
queue-index	Specifies the index of a flow queue.	The value is an integer that ranges from 0 to 7.
pq	Indicates PQ scheduling.	-
wfq	Indicates WFQ scheduling.	-
weight *weight-value*	Specifies the weight of WFQ scheduling.	The value is an integer that ranges from 1 to 100.
shaping *shaping-value*	Specifies the traffic shaping rate.	The value is an integer that ranges from 64 to 10000000, in kbit/s.

Parameter	Description	Value
shaping-percentage *shaping-percentage-value*	Specifies the traffic shaping percentage, that is, percentage of the traffic shaping rate to the PIR of a subscriber queue.	The value is an integer that ranges from 1 to 100.
flow-wred-profile *flow-wred-profile-name*	Specifies the name of a flow queue WRED drop profile.	The value must be the name of an existing flow queue WRED drop profile.

Views

Flow queue profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To manage packets in a flow queue, run this command to set the scheduling mode, traffic shaping rate, and referenced flow queue WRED drop profile.

Prerequisites

A flow queue profile has been created and the flow queue profile view has been displayed.

Precautions

The scheduling mode, traffic shaping rate, and flow queue WRED drop profile can be configured in any sequence. You can configure the scheduling mode, traffic shaping rate, and flow queue WRED drop profile independently or a combination of them.

Example

Configure flow queue profile **flow1** where the WFQ weight of flow queue 0 is 50%, the traffic shaping percentage is 50%, and referenced flow queue WRED drop profile is **wred1**.

```
<HUAWEI> system-view
[HUAWEI] flow-queue-profile flow1
[HUAWEI-flow-queue-flow1] qos queue 0 wfq weight 50 shaping shaping-percentage 50 flow-wred-profile wred1
```

15.9.9 queue-depth (flow queue WRED drop profile view)

Function

The **queue-depth** command sets the length of a flow queue.

The **undo queue-depth** command restores the default length of a flow queue.

By default, the length of a flow queue is 1048576 bytes.

Format

queue-depth *queue-depth-value*

undo queue-depth

Parameters

Parameter	Description	Value
queue-depth-value	Specifies the length of a flow queue.	The value is an integer that ranges from 1024 to 67092480, in bytes. The default value is 1048576.

Views

Flow queue WRED drop profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When packets entering flow queues are processed based on parameters in a flow queue WRED drop profile, the percentage of the packet length to the flow queue length needs to be calculated. When the percentage reaches the lower drop threshold, the device discards packets based on the drop probability. When the percentage reaches the upper drop threshold, the device discards all subsequent packets. You can adjust the flow queue length to optimize the congestion avoidance effect.

Prerequisites

A flow queue WRED drop profile has been created and the flow queue WRED drop profile view has been displayed.

Precautions

When a small flow queue length is used, the delay of packets passing a queue is shortened but the queue buffer capability is lowered. When a large flow queue length is used, the queue buffer capability is improved but the delay of packets passing a queue is extended. In addition, when congestion occurs in a flow queue, many buffer resources are occupied. In this case, packets in other flow queues may be discarded due to insufficient buffer resources. Therefore, the default flow queue length is recommended.

Example

Configure flow queue WRED drop profile **wred1** and set the flow queue length to 2000 bytes.

```
<HUAWEI> system-view
[HUAWEI] flow-wred-profile wred1
[HUAWEI-flow-wred-wred1] queue-depth 2000
```

15.9.10 reset traffic-user-queue statistics

Function

The **reset traffic-user-queue statistics** command clears traffic statistics on subscriber queues.

Format

reset traffic-user-queue statistics interface *interface-type interface-number* **outbound acl** { *bas-acl* | *adv-acl* } [**acl** { *l2-acl* | **name** *acl-name* }]

reset traffic-user-queue statistics interface *interface-type interface-number* **outbound acl** *l2-acl* [**acl** { *bas-acl* | *adv-acl* | **name** *acl-name* }]

reset traffic-user-queue statistics interface *interface-type interface-number* **outbound acl name** *acl-name* [**acl** { *bas-acl* | *adv-acl* | *l2-acl* | **name** *acl-name* }]

reset traffic-user-queue statistics interface *interface-type interface-number* **outbound acl ipv6** { *bas-acl* | *adv-acl* | **name** *acl-name* }

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears traffic statistics on subscriber queues on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
outbound	Clears traffic statistics on subscriber queues in the outbound direction on an interface.	-

Parameter	Description	Value
acl	Clears traffic statistics on subscriber queues based on IPv4 ACLs.	-
ipv6	Clears traffic statistics on subscriber queues based on IPv6 ACLs.	-
bas-acl	Clears traffic statistics on subscriber queues based on basic ACLs.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Clears traffic statistics on subscriber queues based on advanced ACLs.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Clears traffic statistics on subscriber queues based on Layer 2 ACLs.	The value is an integer that ranges from 4000 to 4999.
name *acl-name*	Clears traffic statistics on subscriber queues based on named ACLs. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before re-collecting traffic statistics on subscriber queues in a given period of time, run this command to clear existing traffic statistics on subscriber queues.

Precautions

The cleared traffic statistics on subscriber queues cannot be restored. Exercise caution when you run this command.

Example

Clear traffic statistics on subscriber queues based on ACL 3009 in the outbound direction on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl 3009
```

```
[HUAWEI-acl-adv-3009] rule 1 permit ip
[HUAWEI-acl-adv-3009] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-user-queue outbound acl 3009 pir 2000
[HUAWEI-GigabitEthernet0/0/1] return
<HUAWEI> reset traffic-user-queue statistics interface gigabitethernet 0/0/1 outbound acl 3009
```

15.9.11 sac-profile (system view)

Function

The **sac-profile** command creates an SAC profile and displays its view, or directly displays the view of an existing SAC profile.

The **undo sac-profile** command deletes an SAC profile.

By default, no SAC profile is configured on a device.

NOTE

Only the S5731-S, S5731S-S, S5731-H, and S5731S-H support this command.

Format

sac-profile name *profile-name*

undo sac-profile name *profile-name*

Parameters

Parameter	Description	Value
name *profile-name*	Indicates the name of an SAC profile.	The value is a string of 1 to 35 case-insensitive characters without spaces. If the string is enclosed in double quotation marks ("), the string can contain spaces.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure an SAC profile and perform QoS configurations for users using the profile, for example, re-marking internal priorities based on user ACLs.

Follow-up Procedure

- Set parameters for the SAC profile, for example, internal priority re-marked based on a user ACL.
- Apply the SAC profile in the specified view. For example, in the WLAN scenario, apply an SAC profile in the service scheme view to re-mark the internal priority of packets, so that the device can schedule packets based on the re-marked priority.

Precautions

A device supports a maximum of 31 SAC profiles.

Example

Create an SAC profile named **huawei** and enter the SAC profile view.

```
<HUAWEI> system-view
[HUAWEI] sac-profile name huawei
[HUAWEI-sac-profile-huawei]
```

15.9.12 sac-profile (service scheme view)

Function

The **sac-profile** command binds an SAC profile to a service scheme.

The **undo sac-profile** command unbinds an SAC profile from a service scheme.

By default, no SAC profile is bound to a service scheme.

NOTE

Only the S5731-S, S5731S-S, S5731-H, and S5731S-H support this command.

Format

sac-profile *profile-name*

undo sac-profile

Parameters

Parameter	Description	Value
profile-name	Specifies the name of an SAC profile.	The value must be the name of an existing SAC profile.

Views

Service scheme view

Default Level

3: Management level

Usage Guidelines

After creating a service scheme using the **service-scheme (AAA view)** command, you can run the **sac-profile** command to bind an SAC profile to the service scheme. The user assigned with the service scheme will have the attributes in the SAC profile.

Example

Bind the SAC profile **abc** to the service scheme **huawei**.

```
<HUAWEI> system-view
[HUAWEI] sac-profile name abc
[HUAWEI-sac-profile-abc] quit
[HUAWEI] aaa
[HUAWEI-aaa] service-scheme huawei
[HUAWEI-aaa-service-huawei] sac-profile abc
```

15.9.13 traffic-user-queue (interface view)

Function

The **traffic-user-queue** command creates a subscriber queue on an interface to implement HQoS.

The **undo traffic-user-queue** command deletes a subscriber queue on an interface.

By default, no subscriber queue is configured on an interface.

Format

If a single ACL is used, use the following command:

traffic-user-queue outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } } **pir** *pir-value* [**flow-queue-profile** *flow-queue-profile-name*]

undo traffic-user-queue outbound acl { [**ipv6**] { *bas-acl* | *adv-acl* | **name** *acl-name* } }

If both Layer 2 and Layer 3 ACLs are configured, use the following command:

traffic-user-queue outbound acl { *l2-acl* | **name** *acl-name* } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* } **pir** *pir-value* [**flow-queue-profile** *flow-queue-profile-name*]

undo traffic-user-queue outbound acl { *l2-acl* | **name** *acl-name* } **acl** { *bas-acl* | *adv-acl* | **name** *acl-name* }

traffic-user-queue outbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } **acl** { *l2-acl* | **name** *acl-name* } **pir** *pir-value* [**flow-queue-profile** *flow-queue-profile-name*]

undo traffic-user-queue outbound acl { *bas-acl* | *adv-acl* | **name** *acl-name* } **acl** { *l2-acl* | **name** *acl-name* }

Parameters

Parameter	Description	Value
outbound	Creates a subscriber queue in the outbound direction on an interface to implement HQoS scheduling.	-
acl	Creates a subscriber queue based on IPv4 ACLs to implement HQoS scheduling.	-
ipv6	Creates a subscriber queue based on IPv6 ACLs to implement HQoS scheduling.	-
bas-acl	Creates a subscriber queue based on basic ACLs to implement HQoS scheduling.	The value is an integer that ranges from 2000 to 2999.
adv-acl	Creates a subscriber queue based on advanced ACLs to implement HQoS scheduling.	The value is an integer that ranges from 3000 to 3999.
l2-acl	Creates a subscriber queue based on Layer 2 ACLs to implement HQoS scheduling.	The value is an integer that ranges from 4000 to 4999.
name *acl-name*	Creates a subscriber queue based on named ACLs to implement HQoS scheduling. *acl-name* specifies the name of the ACL.	The value must be the name of an existing ACL.
pir *pir-value*	Specifies the peak information rate (PIR) of a subscriber queue, which is the maximum rate of traffic that can pass through an interface.	The value is an integer that ranges from 64 to 10000000, in kbit/s.

Parameter	Description	Value
flow-queue-profile *flow-queue-profile-name*	Specifies the name of the referenced flow queue profile.	The value must be the name of an existing flow queue profile.

Views

GE interface view, XGE interface view, 25GE interface view, Eth-Trunk interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Multiple users can be differentiated based on ACL rules. When different scheduling and shaping parameters need to be set for different users and differentiated services need to be provided for different service traffic of the same user, run the **traffic-user-queue** command to configure multiple subscriber queues, set different scheduling modes and traffic shaping rates, and reference different flow queue profiles to implement fine-granular scheduling.

Prerequisites

The **acl (system view)** or **acl name** command has been executed to create an ACL.

Example

Create a subscriber queue based on ACLs on the GE0/0/1 to implement HQoS.

```
<HUAWEI> system-view
[HUAWEI] acl 3000
[HUAWEI-acl-adv-3000] rule 5 permit ip source 192.168.0.2 0
[HUAWEI-acl-adv-3000] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] traffic-user-queue outbound acl 3000 pir 1000 flow-queue-profile
flow1
```

15.9.14 user-queue (qos-profile view)

Function

The **user-queue** command creates a subscriber queue in a QoS profile to implement HQoS.

The **undo user-queue** command deletes a subscriber queue from a QoS profile.

By default, no subscriber queue is configured in a QoS profile.

Format

user-queue { **pir** *pir-value* | **flow-queue-profile** *flow-queue-profile-name* } *

undo user-queue

Parameters

Parameter	Description	Value
pir *pir-value*	Specifies the peak information rate (PIR) of a subscriber queue, which is the maximum rate of traffic that can pass through an interface.	The value is an integer that ranges from 64 to 10000000, in kbit/s.
flow-queue-profile *flow-queue-profile-name*	Specifies the name of the referenced flow queue profile. If the name of the referenced flow queue profile is not specified, the flow queue profile **default** is used.	The value must be the name of an existing flow queue profile.

Views

QoS profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure HQoS for authentication users to implement fine-granular scheduling, run the **user-queue** command to create subscriber queues, set different traffic shaping rates, and reference different flow queue profiles.

Prerequisites

A QoS profile has been created using the **qos-profile** command.

The user-defined flow queue profile and flow mapping profile have been created using the **flow-queue-profile** command respectively. If the user-defined flow queue profile and flow mapping profile are not required, use the default ones.

Example

Configure a user queue in the QoS profile **huawei** to implement HQoS.

```
<HUAWEI> system-view
[HUAWEI] qos-profile name huawei
[HUAWEI-qos-huawei] user-queue pir 1000 flow-queue-profile flow1
```

15.10 SAC Configuration Commands

15.10.1 Command Support

Only the following switch models support SAC:

S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S

15.10.2 application name cache type aging-time

Function

The **application name cache type aging-time** command sets the aging time of the entry associated with pre-defined application identification.

The **undo application name cache type aging-time** command restores the default setting.

By default, the aging time of the entry generated upon application identification acceleration is 3600 seconds. In the entry generated upon multi-channel application identification, the aging time of FTP is 15 seconds, other application is 300 seconds.

Format

application name *name* **cache type** { **acceleration aging-time** *aging-time* | **multi-channel aging-time** *aging-time* }

undo application name *name* **cache type** { **acceleration** | **multi-channel** } **aging-time**

Parameters

Parameter	Description	Value
name	Specifies the name of a predefined application.	The value must be the name of an existing application.
acceleration aging-time *aging-time*	Specifies the aging time of the entry generated upon application identification acceleration.	The value is an integer ranging from 1 to 60,000, in seconds. The default value is 3600 seconds.

Parameter	Description	Value
multi-channel aging-time *aging-time*	Specifies the aging time of the entry generated upon multi-channel application identification.	The value is an integer ranging from 1 to 60,000, in seconds. The default value of FTP is 15 seconds, The default value of other applications is 300 seconds.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

The **application name cache type aging-time** command sets the aging time of the entry associated with the identification of predefined applications.

Example

Set the aging time of the entry associated with HTTPS acceleration identification to 5000 seconds and that of the entry associated with SFTP data channel application identification to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] application name HTTPS cache type acceleration aging-time 5000
[HUAWEI-sa] application name SFTP cache type multi-channel aging-time 100
```

15.10.3 category sub-category

Function

The **category sub-category** command configures the category and subcategory of user-defined applications.

The **undo category** command restores the default category and subcategory of user-defined applications.

The default category and subcategory of a user-defined application are **General** and **Other** respectively.

Format

category *category* **sub-category** *sub-category*

undo category

Parameters

Parameter	Description	Value
category	Specifies the category of an application.	See **Table 15-38**.
sub-category	Specifies the subcategory of an application.	See **Table 15-38**.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

One category contains multiple subcategories, but one subcategory belongs to only one category.

The device divides applications into the following categories and subcategories, as shown in **Table 15-38**.

Table 15-38 Category and subcategory of applications

Category	Subcategory	Description
Business_Systems	Auth_Service	Authentication service
	CloudService	Cloud service
	Data_Backup	Data backup
	Database	Database
	E_Government	Electronic government
	Electronic_Business	Electronic business
	Email	Email
	Enterprise_Application	Enterprise application
	File_Access	File access
	Finance	Finance
	Industrial	Industrial
	Internet_Conferencing	Internet conferencing
	Life_Services	Life service
	Remote_Access	Remote access control

Category	Subcategory	Description
	Remote_Desktop	Remote desktop
	Video_Surveillance	Video surveillance
	Wealth_Investment	Wealth investment
	WebMail	Web mail
Entertainment	Blog_Microblog	Microblog
	Forum_Community	Forum community
	Game	Game software
	Instant_Messaging	IM software
	Live_Streaming	Live streaming
	Media_Sharing	Applications for online videos
	Online_Media	Online media
	PeerCasting	P2P web video
	Personals_Dating	Personals dating
	Press_Media	Press media
	RSS_Feed	RSS feed
	Social_Networks	Social networks
	VoIP	VOIP
	WireLess	Wireless terminal application
General_Internet	AppStore	App store
	Browser_Plugin	Website plug-ins
	Cloud_Notes	Cloud notes
	FileShare_P2P	P2P file sharing
	File_Sharing	Fire sharing
	IM_File_Transfer	Applications for IM file transfer
	Internet_Reading	Internet reading
	Map_GPS	GPS map
	Network_Storage	Network storage
	Photo_Sharing	Photo sharing

Category	Subcategory	Description
	Resource_Library	Resource library
	Search_Engines	Search engines
	Software_Update	Software update
	Utility	Utility
	Web_Browsing	Web browsing
Network	Encrypted_Tunnel	Tunneling applications
	IP_Protocol	IP-layer protocols
	Infrastructure	Basic network protocols
	Network_Admin	Network administration
	Proxy	Proxy software
	Security_Risk	Security risk
General	General_UDP	General UDP applications
	General_TCP	General TCP applications
	Other	Other general applications

Example

Configure the category and subcategory of user-defined application **abc** to **Business_Systems** and **Database** respectively.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] category Business_Systems sub-category Database
```

15.10.4 data-model

Function

The **data-model** command specifies the data model of a user-defined application.

The **undo data-model** command restores the default data model of a user-defined application.

The default data model of user-defined applications is **unassigned**.

Format

data-model { **unassigned** | **client-server** | **browser-based** | **networking** | **peer-to-peer** }

undo data-model

Parameters

Parameter	Description	Value
unassigned	Indicates that no model is specified for data transmission.	-
client-server	Indicates applications using the Client/Server (C/S) model, such as client games.	-
browser-based	Indicates web applications, such as web games.	-
networking	Indicates common networking applications, such as HTTP and HTTPS.	-
peer-to-peer	Indicates peer-to-peer applications, such as Thunder and BT.	-

Views

User-defined application view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Set the data model of user-defined application **UD_abc** to **client-server**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] data-model client-server
```

15.10.5 description (user-defined application rule view)

Function

The **description** command configures the description of a user-defined application rule.

The **undo description** command deletes the description of a user-defined application rule.

By default, the user-defined application rule has no description information.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of a user-defined application rule.	The value is a case-sensitive string of 1 to 128 characters. Spaces are supported.

Views

User-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Add description **test** for user-defined application rule **rule1**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-UD_abc-rule-rule1] description test
```

15.10.6 description (user-defined application view)

Function

The **description** command configures the description of a user-defined application.

The **undo description** command deletes the description of a user-defined application.

By default, the user-defined application has no description information.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Specifies the description of a user-defined application.	The value is a case-sensitive string of 1 to 128 characters. Spaces are supported.

Views

User-defined application view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Add description **test** for user-defined application **UD_abc**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] description test
```

15.10.7 detect max-bytes

Function

The **detect max-bytes** command specifies the maximum number of bytes to be detected by the SA module.

The **undo detect max-bytes** command restores the maximum number of bytes detected by the SA module to the default value.

By default, the maximum number of bytes is 2048.

Format

detect max-bytes *max-bytes*

undo detect max-bytes

Parameters

Parameter	Description	Value
max-bytes	Specifies the maximum number of bytes to be detected.	The value is an integer ranging from 1 to 10240.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

This command is used to specify the maximum number of bytes detected by the SA module to prevent certain applications from evading the detection by using small packets. In common cases, the default maximum value can meet the requirement. If the value is too large, the device performance may deteriorate. If the value is too small, the device may fail to detect certain applications.

Example

Set the maximum number of bytes to be detected by the SA module to 4096.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] detect max-bytes 4096
```

15.10.8 detect max-packets

Function

The **detect max-packets** command specifies the maximum number of packets to be detected by the SA module.

The **undo detect max-packets** command restores the maximum number of packets detected by the SA module to the default value.

By default, the maximum number of packets is 8.

Format

detect max-packets *max-packets*

undo detect max-packets

Parameters

Parameter	Description	Value
max-packets	Specifies the maximum number of packets in a session.	The value is an integer ranging from 1 to 64.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

The specified maximum number of packets to be detected covers both directions in a session.

Example

Set the maximum number of packets to be detected by the SA module to **20**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] detect max-packets 20
```

15.10.9 detect max-time

Function

The **detect max-time** command sets the maximum duration in which the SA module detects sessions.

The **undo detect max-time** command restores the maximum duration to the default value.

By default, the maximum duration is 1 minute.

Format

detect max-time *max-time*

undo detect max-time

Parameters

Parameter	Description	Value
max-time	Specifies the maximum session detection duration.	The value is an integer ranging from 0 to 60, in minutes.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Set the maximum duration in which the SA module detects sessions to 5 minutes.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] detect max-time 5
```

15.10.10 detect uni-direction

Function

The **detect uni-direction** command configures the unidirectional detection on the SA module.

The **undo detect uni-direction** command restores to the default detection mode, namely, bidirectional detection.

By default, the SA module works in bidirectional detection mode.

Format

detect uni-direction

undo detect uni-direction

Parameters

None

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

SA detection falls into unidirectional detection and bidirectional detection. If the device is deployed in unidirectional mode, use the **detect uni-direction** command to configure the unidirectional detection mode of the SA module.

Example

Configure the unidirectional detection mode of the SA module.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] detect uni-direction
```

15.10.11 display application

Function

The **display application** command displays information about applications in the system.

Format

display application [**pre-defined** | **user-defined** | **name** *name*]

Parameters

Parameter	Description	Value
pre-defined	Indicates all predefined applications.	-
user-defined	Indicates all user-defined applications.	-
name *name*	Specifies the name of an application.	The value must be the name of an existing application.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

The actual information about each application varies depending on the device.

Example

Display information about all applications.

```
<HUAWEI> display application
Service Awareness Signature Database Information:
Total Applications: 544
-------------------------------------------------------------------------------------------------------------------------------
 AppID Name                         Category              Sub-category               RiskLevel State
 1     BT                        General_Internet       FileShare_P2P              4        activated
 2     PPLive                     Entertainment          Peercasting               5        activated

15.10.12 display application name aging-time

Function

The **display application name aging-time** command displays the aging time of the entry associated with application identification.

Format

display application name *name* **aging-time**

Parameters

Parameter	Description	Value
name	Specifies the name of an application.	The value must be the name of an existing application.

Views

All views

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Display the aging time of the entry associated with SFTP identification.

```
<HUAWEI> display application name SFTP aging-time
Aging Time:
-------------------------------------------------------------------------------
  Application Name                  : sftp
  Acceleration Aging-time(sec)       : 300
  Multi-channel Aging-time(sec)      : 15
-------------------------------------------------------------------------------
```

Table 15-41 Description of the **display application name aging-time** command output

Item	Description
Aging Time	The aging time of the entry associated with the identification of predefined applications.
Application Name	Name of an application.
Acceleration Aging-time(sec)	Aging time of the entry generated upon application identification acceleration.
Multi-channel Aging-time(sec)	Aging time of the entry generated upon multi-channel application identification. If the queried application is not a multi-channel application, **-** is displayed.

15.10.13 display engine session application

Function

The **display engine session application** command displays application identification entries.

Format

display engine session application

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the service awareness (SA) function is configured, the switch identifies application packets and generates application identification entries. You can run the **display engine session application** command to check application identification entries on the switch.

Prerequisites

1. The resource allocation mode has been set to **sac** or **enhanced-sac**. To check the current resource allocation mode of the switch and the resource allocation mode specified using the **assign resource-mode** command, run the **display resource-mode configuration** command. If the resource allocation mode is not **sac** or **enhanced-sac**, run the **assign resource-mode sac** | **enhanced-sac** command to change the resource allocation mode to **sac** or **enhanced-sac**, save the configuration, and restart the switch.
2. The **defence engine enable** command has been run to enable the IAE. When the IAE is enabled, the application signature database is loaded automatically.
3. The **service-awareness enable** command has been run to enable the SA function on the interface.

Example

Display application identification entries generated after the switch identifies application packets.

```
<HUAWEI> display engine session application
Source IP       Destination IP  SPort  DPort  ProtocolID AppName      AppID  Expire(S)
----------------------------------------------------------------------------------------
10.10.1.1       10.20.1.1       51918  23     6          Telnet       415    300
----------------------------------------------------------------------------------------
Total:1
```

Table 15-42 Description of the **display engine session application** command output

Item	Description
Source IP	Source IP address.
Destination IP	Destination IP address.
SPort	Source port number.
DPort	Destination port number.

Item	Description
ProtocolID	Protocol ID.
AppName	Application name.
AppID	Application ID.
Expire(S)	Aging time, in seconds.
Total	Total number of application identification entries.

15.10.14 if-match application

Function

The **if-match application** command configures a matching rule based on the application name in a traffic classifier.

The **undo if-match application** command deletes a matching rule based on the application name in a traffic classifier.

By default, no matching rule based on the application name is configured in a traffic classifier.

Format

if-match application name *appname*

undo if-match application name

Parameters

Parameter	Description	Value
name *appname*	Specifies the name of an application.	The value is a string of characters. The value depends on the applications supported in the signature database. To check the supported application names, run the **display application** command.

Views

Traffic classifier view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **if-match application** command to classify packets based on the application name of packets. This ensures that the switch processes packets matching the same traffic classifier identically.

Precautions

If you run the **if-match application** command in the same traffic classifier view multiple times, only the latest configuration takes effect.

A traffic policy containing such a traffic classifier can be applied only to the inbound direction globally or on a physical or a VLANIF interface.

Both the traffic classifier defining **if-match application** and traffic classifiers defining other matching rules (excluding **if-match discard**) can take effect. Examples are as follows:

- A packet matches two pairs of traffic classifiers and traffic behaviors defined in the same traffic policy, and only one traffic classifier contains **if-match application**. (The other traffic classifier does not contain **if-match discard** or **if-match application**.) In this case, both pairs of traffic classifiers and traffic behaviors take effect for the packet.
- A packet matches two traffic policies, and a traffic classifier contains **if-match application** in only one of the traffic policies. (The other traffic policy does not contain **if-match discard** or **if-match application**.) In this case, both traffic policies take effect for the packet.

Example

Configure a matching rule based on the application name **BT** in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] traffic classifier c1
[HUAWEI-classifier-c1] if-match application name BT
```

15.10.15 ip-address (user-defined application rule view)

Function

The **ip-address** command sets the IPv4 address in a user-defined application rule.

The **undo ip-address** command deletes the IPv4 address in a user-defined application rule.

Format

ip-address *ip-address* [*mask* | *mask-length*]

undo ip-address { *ip-address* [*mask* | *mask-length*] | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies an IPv4 address.	The value is in dotted decimal notation.
mask	Specifies the subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer ranging from 1 to 32.
all	Deletes all IPv4 addresses.	-

Views

User-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can set a single IPv4 address in a user-defined application rule or set the subnet mask or mask length to specify a network segment.

After you configure the IPv4 address, the SA engine will use the transport layer protocol and ports, that is, the 3-tuple to match the network packets. If you know the destination 3-tuple of the detecting flow, you can configure a user-defined 3-tuple to accelerate the application identification. For example, if you have a server, you can configure a 3-tuple rule according to the IPv4 address, port, and protocol of the server, so the rule can identify all the accessing flow to this server. At least one IPv4 address or one port should be in the 3-tuple rule. Note that the IPv4 address set here is only the destination IPv4 address.

Precautions

- The total number of IPv4 and IPv6 addresses in a user-defined application rule cannot be larger than four.
- If an IPv4 address with a mask is configured, the executed command is recorded in the configuration file, but the masked IPv4 address takes effect in the actual configuration. For example, if the **ip address 1.1.1.1 8** command is executed, this command is recorded in the configuration file. However, the actual configuration that takes effect is **ip address 1.0.0.0 8**.

Example

Set the IPv4 address in user-defined application rule **rule1** to **10.1.1.1**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-rule-rule1] ip-address 10.1.1.1
```

15.10.16 label (User-defined application view)

Function

The **label** command specifies the label of a user-defined application.

The **undo label** command cancels the label of a user-defined application.

Format

label *label-name* &<1-8>

undo label [*label-name*]

Parameters

Parameter	Description	Value
label-name	Specify the label of the user-defined application.	For details about the label dimensions and names, see **Table 15-43**.

Views

User-defined application view

Default Level

2: Configuration level

Usage Guidelines

You can specify one or more labels to a user-defined application. No more than 8 labels are supported.

Table 15-43 lists the label dimensions and names.

Table 15-43 Label dimensions and names

Label Dimension	Label Name
Other-Dimension	Database, Business-Applications
Technology-Dimension	Mobile-Supported, Cloud-Based, Encrypted-Communications, P2P-Based, HTTP-Based, Tunneling

Label Dimension	Label Name
Function-Dimension	Network-Storage, Social-Applications, Plays-Game, Browses-Web, Speech, Sends-Mail, Supports-IM, Supports-Video, Supports-VoIP, Supports-File-Transfer
Risk-Dimension	The following label may bring risk to the network. After you configure the risk features, the system automatically calculates the risk level (1 to 5) of the application. Applications with a higher risk level bring about more risks to the network. ● **Exploitable**: indicates that the application has known vulnerabilities. ● **Malware-Vehicle**: indicates applications used by malware. For example, malware can use an application to launch attacks or listen data. ● **Productivity-Loss**: indicates applications compromising work efficiency, for example, applications for entertainment, news, and videos. ● **Bandwidth-Consuming**: indicates applications consuming network bandwidth, such as BT. ● **Evasive**: indicates applications that use ports or protocols for malicious purposes, such as evading firewall inspection. Proxy software is a typical example of such protocols. ● **Data-Loss**: indicates applications for transferring files and uploading texts. Using such applications may cause information leaks.

Example

Configure a matching rule based on the application name **BT** in the traffic classifier **c1**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] label P2P-Based Encrypted-Communications Business-Applications
```

15.10.17 port (user-defined application rule view)

Function

The **port** command specifies a port in a user-defined application rule.

The **undo port** command deletes the port in a user-defined application rule.

Format

port *port*

undo port { *port* | **all** }

Parameters

Parameter	Description	Value
port	Specifies a port in a user-defined application rule.	The value is an integer ranging from 1 to 65535.
all	Deletes all port.	-

Views

User-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

You can specify a maximum of 4 ports in a user-defined application rule.

After you configure the port, the SA engine will use the transport layer protocol and ports, that is, the 3-tuple to match the network packets. If you know the destination 3-tuple of the detecting flow, you can configure a user-defined 3-tuple to accelerate the application identification. For example, if you have a server, you can configure a 3-tuple rule according to the IP address, port, and protocol of the server, so the rule can identify all the accessing flow to this server. At least one IP address or one port should be in the 3-tuple rule. Note that the port number set here is only the destination port number.

Example

Set the port in user-defined application rule **rule1** to 80.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-rule-rule1] port 80
```

15.10.18 port-identification packet-number-threshold

Function

The **port-identification packet-number-threshold** command sets the threshold of packet quantity for port identification in the SA module.

The **undo port-identification packet-number-threshold** command restores the default threshold of packet quantity for port identification in the SA module.

By default, the threshold of packet quantity is 16.

Format

port-identification packet-number-threshold *packets*

undo port-identification packet-number-threshold

Parameters

Parameter	Description	Value
packets	Specifies the number of packets.	The value is an integer ranging from 1 to 64.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

If packets exceeding the threshold are sent to the IAE and their applications cannot be identified, the SA module identifies the application by port. A high threshold compromises the application identification performance while a low threshold increases the false positive rate. The default value (16) is recommended.

Example

Set the threshold of packet quantity for port identification in the SA module to 32.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] port-identification packet-number-threshold 32
```

15.10.19 protocol (user-defined application rule view)

Function

The **protocol** command specifies a transport-layer protocol.

The **undo protocol** command restores the default setting.

The default transport-layer protocol in a user-defined application rule is any. That is, the rule applies to both TCP and UDP packets.

Format

protocol { **tcp** | **udp** }

undo protocol

Parameters

Parameter	Description	Value
port	Indicates the Transmission Control Protocol (TCP).	-
all	Indicates the User Datagram Protocol (UDP).	-

Views

User-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Set the transport-layer protocol in a user-defined application rule to TCP.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-rule-rule1] protocol tcp
```

15.10.20 rule name (user-defined application view)

Function

The **rule name** command creates a user-defined application rule, and displays the user-defined application view.

The **undo rule** command deletes a user-defined application rule.

Format

rule name *name*

undo rule { **name** *name* | **all** }

Parameters

Parameter	Description	Value
name *name*	Specifies the name of a rule.	The value is a case-sensitive character string. The value is a case-sensitive string of 1 to 32 characters. Enclose the name with double quotation marks ("") if the name contains spaces, for example, "user for test". The name that contains spaces has 3 to 34 characters. The name cannot contain question marks (?), commas (,), or hyphens (-). If the name does not contain any space, it also cannot have any double quotation marks ("). In addition, the name cannot be **any** or **all**.
all	Deletes all user-defined application rules.	-

Views

User-defined application view

Default Level

2: Configuration level

Usage Guidelines

If the specified user-defined application rule does not exist, a new application rule is created and the application rule view is displayed. If the specified user-defined application rule exists, the view of the specified user-defined application rule is displayed.

The device uses the 3-tuple, keyword, or the combination to creates rules. The 3-tuple can be the destination 3-tuple (server address, protocol, and port) or source 3-tuple (user source address, protocol, and source port). The keyword indicates the signature of the application data packets or data flow. The signature uniquely identifies the application.

- You can run the **ip-address (user-defined application rule view)**, **port (user-defined application rule view)**, and **protocol (user-defined application rule view)** commands to specify the 3-tuple of an application. After you configure the 3-tuple and commit the configuration, the device uses the destination 3-tuple to match the first packet of a flow. If a match is found, the application of the traffic is the application specified in the 3-tuple. If no match is found, the device uses the source 3-tuple to match the first packet. If a match is found, the application of the traffic is the application specified in the 3-tuple. If no match is found, the application of the traffic is not the application specified in the 3-tuple.

If you use the 3-tuple to configure user-defined application rules, ensure that one rule contains at least one IP address or port.

- You can run the **signature (user-defined application rule view)** command to specify the keyword of an application.

You can configure multiple rules for one user-defined application. These rules are logically ORed. Data flows or packets are of the application once they match one of the rules.

When the number of user-defined application rules on the device exceeds the maximum value but the number of user-defined applications does not exceed the maximum value, you can create user-defined applications but cannot create user-defined application rules.

Example

Create rule **rule1** for user-defined application **UD_abc** and access the rule view.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-UD_abc-rule-rule1]
```

15.10.21 sa

Function

The **sa** command displays the SA view.

Format

sa

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before running this command, you must run the **defence engine enable** command to enable the IAE.

Example

Access the SA view.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa]
```

15.10.22 sa cache enable

Function

The **sa cache enable** command enables application identification acceleration.

The **undo sa cache enable** command disables application identification acceleration.

By default, application identification acceleration is disabled.

Format

sa cache [**risk-level** { **low** | **high** }] **enable**

undo sa cache enable

Parameters

Parameter	Description	Value
risk-level	Indicates the risk level of the SA cache.	-
low	Indicates that the risk level is low.	-
high	Indicates that the risk level is high.	-

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

After application identification acceleration is enabled, the system generates an association entry for an identified application. The follow-up traffic matching the entry is identified as the application without additional application identification, which accelerates application identification.

You can set parameter **risk-level** to control the risk level of the SA module acceleration identification. If **risk-level** is set to low, high-risk acceleration cache entries are not generated. If **risk-level** is set to high or no risk level is specified, low-risk and high-risk acceleration cache entries are generated.

Application identification acceleration applies only to predefined applications of non-multi-channel protocols.

NOTE

Enabling application identification acceleration increases the efficiency but also the false positive rate. If the acceleration cache risk is set to high, the false positive rate is also high.

Example

Enable application identification acceleration.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] sa cache enable
```

15.10.23 service-awareness enable

Function

The **service-awareness enable** command enables the service awareness (SA) function.

The **undo service-awareness enable** command disables the SA function.

By default, the SA function is disabled.

Format

service-awareness enable

undo service-awareness enable

Parameters

None

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, VLANIF interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traditional traffic classification technologies only check the content at Layer 4 and lower layers in packets, for example, source IP address, destination IP address, source port number, destination port number, and service type. It cannot analyze applications in packets. SA is a traffic detection and control technology based on the application layer. Apart from the IP packet header, SA can analyze the content of the application layer.

To identify the application of the traffic passing through an interface, run this command to enable SA on the interface.

Precautions

- The resource allocation mode has been set to **sac** or **enhanced-sac** for the slot corresponding to the interface. To check the current resource allocation mode of the switch and the resource allocation mode specified using the **assign resource-mode** command, run the **display resource-mode configuration** command. If the resource allocation mode is not **sac** or **enhanced-sac**, run the **assign resource-mode sac** | **enhanced-sac** command to change the resource allocation mode to **sac** or **enhanced-sac**, save the configuration, and restart the switch.
- In versions earlier than V200R022C10, SAC takes effect only on access-side interfaces but not tunnel-side interfaces in VXLAN scenarios. This limitation does not apply to V200R022C10 and later versions.

Example

Enable SA on VLANIF 10.

```
<HUAWEI> system view
[HUAWEI] vlan batch 10
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] service-awareness enable
```

15.10.24 signature (user-defined application rule view)

Function

The **signature** command configures a user-defined application signature.

The **undo signature** command deletes a user-defined application signature.

Format

signature context { **flow** | **packet** } **direction** { **request** | **response** | **both** } **plain-string** *plain-string* [**field** *field*]

undo signature

Parameters

Parameter	Description	Value
context	Indicates signature context.	-
flow	Indicates flow-based matching.	-
packet	Indicates packet-based matching.	-
direction	Indicates that the detection direction.	-

Parameter	Description	Value
request	Indicates that the detection direction is the request direction.	-
response	Indicates that the detection direction is the response direction.	-
both	Indicates that the detection direction is both directions.	-
plain-string *plain-string*	Specifies a plain-text string.	The value is a case-sensitive string of 3 to 128 characters. If the keyword contains any space and question mark (?), the value is a string of 5 to 130 characters and must be enclosed with double quotation marks (""), for example, "GET w?". If the keyword contains quotation marks, replace the quotation marks with \x22, for example, to set keyword **abc"d**, enter **abc\x22d**.
field *field*	Specifies a protocol field to search for a signature.	The **General-payload** field can be searched.

Views

User-defined application rule view

Default Level

2: Configuration level

Usage Guidelines

You can configure only one signature for each user-defined application rule.

Example

Configure a plain-text string for the signature in user-defined application rule **rule1**, configure flow-based matching mode, and set the detection direction to **request**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-sa-user-defined-app-UD_abc] rule name rule1
[HUAWEI-sa-user-defined-app-rule-rule1] protocol tcp
[HUAWEI-sa-user-defined-app-rule-rule1] signature context flow direction request plain-string abc field
General-payload
```

15.10.25 user-defined-application name

Function

The **user-defined-application name** command creates a user-defined application and displays its view.

The **undo user-defined-application name** command deletes a user-defined application.

Format

user-defined-application name *name* [**id** *id*]

undo user-defined-application { **name** *name* | **all** }

Parameters

Parameter	Description	Value
name *name*	Specifies the name of a user-defined application.	The value is a case-sensitive character string, and must begin with **UD_**. The length of a name without spaces ranges from 4 to 32 characters. The length of a name with spaces ranges from 6 to 34 characters. If a name contains spaces, the name must be enclosed with quotation marks (for example, "UD_user for test"). The name cannot contain question marks (?), commas (,), or hyphens (-). If the name does not contain any space, it also cannot have any double quotation marks (").
id *id*	Specifies the ID of a user-defined application.	The value is an integer that ranges from 60000 to 60511.
all	Indicates all user-defined applications.	-

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

If the name you specify does not exist, a user-defined application is created and the user-defined application view is displayed. If the specified name exists, the user-defined application view is displayed directly.

Example

Create a user-defined application **UD_abc**.

```
<HUAWEI> system-view
[HUAWEI] defence engine enable
[HUAWEI] sa
[HUAWEI-sa] user-defined-application name UD_abc
[HUAWEI-app-UD_abc] user-defined-application name UD_abc
```

16 Network Management and Monitoring Commands

16.1 SNMP Configuration Commands

16.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

16.1.2 bulk-file

Function

The **bulk-file** command creates a bulk file for bulk statistics collection and displays the bulk file view. If the specified bulk file exists, the command displays the bulk file view directly.

The **undo bulk-file** command deletes a bulk file.

By default, no bulk file is configured in the system.

Format

bulk-file *file-name*

undo bulk-file *file-name*

Parameters

Parameter	Description	Value
file-name	Specifies the name of a bulk file.	The value is a string of 1 to 31 characters. It can only contain digits, letters, underscores (_), and hyphens (-).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before creating a bulk file, run the **bulk-stat enable** command to enable bulk statistics collection.

Before deleting a bulk file, ensure that the bulk file exists and the bulk statistics collection task has been stopped. If the bulk file does not exist or the bulk statistics collection task is still running, the system displays an error message.

Example

Create a bulk file named **iftable**.

```
<HUAWEI> system-view
[HUAWEI] bulk-stat enable
Info: Succeeded in enabling the bulk stat function.
```

```
[HUAWEI] bulk-file iftable
[HUAWEI-bulk-file-iftable]
```

16.1.3 bulk-stat enable

Function

The **bulk-stat enable** command enables the bulk statistics collection function.

The **undo bulk-stat enable** command disables the bulk statistics collection function.

By default, the bulk statistics collection function is disabled.

Format

bulk-stat enable

undo bulk-stat enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To enable the system to collect statistics about multiple objects on the local device, generate a statistics file, and send the file to the NMS through FTP or TFTP, use the **bulk-stat enable** command to enable the bulk statistics collection function.

When disabling the bulk statistics collection function, you need to confirm your action in interactive mode.

Example

Enable the bulk statistics collection function.

```
<HUAWEI> system-view
[HUAWEI] bulk-stat enable
```

Disable the bulk statistics collection function.

```
<HUAWEI> system-view
[HUAWEI] undo bulk-stat enable
Warning: All bulk stat configuration will be deleted. Continue? [Y/N]:y
```

16.1.4 clear configuration snmp-agent trap enable

Function

The **clear configuration snmp-agent trap enable** command deletes alarm configurations related to one or all functions in a batch and restores the default alarm functions.

Format

clear configuration snmp-agent trap enable [**feature-name** *feature-name*]

Parameters

Parameter	Description	Value
feature-name *feature-name*	Deletes configurations of the trap function of a feature.	The value is the name of a feature that has been supported by the device.

Views

System view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After a feature trap function is enabled or disabled using the **snmp-agent trap enable feature-name** *feature-name* [**trap-name** *trap-name*] command, the trap functions of all features are enabled using the **snmp-agent trap enable** command, or the trap functions of all features are disabled using the **snmp-agent trap disable** command. To delete the configurations, run the **clear configuration snmp-agent trap enable** command.

Configuration Impact

- When the trap function is enabled or disabled globally, running the **clear configuration snmp-agent trap enable feature-name** *feature-name* command deletes configurations of the trap function of the feature specified by *feature-name* and restores the status of the trap function to be the same as that of the global trap function.
- When the global trap function is in the default state, running the **clear configuration snmp-agent trap enable feature-name** *feature-name* command deletes configurations of the trap function of the feature specified by *feature-name* and restores the status of the trap function to be the default status.

- Running the **clear configuration snmp-agent trap enable** command deletes configurations of the trap functions of all features and restores all feature alarm functions to the default status.

Example

Delete configurations of the trap functions of all features.

```
<HUAWEI> system-view
[HUAWEI] clear configuration snmp-agent trap enable
```

16.1.5 collect enable

Function

The **collect enable** command enables an existing bulk file.

The **undo collect enable** command disables an existing bulk file.

By default, no bulk file is enabled.

Format

collect enable

undo collect enable

Parameters

None

Views

Bulk file view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a bulk file is created, it is in Stop state and does not participate in data collection and scheduling. After you run the **collect enable** command to enable the bulk file, the bulk file transitions to Ready state and can participate in data collection and scheduling. The **undo collect enable** command disables the bulk file and sets the file state to Stop.

Precautions

Before running the **collect enable** command in a bulk file, run the **transfer** command to configure the primary upload path for the bulk file.

The interval between running the **undo collect enable** and **collect enable** commands in a bulk file must be at least 10 seconds. If the interval is less than 10 seconds, the **collect enable** configuration files.

You can change the maximum number of retransmissions, collection interval, upload interval, and upload holding time, and delete the primary URL for a bulk file only when the bulk file is disabled.

The **collect enable** command takes effect only when the collection interval, upload interval, and upload holding time meet the following requirements: The upload interval is an integral multiple of the collection interval, and the upload holding time is smaller than or equal to the upload interval.

Example

Enable the bulk file **iftable**.

```
<HUAWEI> system-view
[HUAWEI] bulk-stat enable
Info: Succeeded in enabling the bulk stat function.
[HUAWEI] bulk-file iftable
[HUAWEI-bulk-file-iftable] transfer primary protocol ftp username user password pwd host 10 path
folder/bulkstat1
[HUAWEI-bulk-file-iftable] collect enable
```

16.1.6 collect interval

Function

The **collect interval** command sets the statistics collection interval for a bulk file.

The **undo collect interval** command restores the default statistics collection interval.

By default, the statistics collection interval is 5 minutes.

Format

collect interval *interval*

undo collect interval

Parameters

Parameter	Description	Value
interval	Specifies statistics collection interval of a bulk file.	The value can be 5, 10, 15, or 30, in minutes.

Views

Bulk file view

Default Level

2: Configuration level

Usage Guidelines

The file upload interval configured using the **transfer interval** command must be an integral multiple of the statistics collection interval configured using this command.

Before changing the statistics collection interval, run the **undo collect enable** command to disable the statistics collection function.

Example

Set the statistics collection interval to 10 minutes for the bulk file **iftable**.

```
<HUAWEI> system-view
[HUAWEI] bulk-stat enable
[HUAWEI] bulk-file iftable
[HUAWEI-bulk-file-iftable] collect interval 10
```

16.1.7 display bulk-stat

Function

The **display bulk-stat** command displays the configuration of the bulk statistics collection function.

Format

display bulk-stat [*file-name*]

Parameters

Parameter	Description	Value
file-name	Specifies the name of a bulk file.	The value is a string of 1 to 31 characters. It can only contain digits, letters, underscores (_), and hyphens (-).

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display bulk-stat** command displays the configuration of the bulk statistics collection function, including:

- Maximum number of bulk files
- Number of configured bulk files

- Maximum number of instances that can be collected within 5 minutes
- Basic configurations and status of configured bulk files

The **display bulk-stat** *file-name* command displays detailed information about the bulk file with the specified file name, including:

- File name, storage mode, and format of the bulk file
- Statistics collection interval and upload interval of the bulk file
- The primary URL and secondary URL where the bulk file will be uploaded
- Maximum number of retransmissions of the bulk file
- Storage time of the bulk file
- Current status of the bulk file
- Objects included in the bulk file

Example

Display the configuration of the bulk statistics collection function.

```
<HUAWEI> display bulk-stat
bulk statistic info:
--------------------------------
max bulk file number : 10
current bulk file number: 10
current bulk object number: 2000
max data item per 5 minutes: 40000
--------------------------------
index  bulk file name          collect(min)  transfer(min) status
--------------------------------------------------------------------------------------------------------------
 1     bulk1                  5           5             running
 2     bulk2                  5           15             ready
 3     bulk3                  5           10             stop
 4     bulk4                  5           15             ready
--------------------------------------------------------------------------------------------------------------
```

Table 16-1 Description of the **display bulk-stat** command output

Item	Description
max bulk file number	Maximum number of bulk files.
current bulk file number	Number of configured bulk files.
current bulk object number	Number of configured statistics objects.
max data item per 5 minutes	Maximum number of instances that can be collected within 5 minutes.
index	Index of a configured bulk file.
bulk file name	Name of a configured bulk file. You can run the **bulk-file** command to configure this parameter.
collect(min)	Statistics collection interval of a configured bulk file. You can run the **collect interval** command to configure this parameter.

Item	Description
transfer(min)	Upload interval of a configured bulk file. You can run the **transfer interval** command to configure this parameter.
status	Status of a configured bulk file. The value can be: ● ready: The bulk file is ready for batch performance statistics collection. ● running: The system is collecting performance statistics and writing data in the bulk file. ● stop: The system has finished collecting performance statistics in the current collection interval.

Display detailed information about bulk file **iftable**.

```
<HUAWEI> display bulk-stat iftable
bulk file iftable:
--------------------------------
storage: ephemeral
format: bulkASCII
collect interval: 5 min
transfer interval: 15 min
primary transfer URL: sftp://user:password@host/folder/bulkstat1
secondary transfer URL: sftp://10.1.0.1/tftpboot/user/bulkstat1
transfer retry times: 3
file remain time: 15 min
status: running
last transfer success time: 2006-11-29 11:15
last transfer fail time: NULL
total object number: 2
--------------------------------
index: 1
class: single
OID: 1.3.6.1.2.1.10.94.1.1.10.1.1.0.1
start index: NULL
instance number: NULL
--------------------------------
index: 2
class: column
OID:  1.3.6.1.2.1.10.94.1.1.10.1.2
start index: 1
instance number: 3
```

Table 16-2 Description of the **display bulk-stat iftable** command output

Item	Description
storage	Storage mode of the bulk file. Currently, only the ephemeral storage mode is supported.
format	Format of the bulk file.

Item	Description
collect interval	Statistics collection interval of the bulk file. You can run the **collect interval** command to configure this parameter.
transfer interval	Upload interval of the bulk file. You can run the **transfer interval** command to configure this parameter.
transfer retry times	Maximum number of retransmissions of the bulk file. You can run the **transfer retry** command to configure this parameter.
primary transfer URL	Primary URL where the bulk file will be uploaded. You can run the **transfer** command to configure this parameter.
secondary transfer URL	Secondary URL where the bulk file will be uploaded. You can run the **transfer** command to configure this parameter.
file remain time	Storage time of the bulk file. You can run the **transfer remain-time** command to configure this parameter.
last transfer success time	Time of the last file upload success.
last transfer fail time	Time of the last file upload failure.
total object number	Total number of objects in the bulk file.
index	Index of an object.
class	Type of an object. The value can be: ● single: a single statistics object ● column: bulk statistics object
OID	OID of an object.
start index	● When the value of **class** is **single**, the parameter is displayed **NULL**. ● When the value of **class** is **column**, this parameter indicates the start instance index. You can run the **object** command to configure this parameter.

Item	Description
instance number	- When the value of **class** is **single**, the parameter is displayed **NULL**. - When the value of **class** is **column**, this parameter indicates the number of consecutive instances collected from the start instance index. You can run the **object** command to configure this parameter.

16.1.8 display snmp dynamic-control threshold

Function

The **display snmp dynamic-control threshold** command displays the CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks.

Format

display snmp dynamic-control threshold

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

The **set snmp dynamic-control threshold** command is used to configure the CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks. The **display snmp dynamic-control threshold** command is used to check the current CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks.

Example

Check the current CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks.

```
<HUAWEI> display snmp dynamic-control threshold
Info: The current CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks
is 60%.
```

Table 16-3 Description of the **display snmp dynamic-control threshold** command output

Item	Description
The current CPU usage threshold that triggers a device to reduce resources for scheduling SNMP tasks is *threshold*.	When the CPU usage reaches the value specified by *threshold*, the device reduces resources for scheduling SNMP tasks.

16.1.9 display snmp-agent

Function

The **display snmp-agent** command displays the engine ID of the local or remote SNMP agent.

Format

display snmp-agent { **local-engineid** | **remote-engineid** }

Parameters

Parameter	Description	Value
local-engineid	Displays the engine ID of the local SNMP agent.	-
remote-engineid	Displays the engine ID of a remote SNMP agent.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the SNMP agent function is enabled, you can run the **display snmp-agent** { **local-engineid** | **remote-engineid** } command to view the engine ID of the local or remote SNMP agent.

The engine ID of the SNMP agent uniquely identifies an SNMP agent in a management domain. The engine ID of the SNMP agent is an important component of the SNMP agent. It schedules and processes SNMP messages, implements security authentication, access control and so on.

Prerequisites

Before running the **display snmp-agent** { **local-engineid** | **remote-engineid** } command to view the engine ID of the local or remote SNMP agent, you need to run the **snmp-agent** command to enable the SNMP agent function.

Precautions

To configure an engine ID for the local SNMP agent, you can run the **snmp-agent local-engineid** command.

Example

Display the engine ID of the local SNMP agent.

```
<HUAWEI> display snmp-agent local-engineid
   SNMP local EngineID: 800007DB03360102101100
```

Table 16-4 Description of the **display snmp-agent local-engineid** command output

Item	Description
SNMP local EngineID	The engine ID of the local SNMP agent.

16.1.10 display snmp-agent community

Function

The **display snmp-agent community** command displays the configured community name.

Format

display snmp-agent community [**read** | **write**] *

Parameters

Parameter	Description	Value
read	Displays the name of a community with read-only permission.	-
write	Displays the name of a community with read and write permission.	-

Views

All views

Default Level

3: Management level

Usage Guidelines

When configuring a management entity, you can use the **display snmp-agent community** command to check the community name configured on the current agent.

If the parameter **read** or **write** is not specified, the names of all communities are displayed.

You have to configure the community name using the **snmp-agent community** command before you run the **display snmp-agent community** command.

Example

Display the current community name.

```
<HUAWEI> display snmp-agent community
   Community name: %^%#.T|&Whvyf$<Gd"I,wXi5SP_6~Nakk6<<+3H:N-h@aJ6d,l0md%HCeAY8~>X=>xV
\JKNAL=124r839v<*%^%#
       Group name: %^%#.T|&Whvyf$<Gd"I,wXi5SP_6~Nakk6<<+3H:N-h@aJ6d,l0md%HCeAY8~>X=>xV
\JKNAL=124r839v<*%^%#
       Alias name:huawei
       Acl:2001
       Storage type: nonVolatile
```

Table 16-5 Description of the **display snmp-agent community** command output

Item	Description
Community name	Name of a community.
Group name	Name of a group.
Alias name	Alias name for a community
Acl	The ACL takes effect on both IPv4 and IPv6 networks.
Ipv4 acl	The ACL takes effect on only IPv4 network.
Ipv6 acl	The ACL takes effect on only IPv6 network.
Storage type	Mode in which information is stored. Only nonVolatile is supported currently. In this mode, configuration can be restored after the device restarts.

16.1.11 display snmp-agent extend error-code status

Function

The **display snmp-agent extend error-code status** command allows you to check whether the function of sending extended error codes to the NMS is enabled on the device.

Format

display snmp-agent extend error-code status

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

If the NMS does not receive the extended error codes sent from the device, you can run the **display snmp-agent extend error-code status** command to check whether the function of sending extended error codes to the NMS is enabled on the device.

Example

Display whether the function of sending extended error codes to the NMS is enabled on the device.

```
<HUAWEI> display snmp-agent extend error-code status
Extend error-code status: enabled
```

Table 16-6 Description of the display snmp-agent extend error-code status command output

Item	Description
Extend error-code status	Whether the function of sending extended error codes to the NMS is enabled on the device: • enabled: The function is enabled. • disabled: The function is disabled. You can run the **snmp-agent extend error-code enable** command to configure this parameter.

16.1.12 display snmp-agent group

Function

The **display snmp-agent group** command displays information about SNMP user groups.

Format

display snmp-agent group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Displays information about a specified SNMP user group. If this parameter is not specified, the system displays information about all SNMP user groups.	The value is a string of 1 to 32 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When configuring a management object according to the SNMP user group, you can run the **display snmp-agent group** command to view information about the SNMP user group, such as the group name and security model.

Prerequisites

An SNMP user group has been configured using the **snmp-agent group** command.

Example

Display information about all SNMP user groups.

```
<HUAWEI> display snmp-agent group
   Group name: testgroup
       Security model: v3 AuthPriv
       Readview: ViewDefault
       Writeview: dnsmib
       Notifyview: dnsmib
       Storage type: nonVolatile
       Acl: 2001
```

Table 16-7 Description of the **display snmp-agent group** command output

Item	Description
Group name	Name of the SNMP user group.
Security model	Security mode of the SNMP user group: ● v3 AuthPriv: SNMP packets need to be authenticated and encrypted. ● v3 AuthnoPriv: SNMP packets only need to be authenticated. ● v3 noAuthnoPriv: SNMP packets neither need to be authenticated nor encrypted.
Readview	Name of a MIB view with read-only permission of the SNMP user group.
Writeview	Name of a MIB view with read and write permission of the SNMP user group.
Notifyview	Name of a MIB view name with notification permission of the SNMP user group.
Storage-type	Mode in which information is stored. Only nonVolatile is supported currently. In this mode, configuration can be restored after the device restarts.
Acl	The ACL takes effect on both IPv4 and IPv6 networks.
Ipv4 acl	The ACL takes effect on only IPv4 network.
Ipv6 acl	The ACL takes effect on only IPv6 network.

16.1.13 display snmp-agent heartbeat configuration

Function

The **display snmp-agent heartbeat configuration** command displays the configuration of sending heartbeat packets to the NMS.

Format

display snmp-agent heartbeat configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the NMS cannot initiatively obtain the status of the device, run the **snmp-agent heartbeat enable** command to enable the device to send heartbeat packets to the NMS. The device then periodically sends heartbeat packets to the NMS to notify the NMS of its status. To check whether the device is enabled to send heartbeat packets to the NMS, run the **display snmp-agent heartbeat configuration** command.

Example

Display the configuration of sending heartbeat packets to the NMS.

```
<HUAWEI> display snmp-agent heartbeat configuration
SNMP agent heartbeat configuration:
 Status   :     Enabled
 Interval :     60(s)
```

Table 16-8 Description of the **display snmp-agent heartbeat configuration** command output

Item	Description
SNMP agent heartbeat configuration	Configuration of sending heartbeat packets to the NMS.
Status	Whether the device is enabled to send heartbeat packets to the NMS: ● Enabled: The function is enabled. ● Disabled: The function is disabled. You can run the **snmp-agent heartbeat enable** command to configure this parameter.
Interval	The interval at which the device sends heartbeat packets to the NMS. You can run the **snmp-agent heartbeat interval** command to configure this parameter.

16.1.14 display snmp-agent inform

Function

The **display snmp-agent inform** command displays parameters for sending traps to the NMS through Inform packets and statistics about the Inform packets.

Format

display snmp-agent inform [**address udp-domain** *ip-address* [**vpn-instance** *vpn-instance-name*] **params securityname** { *security-name* | **cipher** *security-name* }]

Parameters

Parameter	Description	Value
address udp-domain *ip-address*	Specifies the IP address of the NMS, with the transmission domain of the target host being based on the User Datagram Protocol (UDP). **NOTE** The IP address specified by **address** and the security name specified by **securityname** together identify an NMS.	The value is dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the VPN instance to which the NMS belongs. **NOTE** On the VPN, the VPN instance specified by **vpn-instance**, IP address, and security name together identify an NMS.	The value must be an existing VPN instance name.
params	Indicates information about the NMS.	-
securityname *security-name*	Specifies the user security name displayed on the NMS.	The value is a string of 1 to 32 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
cipher *security-name*	Indicates the unencrypted or encrypted string of security name.	The value is a string of 1 to 32 case-sensitive characters or a string of 32 or 56 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string. ● When the community name is a string of 1 to 32 characters, the string is processed as plain text by default and will be encrypted. ● When the community name is a string of 32 or 56 characters, the string is processed as cipher text by default, and the system will determine whether the string can be parsed.

Views

All views

Default Level

3: Management level

Usage Guidelines

The **display snmp-agent inform** command displays parameters for sending traps to the NMS through Inform packets and statistics about the Inform packets:

- Number of times Inform packets are retransmitted when the device receives no acknowledgement message from the NMS.
- Timeout period for the acknowledgement from the NMS in response to Inform packets.
- Number of Inform packets retransmitted to the NMS.
- Number of Inform packets in the Inform buffer to be acknowledged by the NMS.
- Number of traps sent through Inform packets to the NMS.
- Number of Inform packets discarded when the Inform buffer is full.
- Number of retransmitted Inform packets that are not acknowledged.
- Number of packets acknowledged by the NMS.

If no parameter is specified in the **display snmp-agent inform** command, global parameters for sending traps through Inform packets, all NMS parameters, and packet statistics mode are displayed.

Example

Displays global parameters for sending traps through Inform packets, all NMS parameters, and packets statistics mode.

```
<HUAWEI> display snmp-agent inform
Global config: resend-times 3, timeout 15s, pending 39
Global status: current notification count 1
Target-host ID: VPN instance/IP-Address/Domain/Security name
-/10.1.1.1/-/%^%#O>tf1ssv|~v3.\IY}|@Gk,:%/IX{!OrFazE#1lxR%^%#:
    Config: resend-times 3, timeout 15s
    Status: retries 0, pending 0, sent 0, dropped 0, failed 0, confirmed 0
```

Table 16-9 Description of the **display snmp-agent inform** command output

Item	Description
Global config	Global Inform parameters: - resend-times: indicates the number of times Inform packets are retransmitted when the device receives no acknowledgement message from the NMS. - timeout: indicates timeout period for the acknowledgement from the NMS in response to Inform packets, in seconds. - pending: indicates the number of Inform packets in the Inform buffer to be acknowledged by the NMS. You can run the **snmp-agent inform** command to configure these parameters.
Global status	Statistics about global Inform packets.
Target-host ID: VPN instance/IP-Address/Domain/Security name	You can run the **snmp-agent inform address** command to configure these parameters (except Domain).
Config	Inform packet parameters of the NMS: - resend-times: indicates the number of times Inform packets are retransmitted when the device receives no acknowledgement message from the NMS. - timeout: Indicates timeout period for the acknowledgement from the NMS in response to Inform packets. You can run the **snmp-agent inform address** command to configure these parameters.

Item	Description
Status	Statistics about Inform packets from the switch to the NMS: ● retries: Number of Inform packets retransmitted to the NMS. ● pending: indicates the number of Inform packets in the Inform buffer to be acknowledged by the NMS. ● sent: Number of traps sent through Inform packets to the NMS. ● dropped: Number of Inform packets discarded when the Inform buffer is full. ● failed: Number of retransmitted Inform packets that are not acknowledged. ● confirmed: Number of packets acknowledged by the NMS.

16.1.15 display snmp-agent mib-view

Function

The **display snmp-agent mib-view** command displays the current MIB view.

Format

display snmp-agent mib-view [**exclude** | **include** | **viewname** *view-name*]

Parameters

Parameter	Description	Value
exclude	Displays all MIB views that have excluded MIB subtrees configured.	-
include	Displays all MIB views that have included MIB subtrees configured.	-
viewname *view-name*	Displays a specified MIB view.	The value is a string of 1 to 32 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **snmp-agent mib-view** command creates or updates a MIB view. To check the current MIB view, you can run the **display snmp-agent mib-view** command.

Precautions

The **snmp-agent** command has been run to enable the SNMP Agent. Otherwise, an error message is displayed.

Example

Display the current MIB view.

```
<HUAWEI> display snmp-agent mib-view
   View name:ViewDefault
       MIB Subtree:internet
       Subtree mask:F0(Hex)
       Storage-type: nonVolatile
       View Type:included
       View status:active
```

Table 16-10 Description of the **display snmp-agent mib-view** command output

Item	Description
View name	MIB view name. You can run the **snmp-agent mib-view** command to configure this parameter.
MIB Subtree	MIB subtree. You can run the **snmp-agent mib-view** command to configure this parameter.
Subtree mask	MIB subtree mask.
Storage type	Mode in which information is stored. Only nonVolatile is supported currently. In this mode, configuration can be restored after the device restarts.

Item	Description
View Type	Whether the MIB subtree can be accessed by a MIB view: ● included: The MIB subtree can be accessed by a MIB view. ● excluded: The MIB subtree cannot be accessed by a MIB view. You can run the **snmp-agent mib-view** command to configure this parameter.
View status	Indicates the status of the MIB view.

16.1.16 display snmp-agent notification-log

Function

The **display snmp-agent notification-log** command displays information saved in the trap log buffer.

Format

display snmp-agent notification-log [**info** | **logtime** *starttime* **to** *endtime* | **size** *size*]

Parameters

Parameter	Description	Value
info	Displays parameters of trap logs recorded by the device and statistics about trap logs.	-
logtime *starttime* **to** *endtime*	Specifies the start time and end time of trap logs to be displayed: ● *starttime*: specifies the start time of trap logs. ● *endtime*: specifies the end time of trap logs.	The value is in the HH:MM:SS YYYY/MM/DD format, where HH:MM:SS indicates the hour, minute, and second and YYYY/MM/DD indicates the year, month, and day. HH ranges from 0 to 23; MM and SS range from 0 to 59. YYYY ranges from 2000 to 2099; MM ranges from 1 to 12; DD ranges from 1 to 31. The end time must be later than the start time.

Parameter	Description	Value
size *size*	Specifies the number of latest trap logs to be displayed.	The value is an integer that ranges from 1 to 5000.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can use any of the following methods to view logs in the trap log buffer using the **display snmp-agent notification-log** command:

- Specify the start time and end time of trap logs to be displayed.
- Specify the number of latest trap logs to be displayed.
- Specify no parameter to view all trap logs.

Example

Display parameters of trap logs recorded by the device and statistics about trap logs.

```
<HUAWEI> display snmp-agent notification-log info
Notification log information :
Notification Admin Status: enable
GlobalNotificationsLogged: 0
GlobalNotificationsBumped: 0
GlobalNotificationsLimit: 500
GlobalNotificationsAgeout: 24
Total number of notification log(s): 0
```

Table 16-11 Description of the **display snmp-agent notification-log info** command output

Item	Description
Notification log information	Parameters of trap logs recorded by the device and statistics about trap logs.
Notification Admin Status	Whether the function of recording trap logs is enabled on the device: - enable: The function is enabled. - disable: The function is disabled. You can run the **snmp-agent notification-log enable** command to configure this parameter.
GlobalNotificationsLogged	Number of trap logs recorded currently.

Item	Description
GlobalNotificationsBumped	Number of logs recording discarded traps.
GlobalNotificationsLimit	Maximum number of trap logs that can be saved. You can run the **snmp-agent notification-log** command to configure this parameter.
GlobalNotificationsAgeout	Aging time of trap logs. You can run the **snmp-agent notification-log** command to configure this parameter.
Total number of notification log(s)	Total number of recorded trap logs.

Display the latest 20 trap logs. (In this example, only one trap log is available in the system.)

```
<HUAWEI> display snmp-agent notification-log size 20
 Total number of notifications log(s) : 1

LogTable :
  LogIndex= 12
  LogTime= 229323
  LogDateAndTime= 2007/3/8 10:28:16

  LogVariableIndex= 4
  LogVariableOID= 1.3.6.1.4.1.2011.6.10.1.1.7.1.4.29
  LogVariableValueType= Integer32LogVariableValue = 3
  LogVariableIndex= 5
  LogVariableOID= 1.3.6.1.4.1.2011.6.10.1.1.7.1.5.29
  LogVariableValueType= Integer32LogVariableValue = 2
```

Table 16-12 Description of the **display snmp-agent notification-log size 20** command output

Item	Description
LogTable	Log table.
LogIndex	Index of the log.

Item	Description
LogTime	Difference between the time when the log was recorded and the time when the system started. The unit is 10 ms.
LogDateAndTime	Absolute date and time when the log was recorded.
LogEngineID	Engine ID of the SNMP message recorded in the log.
LogEngineTAddress	IP address and port number of the SNMP message recorded in the log.
LogEngineTDomain	Transmission type of the SNMP message recorded in the log.
LogContextEngineID	Engine ID of context of the SNMP message recorded in the log.
LogContextName	Secure user name, IP address, and VPN instance name.
LogNotificationID	OID of the trap object recorded in the log.
LogVariableTable	Variable table of the log.
LogVariableIndex	Index of a variable.
LogVariableOID	OID of a variable.
LogVariableValueType	Value type of a variable.
LogVariableValue	Value of a variable.

16.1.17 display snmp-agent notify-filter-profile

Function

The **display snmp-agent notify-filter-profile** command displays information about a specified trap filter profile or all trap filter profiles.

Format

display snmp-agent notify-filter-profile [*profile-name*]

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a trap filter profile.	The value is a string of 1 to 32 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

3: Management level

Usage Guidelines

You can use the **display snmp-agent notify-filter-profile** command to view information about configured trap filter profiles. The command can display all the configured trap filter profiles or a specified trap file profile.

Example

Display information about configured trap filter profiles.

```
<HUAWEI> display snmp-agent notify-filter-profile
  Notify-filter name:snmpv2
  Notify-filter Subtree:snmpV2
  Notify-filter Subtree mask:F8(Hex)
  Notify-filter Storage-type:nonVolatile
  Notify-filter Type:included
  Notify-filter status:active
```

Table 16-13 Description of the **display snmp-agent notify-filter-profile** command output

Item	Description
Notify-filter name	Name of a trap filter profile. You can run the **snmp-agent notify-filter-profile** command to configure this parameter.
Notify-filter Subtree	Filtered MIB subtree. You can run the **snmp-agent notify-filter-profile** command to configure this parameter.
Notify-filter Subtree mask	Mask of a MIB subtree.

Item	Description
Notify-filter Storage-type	Mode in which information is stored. Only nonVolatile is supported currently. In this mode, configuration can be restored after the device restarts.
Notify-filter Type	Whether traps of the MIB subtree are sent to the NMS: ● included: Traps of the MIB subtree are sent to the NMS. ● excluded: Traps of the MIB subtree are not sent to the NMS. You can run the **snmp-agent notify-filter-profile** command to configure this parameter.
Notify-filter status	Status of a trap filter profile.

16.1.18 display snmp-agent statistics

Function

The **display snmp-agent statistics** command displays statistics about SNMP packets on the switch.

Format

display snmp-agent statistics

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

In an SNMP management system, the NMS and the SNMP Agent exchange SNMP messages as follows:

- The NMS acts as a manager to send an SNMP Request message to the SNMP Agent.
- The SNMP Agent searches the MIB on the device for the required information and sends an SNMP Response message to the NMS.

- When the trap triggering conditions are met, the SNMP Agent sends a trap to the NMS to report the event occurring on the device. In this manner, the network administrator can process the event occurring on the network in time.
