1. Run the **dhcp option82 vendor-specific format vendor-sub-option 2 ip-address** *ip-address* command in the system view to use the Sub Option2 field that is customized by the vendor in the Option82 field to carry the VTEP IP address of the local device.
2. Run the **dhcp option82 encapsulation vendor-specific-id** command in the BD view to insert the sub-option customized by the vendor into the Option82 field.
3. Run the **dhcp option82** { **insert** | **rebuild** } **enable** command in the BD view to configure the Option82 field to be inserted into DHCP packets.
4. (Optional) Run the **dhcp relay information enable** command in the VBDIF interface view to enable the Option 82 function for the DHCP relay agent.

Example

Enable the re-routing function for the DHCP relay agent on VBDIF100 of a distributed gateway.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] bridge-domain 100
[HUAWEI-bd100] quit
[HUAWEI] interface vbdif 100
[HUAWEI-Vbdif100] dhcp select relay
[HUAWEI-Vbdif100] dhcp relay anycast gateway re-route enable
```

6.3.21 dhcp option template

Function

The **dhcp option template** command creates a DHCP Option template and enters the DHCP Option template view.

The **undo dhcp option template** command deletes a configured DHCP Option template.

By default, no DHCP Option template is created on the device.

Format

dhcp option template *template-name*

undo dhcp option template *template-name*

Parameters

Parameter	Description	Value
template-name	Specifies the name of the DHCP Option template.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain digits, letters, underscores (_), hyphens (-), and dots (.), but cannot be set to **-** or **--**.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on a DHCP server. During network deployment, a DHCP server dynamically allocates IP addresses with leases to clients or allocates fixed IP addresses to some clients. For example, laptops or terminals are often moved to different places in enterprises, and they can obtain IP addresses using the dynamic allocation mode. However, IP addresses obtained dynamically are randomly allocated, and cannot be set to specified IP addresses. To allocate fixed IP addresses to some fixed terminals (such as IP phones), run the **static-bind** command in the global address view to bind IP addresses to MAC addresses of the clients so that the clients are allocated fixed IP addresses.

In some cases, you need to allocate other network configuration parameters except IP addresses to fixed static terminals. For example, besides obtaining an IP address, an IP phone needs information such as the startup configuration file to register normally. In this case, you can configure a DHCP Option template and configure network configuration parameters except the IP address required by the client in the DHCP Option template. Then bind the DHCP Option template to the fixed terminal in the global address pool. The DHCP server then allocates the IP address and other parameters to the terminal.

Precautions

Network parameters configured in the DHCP Option template view take effect only for static clients. A DHCP Option template can be bound to multiple clients.

Run the **static-bind ip-address** *ip-address* **mac-address** *mac-address* [**option-template** *template-name*] command to configure a DHCP Option template that is bound to static clients.

Example

Create a DHCP Option template named **test**.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template test
```

6.3.22 dhcp relay gateway-switch enable

Function

The **dhcp relay gateway-switch enable** command enables automatic gateway switching on the DHCP relay agent.

The **undo dhcp relay gateway-switch enable** command disables automatic gateway switching on the DHCP relay agent.

By default, automatic gateway switching is disabled on the DHCP relay agent.

Format

dhcp relay gateway-switch enable

undo dhcp relay gateway-switch enable

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp relay gateway-switch enable** command is used on DHCP relay agents. This command allows a DHCP relay agent to use a secondary IP address as the gateway address to apply for IP addresses for users when it has failed to use the primary IP address to apply for user IP addresses.

Prerequisites

DHCP has been enabled globally by using the **dhcp enable** command in the system view. DHCP relay has been enabled on an interface by using the **dhcp select relay** command.

Precautions

- After VRRP is configured, if the interface (enabled with DHCP relay) has a primary IP address and several secondary IP addresses, the DHCP relay agent by default uses the virtual IP address first configured for the VRRP group to apply for IP addresses for users. If IP addresses fail to be applied for, the DHCP relay agent tries other virtual IP addresses of the VRRP group one by one based on the VRRP virtual IP address configuration sequence until users successfully obtain IP addresses.
- The DHCP relay agent switches the gateway address from the primary to a secondary IP address only when it has failed to apply an IP address for a user using the primary IP address at least three times and the interval between the first and last failures exceeds 24 seconds.
- Before running this command on an interface, ensure that the interface has a primary IP address and at least one secondary IP address.
- An interface can have a primary IP address and several secondary IP addresses. The system tries the secondary IP addresses one by one based on the IP address configuration sequence until users successfully obtain IP addresses.

Example

Enable automatic gateway switching on DHCP relay-enabled VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ip address 192.168.30.1 255.255.255.0
[HUAWEI-Vlanif10] ip address 192.168.31.1 255.255.255.0 sub
[HUAWEI-Vlanif10] dhcp select relay
[HUAWEI-Vlanif10] dhcp relay server-ip 192.168.20.1
[HUAWEI-Vlanif10] dhcp relay gateway-switch enable
```

Enable automatic gateway switching on DHCP relay-enabled GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.30.1 255.255.255.0
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.31.1 255.255.255.0 sub
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
[HUAWEI-GigabitEthernet0/0/1] dhcp relay server-ip 192.168.20.1
[HUAWEI-GigabitEthernet0/0/1] dhcp relay gateway-switch enable
```

6.3.23 dhcp relay giaddr source-interface

Function

The **dhcp relay giaddr source-interface** command configures a source interface for relayed DHCP messages and fills the primary IP address of the source interface in the giaddr field of these messages.

The **undo dhcp relay giaddr source-interface** command restores the default configuration.

By default, no source interface for relayed DHCP messages is configured, and the IP address of the DHCP relay agent is filled in the giaddr field of these messages.

NOTE

This command is supported on the following devices: S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6735-S, S6720-EI, S6720S-EI.

Format

dhcp relay giaddr source-interface *interface-type interface-number*

undo dhcp relay giaddr source-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies a source interface for relayed DHCP messages. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number.	-

Views

VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network with distributed VXLAN gateways where VBDIF interfaces are enabled with the DHCP relay function, a distributed gateway (as a DHCP relay agent) fills the IP address of its VBDIF interface in the giaddr field of a DHCP DISCOVER message to be sent to DHCP servers. When replying with a DHCP OFFER message, a DHCP server sets the destination IP address to the IP address of the VBDIF interface in the giaddr field carried in its received DHCP DISCOVER message. However, since the IP addresses of VBDIF interfaces on different distributed gateways are the same, the DHCP OFFER message from a DHCP server may be forwarded to a distributed gateway rather than the one relaying the DHCP DISCOVER message received by the server. As a result, the user sending the DHCP DISCOVER message cannot obtain an IP address.

To resolve this issue, you can configure a source interface for relayed DHCP messages on VBDIF interfaces of all distributed gateways. The distributed gateways (as DHCP relay agents) then fill the primary IP address of the specified source interface in the giaddr field of DHCP DISCOVER messages to be relayed to DHCP servers. Since the primary IP address of the source interface configured on each VBDIF interface is unique among all distributed gateways, as long as this IP address is reachable to DHCP servers, the DHCP OFFER messages from DHCP servers can be sent to the correct distributed gateways.

Prerequisites

DHCP relay has been enabled using the **dhcp select relay** command in the VBDIF interface view.

Follow-up Procedure

By default, a DHCP server selects an IP address from the address pool on the network segment specified in the giaddr field of its received DHCP DISCOVER messages. After this command is run to configure a source interface for relayed DHCP messages on a DHCP relay-enabled interface (which is the gateway for its downlink DHCP clients), the primary IP address of the specified source interface is filled in the giaddr field of DHCP DISCOVER messages destined for DHCP servers. If DHCP servers still select an IP address from the address pool on the network segment specified in the giaddr field, DHCP clients cannot access the network after obtaining IP addresses. This is because the primary IP address of the source interface is on a different network segment from that of the DHCP relay-enabled interface. To resolve the preceding problem, you need to run the **dhcp relay information link-selection insert enable** command to insert the Link-selection sub-option of the Option82 field into relayed DHCP DISCOVER messages, and to fill the IP address of the DHCP relay-enabled interface in the Link-selection suboption. In this case, DHCP servers select IP addresses from the address pool on the network segment specified in the Link-selection sub-option of the Option 82 field of their received DHCP DISCOVER messages.

Precautions

- The primary IP address of the source interface for relayed DHCP messages must be reachable to DHCP servers.
- The source interface and VBDIF interfaces enabled with the DHCP relay function can be bound to different VPNs.
- The DHCP server must be able to parse the Link-selection sub-option.

Example

On VBDIF 100, configure Loopback 1 as the source interface for relayed DHCP messages.

```
<HUAWEI> system-view
[HUAWEI] interface loopback 1
[HUAWEI-LoopBack1] ip address 10.1.1.1 24
[HUAWEI-LoopBack1] quit
[HUAWEI] dhcp enable
[HUAWEI] bridge-domain 100
[HUAWEI-bd100] quit
[HUAWEI] interface vbdif 100
[HUAWEI-Vbdif100] dhcp select relay
[HUAWEI-Vbdif100] dhcp relay giaddr source-interface loopback 1
```

6.3.24 dhcp relay information enable

Function

The **dhcp relay information enable** command enables the Option 82 function for the DHCP relay agent.

The **undo dhcp relay information enable** command disables the Option 82 function for the DHCP relay agent.

By default, the Option 82 function is disabled for the DHCP relay agent.

Format

dhcp relay information enable

undo dhcp relay information enable

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to the DHCP relay agent. When DHCP Request messages carry Option 82 information, the DHCP server can locate user positions accurately and assign IP addresses to users using different policies. After the Option 82 function is enabled on the DHCP relay agent, the device checks the Option 82 field contained in the packets and processes the packets using corresponding policies.

Prerequisites

DHCP has been enabled by running the **dhcp enable** command in the system view.

DHCP relay has been enabled by running the **dhcp select relay** command in the interface view.

Precautions

If you run the **dhcp relay information enable** command on an interface and the **dhcp option82** { **insert** | **rebuild** } **enable** command in the VLAN view or on a physical interface in the VLAN simultaneously, only the **dhcp relay information enable** command takes effect.

Follow-up Tasks

Run the **dhcp relay information strategy** { **drop** | **keep** | **replace** } command in the interface view to configure strategies for the DHCP relay agent to process Option 82 information.

Example

Enable the Option 82 function for the DHCP relay agent on the VLANIF100 interface.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcp select relay
[HUAWEI-Vlanif100] dhcp relay information enable
```

Enable the Option 82 function for the DHCP relay agent on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
[HUAWEI-GigabitEthernet0/0/1] dhcp relay information enable
```

6.3.25 dhcp relay information strategy

Function

The **dhcp relay information strategy** command configures the strategies used by a DHCP relay agent to process Option 82 information.

The **undo dhcp relay information strategy** command restores the default setting.

By default, the strategy used by a DHCP relay agent to process Option 82 information is **replace**.

Format

dhcp relay information strategy { **drop** | **keep** | **replace** }

undo dhcp relay information strategy

Parameters

Parameters	Description	Value
drop	Configures the DHCP relay agent to drop Option 82 information.	-

Parameters	Description	Value
keep	Configures the DHCP relay agent to keep Option 82 information.	-
replace	Configures the DHCP relay agent to replace Option 82 information.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to the DHCP relay agent. When DHCP Request messages carry Option 82 information, the DHCP server can locate user positions accurately and assign IP addresses to users using different policies. When a DHCP relay agent receives DHCP Request messages, it uses one of the following strategies to process Option 82 information:

- Drop:
  - If the received DHCP message does not carry an Option 82 field, the DHCP relay agent forwards the message directly without processing it.
  - If the received DHCP message carries an Option 82 field, the DHCP relay agent drops the Option 82 field and forwards the message.
- Keep:
  - If the received DHCP message does not carry an Option 82 field, the DHCP relay agent forwards the message directly without processing it.
  - If the received DHCP message carries an Option 82 field, the DHCP relay agent keeps the Option 82 field and forwards the message.
- Replace:
  - If the received DHCP message does not carry an Option 82 field, the DHCP relay agent inserts an Option 82 field configured by the administrator into the received message and forwards the message.
  - If the received DHCP message carries an Option 82 field, the DHCP relay agent replaces it with the Option 82 field configured by the administrator and forwards the message.

Prerequisites

DHCP has been enabled by running the **dhcp enable** command in the system view.

DHCP relay has been enabled by running the **dhcp select relay** command in the interface view.

The Option 82 function has been enabled for the DHCP relay agent by using the **dhcp relay information enable** command.

Example

Configure the DHCP relay agent to drop Option 82 information on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcp select relay
[HUAWEI-Vlanif100] dhcp relay information enable
[HUAWEI-Vlanif100] dhcp relay information strategy drop
```

Configure the DHCP relay agent to drop Option 82 information on the GE0/0/1 interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
[HUAWEI-GigabitEthernet0/0/1] dhcp relay information enable
[HUAWEI-GigabitEthernet0/0/1] dhcp relay information strategy drop
```

6.3.26 dhcp relay information link-selection insert enable

Function

The **dhcp relay information link-selection insert enable** command inserts the Link-selection sub-option of the Option82 field into DHCP messages.

The **undo dhcp relay information link-selection insert enable** command restores the default configuration.

By default, the Link-selection sub-option of the Option82 field is not inserted into DHCP messages.

NOTE

This command is supported on the following devices: S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6735-S, S6720-EI, S6720S-EI.

Format

dhcp relay information link-selection insert enable

undo dhcp relay information link-selection insert enable

Parameters

None

Views

VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network with VXLAN distributed gateways as DHCP relay agents, to ensure that the DHCP OFFER messages from DHCP servers can arrive at the correct distributed gateways, you need to run the **dhcp relay giaddr source-interface** command on the distributed gateways to configure a source interface for relayed DHCP messages and fill the primary IP address of the source interface in the giaddr field. By default, DHCP servers select IP addresses from the address pool on the network segment specified in the giaddr field of their received DHCP DISCOVER messages. After the preceding command is run, since the primary IP address of the source interface is on a different network segment from that of the DHCP relay-enabled interface (which is the gateway for its downlink DHCP clients), if DHCP servers still select IP addresses from the address pool on the network segment specified in the giaddr field, DHCP clients cannot access the network after obtaining IP addresses.

To solve the preceding problem, run the **dhcp relay information link-selection insert enable** command to insert the Link-selection sub-option of the Option82 field into DHCP DISCOVER messages forwarded by the DHCP relay agent, and to fill in the IP address of the DHCP relay-enabled interface in the Link-selection sub-option. In this case, DHCP servers select IP addresses from the address pool on the network segment specified in the Link-selection sub-option of the Option 82 field of their received DHCP DISCOVER messages.

Prerequisites

DHCP relay has been enabled using the **dhcp select relay** command in the VBDIF interface view.

Precautions

- DHCP servers must be able to parse the Link-selection sub-option.
- After the **dhcp relay information link-selection insert enable** command is run, the Link-selection sub-option is added to DHCP messages, removing the need to configure policies for Option 82 insertion and processing. A DHCP relay agent processes the Link-selection sub-option in different ways depending on the policies for Option 82 insertion and processing:
  - Without policies for Option 82 insertion and processing: The DHCP relay agent inserts the Option 82 field with the Link-selection sub-option into DHCP messages. When forwarding a DHCP message with the Option 82 field, the DHCP relay agent deletes the original Option 82 field and inserts the locally configured Option 82 field with the Link-selection sub-option.
  - With policies for Option 82 insertion and processing: How the DHCP relay agent inserts the Link-selection sub-option into DHCP messages is

determined by the configured policies. For example, if the Option 82 insertion mode is set to **insert**, the DHCP relay agent does not insert the Link-selection sub-option into DHCP messages when receiving DHCP messages carrying the Option 82 field.

You can run the **dhcp option82** { **insert** | **rebuild** } **enable** command to configure the Option 82 insertion mode, and run the **dhcp relay information enable** and **dhcp relay information strategy** { **drop** | **keep** | **replace** } commands to configure an Option 82 processing policy.

Example

On VBDIF 100, configure the function of inserting the Link-selection sub-option of the Option82 field into DHCP messages.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] bridge-domain 100
[HUAWEI-bd100] quit
[HUAWEI] interface vbdif 100
[HUAWEI-Vbdif100] dhcp select relay
[HUAWEI-Vbdif100] dhcp relay information link-selection insert enable
```

6.3.27 dhcp relay release

Function

The **dhcp relay release** command configures a DHCP relay agent to send a release message to a DHCP server for releasing the IP address assigned to a DHCP client.

Format

In the system view:

dhcp relay release *client-ip-address mac-address* [**vpn-instance** *vpn-instance-name*] [*server-ip-address*]

In the interface view:

dhcp relay release *client-ip-address mac-address* [*server-ip-address*]

Parameters

Parameter	Description	Value
client-ip-address	Specifies the IP address of a DHCP client.	The value is in dotted decimal notation.
mac-address	Specifies the MAC address of a DHCP client.	The value is in H-H-H format. H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
server-ip-address	Specifies the IP address of a DHCP server. If this parameter is specified, a DHCP relay agent sends a release message to the specified DHCP server for releasing the IP address assigned to a DHCP client.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance to which the specified DHCP server releasing IP addresses belongs.	The value must be an existing VPN instance name.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. In some situations, for example, a user is forced to go offline, the user's IP address is no longer used. However, the user cannot access the network, and will not send a DHCP release message to the DHCP server to release the IP address assigned by the DHCP server. Before the IP address lease expires, the DHCP server will not assign the user's IP address to another client, wasting IP addresses. In this case, you can run the **dhcp relay release** command to configure a DHCP relay agent to send a DHCP release message to the DHCP server. After receiving the message, the DHCP server sets the status of the IP address to idle. The DHCP server then can assign the released IP address to another client.

If a DHCP server IP address is specified, the DHCP relay agent sends an address release request only to the specified DHCP server. If no DHCP server address is specified, the following situations occur:

- When the **dhcp relay release** command is run in the system view, the DHCP relay agent sends an address release request to DHCP servers on all the interfaces working in DHCP relay mode.

- When the **dhcp relay release** command is run in the interface view, the DHCP relay agent sends an address release request to all DHCP servers on the VLANIF interface.

Precautions

The **dhcp relay release** command only releases the IP addresses dynamically assigned by DHCP servers.

When multiple DHCP relay agents are connected between the DHCP client and server, this command must be executed on the first DHCP relay agent.

Example

Configure a DHCP relay agent to send a release message to the DHCP server at 10.1.1.1 for releasing the IP address 192.168.1.1 assigned to the DHCP client whose MAC address is 00e0-fc34-2000.

```
<HUAWEI> system-view
[HUAWEI] dhcp relay release 192.168.1.1 00e0-fc12-3456 10.1.1.1
```

6.3.28 dhcp relay request server-match enable

Function

The **dhcp relay request server-match enable** command configures a DHCP relay agent to check the DHCP server identifier (Option54) in a DHCP Request message to be forwarded.

The **undo dhcp relay request server-match enable** command configures a DHCP relay agent not to check the DHCP server identifier (Option54) in a DHCP Request message to be forwarded.

By default, a DHCP relay agent checks the DHCP server identifier (Option54) in a DHCP Request message to be forwarded.

Format

dhcp relay request server-match enable

undo dhcp relay request server-match enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During the four-message exchange process, the DHCP Offer message sent by a DHCP server carries the DHCP server identifier (Option54) to identify the server. After receiving the DHCP Offer message, the DHCP client records the DHCP server identifier and carries it in the DHCP Request message to be replied to indicate which DHCP server is selected. When the DHCP relay agent forwards the DHCP Request message, it checks the DHCP server identifier in the message and forwards the message only to the corresponding DHCP server.

If multiple DHCP servers are deployed on the network and the design of a server does not comply with standards, the DHCP server identifier carried in the DHCP Offer message to be sent by the server is not its identifier. As a result, the DHCP server identifier carried in the DHCP Request message is incorrect, the DHCP relay agent forwards the message to an incorrect DHCP server rather than the matching DHCP server, and the client fails to obtain an IP address.

To resolve this issue, you can run the **undo dhcp relay request server-match enable** command, so that the DHCP relay agent does not check the DHCP server identifier (Option54) in the DHCP Request message to be forwarded and forwards the message to all relayed DHCP servers, ensuring that the matching DHCP server can receive the DHCP Request message.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Example

Configure a DHCP relay agent not to check the DHCP server identifier (Option54) in a DHCP Request message to be forwarded.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] undo dhcp relay request server-match enable
```

6.3.29 dhcp relay reply forward all enable

Function

The **dhcp relay reply forward all enable** command configures a DHCP relay agent to forward all DHCP ACK messages.

The **undo dhcp relay reply forward all enable** command restores the default setting.

By default, a DHCP relay agent forwards only the first received DHCP ACK message.

Format

dhcp relay reply forward all enable

undo dhcp relay reply forward all enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As defined in RFC2131, the DHCP server that provides only IP addresses for DHCP clients replies with DHCP ACK messages. After receiving a DHCP ACK message, a DHCP relay agent searches for the entry based on the DHCP client's MAC address contained in the message, forwards the message to the corresponding client, and then immediately deletes the entry matching the client.

If multiple DHCP servers are deployed on the network, the design of a server does not comply with standards, and a DHCP client requests for an IP address, the server does not provide an IP address for the DHCP client but replies with a DHCP ACK message. If the DHCP relay agent first receives the DHCP ACK message replied by the server, it incorrectly forwards the message to the client and deletes the corresponding entry. After the DHCP relay agent receives the correct DHCP ACK message, it cannot forward the message because the entry matching the client has been deleted. As a result, the client cannot obtain an IP address.

To resolve this issue, you can run the **dhcp relay reply forward all enable** command, so that the DHCP relay agent does not immediately delete the entry matching a client after forwarding a DHCP ACK message to the client. Instead, the DHCP relay agent deletes the entry that has been aged out to ensure that the subsequently received DHCP ACK messages can be forwarded to the client.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Example

Configure a DHCP relay agent to forward all DHCP ACK messages.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp relay reply forward all enable
```

6.3.30 dhcp relay server-ip

Function

The **dhcp relay server-ip** command configures a DHCP server address on an interface enabled with DHCP relay.

The **undo dhcp relay server-ip** command deletes the configured DHCP server addresses on an interface enabled with DHCP relay.

By default, no DHCP server IP address is configured on an interface enabled with DHCP relay.

Format

dhcp relay server-ip [**vpn-instance** *vpn-name* | **public-net**] *ip-address*

undo dhcp relay server-ip { [**vpn-instance** *vpn-name* | **public-net**] *ip-address* | **all** }

Parameters

Parameter	Description	Value
vpn-instance *vpn-name*	Specifies the name of a VPN instance.	The value must be the name of an existing VPN instance.
public-net	Indicates that the public network is used to forward packets.	-
ip-address	Specifies the IP address of a DHCP server.	The value is in dotted decimal notation.
all	Deletes all the DHCP server IP addresses configured on an interface.	-

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. When a DHCP client needs to send a DHCP DISCOVER message to a DHCP server on a different network segment through a DHCP relay agent, you must configure the DHCP server IP address on the DHCP relay agent. If the DHCP server and DHCP client are not in the same VPN, you also need to specify the VPN where the DHCP server resides.

When a DHCP relay agent forwards a DHCP DISCOVER message, it does not check whether the DHCP server is Down. If multiple DHCP server addresses are configured on an interface, multiple DHCP servers respond with DHCP OFFER messages to the DHCP client. However, the DHCP client uses the first received DHCP OFFER message. As a result, IP addresses in the IP address pool on the first DHCP server are insufficient, but available IP addresses in the IP address pools on the other DHCP servers are not allocated. To make each DHCP server allocate the same number of IP addresses, a DHCP relay agent changes the forwarding order each time it forwards a DHCP DISCOVER message, so that load balancing is implemented among DHCP servers. A DHCP relay agent forwards a DHCP DISCOVER message as follows:

- The DHCP relay agent forwards the message to all DHCP servers by default, and changes the forwarding order each time it forwards a DHCP DISCOVER message.
- You can configure the **ip relay address cycle** command to reduce the number of messages received by a DHCP server and lessen the load of a DHCP server. After this command is configured, the DHCP relay agent forwards a received DHCP DISCOVER message to one DHCP server at a time, and forwards the DHCP DISCOVER message to a different DHCP server each time it receives the message.

Prerequisites

DHCP relay has been enabled on the interface using the **dhcp select relay** command.

Precautions

To configure multiple DHCP server IP addresses, run this command for multiple times.

Each interface enabled with DHCP relay can be configured with a maximum of 20 DHCP server IP addresses.

If the interface enabled with DHCP relay is bound to a VPN instance but no VPN instance is specified for the DHCP server served by the DHCP relay agent, the DHCP relay agent sends packets through the VPN instance to which the interface belongs by default. If a VPN instance is specified for the DHCP server, the DHCP relay agent sends packets through the VPN instance specified for the DHCP server.

Example

Configure DHCP relay and three DHCP server IP addresses on VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] dhcp select relay
[HUAWEI-Vlanif10] dhcp relay server-ip 10.1.1.2
[HUAWEI-Vlanif10] dhcp relay server-ip vpn-instance temp 10.1.1.3
[HUAWEI-Vlanif10] dhcp relay server-ip public-net 192.0.2.1
```

Configure DHCP relay and three DHCP server IP addresses on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
```

```
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
[HUAWEI-GigabitEthernet0/0/1] dhcp relay server-ip 10.1.1.2
[HUAWEI-GigabitEthernet0/0/1] dhcp relay server-ip vpn-instance temp 10.1.1.3
[HUAWEI-GigabitEthernet0/0/1] dhcp relay server-ip public-net 192.0.2.1
```

6.3.31 dhcp relay server-select

Function

The **dhcp relay server-select** command configures a DHCP server group for a DHCP relay agent.

The **undo dhcp relay server-select** command deletes the configured DHCP server group of a DHCP relay agent.

By default, no DHCP server group is configured.

Format

dhcp relay server-select *group-name*

undo dhcp relay server-select

Parameters

Parameter	Description	Value
group-name	Specifies the name of a DHCP server group.	The value is a string of 1 to 32 case-sensitive characters without spaces.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp relay server-select** command applies to DHCP relay agents. When a DHCP client needs to send DHCP requests to a DHCP server using a DHCP relay agent, you can run the **dhcp relay server-select** command to specify a DHCP server group for the DHCP relay agent and configure the DHCP server address.

Prerequisites

1. A DHCP server group has been created using the **dhcp server group** command.
2. The DHCP relay function has been enabled using the **dhcp select relay** command so that the system can forward DHCP packets to the specified DHCP server.

Precautions

- Multiple interfaces can be configured with the same DHCP server group, and one interface can be configured with only one DHCP server group.
- If you run the **dhcp relay server-select** command in the same interface view for multiple times, only the latest configuration takes effect. If a specified DHCP server group does not exist, the configuration fails; however, the latest configured DHCP server group still takes effect.

Example

Configure the DHCP server group of a DHCP relay agent as **group1** on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server group group1
[HUAWEI-dhcp-server-group-group1] dhcp-server 10.10.10.10
[HUAWEI-dhcp-server-group-group1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcp select relay
[HUAWEI-Vlanif100] dhcp relay server-select group1
```

Configure the DHCP server group of a DHCP relay agent as **group1** on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server group group1
[HUAWEI-dhcp-server-group-group1] dhcp-server 10.10.10.10
[HUAWEI-dhcp-server-group-group1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
[HUAWEI-GigabitEthernet0/0/1] dhcp relay server-select group1
```

6.3.32 dhcp relay trust option82

Function

The **dhcp relay trust option82** command enables Option 82 on the DHCP relay agent.

The **undo dhcp relay trust option82** command disables Option 82 on the DHCP relay agent.

By default, Option 82 is enabled on the DHCP relay agent.

Format

dhcp relay trust option82

undo dhcp relay trust option82

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on the DHCP relay agent to enable the Option 82 function. After receiving a DHCP packet that carries the Option 82 field but the giaddr field of the packet is 0, the DHCP relay agent processes the packet by default. Using the **undo dhcp relay trust option82** command, the DHCP relay agent discards the packet.

Prerequisites

DHCP has been enabled globally by using the **dhcp enable** command.

Example

Enable Option 82 trusted of the DHCP relay agent.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp relay trust option82
```

6.3.33 dhcp select global

Function

The **dhcp select global** command enables an interface to use the global address pool.

The **undo dhcp select global** command disables an interface from using the global address pool.

By default, an interface is disabled from using the global address pool.

Format

dhcp select global

undo dhcp select global

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp select global** command applies to DHCP servers. After receiving a DHCP Request message from a DHCP client, a DHCP server assigns an IP address from the local address pool to the client. Run the **dhcp select global** command to configure the device to assign IP addresses from the global address pool. When no interface address pool is created for the DHCP server, the DHCP server assigns an IP address from the global address pool to an online user.

The device can also assign IP addresses from an interface address pool using the **dhcp select interface** command in the interface view.

Prerequisites

- DHCP has been enabled using the **dhcp enable** command in the system view.

Precautions

- When the device is configured as a DHCP server, if the server's real IP address is configured as the DHCP server IP address on a DHCP relay agent, the server's Layer 3 interface that receives relayed DHCP messages can process these messages, without the need of running the **dhcp select global** command on the interface.
- When the device is configured as a DHCP server, if the VRRP virtual IP address of the server's Layer 3 interface that does not receive DHCP messages is configured as the DHCP server IP address on the DHCP relay agent, the DHCP server cannot process messages relayed by the DHCP relay agent. The DHCP server can process messages relayed by the DHCP relay agent only if the VRRP virtual IP address of the server's Layer 3 interface that receives DHCP messages is configured as the DHCP server IP address on the DHCP relay agent and the **dhcp select global** command is configured on this Layer 3 interface.

Example

Enable VLANIF100 to use the global address pool.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select global
```

Enable GE0/0/1 to use the global address pool.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select global
```

6.3.34 dhcp select interface

Function

The **dhcp select interface** command enables an interface to use the interface address pool.

The **undo dhcp select interface** command disables an interface from using the interface address pool.

By default, the DHCP server function using the interface address pool is disabled on an interface.

Format

dhcp select interface

undo dhcp select interface

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp select interface** command applies to DHCP servers. After receiving a DHCP Request message from a DHCP client, a DHCP server assigns an IP address from the local address pool to the client. Run the **dhcp select interface** command to configure a DHCP server to assign IP addresses from the interface address pool to clients.

The device can also assign IP addresses from a global address pool using the **dhcp select global** command.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

An IP address has been configured for an interface using the **ip address** command. The IP addresses assigned by the address pool and configured on the interface are on the same network segment.

Example

Enable VLANIF100 to use the interface address pool.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.2 24
[HUAWEI-Vlanif100] dhcp select interface
```

Enable GE0/0/1 to use the interface address pool.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.2 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
```

6.3.35 dhcp select relay

Function

The **dhcp select relay** command enables the DHCP relay function.

The **undo dhcp select relay** command disables the DHCP relay function.

By default, the DHCP relay function is disabled.

Format

dhcp select relay

undo dhcp select relay

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp select relay** command applies to DHCP relay agents. If the DHCP server and client are on the same network segment, they can directly communicate with each other using DHCP. In this case, no DHCP relay agent is needed. If the DHCP server and client are on different network segments, the DHCP relay function must be enabled to forward DHCP messages.

Prerequisites

The DHCP function has been enabled using the **dhcp enable** command in the system view.

Follow-up Tasks

- To ensure that a DHCP relay agent can forward DHCP packets to a DHCP server, run the **dhcp relay server-select** or **dhcp relay server-ip** command on the DHCP relay-enabled interface to configure the correct IP address of the DHCP server.
- To ensure that a DHCP server can forward DHCP packets to a DHCP relay agent, you must configure a route to the DHCP relay agent on the DHCP server.

Precautions

- The DHCP server must select an IP address in the same network segment with the DHCP relay agent from the global address pool to ensure that the DHCP client obtains an IP address on the local network segment. No interface address pool can be configured on the interface that connects the DHCP server and relay agent.

Example

Enable the DHCP relay function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcp select relay
```

Enable the DHCP relay function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] dhcp select relay
```

6.3.36 dhcp server alarm ip-used percentage

Function

The **dhcp server alarm ip-used percentage** command configures the percentage of used addresses in an interface address pool at which an address exhaustion alarm is generated and the percentage at which the alarm is cleared.

The **undo dhcp server alarm ip-used percentage** command restores the default percentage of used addresses in an interface address pool at which an address exhaustion alarm is generated and the default percentage at which the alarm is cleared.

By default, an alarm is generated when the percentage of used addresses in an interface address pool reaches 100%, and the alarm is cleared when the percentage is 50%.

Format

dhcp server alarm ip-used percentage *alarm-resume-percentage alarm-percentage*

undo dhcp server alarm ip-used percentage

Parameters

Parameter	Description	Value
alarm-resume-percentage	Specifies the percentage of used addresses in an interface address pool at which an address exhaustion alarm is cleared.	The value is an integer that ranges from 1 to 100. The default value is 50. **NOTE** The percentage of used addresses in an interface address pool at which the address exhaustion alarm is cleared cannot exceed the percentage at which an address exhaustion alarm is generated.
alarm-percentage	Specifies the percentage of used addresses in an interface address pool at which an address exhaustion alarm is generated.	The value is an integer that ranges from 1 to 100. The default value is 100.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the addresses in an interface address pool are used up, an address exhaustion alarm is generated to notify the administrator. The alarms corresponding to this command are as follows:

- When the number of used IP addresses in an IP address pool reaches the alarm threshold, the alarm hwUsedIPReachThreshold with ID 1.3.6.1.4.1.2011.6.8.2.2.0.6 is generated.
- When the number of used IP addresses in an IP address pool falls below the alarm clear threshold, the alarm hwUsedIPReachThresholdResume with the ID 1.3.6.1.4.1.2011.6.8.2.2.0.7 is generated.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

The percentage of used addresses in an interface address pool at which the address exhaustion alarm is cleared cannot exceed the percentage at which an address exhaustion alarm is generated.

Example

Configure the percentage of used IP addresses in the interface address pool of VLANIF 100 at which an address exhaustion alarm is generated and the percentage at which the alarm is cleared.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server alarm ip-used percentage 80 90
```

Configure the percentage of used IP addresses in the interface address pool of GE0/0/1 at which an address exhaustion alarm is generated and the percentage at which the alarm is cleared.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server alarm ip-used percentage 80 90
```

6.3.37 dhcp server bootfile

Function

The **dhcp server bootfile** command configures the name of the startup configuration file for a DHCP client.

The **undo dhcp server bootfile** command deletes the configured name of the startup configuration file for a DHCP client.

By default, the startup configuration file name is not configured for a DHCP client.

Format

dhcp server bootfile *bootfile*

undo dhcp server bootfile

Parameters

Parameter	Description	Value
bootfile	Specifies the name of the startup configuration file for a DHCP client.	The value is a string of 1 to 127 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Besides assigning IP addresses, a DHCP server can also provide the required network configuration parameters, such as the startup configuration file name for the DHCP clients. After the name of the startup configuration file is configured using the **dhcp server bootfile** command, the Offer and ACK packets sent from the DHCP server carry this file name. The DHCP client can acquire the startup configuration file from the specified server based on the file name.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.

3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Configure the name of the startup configuration file as **start.ini** for the DHCP client on the Vlanif100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 255.255.255.0
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server bootfile start.ini
```

Configure the name of the startup configuration file as **start.ini** for the DHCP client on the GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.1.1 255.255.255.0
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server bootfile start.ini
```

6.3.38 dhcp server bootp

Function

Using the **dhcp server bootp** command, you can enable a DHCP server to respond to a Bootstrap Protocol (BOOTP) request.

Using the **undo dhcp server bootp** command, you can disable a DHCP server from responding to a BOOTP request.

By default, a DHCP server does not respond to a BOOTP request.

Format

dhcp server bootp

undo dhcp server bootp

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A DHCP server and a BOOTP server may reside on the same network segment. The BOOTP server assigns static IP addresses to BOOTP clients. As defined in the DHCP protocol, a DHCP server can also respond to BOOTP requests to assign IP addresses to BOOTP clients. BOOTP clients may obtain IP addresses from the DHCP server but not the BOOTP server.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

Follow-up Procedure

Using the **dhcp server bootp automatic** command in the system view, you can enable the DHCP server to allocate IP addresses to BOOTP clients.

Example

Enable a DHCP server to respond to a BOOTP request.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server bootp
```

6.3.39 dhcp server bootp automatic

Function

The **dhcp server bootp automatic** command enables the DHCP server to dynamically allocate IP addresses to BOOTP clients.

The **undo dhcp server bootp automatic** command disables the DHCP server from dynamically allocating IP addresses to BOOTP clients.

By default, a DHCP server does not dynamically allocate IP addresses to BOOTP clients.

Format

dhcp server bootp automatic

undo dhcp server bootp automatic

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. When BOOTP clients need to obtain their IP addresses, DNS server's IP address, and gateway IP address from a DHCP server, you need to run the **dhcp server bootp automatic** command to enable the DHCP server to dynamically allocate IP addresses to BOOTP clients.

Prerequisites

- DHCP has been enabled globally using the **dhcp enable** command in the system view.
- The DHCP server has been enabled to respond to BOOTP requests by using the **dhcp server bootp** command, or **dhcp server bootp automatic** cannot take effect.

Precautions

When the device functions as the DHCP server, the device can allocate IP addresses to BOOTP clients if the BOOTP clients reside on the same network as the DHCP server. You can run the **dhcp server bootp automatic** command to dynamically allocate IP addresses. You can also run the **static-bind** command or the **dhcp server static-bind** command to allocate IP addresses to BOOTP clients in the static binding mode.

Example

Enable the DHCP server to allocate IP addresses to BOOTP clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server bootp
[HUAWEI] dhcp server bootp automatic
```

6.3.40 dhcp server conflict auto-recycle interval

Function

The **dhcp server conflict auto-recycle interval** command enables automatic reclaim of conflicting IP addresses in the interface address pool and configures the interval for the automatic reclaim.

The **undo dhcp server conflict auto-recycle interval** command disables automatic reclaim of conflicting IP addresses in the interface address pool and deletes the configured interval for the automatic reclaim.

By default, automatic reclaim of conflicting IP addresses in the interface address pool is disabled.

Format

dhcp server conflict auto-recycle interval day *day* [**hour** *hour* [**minute** *minute*]]

undo dhcp server conflict auto-recycle interval

Parameters

Parameter	Description	Value
day *day*	Specifies the interval for the automatic reclaim, in days.	The value is an integer that ranges from 0 to 999, in days. The default value is 0.
hour *hour*	Specifies the interval for the automatic reclaim, in hours.	The value is an integer that ranges from 0 to 23, in hours. The default value is 0.
minute *minute*	Specifies the interval for the automatic reclaim, in minutes.	The value is an integer that ranges from 0 to 59, in minutes. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on a DHCP server. When a DHCP server allocates IP addresses to clients, IP address conflict may occur because IP addresses of some hosts have been manually configured. In this case, the DHCP server considers these IP addresses as conflicting IP addresses, and allocates available IP addresses from the conflicting IP addresses to clients only after available IP addresses in the address pool are used up. To reclaim conflicting IP addresses promptly, the administrator can run this command to enable automatic reclaim and specify the reclaim interval.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Enable automatic reclaim for conflicting IP addresses in the address pool on VLANIF 100, and set the interval for automatic reclaim to one day.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server conflict auto-recycle interval day 1
```

Enable automatic reclaim for conflicting IP addresses in the address pool on GE0/0/1, and set the interval for automatic reclaim to one day.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server conflict auto-recycle interval day 1
```

6.3.41 dhcp server database

Function

The **dhcp server database** command enables the function to save the current DHCP data to storage devices.

The **undo dhcp server database** command disables the function to save the DHCP data to storage devices.

By default, DHCP data is not saved to storage devices.

Format

dhcp server database { **enable** | **recover** | **write-delay** *interval* }

undo dhcp server database { **enable** | **recover** | **write-delay** }

Parameters

Parameter	Description	Value
enable	Enables the function to save DHCP data to storage devices.	-
recover	Recovers DHCP configurations using DHCP data in storage device.	-
write-delay *interval*	Specifies the interval at which DHCP data is saved.	The value is an integer ranging from 300 to 86400, in seconds. The default value is 7200 seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device functions as a DHCP server, run the **dhcp server database enable** command to enable the device to save DHCP data to storage devices. This avoids data loss caused by device faults. Then the system generates **lease.txt** and **conflict.txt** files in the storage device. The two files save address lease information and address conflict information respectively. Run the **display dhcp server database** command to check the storage device for saving DHCP data. After the **dhcp server database enable** command is run, current DHCP data is automatically saved at the specified interval, and previous data files are overwritten. The interval can be set using the **dhcp server database write-delay** *interval* command.

If a fault occurs on the device, run the **dhcp server database recover** command to recover DHCP data from storage devices during the system restarts.

Prerequisites

The **dhcp server database enable** command has been run to enable the device to save DHCP data to storage devices, and ensure that the storage devices work properly.

Precautions

- The lease.txt and conflict.txt files are overwritten periodically; therefore, you are advised to back up and save the two files to other locations.
- The time displayed in the lease.txt and conflict.txt files is the UTC time rather than the system time, and you do not need to pay attention to time zone information.
- During the interval, if the device restarts unexpectedly, DHCP data generated at the interval is lost. Users can only recover the last successfully saved DHCP data from storage device files.

Example

Enable the device to save the current DHCP data to storage devices and set the interval at which DHCP data is saved to 2000s.

```
<HUAWEI> system-view
[HUAWEI] dhcp server database enable
[HUAWEI] dhcp server database write-delay 2000
```

Recover DHCP configuration using the DHCP data saved on storage devices.

```
<HUAWEI> system-view
[HUAWEI] dhcp server database recover
```

6.3.42 dhcp server dns-list

Function

The **dhcp server dns-list** command configures DNS server addresses for an interface address pool.

The **undo dhcp server dns-list** command deletes the specified DNS server addresses from an interface address pool.

By default, no DNS server address is configured in an interface address pool.

Format

dhcp server dns-list { *ip-address* &<1-8> | **unnumbered interface** *interface-type interface-number* }

undo dhcp server dns-list { **all** | *ip-address* | **unnumbered interface** }

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of the DNS server. You can configure up to eight IP addresses for the DNS servers and separate two IP addresses with a space.	The value is in dotted decimal notation.
unnumbered interface *interface-type interface-number*	Borrows the DNS server address obtained by the interface as the DNS server IP address.	-
all	Deletes all IP addresses of DNS servers specified for the client.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. If user hosts access hosts on the network through the domain name, user hosts need to send DNS Request messages to the DNS server and resolve the domain name. To enable DNS services on the DHCP client, specify the DNS server address for the interface address pool on the DHCP server. The DHCP server can assign both the specified DNS server address and an IP address to the client. To configure DNS server addresses for a global address pool, run the **dns-list** command.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- Each address pool can be configured with a maximum of eight DNS server addresses. If multiple DNS server addresses are configured, the first DNS server address assigned to the DHCP client functions as the primary address and other addresses are secondary addresses.
- To specify multiple DNS servers, enter multiple DNS server addresses in the **dhcp server dns-list** command.

Example

Specify a DNS server at 10.10.1.254 for domain name resolution when IP addresses in the interface address pool on VLANIF100 are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server dns-list 10.10.1.254
```

Specify a DNS server at 192.168.1.254 for domain name resolution when IP addresses in the interface address pool on GE0/0/1 are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server dns-list 192.168.1.254
```

6.3.43 dhcp server domain-name (interface view)

Function

The **dhcp server domain-name** command configures a DNS domain name assigned to a DHCP client.

The **undo dhcp server domain-name** command deletes a specified domain name.

By default, no domain name is configured for the DHCP client.

Format

dhcp server domain-name *domain-name*

undo dhcp server domain-name

Parameters

Parameter	Description	Value
domain-name	Specifies the domain name that the DHCP server assigns to the client.	The value is a string of 1 to 63 characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. Run the **dhcp server domain-name** command on a DHCP server to specify a domain name for each interface address pool. When allocating IP addresses to clients, the DHCP server also sends the domain names to the clients.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

If no domain name is specified for an interface address pool, a DHCP server does not send a domain name to clients, and users cannot access the Web service by using a domain name.

To configure a domain name for the global address pool, run the **domain-name** command.

Example

Set the domain name assigned by the DHCP address pool on the interface to **example.com**.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server domain-name example.com
```

Specify the domain name in the address pool on GE0/0/1 as **example.com**.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server domain-name example.com
```

6.3.44 dhcp server excluded-ip-address

Function

The **dhcp server excluded-ip-address** command specifies the range of IP addresses that cannot be automatically assigned to clients from an interface address pool.

The **undo dhcp server excluded-ip-address** command deletes the specified range of IP addresses that cannot be automatically assigned to clients from an interface address pool.

By default, all IP addresses in an address pool can be automatically assigned to clients.

Format

dhcp server excluded-ip-address *start-ip-address* [*end-ip-address*]

undo dhcp server excluded-ip-address *start-ip-address* [*end-ip-address*]

Parameters

Parameter	Description	Value
start-ip-address	Specifies the start IP address of the IP address segment where addresses cannot be automatically assigned to clients.	The value is in dotted decimal notation.

Parameter	Description	Value
end-ip-address	Specifies the end IP address of the IP address segment where addresses cannot be automatically assigned to clients. If *end-ip-address* is not specified, only the IP address corresponding to *start-ip-address* cannot be automatically assigned.	The value is in dotted decimal notation. *end-ip-address* and *start-ip-address* must be on the same network segment and *end-ip-address* must be larger than *start-ip-address*.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp server excluded-ip-address** command applies to DHCP servers. Fixed IP addresses are allocated to some specific hosts (such as the WWW server) on the network for a long time. If these hosts' IP addresses are overlapped with IP addresses in the address pool and the DHCP server allocates these overlapped IP addresses to other hosts, IP address conflicts may occur. To prevent such IP address conflicts, you need to exclude these IP addresses from being automatically assigned in the address pool.

You can run the **dhcp server excluded-ip-address** command to specify the IP addresses or the range of IP addresses that cannot be automatically assigned to clients in the interface address pool.

You can run the **excluded-ip-address** command to specify the IP addresses or the range of IP addresses that cannot be automatically assigned to clients in the global address pool.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.

3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- IP addresses that cannot be automatically assigned must be in the address pool. If IP address range in the address pool is changed using the **dhcp server ip-range** command, IP addresses that are configured not to be automatically assigned must be within the new IP address range.
- You do not need to exclude the gateway address configured using the **dhcp server gateway-list** command from being automatically allocated. The device automatically adds the gateway address into the list of IP addresses that cannot be automatically allocated.

  You do not need to exclude the IP address of a server's interface connecting to a client from being automatically allocated. The device automatically sets the status of the interface IP address to Conflict during address assignment.
- If you run this command multiple times, you can specify multiple IP addresses or ranges of IP addresses that cannot be automatically assigned to clients from the specified address pool.
- You can run the **display ip pool** command to check the IP addresses in use in the current address pool, so that you can exclude the unused IP addresses from being automatically assigned to clients. If you need to exclude IP addresses in Used and Conflict states from being automatically assigned to clients after address reclamation, you can also run the **excluded-ip-address** command. If an IP address has been bound to a specific MAC address, adding the IP address to the IP address list in which IP addresses are not automatically assigned to clients will unbind the IP address from the MAC address.

Example

Disable IP addresses 192.168.1.1 to 192.168.1.20 from being automatically assigned to clients from the address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server excluded-ip-address 192.168.1.1 192.168.1.20
```

Disable IP address 192.168.1.30 in Used state from being automatically assigned to clients from the address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server excluded-ip-address 192.168.1.30
Warning: The address is in used or conflict state. Are you sure to continue excluding the address?[Y/N]:y
```

Disable IP addresses 10.10.10.11 to 10.10.10.20 from being automatically assigned to clients from the address pool on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
```

```
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server excluded-ip-address 10.10.10.11 10.10.10.20
```

6.3.45 dhcp server force insert option

Function

The **dhcp server force insert option** command configures a DHCP server to forcibly insert an Option field specified in the interface address pool to a DHCP Response packet that it sends to a DHCP client.

The **undo dhcp server force insert option** command deletes the Option field forcibly inserted to a DHCP Response packet that a DHCP server sends to a DHCP client.

By default, a DHCP server does not forcibly insert an Option field to a DHCP Response packet that it sends to a DHCP client.

Format

dhcp server force insert option *code* &<1-254>

undo dhcp server force insert option *code* &<1-254>

Parameters

Parameter	Description	Value
code	Specifies the code for a forcibly replied option. You can configure a DHCP server to forcibly reply one or more options.	The value is an integer that ranges from 1 to 254.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In general, when a DHCP client applies for an IP address from a DHCP server, parameters contained in the DHCP Request packet specify the options the client requires. The DHCP server inserts the required options to a DHCP Response packet.

Sometimes, a device, functioning as a DHCP server, receives a DHCP Request packet that contains no parameter specifying the options the client requires. However, the client still wants to obtain the options configured on the interface address pool. You can run the **dhcp server force insert option** *code* &<1-254> command to configure the DHCP server to forcibly insert an Option field to the DHCP Response packet.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.
4. The Option field has been configured in the interface address pool using the **dhcp server option** *code* [**sub-option** *sub-code*] { **ascii** *ascii-string* | **hex** *hex-string* | **cipher** *cipher-string* | **ip-address** *ip-address* &<1-8> } command in the interface view.

Example

Configure a DHCP server to forcibly insert Option 4 to a DHCP Response packet on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server option 4 hex 11 22
[HUAWEI-Vlanif100] dhcp server force insert option 4
```

Configure a DHCP server to forcibly insert Option 4 to a DHCP Response packet on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server option 4 hex 11 22
[HUAWEI-GigabitEthernet0/0/1] dhcp server force insert option 4
```

6.3.46 dhcp server force response

Function

The **dhcp server force response** command forces a DHCP server to reply with a DHCP NAK message.

The **undo dhcp server force response** command disables the function of forcing a DHCP server to reply with a DHCP NAK message.

By default, a DHCP server is not forced to reply with a DHCP NAK message.

Format

dhcp server force response

undo dhcp server force response

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Scenario

When a DHCP client goes online in two steps, the IP address requested by the DHCP client is in the IP address pool, but no lease record of the DHCP client is found in the address pool. For example, after obtaining an IP address from another DHCP server, a wireless user roams to the current DHCP server and the original IP address is in the address pool of the current DHCP server. Alternatively, the address pool is reset and the original user needs to go online again. In this case, when receiving a DHCP Request message from the DHCP client, the DHCP server keeps silent and does not reply the DHCP client with a DHCP NAK message. The DHCP client can apply for an IP address to go online again in four steps only after the two steps for the client to go online time out. As a result, the DHCP client is slow in obtaining an IP address. To force the DHCP server to reply with a DHCP NAK message, you can run the **dhcp server force response** command, so that the DHCP client can quickly enter the four-step process for going online and apply for an IP address again.

Prerequisites

DHCP has been enabled on the device using the **dhcp enable** command.

Example

Force a DHCP server to reply with a DHCP NAK message.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server force response
```

6.3.47 dhcp server gateway-list

Function

The **dhcp server gateway-list** command sets the default gateway IP address that a DHCP server pre-allocates to DHCP clients.

The **undo dhcp server gateway-list** command deletes the configured default gateway IP address.

By default, the default gateway IP address that a DHCP server pre-allocates to DHCP clients is not configured.

Format

dhcp server gateway-list *ip-address* &<1-8>

undo dhcp server gateway-list { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies an IP address. You can configure a maximum of eight gateway addresses, which are separated by spaces.	The value is in decimal dotted notation.
all	Indicates all IP addresses.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To load balance traffic and improve network reliability, you can configure multiple default gateway addresses.

NOTICE

The default gateway address allocated to the DHCP client can only be a class A, B, or C address, and cannot be a broadcast address, a host address, or a class A address whose network address is 0.

If the VRRP virtual IP address is configured on the interface and no gateway address is pre-allocated to the DHCP client using the **dhcp server gateway-list** command, the DHCP server uses the first VRRP virtual IP address as the gateway address to be allocated to the client. If no VRRP virtual IP address is configured on the interface, the DHCP server uses the physical IP address of the interface as the gateway address to be allocated to the client.

If the **dhcp server gateway-list** command is not configured, the gateway address allocated by the DHCP server to the DHCP client may fail to be displayed in trace information during fault diagnosis. Therefore, you are advised to configure this command if the DHCP server function based on an interface address pool is used.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Enable a DHCP server on a VLANIF100 to pre-allocate default gateway address 10.1.1.1 to DHCP clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server gateway-list 10.1.1.1
```

Enable a DHCP server on GE0/0/1 to pre-allocate default gateway address 10.1.1.1 to DHCP clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server gateway-list 10.1.1.1
```

6.3.48 dhcp server group

Function

The **dhcp server group** command creates a DHCP server group and displays the DHCP server group view or directly displays the view of the existing DHCP server group.

The **undo dhcp server group** command deletes an existing DHCP server group.

By default, no DHCP server group is configured.

Format

dhcp server group *group-name*

undo dhcp server group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a DHCP server group.	The value is a string of 1 to 32 case-sensitive characters without spaces. It can contain digits, letters, and special characters such as underscores (_), hyphens (-), and periods (.). It cannot be set to **-** or **--**.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. Generally, a DHCP relay agent serves multiple DHCP servers. To manage these DHCP servers in a unified manner, run the **dhcp server group** command to create a DHCP server group. The DHCP server group then assigns IP addresses to users using the DHCP relay agent.

Follow-up Procedure

- Run the **dhcp-server** command to add DHCP servers to the DHCP server group.
- Run the **dhcp relay server-select** command in the interface view to specify a DHCP server group for the DHCP relay agent.

Precautions

You can configure a maximum of 32 DHCP server groups in the system, and a maximum of 20 DHCP servers in a DHCP server group.

Example

Create a DHCP server group named **dhcp-srv1**.

```
<HUAWEI> system-view
[HUAWEI] dhcp server group dhcp-srv1
```

6.3.49 dhcp server ip-range

Function

The **dhcp server ip-range** command sets the range of IP addresses that a DHCP server pre-allocates to DHCP clients.

The **undo dhcp server ip-range** command deletes the configured IP address range.

By default, the range of IP addresses that a DHCP server pre-allocates to DHCP clients is not configured.

Format

dhcp server ip-range *start-ip-address end-ip-address*

undo dhcp server ip-range

Parameters

Parameter	Description	Value
start-ip-address	Specifies the start IP address.	The value is in decimal dotted notation.
end-ip-address	Specifies the end IP address.	The value is in decimal dotted notation.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **dhcp server ip-range** *start-ip-address end-ip-address* command to change the range of IP addresses in an address pool based on actual usage of IP addresses.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Enable a DHCP server on a VLANIF100 to pre-allocate IP addresses 192.168.1.2 to 192.168.1.100 to DHCP clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server ip-range 192.168.1.2 192.168.1.100
```

Enable a DHCP server on GE0/0/1 to pre-allocate IP addresses 192.168.1.2 to 192.168.1.100 to DHCP clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server ip-range 192.168.1.2 192.168.1.100
```

6.3.50 dhcp server lease

Function

The **dhcp server lease** command specifies the IP address lease for addresses in an interface address pool.

The **undo dhcp server lease** command restores the default IP address lease of addresses in an interface address pool.

By default, the IP address lease of addresses in an interface address pool is one day.

Format

dhcp server lease { **day** *day* [**hour** *hour* [**minute** *minute*]] | **unlimited** }

undo dhcp server lease

Parameters

Parameter	Description	Value
day *day*	Specifies the number of days in the IP address lease.	The value is an integer that ranges from 0 to 999. The default value is 1.

Parameter	Description	Value
hour *hour*	Specifies the number of hours in the IP address lease.	The value is an integer that ranges from 0 to 23. The default value is 0.
minute *minute*	Specifies the number of minutes in the IP address lease.	The value is an integer that ranges from 0 to 59. The default value is 0.
unlimited	Indicates that the IP address lease is unlimited.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. To meet different client requirements, DHCP supports dynamic, automatic, and static address assignment.

DHCP clients require different IP address leases.

- If a host (such as the DNS server) needs to use a fixed IP address for a long time, run the **dhcp server lease unlimited** command to configure the IP address lease as unlimited.
- If a host (such as a portable computer) needs to use a temporary IP address, run the **dhcp server lease** command to specify an IP address lease. After the lease expires, the DHCP server withdraws the IP address and assigns the address to other clients. In scenarios with high user mobility, new clients may fail to obtain IP addresses if allocated addresses are not reclaimed for a long time. As such, shortening the DHCP lease is recommended. For example, in Wi-Fi access scenarios of an airport or station, you can change the DHCP lease to 30 minutes.

When a DHCP client starts and 50% or 87.5% of its IP address lease has passed, the DHCP client sends a DHCP Request message to the DHCP server to renew the lease.

- If the IP address can still be assigned to the client, the DHCP server informs the client of a renewed IP address lease.

- If the IP address can no longer be assigned to the client, the DHCP server informs the client that the IP address lease cannot be renewed.

You can run the **display ip pool** command to view information about the IP address lease. The values of the **lease** and **left** fields in the command output indicate the configured lease time and remaining lease time, respectively.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

Different IP address leases can be specified for different interface address pools on a DHCP server. All IP addresses in an interface address pool have the same lease.

If the IP address lease of an address pool is changed using this command, newly assigned IP addresses use the new IP address lease. IP addresses assigned before the change still use the original IP address lease before the lease is updated, and use the new lease after the lease is updated.

Example

Set the IP address lease of the address pool on VLANIF100 to 2 days 2 hours and 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server lease day 2 hour 2 minute 30
```

Set the IP address lease of the address pool on GE0/0/1 to 2 days 2 hours and 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server lease day 2 hour 2 minute 30
```

6.3.51 dhcp server logging

Function

The **dhcp server logging** command enables the logging function during IP address allocation of the DHCP server in the interface view.

The **undo dhcp server logging** command disables the logging function during IP address allocation of the DHCP server in the interface view.

By default, the logging function during IP address allocation of the DHCP server is disabled.

Format

dhcp server logging [**allocation-fail** | **allocation-success** | **release** | **renew-fail** | **renew-success** | **detect-conflict** | **recycle-conflict**] *

undo dhcp server logging [**allocation-fail** | **allocation-success** | **release** | **renew-fail** | **renew-success** | **detect-conflict** | **recycle-conflict**] *

Parameters

Parameter	Description	Value
allocation-fail	Displays logs when address allocation fails.	-
allocation-success	Displays logs when address allocation succeeds.	-
release	Displays logs when addresses are released.	-
renew-fail	Displays logs when address lease renewal fails.	-
renew-success	Displays logs when address lease renewal succeeds.	-
detect-conflict	Displays logs when address conflict occurs.	-
recycle-conflict	Displays logs when conflicting addresses are reclaimed.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on a DHCP server. When the DHCP server allocates IP addresses to clients, it records address allocation information to facilitate routine maintenance and fault location. After the logging function during IP address allocation of the DHCP server is configured using the **dhcp server logging** command, the DHCP server records logs about address allocation, conflict, lease renewal, and release.

Run the **display ip pool interface** *interface-pool-name* command to check the status of the logging function during IP allocation of the DHCP server.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- With this logging function enabled, if a large number of DHCP clients request IP addresses from the DHCP server, the server frequently records logs. The server performance may therefore be affected.
- IP address allocation logs are recorded in the AM module. To view log information, the information center must be enabled. In addition, default settings for log output vary depending on various factors including the log level and output direction. For details, see Information Center Configuration in the *CLI-based Configuration - Device Management Configuration Guide*.

  For example, the level of logs indicating that an IP address is successfully allocated, an IP address is successfully renewed, and an IP address is successfully released is informational, and these logs are not recorded in the log buffer by default. You can run the **info-center source AM channel 4 log level informational** command to change the level of the logs to be recorded in the log buffer. You can then run the **display logbuffer** command to check the preceding logs.

Example

Enable the logging function during IP address allocation of the DHCP server on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 192.168.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server logging
```

Enable the logging function during IP address allocation of the DHCP server on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 192.168.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server logging
```

6.3.52 dhcp server mask

Function

The **dhcp server mask** command sets the subnet mask of IP addresses that a DHCP server pre-allocates to DHCP clients.

The **undo dhcp server mask** command deletes the configured subnet mask.

By default, the subnet mask of IP addresses that a DHCP server pre-allocates to DHCP clients is not configured.

Format

dhcp server mask { *mask* | *mask-length* }

undo dhcp server mask

Parameters

Parameter	Description	Value
mask	Specifies a subnet mask.	The value is in decimal dotted notation.
mask-length	Specifies the length of the subnet.	The value is an integer ranging from 0 to 32.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After enabling the DHCP server function on an interface, you can configure the range and subnet mask of IP addresses that a DHCP server pre-allocates to DHCP clients. Run the **dhcp server ip-range** command to configure the IP address range and run the **dhcp server mask** command to configure the subnet mask of the IP addresses.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Set the subnet mask of IP addresses that a DHCP server on a VLANIF100 pre-allocates to DHCP clients to 255.255.255.0.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server mask 255.255.255.0
```

Set the subnet mask of IP addresses that a DHCP server on GE0/0/1 pre-allocates to DHCP clients to 255.255.255.0.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server mask 255.255.255.0
```

6.3.53 dhcp server nbns-list

Function

The **dhcp server nbns-list** command configures Network Basic Input Output System (NetBIOS) server addresses for an interface address pool.

The **undo dhcp server nbns-list** command deletes the NetBIOS server address from an interface address pool.

By default, no NetBIOS server address is configured for an interface address pool.

Format

dhcp server nbns-list *ip-address* &<1-8>

undo dhcp server nbns-list { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the NetBIOS server address.	The value is in dotted decimal notation.
all	Deletes all NetBIOS server addresses.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. Before hosts communicate with each other, a NetBIOS server needs to resolve the accessed NetBIOS hostname to an IP address. To enable hosts to communicate with each other, run the **dhcp server nbns-list** command to configure NetBIOS server addresses for an interface address pool. When assigning IP addresses to clients, a DHCP server also assigns the configured NetBIOS server addresses to clients. To configure NetBIOS server addresses for a global address pool, run the **nbns-list** command.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

Each interface can be configured with a maximum of eight NetBIOS server addresses. The first assigned address functions as the primary address, and other addresses function as secondary addresses.

Example

Specify a NetBIOS server at 192.168.1.99 for domain name resolution when IP addresses in the interface address pool on VLANIF100 are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server nbns-list 192.168.1.99
```

Specify a NetBIOS server at 192.168.1.99 for domain name resolution when IP addresses in the interface address pool on GE0/0/1 are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
```

```
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server nbns-list 192.168.1.99
```

6.3.54 dhcp server netbios-type

Function

The **dhcp server netbios-type** command specifies the NetBIOS node type for a DHCP client connecting to an interface.

The **undo dhcp server netbios-type** command deletes the specified NetBIOS node type of a DHCP client connecting to an interface.

By default, no NetBIOS node type is specified for a DHCP client connecting to an interface.

Format

dhcp server netbios-type { **b-node** | **h-node** | **m-node** | **p-node** }

undo dhcp server netbios-type

Parameters

Parameter	Description	Value
b-node	Indicates a node in broadcast mode. A b-node obtains the mapping in broadcast mode.	-
h-node	Indicates a node in hybrid mode. An h-node is a b-type node enabled with the end-to-end communication mechanism.	-
m-node	Indicates a node in mixed mode. An m-node is a p-type node with some broadcast features.	-
p-node	Indicates a node in peer-to-peer mode. This node obtains mappings by communicating with the NetBIOS server.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. When DHCP clients use NetBIOS on the WAN to communicate, their host names and IP addresses need to be mapped. You can run the **dhcp server netbios-type** command to configure the NetBIOS node type for an interface address pool. When assigning an IP address to the client, the DHCP server also sends the specified NetBIOS node type to the client.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

To specify the NetBIOS node type for a client in the global address pool, run the **netbios-type** command.

Example

Set the NetBIOS node type for a client in the address pool on VLANIF100 to **p-node**.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server netbios-type p-node
```

Set the NetBIOS node type for a client in the address pool on GE0/0/1 to **p-node**.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server netbios-type p-node
```

6.3.55 dhcp server next-server

Function

The **dhcp server next-server** command specifies a server IP address for DHCP clients.

The **undo dhcp server next-server** command cancels the configuration.

By default, no server IP address is specified by the DHCP Server for DHCP clients.

Format

dhcp server next-server *ip-address*

undo dhcp server next-server

Parameters

Parameter	Description	Value
ip-address	Specifies a server IP address.	The value is in dotted decimal notation.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp server next-server** command is used on DHCP servers. When assigning a DHCP client an IP address, a DHCP server can also assign the DHCP client an IP address of the server that provides network services for the client. For example, some clients like IP phones still need other configuration parameters after automatically obtaining IP addresses. You can run the **dhcp server next-server** command to specify the server address used after a client obtains an IP address. The client then requests the configuration parameters from the specified server after obtaining an IP address.

If users use addresses in the interface address pool, run the **dhcp server next-server** command to specify the DHCP server IP address. If users use addresses in the global address pool, run the **next-server** command to specify the DHCP server IP address.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- The **dhcp server next-server** command takes effect for only users who use addresses in the interface address pool.
- If you run the **dhcp server next-server** command multiple times, only the latest configuration takes effect.

Example

Specify the server IP address 192.168.1.2 in the interface address pool on VLANIF100 used to provide services for terminal users.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.2 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server next-server 192.168.1.2
```

Specify the server IP address 192.168.1.2 in the interface address pool on GE0/0/1 used to provide services for terminal users.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.2 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server next-server 192.168.1.2
```

6.3.56 dhcp server option

Function

The **dhcp server option** command sets user-defined option for an interface address pool.

The **undo dhcp server option** command deletes user-defined option from an interface address pool.

By default, no user-defined option is configured in an interface address pool.

Format

dhcp server option *code* [**sub-option** *sub-code*] { **ascii** *ascii-string* | **hex** *hex-string* | **cipher** *cipher-string* | **ip-address** *ip-address* &<1-8> }

undo dhcp server option [*code* [**sub-option** *sub-code*]]

Parameters

Parameter	Description	Value
code	Specifies the code for a user-defined option.	The value is an integer that ranges from 1 to 254, except values 1, 3, 6, 15, 44, 46, 50, 51, 52, 53, 54, 55, 57, 58, 59, 61, 82, 120, 121 and 184. **NOTE** ● The format of option82, Option121 and Option184 are different from the other codes of a customized option. ● There are well-known options and customized options. For details about well-known options, see RFC 2132. ● When the switch functions as a DHCP client, Option 148 can be used in an EasyDeploy scenario and is not recommended in other scenarios.
sub-option *sub-code*	Specifies the code of a user-defined sub-option.	The value is an integer that ranges from 1 to 254. For details about well-known options, see RFC 2132.
ascii *ascii-string*	Specifies the user-defined option code as an ASCII character string.	The value is a string of 1 to 255 characters when **sub-option** is not specified, or a string of 1 to 253 characters when **sub-option** is specified.

Parameter	Description	Value
hex *hex-string*	Specifies the user-defined option code as a hexadecimal string.	The value is a hexadecimal string with an even number of digits, for example, hh or hhhh. If **sub-option** is not specified, the even number is in the range of 2 to 254. If **sub-option** is specified, the even number is in the range of 2 to 252. The value can be a combination of digits (0-9) and letters (A-F and a-f).
cipher *cipher-string*	Specifies the user-defined option code as a ciphertext character string.	The value is a string, you can enter a character string in explicit text or cipher text. ● The character string in explicit text is a string of 1 to 64 characters. ● The character string in cipher text is a string of 32 to 104 characters. No matter whether the character string is entered in explicit or cipher text, the character string is displayed in cipher text in the configuration file and in explicit text in packets.
ip-address *ip-address*	Specifies the user-defined option code as an IP address.	The value is in dotted decimal notation.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. The Option field in a DHCP packet carries control information and parameters, including basic information such as the DNS service, NetBIOS service, and IP address lease. If a DHCP server is configured with option, when a DHCP client applies for an IP address from an interface address pool, the client can obtain configurations in the Option field of the DHCP response packet from the DHCP server without having to configure the DNS service, NetBIOS service, or IP address lease separately.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- When the password is contained in option, the **ascii** or **hex** type is insecure. Set the option type to **cipher**. A secure password should contain at least two types of the following: lowercase letters, uppercase letters, number, and special characters. In addition, the password must consist of six or more than eight characters.
- The **dhcp server option** command configures basic functions, such as the NetBIOS service and IP address lease. The system also provides commands to configure these functions separately. These commands take precedence over the **dhcp server option** command.
- To set user-defined option for a global address pool, run the **option** command.
- When users on an enterprise's intranet use a proxy server to connect to the Internet, you need to configure proxy server parameters so that users can use browsers to access the network. The Web Proxy Auto-Discovery Protocol (WPAD) implements automatic configuration of these parameters. The administrator does not need to manually configure these parameters on each client. To implement the WPAD function, the administrator needs to deploy the configuration file of the proxy server in advance, and then run the **dhcp server option 252 ascii** *ascii-string* command to specify the URL of the configuration file. The *ascii-string* parameter specifies the URL of the configuration file, in the format of https://*xxx*/proxy.pac. Set *ascii-string* according to the actual location of the configuration file. When a browser accesses the network, the browser requests the DHCP server to send the URL of the configuration file on the proxy server, and then downloads the configuration file to conduct automatic configuration. After the configuration is completed, the browser can access the network.

NOTE

The value of *ascii-string* cannot be enclosed in double quotation marks as "*ascii-string*". Otherwise, terminals cannot parse Option252.

Example

Set Option64 to 0x11 (a hexadecimal number) for the interface address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server option 64 hex 11
```

Set Option64 to 0x11 (a hexadecimal number) for the interface address pool on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server option 64 hex 11
```

6.3.57 dhcp server option121

Function

The **dhcp server option121** command configures a classless static route allocated by a DHCP server to a client.

The **undo dhcp server option121** command deletes a classless static route allocated by a DHCP server to a client.

By default, the classless static route allocated to a client is not configured.

Format

dhcp server option121 ip-address { *ip-address mask-length gateway-address* } &<1-8>

undo dhcp server option121 [**ip-address** *ip-address mask-length gateway-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the destination IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
gateway-address	Specifies the gateway address of a route.	The value is in dotted decimal notation.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp server option121 ip-address** command applies to only the DHCP server. The **dhcp server option121 ip-address** command configures Option 121 that defines a classless static route allocated to a client from an interface address pool.

mask-length and *gateway-address* specify a classless static route. The **dhcp server option121 ip-address** command configures a maximum of eight classless static routes.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.
4. The **undo dhcp server option121** command will delete all classless static routes. To delete one classless static route, run the **undo dhcp server option121 ip-address** *ip-address mask-length gateway-address* command.

Example

Configure a classless static route allocated by a DHCP server to a client in the interface address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.2 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server option121 ip-address 10.10.10.10 24 192.168.11.11
```

Configure a classless static route allocated by a DHCP server to a client in the interface address pool on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.2 24
```

```
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server option121 ip-address 10.10.10.10 24 192.168.11.11
```

6.3.58 dhcp server option125 vendor-specific

Function

The **dhcp server option125 vendor-specific** command configures the vendor ID in Option 125 delivered by a DHCP server to a client.

The **undo dhcp server option125 vendor-specific** command deletes the vendor ID in Option 125 delivered by a DHCP server to a client.

By default, no vendor ID is configured in Option 125 delivered by a DHCP server to a client.

Format

dhcp server option125 vendor-specific *vendor-id*

undo dhcp server option125 vendor-specific

Parameters

Parameter	Description	Value
vendor-id	Indicates the vendor ID, which is assigned by the IANA. 2011 indicates Huawei.	The value is an integer in the range from 1 to 4294967295.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a DHCP client sends a DHCP Discover message carrying a vendor ID to a DHCP server, the DHCP server needs to exchange the vendor information with the client using Option 125. You can run the **dhcp server option 125** [**sub-option** *sub-code*] **ascii** *ascii-string* command to configure the vendor ID in Option 125 delivered by a DHCP server to a client. However, it is complex to convert the vendor ID into an ASCII character string.

To simplify the configuration, you can run the **dhcp server option125 vendor-specific** *vendor-id* command to specify the vendor ID in Option 125 of packets sent from a DHCP server to a client.

Prerequisites

1. IP addresses have been configured in an interface address pool using the **ip address** command.
2. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.
3. Fields except **Vendor-ID** in Option 125 have been configured for the interface address pool using the **dhcp server option 125 ascii** *ascii-string* command. The **Vendor-ID** field in Option 125 occupies four bytes. Therefore, the *ascii-string* value is a string of 1 to 251 bytes.
4. (Optional) The **dhcp server force insert option 125** command has been used to configure the DHCP server to insert the Option 125 field specified for the interface address pool into the DHCP response packet sent from a DHCP server to a client. This resolves the problem in the following situation: The device functions as a DHCP server, and the DHCP request packet sent by a DHCP client does not carry Option 125. However, the DHCP client still expects the DHCP server to deliver Option 125 configured for the interface address pool.

Precautions

This command and the **dhcp server option 125 sub-option** *sub-code* **ascii** *ascii-string* are mutually exclusive on an interface.

Example

Configure the VLAN and vendor information in Option 125 for the interface address pool on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.2 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server option 125 ascii id:vlan=100
[HUAWEI-Vlanif100] dhcp server option125 vendor-specific 2011
```

Configure the VLAN and vendor information in Option 125 for the interface address pool on GE 0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.2 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server option 125 ascii id:vlan=10
[HUAWEI-GigabitEthernet0/0/1] dhcp server option125 vendor-specific 2011
```

6.3.59 dhcp server option184

Function

The **dhcp server option184** command configures Option 184 allocated by a DHCP server to a client.

The **undo dhcp server option184** command deletes Option 184 allocated by a DHCP server to a client.

By default, Option 184 allocated by a DHCP server to a client is not configured.

Format

dhcp server option184 { **as-ip** *ip-address* | **fail-over** *ip-address dialer-string* | **ncp-ip** *ip-address* | **voice-vlan** *vlan-id* }

undo dhcp server option184 [**as-ip** | **fail-over** | **ncp-ip** | **voice-vlan**]

Parameters

Parameter	Description	Value
ncp-ip *ip-address*	Specifies the IP address of the network call processor (NCP).	The value is in dotted decimal notation.
as-ip *ip-address*	Specifies the IP address of the backup NCP.	The value is in dotted decimal notation.
fail-over *ip-address*	Specifies the IP address in the failover route.	The value is in dotted decimal notation.
dialer-string	Specifies the dialer string.	The value is a string of 1 to 64 characters.
voice-vlan *vlan-id*	Specifies the ID of a voice VLAN.	The value is an integer that ranges from 1 to 4094.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp server option184** command applies to only the DHCP server and configures Option 184 allocated by a DHCP server to a client in an interface address pool.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Example

Configure Option 184 allocated by a DHCP server to a client in the interface address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.2 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server option184 as-ip 10.10.10.10
```

Configure Option 184 allocated by a DHCP server to a client in the interface address pool on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.2 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server option184 as-ip 10.10.10.10
```

6.3.60 dhcp server ping

Function

The **dhcp server ping** command sets the maximum number of ping packets to be sent and the maximum response time of a ping packet.

The **undo dhcp server ping** command restores the default setting.

By default, the DHCP server sends 2 ping packets and the maximum response time is 500 ms.

Format

dhcp server ping { **packet** *number* | **timeout** *milliseconds* } *

undo dhcp server ping { **packet** | **timeout** }

Parameters

Parameter	Description	Value
packet *number*	Specifies the maximum number of ping packets to be sent.	The value is an integer ranging from 0 to 10. The value 0 indicates that no ping operation is performed.

Parameter	Description	Value
timeout *milliseconds*	Specifies the maximum response time of a ping packet.	The value is an integer that ranges from 0 to 10000, in milliseconds. The value 0 indicates that no ping operation is performed.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. Repetitive IP address assignment will cause IP address conflicts. To solve this problem, before assigning an IP address to a client, the DHCP server needs to send ping packets using the **dhcp server ping** command to check whether the IP address is in use. Address detection checks whether the DHCP server receives any response within a certain period of time. If there is no response within a certain period of time, the DHCP server continues to send ping packets to this address until the number of ping packets reaches the maximum value. If there is still no response, it indicates that the IP address is not in use. This ensures that the IP address assigned to the client is unique.

Prerequisites

DHCP has been enabled using the **dhcp enable** command.

Example

Set the maximum number of ping packets to 3 and the maximum response time to 400 ms.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server ping packet 3
[HUAWEI] dhcp server ping timeout 400
```

6.3.61 dhcp server sip-server

Function

The **dhcp server sip-server** command configures the SIP server IP address assigned to a DHCP client on an interface address pool.

The **undo dhcp server sip-server** command deletes the configured SIP server IP address assigned to a DHCP client on an interface address pool.

By default, the SIP server IP address assigned to a DHCP client on an interface address pool is not configured.

Format

dhcp server sip-server { **ip-address** *ip-address* &<1-2> | **list** *domain-name* &<1-2> }

undo dhcp server sip-server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies an IP address for the SIP server.	The value is in dotted decimal notation.
list *domain-name*	Specifies the domain name of the SIP server.	The value is a string of 1 to 63 characters.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to the DHCP server. To enable DHCP clients to normally access the Internet, the DHCP server needs to specify the SIP server IP address in the interface address pool when assigning IP addresses to the clients.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- A maximum of two SIP server addresses can be configured in each address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- Before specifying the IP address or name for a SIP server, ensure that the SIP server exists.
- If you run this command repeatedly, the latest configuration overrides the previous ones.

Example

Specify 10.1.1.1 as the IP address of the SIP server when addresses in the interface VLANIF100 address pool are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server sip-server ip-address 10.1.1.1
```

Specify 10.1.1.1 as the IP address of the SIP server when addresses in the interface GE0/0/1 address pool are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server sip-server ip-address 10.1.1.1
```

6.3.62 dhcp server sname

Function

The **dhcp server sname** command configures the name of the server where the DHCP client obtains the startup configuration file.

The **undo dhcp server sname** command deletes the configured name of the server where the DHCP client obtains the startup configuration file.

By default, the name of the server where the DHCP client obtains the startup configuration file is not configured.

Format

dhcp server sname *sname*

undo dhcp server sname

Parameters

Parameter	Description	Value
sname	Specifies the name of the server where the DHCP client obtains the startup configuration file.	The value is a string of 1 to 63 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Besides assigning IP addresses, a DHCP server can also provide the required network configuration parameters, such as the startup configuration file name for the DHCP clients. After the name of the server where the DHCP client obtains the startup configuration file is configured using the **dhcp server sname** command, the DHCP client obtains the startup configuration file from this server.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.
4. The startup configuration file name has been configured for the DHCP client using the **dhcp server bootfile**.

Follow-up Procedures

Ensure that the route between the DHCP client and the file server where the DHCP client obtains the startup configuration file is reachable.

Example

Configure the name of the server where the DHCP client obtains the startup configuration file as **Test** in the interface address pool on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.1.1.1 255.255.255.0
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server bootfile start.ini
[HUAWEI-Vlanif100] dhcp server sname Test
```

Configure the name of the server where the DHCP client obtains the startup configuration file as **Test** in the interface address pool on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.1.1.1 255.255.255.0
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server bootfile start.ini
[HUAWEI-GigabitEthernet0/0/1] dhcp server sname Test
```

6.3.63 dhcp server static-bind

Function

The **dhcp server static-bind** command binds an IP address in an interface address pool to a MAC address.

The **undo dhcp server static-bind** command unbinds the IP address in an interface address pool from a MAC address.

By default, an IP address in an interface address pool is not bound to any MAC address.

Format

dhcp server static-bind ip-address *ip-address* **mac-address** *mac-address* [**description** *description*]

undo dhcp server static-bind [**ip-address** *ip-address* | **mac-address** *mac-address*]

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IP address to be bound. The IP address must be valid in an interface address pool.	The value is in dotted decimal notation.

Parameter	Description	Value
mac-address *mac-address*	Specifies the user MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.
description *description*	Specifies the user description.	The value is a string of 1 to 256 case-sensitive characters. It can contain spaces.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp server static-bind** command applies to DHCP servers. When planning a network, you need to allocate fixed IP addresses to some important hosts to ensure reliability. In this case, you can bind IP addresses in the address pool to the MAC addresses of these hosts. After the preceding configuration is complete, if the host of the MAC address to which the IP address is bound request an IP address from the DHCP server, the DHCP server finds the bound IP address based on the host's MAC address and allocates this IP address to the host, ensuring that the IP address obtained by the host is fixed.

You can run the **dhcp server static-bind** command to bind an IP address in an interface address pool to a MAC address.

You can run the **static-bind** command to bind an IP address in a global address pool to a MAC address.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. IP addresses in the interface address pool have been configured using the **ip address** command.
3. The DHCP server function has been enabled on the interface using the **dhcp select interface** command.

Precautions

- Ensure that the bound IP address is not configured as the IP address that cannot be allocated using the **dhcp server excluded-ip-address** command.
- IP addresses that are used can also be statically bound to MAC addresses or unbound from MAC addresses. When an IP address is statically bound to a MAC address, ensure that the MAC address to be bound is the same as the MAC address of the user who actually uses the IP address.
- The DHCP server preferentially allocates the IP address that has been statically bound to the client's MAC address.
- After an IP address is bound to a MAC address, the IP address does not expire. After an automatically allocated IP address is statically bound to a MAC address, the lease time of the IP address becomes unlimited. After the static binding between the IP address and the MAC address is deleted, the lease time of the IP address becomes the same as that configured in the address pool.

Example

Configure a DHCP server to assign a fixed IP address 10.10.10.20 in the interface address pool on vlanif 100 to a host with the MAC address 00e0-fcf3-2a3b.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address 10.10.10.10 24
[HUAWEI-Vlanif100] dhcp select interface
[HUAWEI-Vlanif100] dhcp server static-bind ip-address 10.10.10.20 mac-address 00e0-fcf3-2a3b
```

Configure a DHCP server to assign a fixed IP address 10.10.10.20 in the interface address pool on GE0/0/1 to a host with the MAC address 00e0-fcf3-2a3b.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address 10.10.10.10 24
[HUAWEI-GigabitEthernet0/0/1] dhcp select interface
[HUAWEI-GigabitEthernet0/0/1] dhcp server static-bind ip-address 10.10.10.20 mac-address 00e0-
fcf3-2a3b
```

6.3.64 dhcp server trust option82

Function

The **dhcp server trust option82** command enables Option 82 on the DHCP server.

The **undo dhcp server trust option82** command disables Option 82 on the DHCP server.

By default, the DHCP server trusts Option 82.

Format

dhcp server trust option82

undo dhcp server trust option82

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on the DHCP server to enable the Option 82 function. After receiving a DHCP packet that carries the Option 82 field but the giaddr is 0, the DHCP server processes the packet by default. Using the **undo dhcp server trust option82** command, the DHCP server discards the packet.

Prerequisites

DHCP has been enabled globally by using the **dhcp enable** command.

Example

Enable Option 82 of the DHCP server.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp server trust option82
```

6.3.65 dhcp-server

Function

The **dhcp-server** command adds DHCP servers to a DHCP server group.

The **undo dhcp-server** command deletes DHCP servers from a DHCP server group.

By default, no DHCP server is configured in a DHCP server group.

Format

dhcp-server [**vpn-instance** *vpn-name* | **public-net**] *ip-address* [*ip-address-index*]

undo dhcp-server { [**vpn-instance** *vpn-name* | **public-net**] *ip-address* | *ip-address-index* }

Parameters

Parameter	Description	Value
vpn-instance *vpn-name*	Specifies the name of a VPN instance.	The value must be the name of an existing VPN instance.
public-net	Indicates that the public network is used to forward packets.	-
ip-address	Specifies the IP address of a DHCP server.	The value is in dotted decimal notation.
ip-address-index	Specifies an index for a DHCP server IP address. If you do not specify the server index, the system assigns an idle index to the server.	The value is an integer that ranges from 0 to 19.

Views

DHCP server group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp-server** command applies to DHCP relay agents. To ensure that the DHCP relay agent can forward messages to multiple DHCP servers, configure multiple DHCP servers in a DHCP server group.

Precautions

- Each DHCP server group can be configured with a maximum of 20 DHCP servers. You can delete a DHCP server by specifying *ip-address-index*.
- If a VPN instance is bound to an interface, the DHCP server group must be bound to this VPN instance.
- If the interface enabled with DHCP relay is bound to a VPN instance but no VPN instance is specified for a DHCP server in a DHCP server group, the DHCP relay agent sends packets through the VPN instance to which the interface belongs by default. If a VPN instance is specified for a DHCP server in a DHCP server group, the DHCP relay agent sends packets through the VPN instance specified for the DHCP server.

Example

Add the DHCP server at 10.10.78.56 to the DHCP server group **dhcp-srv1**.

```
<HUAWEI> system-view
[HUAWEI] dhcp server group dhcp-srv1
[HUAWEI-dhcp-server-group-dhcp-srv1] dhcp-server 10.10.78.56
```

6.3.66 dhcp set ttl

Function

The **dhcp set ttl** command sets the TTL value for DHCP Discover messages after they are forwarded by the DHCP relay agent at Layer 3.

The **undo dhcp set ttl** command restores the default setting.

By default, the TTL value of DHCP Discovery messages decreases by 1 after they are forwarded by the DHCP relay agent at Layer 3.

Format

dhcp set ttl { **unvaried** | *ttl-value* }

undo dhcp set ttl

Parameters

Parameter	Description	Value
unvaried	Indicates that the TTL value of DHCP Discovery messages remains unchanged after the messages are forwarded by the DHCP relay agent at Layer 3. That is, the device does not reduce the TTL value by 1.	-
ttl-value	Specifies a fixed TTL value for DHCP Discovery messages after they are forwarded by the DHCP relay agent at Layer 3.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcp set ttl** command is used on DHCP relay agents. When a DHCP relay agent forwards DHCP Discovery messages at Layer 3, it reduces the TTL value of the messages by 1 by default. Assume that the TTL value of a DHCP Discovery message received by the DHCP relay agent is 1. If the DHCP relay agent reduces the TTL value by 1, the TTL value changes to 0. The next-hop routing device will discard the message as its TTL value is 0. As a result, the DHCP server cannot receive the DHCP Discovery message forwarded by the DHCP relay agent. To ensure that the DHCP server can receive the DHCP Discovery message sent from the client, run the **dhcp set ttl** command to set the TTL value of the DHCP Discovery message to a non-zero value after the message is forwarded at Layer 3.

NOTE

If the DHCP relay agent connects to a special client whose TTL value of DHCP Discovery messages is 1, and if there are routing devices between the DHCP relay agent and DHCP server, run the **dhcp set ttl** *ttl-value* command to specify a fixed TTL value (16 is recommended) for DHCP Discovery messages after they are forwarded by the DHCP relay agent at Layer 3.

Prerequisites

The DHCP function has been enabled globally using the **dhcp enable** command.

Example

Set the TTL value of DHCP Discovery messages to 16 after the messages are forwarded by the DHCP relay agent at Layer 3.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp set ttl 16
```

6.3.67 dhcp speed-limit auto

Function

The **dhcp speed-limit auto** command enables dynamic rate limiting on DHCP packets.

The **undo dhcp speed-limit auto** command disables dynamic rate limiting on DHCP packets.

By default, dynamic rate limiting is disabled on DHCP packets.

Format

dhcp speed-limit auto

undo dhcp speed-limit auto

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure security or facilitate management, users may require that the DHCP packet processing rate should be limited. If the rate is not limited, CPU and memory resources can be used up due to malicious attacks.

Table 6-16 and **Table 6-17** list the mapping between the DHCP packet rate and CPU/memory usage after dynamic rate limiting on DHCP packets is enabled.

Table 6-16 DHCP packet rate and CPU usage

CPU Usage (%)	DHCP Packet Rate (packets/second)
(70–85)	100
[85–100)	50
100	10

Table 6-17 DHCP packet rate and memory usage

Memory Usage (%)	DHCP Packet Rate (packets/second)
(65–75)	100
[75–85)	50
[85–100)	10

Prerequisites

DHCP has been enabled globally by using the **dhcp enable** command.

Precautions

- When the CPU usage is higher than 70% or the memory usage is higher than 65%, the DHCP packet processing rate is limited.
- The DHCP packet processing rate is the same as the smaller rate among the rates corresponding to the CPU or memory usage. For example, when the CPU usage is 80% and the memory usage is 80%, the DHCP packet rate is 50.

Example

Enable dynamic rate limiting on DHCP packets.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcp speed-limit auto
```

6.3.68 dhcp udp-checksum enable

Function

The **dhcp udp-checksum enable** command enables a device to add the UDP header checksum to DHCP packets to be sent.

The **undo dhcp udp-checksum enable** command disables a device from adding the UDP header checksum to DHCP packets to be sent.

By default, the UDP header checksum carried in DHCP packets sent by a device is 0, and the peer device does not verify the checksum.

Format

dhcp udp-checksum enable

undo dhcp udp-checksum enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the peer device does not comply with protocol standards, the peer device still verifies the UDP header checksum when the checksum carried in DHCP packets is 0. In this case, you can run the **dhcp udp-checksum enable** command to enable the device to add the UDP header checksum to DHCP packets to be sent.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

A device can add the UDP header checksum to DHCP packets to be sent only if the device functions as a DHCP server.

Example

Enable a device to add the UDP header checksum to DHCP packets to be sent.

```
<HUAWEI> system-view
[HUAWEI] dhcp udp-checksum enable
```

6.3.69 display dhcp client

Function

The **display dhcp client** command displays DHCP/BOOTP client lease information.

Format

display dhcp client [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays DHCP/BOOTP client lease information on a specified interface: ● *interface-type*: specifies the interface type. ● *interface-number*: specifies the number of the interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When a device functions as a DHCP/BOOTP client, you can run this command to view DHCP/BOOTP client lease information.

Example

Display DHCP client lease information.

```
<HUAWEI> display dhcp client
DHCP client lease information on interface Vlanif119 :
 Current machine state         : Bound
 Internet address assigned via : DHCP
 Physical address              : 00e0-fccd-a896

```

```
Host name                    : client    Request option list           : 1 3 6 15 28 33 44 121 184
Class identifier             : huawei
Client identifier            : 00e0-fccd-a896
```

Table 6-18 Description of the **display dhcp client** command output

Item	Description
DHCP client lease information on interface *if1*	DHCP client lease information on the interface if1.
Current machine state	Current device status. The value can be: - **Halt**: indicates the state of stopping applying for IP addresses. - **Init**: indicates the initialization state. - **Waiting offer**: indicates the state of waiting for an OFFER message. - **Selecting**: indicates the state that the state machine enters after DHCP DISCOVER messages are sent to search for DHCP servers. In this state, the device is waiting for response messages from DHCP servers. - **Requesting**: indicates the state that the state machine enters after DHCP REQUEST messages are sent to request IP addresses. In this state, the device is waiting for response messages from DHCP servers. - **Bound**: indicates the state that the state machine enters after the device successfully obtains an IP address by receiving the DHCP ACK message from a DHCP server. - **Renewing**: indicates the state that the state machine enters after T1 timer times out. - **Rebind**: indicates the state that the state machine enters after T2 timer times out.
Internet address assigned via	Indicates that the device IP address is obtained through DHCP or BOOTP.
Physical address	Device MAC address.
IP address	Device IP address.
Subnet mask	Mask of the device IP address.

Item	Description
Gateway ip address	Gateway address of the DHCP or BOOTP server.
DHCP server	IP address of the DHCP server (no value for a BOOTP client).
Lease obtained at	Time the lease is obtained.
Lease expires at	Time the lease expires (no value for a BOOTP client).
Lease renews at	Lease renewal timer, which is 50% of the lease (no value for a BOOTP client).
Lease rebinds at	Rebinding timer, which is 87.5% of the lease (no value for a BOOTP client).
Classless static route	Classless static route.
Host name	Information in Option 12, which is the host name of the client.
Request option list	Information in Option 55, which is the parameter list requested by the client.
Class identifier	Information in Option 60, which is the vendor class identifier of the client.
Client identifier	Information in Option 61, which is the client identifier.

6.3.70 display dhcp client statistics

Function

The **display dhcp client statistics** command displays message statistics on a DHCP/BOOTP client.

Format

display dhcp client statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type* *interface-number*	Displays packet statistics on a specified interface of the DHCP/BOOTP client: - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the device functions as the DHCP client, the **display dhcp client statistics** command displays message statistics.

Example

Display message statistics on a DHCP/BOOTP client.

```
<HUAWEI> display dhcp client statistics
DHCP message statistics on interface GigabitEthernet0/0/1GigabitEthernet0/0/1 :
Input: total 0 packets
  Bootp reply            :          0
  Offer                  :          0
  Ack                    :          0
  Nak                    :          0
  Dropped untrusted reply :          0
Output: total 0 packets
  Bootp request          :          0
  Discover               :          0
  Request                :          0
    Request of init-reboot:          0
    Request of selecting  :          0
    Request of renewing   :          0
    Request of rebinding  :          0
  Decline                :          0
  Release                :          0
```

Table 6-19 Description of the **display dhcp client statistics** command output

Item	Description
Input	Total number of DHCP messages received by the client.
Bootp reply	Number of BOOTP replies received by the client from the server.
Offer	Number of Offer messages received by the client from the server.
Ack	Number of ACK messages received by the client from the server.
Nak	Number of NAK messages received by the client from the server.
Dropped untrusted reply	Number of untrusted reply messages discarded by the device.
Output	Total number of messages forwarded by the client.
Bootp request	Number of BOOTP requests received by the server from the client.
Discover	Number of Discover messages received by the server from the client.
Request	Number of Request messages received by the server from the client.
Request of init-reboot	Number of Request of init-reboot messages received by the server from the client.
Request of selecting	Number of Request of selecting messages received by the server from the client.
Request of renewing	Number of Request of renewing messages received by the server from the client.
Request of rebinding	Number of Request of rebinding messages received by the server from the client.
Decline	Number of Decline messages received by the server from the client.
Release	Number of Release messages received by the server from the client.

6.3.71 display dhcp configuration

Function

The **display dhcp configuration** command displays the configuration of a DHCP public module.

Format

display dhcp configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the configuration of a DHCP public module.

Example

Display the configuration of a DHCP public module.

```
<HUAWEI> display dhcp configuration
  DHCP global running information :
  DHCP                                      : Enable
  DHCP speed limit                          : Disable  (default)
  DHCP anti-attack check duplicate option   : Disable  (default)
  DHCP broadcast suppress                   : Disable  (default)
  DHCP anti-attack check udp-checksum       : Enable   (default)
  DHCP anti-attack check magic-cookie       : Disable  (default)
  DHCP udp-checksum                         : Disable  (default)
```

Table 6-20 Description of the **display dhcp configuration** command output

Item	Description
DHCP global running information	Global configuration of a DHCP public module.

Item	Description
DHCP	Whether DHCP is enabled. The value can be: - Enable: DHCP is enabled. - Disable (default): DHCP is disabled. By default, DHCP is disabled. To configure this parameter, run the **dhcp enable** command.
DHCP speed limit	Whether dynamic DHCP packet rate limiting is enabled. The value can be: - Enable: This function is enabled. - Disable (default): This function is disabled. By default, dynamic DHCP packet rate limiting is disabled. To configure this parameter, run the **dhcp speed-limit auto** command.
DHCP anti-attack check duplicate option	Whether the function of checking and discarding DHCP packets with duplicate options is enabled. The value can be: - Enable: This function is enabled. - Disable (default): This function is disabled. By default, the function of checking and discarding DHCP packets with duplicate options is disabled. To configure this parameter, run the **dhcp anti-attack check duplicate option** command.
DHCP broadcast suppress	Whether DHCP broadcast suppression is enabled. The value can be: - Enable: This function is enabled. - Disable (default): This function is disabled. By default, DHCP broadcast suppression is disabled. To configure this parameter, run the **dhcp broadcast suppress enable** command.

Item	Description
DHCP anti-attack check udp-checksum	Whether the function of checking the UDP header checksum in a DHCP packet and discarding a DHCP packet with an incorrect checksum is enabled. The value can be: ● Enable (default): This function is enabled. By default, a device checks the UDP header checksum in a DHCP packet and discards a DHCP packet with an incorrect checksum. ● Disable: This function is disabled. To configure this parameter, run the **dhcp anti-attack check duplicate option** command.
DHCP anti-attack check magic-cookie	Whether the function of checking the magic cookie field in a DHCP packet and discarding a DHCP packet with an incorrect magic cookie field value is enabled. The value can be: ● Enable: This function is enabled. ● Disable (default): This function is disabled. By default, a device does not check the magic cookie field in a DHCP packet but directly forwards a DHCP packet with an incorrect magic cookie field value. To configure this parameter, run the **dhcp anti-attack check magic-cookie** command.
DHCP udp-checksum	Whether a device is enabled to add the UDP header checksum to DHCP packets to be sent. The value can be: ● Enable: The device is enabled to add the UDP header checksum to DHCP packets to be sent. ● Disable (default): The device is disabled from adding the UDP header checksum to DHCP packets to be sent. By default, the UDP header checksum carried in DHCP packets sent by a device is 0, and the peer device does not verify the checksum. To configure this parameter, run the **dhcp udp-checksum enable** command.

6.3.72 display dhcp option template

Function

The **display dhcp option template** command displays the configuration of a DHCP Option template.

Format

display dhcp option template [**name** *template-name*]

Parameters

Parameter	Description	Value
name *template-name*	Displays the configuration of a specified DHCP Option template.	The template must be an existing DHCP Option template.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring a DHCP Option template, you can run the **display dhcp option template** command to view the configuration of the DHCP Option template, including the template name, number, IP address of a server configured for the client after the client automatically obtains the IP address, domain name, and values of customized options.

Example

Display the configuration of the DHCP Option template named **test**.

```
<HUAWEI> display dhcp option template name test
 -------------------------------------------------------------------------------
  Template-Name  : test
  Template-No    : 1
  Next-server    : 192.168.1.5
  Domain-name    : example.com
  DNS-server0    : 192.168.2.7
  DNS-server1    : 192.168.2.8
  NBNS-server0   : 192.168.1.7
  NBNS-server1   : 192.168.1.8
```

```
 Netbios-type   : b-node
 Gateway-0      : 192.168.1.10
```

Display the configurations of all DHCP Option templates.

```
<HUAWEI> display dhcp option template
 -------------------------------------------------------------------------------
 Template-Name  : template1
 Template-No    : 0
 Next-server    : 10.1.1.4
 Domain-name    : -
 DNS-server0    : -
 NBNS-server0   : -
 Netbios-type   : -
 Gateway-0      : -

 -------------------------------------------------------------------------------
 Template-Name  : template2
 Template-No    : 1
 Next-server    : 192.168.1.5
 Domain-name    : example.com
 Option-code      : 64
   Option-subcode : 3
     Option-type  : hex
     Option-value : 11
 DNS-server0    : 192.168.2.7
 DNS-server1    : 192.168.2.8
 NBNS-server0   : 192.168.2.7
 NBNS-server1   : 192.168.2.8
 Netbios-type   : b-node
 Gateway-0      : 192.168.1.10
```

Table 6-21 Description of the **display dhcp option template** command output

Item	Description
Template-Name	Name of the DHCP Option template. To specify the parameter, run the **dhcp option template** command.
Template-No	Index value of the DHCP Option template.
Next-server	IP address of a server configured for the client after the client automatically obtains the IP address. To specify the parameter, run the **next-server** command in the DHCP Option template view.
Domain-name	Name of a domain. To specify the parameter, run the **domain-name** command in the DHCP Option template view.
Option-code	Code for a customized option. To specify the parameter, run the **option** command in the DHCP Option template view.

Item	Description
Option-subcode	Code for a customized sub-option. To specify the parameter, run the **option** command in the DHCP Option template view.
Option-type	Character string type for a customized option. To specify the parameter, run the **option** command in the DHCP Option template view.
Option-value	Character string value for a customized option. To specify the parameter, run the **option** command in the DHCP Option template view.
DNS-server0	Address of the DNS server. Currently, a maximum of eight DNS server addresses can be configured. Values 0 and 1 indicate the first and second DNS server addresses respectively. To specify the parameter, run the **dns-list** command in the DHCP Option template view.
NBNS-server0	Address of the NetBIOS server. Currently, a maximum of eight NetBIOS server addresses can be configured in a DHCP Option template. Values 0 and 1 indicate the first and second NetBIOS server addresses respectively. To specify the parameter, run the **nbns-list** command in the DHCP Option template view.
Netbios-type	NetBIOS node type. To specify the parameter, run the **netbios-type** command in the DHCP Option template view.
Gateway-0	Gateway address. Currently, a maximum of eight gateway addresses can be configured. The value 0 indicates the first gateway address. To specify the parameter, run the **gateway-list** command in the DHCP Option template view.

6.3.73 display dhcp relay

Function

The **display dhcp relay** command displays configuration information about a DHCP relay agent.

Format

display dhcp relay { **configuration** | **all** | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
configuration	Displays configuration information about DHCP relay agents configured globally and on all interfaces.	-
all	Displays configuration information about DHCP relay agents configured on all interfaces.	-
interface *interface-type interface-number*	Displays configuration information about a DHCP relay agent configured on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check configuration information about DHCP relay agents configured globally and on interfaces.

Example

Display configuration information about DHCP relay agents on all interfaces.

```
<HUAWEI> display dhcp relay configuration
  DHCP relay global running information :
  DHCP relay address cycle           : Disable (default)
  DHCP relay trust option82          : Enable  (default)
  DHCP relay request server-match    : Enable  (default)
  DHCP relay reply forward all       : Disable (default)
 DHCP relay agent running information of interface
Vbdif100 :
 Server IP address [00] : 10.1.1.1
 Gateway address in use : 10.10.1.10
 Anycast gateway re-route: disable
 GIADDR source interface : LoopBack1
 Link-selection insert  : enable
 DHCP relay agent running information of interface Vlanif5 :
 Server group name      : group1
 Gateway address in use : 10.100.100.1
 Gateway switch         : enable
 DHCP relay agent running information of interface Vlanif100 :
 Server IP address [00] : 10.2.2.3
 VPN instance      [00] : vpn1
 Gateway address in use : 10.2.2.2
```

Table 6-22 Description of the **display dhcp relay configuration** command output

Item	Description
DHCP relay global running information	Configuration information about DHCP relay agents configured globally.
DHCP relay address cycle	Whether the DHCP server polling function is enabled on a DHCP relay agent. - Enable: The DHCP server polling function is enabled on a DHCP relay agent. - Disable: The DHCP server polling function is disabled on a DHCP relay agent. To configure this item, run the **ip relay address cycle** command.
DHCP relay trust option82	Whether Option 82 is enabled on a DHCP relay agent. - Enable: Option 82 is enabled on a DHCP relay agent. - Disable: Option 82 is disabled on a DHCP relay agent. To configure this item, run the **dhcp relay trust option82** command.

Item	Description
DHCP relay request server-match	Whether a DHCP relay agent is enabled to check the DHCP server identifier (Option54) in a DHCP Request message to be forwarded. ● Enable: A DHCP relay agent is enabled to check the DHCP server identifier (Option54) in a DHCP Request message to be forwarded. ● Disable: A DHCP relay agent is disabled from checking the DHCP server identifier (Option54) in a DHCP Request message to be forwarded. To configure this item, run the **dhcp relay request server-match enable** command.
DHCP relay reply forward all	Whether a DHCP relay agent is enabled to forward all DHCP ACK messages. ● Enable: A DHCP relay agent is enabled to forward all DHCP ACK messages. ● Disable: A DHCP relay agent is disabled from forwarding all DHCP ACK messages. To configure this item, run the **dhcp relay reply forward all enable** command.
DHCP relay agent running information of interface *if*	DHCP relay agent configuration of the *if* interface.
Server group name	Group name of the DHCP Server. To specify the parameter, run the **dhcp relay server-select** command.
Server IP address [x]	IP address of a DHCP server in the DHCP server group. The value x is the index of a DHCP server. To specify the parameter, run the **dhcp-server** command.
VPN instance [xx]	VPN instance bound to the interface. The value xx indicates the index of the VPN instance. **NOTE** This field is displayed in the command output only when a VPN instance is specified using the **dhcp relay server-ip** command.
Gateway address in use	IP address of the DHCP gateway. To specify the parameter, run the **gateway** command in the DHCP server group view.

Item	Description
Anycast gateway re-route	Whether the re-routing function for the DHCP relay agent is enabled. The value can be: - Enable: The re-routing function for the DHCP relay agent is enabled. - Disable: The re-routing function for the DHCP relay agent is disabled. To configure this item, run the **dhcp relay anycast gateway re-route enable** command.
GIADDR source interface	Source interface of DHCP relayed packets. To configure this item, run the **dhcp relay giaddr source-interface** command.
Link-selection insert	Whether the function of inserting the Link-selection suboption of the Option82 field into DHCP packets is enabled. The value can be: - Enable: The function of inserting the Link-selection suboption of the Option82 field into DHCP packets is enabled. - Disable: The function of inserting the Link-selection suboption of the Option82 field into DHCP packets is disabled. To configure this item, run the **dhcp relay information link-selection insert enable** command.
Gateway switch	Whether automatic gateway switchover is enabled on a DHCP relay agent. The value can be: - Enable: The automatic gateway switchover on a DHCP relay agent is enabled. - Disable: The automatic gateway switchover on a DHCP relay agent is disabled. To configure this item, run the **dhcp relay gateway-switch enable** command.

6.3.74 display dhcp relay statistics

Function

The **display dhcp relay statistics** command displays message statistics on a DHCP relay agent.

Format

display dhcp relay statistics [**server-group** *group-name*]

Parameters

Parameter	Description	Value
server-group *group-name*	Displays message statistics on DHCP relay agents connected to DHCP servers in a specified DHCP server group. If this parameter is not specified, message statistics on DHCP relay agents connected to all DHCP servers are displayed.	The value must be an existing DHCP server group on the device.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display dhcp relay statistics** command to view the statistics about the packets received and sent by a DHCP relay agent, so as to check whether the client is correctly configured or the network is connected.

- Run the **display dhcp relay statistics server-group** *group-name* command to check message statistics on DHCP relay agents connected to DHCP servers in a specified DHCP server group. The DHCP server group name needs to be specified.
- Run the **display dhcp relay statistics** command to check message statistics on all DHCP relay agents besides DHCP relay agents connected to DHCP servers in the DHCP server group.

Follow-up Procedure

After detecting incorrect message statistics on a DHCP relay agent, run the **reset dhcp relay statistics** [**server-group** *group-name*] command to clear message statistics on the DHCP relay agent.

Example

Display message statistics on a DHCP relay agent.

```
<HUAWEI> display dhcp relay statistics
 The statistics of DHCP RELAY:
   DHCP packets received from clients         : 0
      DHCP DISCOVER packets received         : 0
      DHCP REQUEST packets received          : 0
      DHCP RELEASE packets received          : 0
      DHCP INFORM packets received           : 0
      DHCP DECLINE packets received          : 0
   DHCP packets sent to clients              : 0
      Unicast packets sent to clients        : 0
      Broadcast packets sent to clients      : 0
   DHCP packets received from servers         : 0
      DHCP OFFER packets received            : 0
      DHCP ACK packets received              : 0
      DHCP NAK packets received              : 0
   DHCP packets sent to servers              : 0
   DHCP Bad packets received                 : 0
```

Table 6-23 Description of the **display dhcp relay statistics** command output

Item	Description
DHCP packets received from clients	DHCP messages received from clients.
DHCP DISCOVER packets received	DHCP Discover messages received from clients.
DHCP REQUEST packets received	DHCP Request messages received from clients.
DHCP RELEASE packets received	DHCP Release messages received from clients.
DHCP INFORM packets received	DHCP Inform messages received from clients.
DHCP DECLINE packets received	DHCP Decline messages received from clients.
DHCP packets sent to clients	DHCP messages sent to clients.
Unicast packets sent to clients	Unicast packets sent to clients.
Broadcast packets sent to clients	Broadcast packets sent to clients.
DHCP packets received from servers	DHCP messages received from servers.
DHCP OFFER packets received	DHCP Offer messages received from servers.
DHCP ACK packets received	DHCP ACK messages received from servers.
DHCP NAK packets received	DHCP NAK messages received from servers.
DHCP packets sent to servers	DHCP messages sent to servers.

Item	Description
DHCP Bad packets received	DHCP error messages received.

6.3.75 display dhcp server configuration

Function

The **display dhcp server configuration** command displays DHCP server configuration.

Format

display dhcp server configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the Switch functions as a DHCP server, you can run the **display dhcp server configuration** command to check DHCP server configuration.

Example

Display DHCP server configuration.

```
<HUAWEI> display dhcp server configuration
  DHCP server global running information :
  DHCP server bootp                : Disable (default)
  DHCP server bootp automatic      : Disable (default)
  DHCP server ping packet          : 2       (default)
  DHCP server ping timeout         : 500     (default)
  DHCP server trust option82       : Enable  (default)
  DHCP server force response       : Disable (default)

  DHCP server running information for interface Vlanif10 :
  DHCP server mode                 : Interface

  DHCP server running information for interface
Vlanif20 :
  DHCP server mode                 : Global
```

Table 6-24 Description of the **display dhcp server configuration** command output

Item	Description
DHCP server global running information	Global DHCP server configuration.
DHCP server bootp	Whether the DHCP server is enabled to respond to BOOTP requests. To configure this item, run the **dhcp server bootp** command.
DHCP server bootp automatic	Whether the DHCP server is enabled to dynamically assign IP addresses to BOOTP clients. To configure this item, run the **dhcp server bootp automatic** command.
DHCP server ping packet	Maximum number of ping packets sent by the DHCP server. To configure this item, run the **dhcp server ping** command.
DHCP server ping timeout	Maximum time to wait for a response to the ping packet sent by the DHCP server. To configure this item, run the **dhcp server ping** command.
DHCP server trust option82	Whether the DHCP server is enabled to trust the Option 82 field. To configure this item, run the **dhcp server trust option82** command.
DHCP server force response	Whether the DHCP server is enabled to reply with DHCP NAK messages. To configure this item, run the **dhcp server force response** command.
DHCP server running information for interface *ifn*	DHCP server configuration on an interface.
DHCP server mode	DHCP server mode. The value can be: ● Interface: indicates a DHCP server based on an interface address pool. To configure this item, run the **dhcp select interface** command. ● Global: indicates a DHCP server based on the global address pool. To configure this item, run the **dhcp select global** command.

6.3.76 display dhcp server database

Function

The **display dhcp server database** command displays information about the DHCP database.

Format

display dhcp server database

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display dhcp server database** command displays the storage path and file name of DHCP data on a DHCP server. This information helps to check:

- Whether the function that saves DHCP data to the storage device is enabled. If this function is not enabled, run the **dhcp server database** command to enable it.
- Whether the interval at which DHCP data is saved is proper.
- Whether the function that recovers DHCP data from the storage device after the system restarts is enabled.

Precautions

The function that saves DHCP data to storage devices and the function that recovers DHCP data from storage devices can be enabled in any sequence.

Example

Display information about the DHCP database.

```
<HUAWEI> display dhcp server database
 Status: disable
 Recover from files after reboot: disable
 File saving lease items: flash:/dhcp/lease.txt
 File saving conflict items: flash:/dhcp/conflict.txt
 Save Interval: 300 (seconds)
```

Table 6-25 Description of the **display dhcp server database** command output

Item	Description
Status	Whether to save the data to the storage device: ● disable ● enable The value is set using the **dhcp server database** command.
Recover from files after reboot	Whether to recover data from the file on the storage device after the system restarts: ● disable ● enable The value is set using the **dhcp server database** command.
File saving lease items	File name and path of the file for storing address lease information.
File saving conflict items	File name and path of the file for storing address conflict information.
Save Interval	Interval at which DHCP data is saved, in seconds. The value is set using the **dhcp server database** command.

6.3.77 display dhcp server group

Function

The **display dhcp server group** command displays the configuration of a DHCP server group.

Format

display dhcp server group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Displays the configuration of a specified DHCP server group.	The value must be an existing DHCP server group on the device.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display dhcp server group** command displays information about all the DHCP server groups of a DHCP relay agent and the number of DHCP servers in the DHCP server groups. If *group-name* is specified, the **display dhcp server group** *group-name* command displays DHCP server addresses and the number of DHCP servers in a specified DHCP server group.

Prerequisites

A DHCP server group has been created on a DHCP relay agent using the **dhcp server group** command.

Example

Display the configuration of the DHCP server group **myServers**.

```
<HUAWEI> display dhcp server group myServers
 Group-name          : myServers
   (0)  Server-IP    : 10.1.1.1
        VPN instance : vpn1
  Gateway            : 10.10.10.1
```

Table 6-26 Description of the **display dhcp server group** command output

Item	Description
Group-name	Name of a DHCP server group. To specify the parameter, run the **dhcp server group** command.
(x) Server-IP	IP addresses of DHCP servers in a DHCP server group. x is the index of the IP addresses and ranges from 0 to 19. To specify the parameter, run the **dhcp-server** command.
VPN instance	VPN instance to which the DHCP server group belongs. **NOTE** This field is displayed in the command output only when a VPN instance is specified using the **dhcp-server** command.

Item	Description
Gateway	Gateway address of the DHCP server in the DHCP server group. To specify the parameter, run the **gateway** command in the DHCP server group view.

6.3.78 display dhcp server statistics

Function

The **display dhcp server statistics** command displays statistics on a DHCP server.

Format

display dhcp server statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the display dhcp server statistics command to check whether the client is correctly configured or the network is connected.

Follow-up Procedure

After detecting incorrect message statistics on a DHCP server, run the **reset dhcp server statistics** command to clear message statistics on the DHCP server.

Example

Display statistics on the DHCP server.

```
<HUAWEI> display dhcp server statistics
 DHCP Server Statistics:

 Client Request:              6
  Dhcp Discover:              1
  Dhcp Request:               4
  Dhcp Decline:               0
  Dhcp Release:               1
```

```
 Dhcp Inform:            0
Server Reply:            4
 Dhcp Offer:             1
 Dhcp Ack:               3
 Dhcp Nak:               0
Bad Messages:            0
```

Table 6-27 Description of the **display dhcp server statistics** command output

Item	Description
DHCP Server Statistics	Statistics on the DHCP server.
Client Request	Number of DHCP messages sent from the DHCP client to the DHCP server.
Dhcp Discover, Dhcp Request, Dhcp Decline, Dhcp Release, Dhcp Inform	Numbers of different types of DHCP messages sent from the DHCP client to the DHCP server.
Server Reply	Number of DHCP messages sent from the DHCP server to the DHCP client.
Dhcp Offer, Dhcp Ack, Dhcp Nak	Numbers of different types of DHCP messages sent from the DHCP server to the DHCP client.
Bad Messages	Number of unknown messages.

6.3.79 display dhcp statistics

Function

The **display dhcp statistics** command displays DHCP message statistics.

Format

display dhcp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display dhcp statistics** command displays statistics about sent and received DHCP messages.

Example

Display DHCP message statistics.

```
<HUAWEI> display dhcp statistics
Input: total 172 packets, discarded 0 packets
  Bootp request          :          0,  Bootp reply            :          0
  Discover               :          0,  Offer                  :        172
  Request                :          0,  Ack                    :          0
  Release                :          0,  Nak                    :          0
  Decline                :          0,  Inform                 :          0

  Rx buffers full        :       2978,  L2fdb lookup failed    :         38

Output: total 172 packets, discarded 0 packets
```

Table 6-28 Description of the **display dhcp statistics** command output

Item	Description
Bootp request	Number of BOOTP requests sent by the device that functions as the client.
Bootp reply	Number of BOOTP replies received by the client from the server.
Discover	Number of Discover messages received by the server from the client.
Offer	Number of Offer messages received by the client from the server.
Request	Number of BOOTP requests received by the server from the client.
Ack	Number of ACK messages received by the client from the server.
Release	Number of Release messages received by the server from the client.
Nak	Number of NAK messages received by the client from the server.
Decline	Number of Decline messages sent by the client.
Inform	Number of Inform messages sent by the client.

Item	Description
Rx buffers full or L2fdb lookup failed	Information displayed when the DHCP service is abnormal. The displayed information includes: - Rx buffers full: Total number of DHCP packets discarded because the remaining queue length is shorter than the reserved threshold. - L2fdb lookup failed: Total number of DHCP ACK packets discarded because the DHCP snooping module fails to find user-side interfaces. - High cpu occupancy: Total number of DHCP packets discarded because the CPU usage is excessively high. - Port blocked: Total number of DHCP packets discarded because the inbound interface is blocked. - Bad vlan id: Total number of DHCP packets discarded because the interfaces receiving the DHCP packets are not added to the VLANs corresponding to the VLAN tags carried in the packets or the DHCP packets received on interfaces carry VLAN tags not in the range from 1 to 4094. - Memory exhausted: Total number of DHCP packets discarded because the memory is exhausted. - L3if protocol down: Total number of DHCP packets discarded because the Layer 3 protocol of the source interface goes Down. - Rate limit: Total number of DHCP packets discarded because rates of the packets exceed the limit, when the **dhcp snooping check dhcp-rate enable** command is configured. - Bad packet length: Total number of DHCP packets discarded because the packet length is not in the range of 50 to 2048 bytes. - Bad ip header length: Total number of DHCP packets discarded because the IP header length is not in the range of 20 to 60 bytes

Item	Description
	- Bad ip header checksum: Total number of DHCP packets discarded because the checksum of the IP header is incorrect. - Bad udp checksum: Total number of DHCP packets discarded because the checksum of the UDP header is incorrect. - Hops exceeded: Total number of DHCP request packets discarded by the DHCP relay agent because the hop count exceeds 16. - Bad magic cookie: Total number of DHCP packets discarded because the magic-cookie field is incorrect. - Duplicate option: Total number of DHCP packets discarded because the option fields are duplicate. - Bad option length: Total number of DHCP packets discarded because the option field length is incorrect. - End option absent: Total number of DHCP packets discarded because of the incorrect end option. - Dest-port equals source: Total number of DHCP packets discarded because the source interface is also the outbound interface. - Bad chaddr: Total number of DHCP packets discarded due to incorrect client MAC addresses. A DHCP packet is discarded due to an incorrect client MAC address if a DHCP relay agent finds that the MAC address in the CHADDR field of the DHCP packet is not a unicast address, a DHCP snooping-enabled device finds that the MAC address in the CHADDR field of the DHCP request packet is different from the source MAC address, or the MAC address in the CHADDR field of the DHCP packet conflicts with the DHCP server MAC address. - Bad giaddr: Total number of DHCP packets discarded due to incorrect values in the GIADDR field, when

Item	Description
	the **dhcp snooping check dhcp-giaddr enable** command is configured to check whether the GIADDR field in received DHCP packets is 0 or carries an invalid IP address, such as a loopback address. ● Bad request: Total number of invalid DHCP request packets that are discarded, when the **dhcp snooping check dhcp-request enable** command is configured to check the validity of DHCP packets. ● Bad reply: Total number of DHCP response packets discarded by untrusted interfaces configured with the **dhcp snooping enable** command. ● Bad dest udp-port: Total number of DHCP request packets discarded by the DHCP relay agent because the destination port number is UDP port 68. ● Bad message type: Total number of DHCP packets discarded because they are neither requests nor responses. ● Max-user limit: Total number of DHCP packets discarded because the maximum number of users (configured by using the **dhcp snooping max-user-number** command) is exceeded. ● Add bindtable failed: Total number of DHCP packets discarded because dynamic binding entries are added. New dynamic binding entries may be added if the user-side interface is Down, or IPSG is configured but ACL resources are insufficient. ● Client transferred: Total number of DHCP packets discarded because the **undo dhcp snooping user-transfer enable** command is configured to disable location transition for DHCP snooping users.

Item	Description
	- Other error: Total number of DHCP packets discarded due to other reasons.

6.3.80 display ip pool

Function

The **display ip pool** command displays configured IP address pool information.

Format

display ip pool

display ip pool interface *interface-pool-name* [*start-ip-address* [*end-ip-address*] | **all** | **conflict** | **expired** | **used**]

display ip pool name *ip-pool-name* [*start-ip-address* [*end-ip-address*] | **all** | **conflict** | **expired** | **used** [**user-type** { **dhcp** | **l2tp** | **ipsec** | **ssl-vpn** }]]

display ip pool vpn-instance *vpn-instance-name*

display ip pool global interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface *interface-pool-name*	Displays the configuration of the specified interface address pool. **NOTE** An interface address pool is often specified using the interface type and interface number, which are not separated by spaces.	The interface address pool must exist on the device.
name *ip-pool-name*	Displays the configuration of the specified global address pool.	The global address pool must exist on the device.
start-ip-address [*end-ip-address*]	Displays the IP addresses within the range specified by the start IP address in an IP address pool. If *end-ip-address* is specified, the end IP address is also specified.	The value is in dotted decimal notation.

Parameter	Description	Value
all	Displays information about all IP addresses in an IP address pool.	-
conflict	Displays information about conflicting IP addresses in an address pool. (If an IP address that the DHCP server prepares to assign to a user exists on the network, the IP address will be added to the conflict list. This problem occurs when a static IP address is configured or an active/standby switchover occurs in a VRRP group if the range of IP addresses in the address pools on the master and backup devices overlap.)	-
expired	Displays information about expired and idle IP addresses in an IP address pool.	-
used [**user-type** { **dhcp** | **l2tp** | **ipsec** | **ssl-vpn** }]	Displays information about used IP addresses of the specified user type in an IP address pool: ● **dhcp** indicates users who obtain IP addresses through DHCP. ● **l2tp** indicates L2TP users. ● **ipsec** indicates IPSec users. ● **ssl-vpn** indicates SSL VPN users.	-
vpn-instance *vpn-instance-name*	Displays information about the address pool in a specified VPN instance.	The value must be an existing VPN instance name.
global interface *interface-type interface-number*	Displays information about the address pool on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ip pool** command to view information about configured IP address pools and IP addresses in them, including the IP address pool name, lease, lock status, and IP address status.

Example

Display information about conflicting addresses in the IP address pool named **test**.

```
<HUAWEI> display ip pool name test conflict
 Pool-name        : test
 Pool-No          : 1
 Lease            : 1 Days 0 Hours 0 Minutes
 Domain-name      : -
 Option-code      : 60
  Option-subcode : --
  Option-type    : cipher
  Option-value   : %^%#5g)NPN1M,$M;pQ-lT\P>Al6QN4#ldIVVjD69XlCN%^%#
 DNS-server0      : -
 NBNS-server0     : -
 Netbios-type     : -
 Position         : Local
 Status           : Unlocked
 Gateway-0        : -
 Network          : 192.168.0.0
 Mask             : 255.255.255.0
 VPN instance     : --
 Bootfile         : 43534
 Logging          : Enable
 Conflicted address recycle interval: 1 Days 0 Hours 0 Minutes
 Address Statistic: Total       :254       Used        :1
                    Idle        :252       Expired     :2
                    Conflict    :1         Disabled    :0

 -----------------------------------------------------------------------------
 Network section
       Start           End       Total    Used Idle(Expired) Conflict Disabled
 -----------------------------------------------------------------------------
    192.168.0.1   192.168.0.254     254       1        252(2)       1     0

 -----------------------------------------------------------------------------
```

Table 6-29 Description of the **display ip pool** command output

Item	Description
Pool-name	Name of an IP address pool. To configure this parameter, run the **ip pool (system view)** command.
Pool-No	Index of the IP address pool.

Item	Description
Lease	Lease of the IP address pool. To configure this parameter, run the **lease** command.
Domain-name	Domain name. To configure this parameter, run the **domain-name** command.
Option-code	Value of a customized option. To configure this parameter, run the **option** command.
Option-subcode	Value of a customized sub-option. To configure this parameter, run the **option** command.
Option-type	Type of a customized option code: ● ascii: indicates that the customized option code is an ASCII character string. ● hex: indicates that the customized option code is a hexadecimal string. ● cipher: indicates that the customized option code is a ciphertext character string. To configure this parameter, run the **option** command.
Option-value	Content of a customized option. To configure this parameter, run the **option** command.
DNS-server0	Address of the DNS server. Currently, an IP address pool can be configured with up to eight DNS servers. The value 0 indicates the first DNS server address and the value 1 indicates the second DNS server address. To configure this parameter, run the **dns-list** command.
NBNS-server0	Address of the NetBIOS server. Currently, an address pool can be configured with up to eight NetBIOS server addresses. The value 0 indicates the first NetBIOS server address. To configure this parameter, run the **nbns-list** command.

Item	Description
Netbios-type	NetBIOS type. To configure this parameter, run the **netbios-type** command.
Position	Position of the IP address pool.
Status (First)	Status of the IP address pool. To configure this parameter, run the **lock (IP address pool view)** command.
Gateway-0	Gateway address. Currently, a maximum of eight gateway addresses can be configured in an IP address pool. The value 0 indicates the first gateway address. To configure this parameter, run the **gateway-list** command.
Network	Network segment of the IP address pool.
Mask	Subnet mask of the IP address pool. To configure this parameter, run the **network (IP address pool view)** command.
Bootfile	Name of the startup configuration file configured for the DHCP client. To configure this parameter, run the **bootfile** command.
VPN instance	Name of a VPN instance.
Logging	Status of the logging function when the DHCP server assigns IP addresses. ● Enable ● Disable To configure this parameter, run the **logging** or **dhcp server logging** command.
Conflicted address recycle interval	Interval for automatically reclaiming conflicting IP addresses in the IP address pool. To configure this parameter, run the **conflict auto-recycle interval day** *day* [**hour** *hour* [**minute** *minute*]] command.

Item	Description
Address Statistic	Statistics about IP addresses in the IP address pool.
Start	Start IP address of the IP address pool.
End	End IP address of the IP address pool.
Total	Total number of IP addresses in the IP address pool. Total = Used + Idle(Expired) + Conflict + Disable
Used	Number of used IP addresses in the IP address pool.
Idle(Expired)	Number of idle (expired) IP addresses in the address pool. **NOTE** If the mask length of the address pool is shorter than that of the interface IP address on the DHCP server, users may fail to go online even when there are idle IP addresses in the address pool.
Conflict	Number of conflicting IP addresses in the IP address pool. **NOTE** If there are many conflicting IP addresses in the address pool, it is recommended that you configure the **conflict auto-recycle interval** command to reclaim conflicting IP addresses periodically. This configuration reduces occupation of idle IP addresses in the address pool and prevents IP address conflicts on the network.
Disabled	Number of disabled IP addresses in the IP address pool.

Item	Description
Client-ID format as follows	Client ID format: ● DHCP: mac-address. The client ID format of DHCP users is a MAC address. ● PPPoE: mac-address. The client ID format of PPPoE users is a MAC address. ● IPSec: user-id/portnumber/vrf. The client ID format of IPSec users is a user ID, port number, or VPN index. ● PPP: interface index. The client ID format of PPP users is an interface index. ● L2TP: cpu-slot/session-id. The client ID format of L2TP users is a CPU ID-slot ID or session ID. ● SSL-VPN: user-id/session-id. The client ID format of SSL-VPN users is a user ID or session ID.
Index	Index.
IP	IP address.
Client-ID	DHCP client ID.
Type	DHCP client type. The types include DHCP, PPPoE, IPSec, PPP, L2TP, and SSL-VPN.
Left	Remaining lease of an IP address. When the result of the calculation formula ([**Lease** – **Left**]/**Lease**) is 50% or 87.5%, the DHCP client sends a DHCP Request message to the DHCP server to renew the lease. If the renewal succeeds, the value of the **Left** field is recounted. If the renewal fails, the DHCP client requests an IP address again and the status of its original IP address is set to **Expired**.

Item	Description
Status (Second)	Status of an IP address: - Used: indicates that the IP address is used. - Idle: indicates that the IP address is idle. - Expired: indicates that the lease of the IP address expires and the IP address is idle. - Conflict: indicates that the IP address conflicts with another IP address on the network. - Disable: indicates that the IP address cannot be used. - Static-bind: indicates that the IP address is bound to a MAC address. - Static-bind used: indicates that the IP address is bound to a MAC address and used.

6.3.81 dns-list

Function

The **dns-list** command configures the DNS server address for the DHCP client.

The **undo dns-list** command deletes a configured DNS server address.

By default, no DNS server address is configured.

Format

IP address pool view

dns-list { *ip-address* &<1-8> | **unnumbered interface** *interface-type interface-number* }

undo dns-list { *ip-address* | **unnumbered interface** | **all** }

DHCP Option template view

dns-list *ip-address* &<1-8>

undo dns-list { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the DNS server address.	The value is in dotted decimal notation. A maximum of eight DNS server addresses can be configured. These IP addresses are separated by spaces.
unnumbered interface *interface-type interface-number*	Borrows the DNS server address obtained by the interface as the DNS server IP address.	-
all	Deletes all DNS server addresses.	-

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. If user hosts access hosts on the network by domain names, user hosts need to send DNS requests to the DNS server and resolve the domain name to access for communication. To connect a DHCP client to the network, configure a DHCP server address so that the DHCP server can assign both the specified DNS server address and an IP address to the client. To configure DNS server addresses for an interface address pool, run the **dhcp server dns-list** command.

Precautions

In the IP address pool view and DHCP Option template view, a device can be configured with a maximum of eight DNS server addresses respectively. The address first assigned to the clients functions as the primary address, and the other seven addresses function as secondary addresses.

Example

In the IP address pool view, set the IP address of the DNS server to 10.10.10.10.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] dns-list 10.10.10.10
```

In the DHCP Option template view, set the IP address of the DNS server to 10.10.10.10.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] dns-list 10.10.10.10
```

6.3.82 domain-name

Function

The **domain-name** command configures the domain name suffix for DHCP clients.

The **undo domain-name** command deletes a configured domain name suffix.

By default, no domain name suffix is configured for DHCP clients.

Format

domain-name *domain-name*

undo domain-name

Parameters

Parameter	Description	Value
domain-name	Specifies a domain name to be assigned to a DHCP client.	The value is a string of 1 to 63 characters without spaces. **NOTE** When quotation marks are used around the string, spaces are allowed in the string.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

This command applies to DHCP servers. When allocating an IP address to a client, a DHCP server can also assign a domain name suffix to the client. You can run the **domain-name** command on the DHCP server to specify the domain name suffix for clients. After this command is run, the DHCP server will send the domain name suffix to a client when allocating an IP addresses to the client.

To configure a domain name for an interface address pool, run the **dhcp server domain-name (interface view)** command.

Example

In the IP address pool view, configure the domain name suffix assigned to the DHCP client as **example.com**.

```
<HUAWEI> system-view
[HUAWEI] ip pool test
[HUAWEI-ip-pool-test] domain-name example.com
```

In the DHCP Option template, configure the domain name suffix assigned to the DHCP client as **example.com**.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] domain-name example.com
```

6.3.83 excluded-ip-address

Function

The **excluded-ip-address** command specifies the range of IP addresses that cannot be automatically assigned to clients from an address pool.

The **undo excluded-ip-address** command deletes the specified range of IP addresses that cannot be automatically assigned to clients from an address pool.

By default, all IP addresses in an address pool can be automatically assigned to clients.

Format

excluded-ip-address *start-ip-address* [*end-ip-address*]

undo excluded-ip-address *start-ip-address* [*end-ip-address*]

Parameters

Parameter	Description	Value
start-ip-address	Specifies the start IP address of the IP address segment where addresses cannot be automatically assigned to clients.	The value is in dotted decimal notation.
end-ip-address	Specifies the end IP address of the IP address segment where addresses cannot be automatically assigned to clients. If *end-ip-address* is not specified, only the IP address corresponding to *start-ip-address* cannot be automatically assigned.	The value is in dotted decimal notation. *end-ip-address* and *start-ip-address* must be on the same network segment and *end-ip-address* must be larger than *start-ip-address*.

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **excluded-ip-address** command applies to DHCP servers. Fixed IP addresses are allocated to some specific hosts (such as the WWW server) on the network for a long time. If these hosts' IP addresses are overlapped with IP addresses in the address pool and the DHCP server allocates these overlapped IP addresses to other hosts, IP address conflicts may occur. To prevent such IP address conflicts, you need to exclude these IP addresses from being automatically assigned in the address pool.

You can run the **excluded-ip-address** command to specify the IP addresses or the range of IP addresses that cannot be automatically assigned to clients in the global address pool.

You can run the **dhcp server excluded-ip-address** command to specify the IP addresses or the range of IP addresses that cannot be automatically assigned to clients in the interface address pool.

Prerequisites

Network segment addresses that can be assigned from the global address pool have been configured using the **network (IP address pool view)** command.

Precautions

- The excluded IP address or IP address segment must be in the local address pool.
- You do not need to exclude the gateway address configured using the **gateway-list** command from being automatically allocated. The device automatically adds the gateway address into the list of IP addresses that cannot be automatically allocated.

  You do not need to exclude the IP address of a server's interface connecting to a client from being automatically allocated. The device automatically sets the status of the interface IP address to Conflict during address assignment.
- If you run the **excluded-ip-address** command multiple times, you can specify multiple IP addresses or ranges of IP addresses that cannot be automatically assigned to clients from the specified address pool.
- You can run the **display ip pool** command to check the IP addresses in use in the current address pool, so that you can exclude the unused IP addresses from being automatically assigned to clients. If you need to exclude IP addresses in Used and Conflict states from being automatically assigned to clients after address reclamation, you can also run the **excluded-ip-address** command. If an IP address has been bound to a specific MAC address, adding the IP address to the IP address list in which IP addresses are not

automatically assigned to clients will unbind the IP address from the MAC address.

Example

Disable IP addresses 10.10.10.10 to 10.10.10.20 from being automatically assigned to clients from the address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] network 10.10.10.0 mask 24
[HUAWEI-ip-pool-global1] excluded-ip-address 10.10.10.10 10.10.10.20
```

Disable IP address 10.10.10.30 in Used state from being automatically assigned to clients from the address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] network 10.10.10.0 mask 24
[HUAWEI-ip-pool-global1] excluded-ip-address 10.10.10.30
Warning: The address is in used or conflict state. Are you sure to continue excluding the address?[Y/N]:y
```

6.3.84 force insert option

Function

The **force insert option** command configures a DHCP server to forcibly insert an Option field specified in the global address pool or DHCP Option template to a DHCP Response packet that it sends to a DHCP client.

The **undo force insert option** command deletes the Option field forcibly inserted to a DHCP Response packet that a DHCP server sends to a DHCP client.

By default, a DHCP server does not forcibly insert an Option field to a DHCP Response packet that it sends to a DHCP client.

Format

force insert option *code* &<1-254>

undo force insert option *code* &<1-254>

Parameters

Parameter	Description	Value
code	Specifies the code for a forcibly replied option. You can configure a DHCP server to forcibly reply one or more options.	The value is an integer that ranges from 1 to 254.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a DHCP client applies for an IP address from a DHCP server, parameters contained in the DHCP Request packet specify the options the client requires. The DHCP server inserts the required options to a DHCP Response packet.

Sometimes, the DHCP server on the existing network receives a DHCP Request packet that contains no parameter specifying the options the client requires. However, the client still wants to obtain the options configured on the global address pool. You can run the **force insert option** *code* &<1-254> command to configure the DHCP server to forcibly insert an Option field to the DHCP Response packet.

Prerequisites

The Option field has been configured in the global address pool by running the **option** *code* [**sub-option** *sub-code*] { **ascii** *ascii-string* | **hex** *hex-string* | **cipher** *cipher-string* | **ip-address** *ip-address* &<1-8> } command in the global address pool view.

Example

Configure a DHCP server to forcibly insert Option 4 to a DHCP Response packet in the address pool **pool1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool pool1
[HUAWEI-ip-pool-pool1] option 4 hex 11 22
[HUAWEI-ip-pool-pool1] force insert option 4
```

Configure a DHCP server to forcibly insert Option 4 to a DHCP Response packet in the DHCP Option template **template1**.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] option 4 hex 11 22
[HUAWEI-dhcp-option-template-template1] force insert option 4
```

6.3.85 gateway (DHCP server group view)

Function

The **gateway** command specifies an egress gateway address of the DHCP server in the DHCP server group view.

The **undo gateway** command restores the default setting.

By default, no egress gateway address is specified.

Format

gateway *ip-address*

undo gateway

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of an egress gateway.	The value is in dotted decimal notation.

Views

DHCP server group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. If a DHCP server and its DHCP relay agent are on different network segments, you can run the **gateway** command to specify an egress gateway address for the DHCP relay agent. In this way, the DHCP relay agent can communicate with the DHCP server. Run the **gateway-list** command to configure an egress gateway for the DHCP server.

Precautions

- If an egress gateway is not configured for a DHCP relay agent using the **gateway** command, the DHCP relay agent uses the VLANIF interface address as the gateway address to communicate with the DHCP server.
- When two switch devices function as the DHCP server and DHCP relay agent respectively, they must use the same egress gateway address.

Example

Specify the egress gateway address of the server group **myServers** as 10.10.10.1.

```
<HUAWEI> system-view
[HUAWEI] dhcp server group myServers
[HUAWEI-dhcp-server-group-myServers] gateway 10.10.10.1
```

6.3.86 gateway-list

Function

The **gateway-list** command configures an egress gateway address for a DHCP client.

The **undo gateway-list** command deletes a configured egress gateway address.

By default, no egress gateway address is configured.

Format

gateway-list *ip-address* &<1-8>

undo gateway-list { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of an egress gateway.	The value is in dotted decimal notation.
all	Deletes all gateway addresses.	-

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. If a DHCP server and its client are on different network segments, you can run the **gateway-list** command to specify an egress gateway address. In this way, the DHCP server and client can communicate with each other. Then the DHCP server can assign both an IP address and the specified egress gateway address to the client. You can configure multiple gateways in a global address pool to load balance traffic and improve network reliability.

To configure an egress gateway for a DHCP relay agent, run the **gateway (DHCP server group view)** command.

Configuration Impact

If a gateway address is configured on the DHCP server, a DHCP client will obtain the gateway address from the DHCP server and automatically generates a default route to the gateway address. If you run the **option121** command on the DHCP server to allocate classless static routes to DHCP clients, the DHCP client uses an allocated classless static route and does not automatically generate a default route to the gateway address.

Precautions

- The IP addresses specified in the **excluded-ip-address** command cannot be configured as a gateway address.
- After an IP address is configured as a gateway address, the device adds the IP address to the list of IP addresses that cannot be automatically allocated, removing the need to run the **excluded-ip-address** command.
- In the IP address pool view or DHCP Option template view, a maximum of eight egress gateway addresses can be configured on the device. These gateway addresses cannot be subnet broadcast addresses.
- When configuring an egress gateway address for the global address pool of a DHCP server, ensure that this egress gateway address is the same as that of the DHCP relay agent.

Example

In the IP address pool view, set the egress gateway address for the DHCP client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] gateway-list 10.1.1.1
```

In the DHCP Option template view, set the egress gateway address for the DHCP client to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] gateway-list 10.1.1.1
```

6.3.87 ip address bootp-alloc

Function

The **ip address bootp-alloc** command enables the BOOTP client function on an interface.

The **undo ip address bootp-alloc** command disables the BOOTP client function from an interface.

By default, the BOOTP client function is disabled on an interface.

Format

ip address bootp-alloc [**unicast**]

undo ip address bootp-alloc

Parameters

Parameter	Description	Value
unicast	Indicates that the client requests the server to unicast response packets to the client.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

DHCP is developed based on the BOOTP protocol. The device supports both DHCP and BOOTP and allows hosts to obtain IP addresses by BOOTP.

To enable an interface to obtain IP addresses using BOOTP, you can enable the BOOTP client function on the interface. A BOOTP client requests for an IP address from the server using BOOTP. The BOOTP client has two functions:

- Sends BOOTP Request messages to the server.
- Processes BOOTP Reply messages from the server.

To obtain an IP address, the BOOTP client sends a BOOTP Request message to the server. When the server receives the BOOTP Request message, it sends a BOOTP response message to the BOOTP client. The BOOTP client obtains the assigned IP address from the response message.

Precautions

Interfaces of the Switch can have IP addresses statically configured using the **ip address** command or dynamically obtain IP addresses using the **ip address bootp-alloc** command. A static IP address takes precedence over a dynamic IP address. If the interface has dynamically obtained an IP address after the **ip address bootp-alloc** command is executed, running the **undo ip address** command deletes the IP address and the **ip address bootp-alloc** command. If the interface does not obtain an IP address after the **ip address bootp-alloc** command is executed, running the **undo ip address** command does not delete the **ip address bootp-alloc** command.

Example

Enable the BOOTP client function on VLANIF100 to obtain an IP address.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address bootp-alloc
```

Enable the BOOTP client function on GE0/0/1 to obtain an IP address.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address bootp-alloc
```

6.3.88 ip address dhcp-alloc

Function

The **ip address dhcp-alloc** command enables the DHCP client function on an interface.

The **undo ip address dhcp-alloc** command disables the DHCP client function on an interface.

By default, the DHCP client function is enabled on VLANIF 1 of the S1720GW-E and S1720GWR-E. On other devices, the DHCP client function is disabled on an interface.

Format

ip address dhcp-alloc [**unicast**]

undo ip address dhcp-alloc

Parameters

Parameter	Description	Value
unicast	Indicates that the client requests the server to unicast response packets.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable an interface on the Switch to obtain an IP address using DHCP, enable the DHCP client function on the interface. A DHCP client applies for an IP address from the server using DHCP. The DHCP client has two functions:

- Sends DHCPREQUEST messages to the server.
- Processes DHCPACK messages from the server.

To obtain an IP address, the DHCP client sends a DHCPREQUEST message to the server. After the server receives the DHCPREQUEST message, it sends a DHCPACK message to the DHCP client. The DHCP client obtains the assigned IP address from the DHCPACK message.

Precautions

Interfaces of the device can have IP addresses statically configured using the **ip address** command or dynamically obtain IP addresses using the **ip address dhcp-alloc** command. A static IP address takes precedence over a dynamic IP address. If the interface has dynamically obtained an IP address after the **ip address dhcp-alloc** command is executed, running the **undo ip address** command deletes the IP address and the **ip address dhcp-alloc** command configuration. If no IP address is obtained through the **ip address dhcp-alloc** command, running the **undo ip address** command does not delete the **ip address dhcp-alloc** command configuration.

For the S1720GW-E and S1720GWR-E, if no IP address is configured on the device, VLANIF 1 uses the IP address 192.168.1.253 255.255.255.0 by default, and the **ip address dhcp-alloc unicast** command is configured on the interface by default. After VLANIF 1 obtains an IP address through DHCP successfully, the IP address 192.168.1.253 255.255.255.0 is deleted. If the DHCP client function is enabled on another VLANIF interface, the VLANIF interface cannot obtain the IP address in the same network segment as that of VLANIF 1, which prevents address conflict.

Example

Enable the DHCP client function on VLANIF100 to obtain an IP address.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip address dhcp-alloc
```

Enable the DHCP client function on GE0/0/1 to obtain an IP address.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip address dhcp-alloc
```

6.3.89 ip pool (system view)

Function

The **ip pool** command creates a global address pool.

The **undo ip pool** command deletes a global address pool.

By default, no global address pool is created.

Format

ip pool *ip-pool-name*

undo ip pool *ip-pool-name*

Parameters

Parameter	Description	Value
ip-pool-name	Specifies the name for an IP address pool.	The value is a string of 1 to 64 case-insensitive characters without spaces. It can contain digits, letters, and special characters such as underscores (_), hyphens (-), and periods (.). It cannot be set to **-** or **--**.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. When configuring a DHCP server, run the **ip pool** command in the system view to create a global IP address pool and set parameters for the global IP address pool, including a gateway address, the IP address lease, and a VPN instance. Then the configured DHCP server can assign IP addresses in the IP address pool to clients.

Precautions

A maximum of 128 address pools, including global address pools and interface address pools, can be created on the device.

Follow-up Procedure

Run the **network** command in the IP address pool view to specify the range of the IP addresses that can be allocated in the pool.

Example

Create a global address pool named **global1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
```

6.3.90 ip relay address cycle

Function

The **ip relay address cycle** command enables the DHCP server polling function on a DHCP relay agent.

The **undo ip relay address cycle** command disables the DHCP server polling function on a DHCP relay agent.

By default, DHCP server polling is disabled on a DHCP relay agent.

Format

ip relay address cycle

undo ip relay address cycle

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. When multiple DHCP server addresses are configured on a DHCP relay agent, the DHCP relay agent forwards DHCP Discover messages to all servers by default. As a result, DHCP servers need to process a large number of messages, leading to heavy loads of servers. To solve this problem, configure the **ip relay address cycle** command. After this command is configured, the DHCP relay agent forwards a received DHCP Discover message to one DHCP server at a time, and forwards the DHCP Discover message to a different DHCP server each time it receives the message. Multiple DHCP servers then can allocate the same number of IP addresses, implementing load balancing among DHCP servers.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

After the **ip relay address cycle** command is run, the DHCP relay agent forwards a received DHCP Discover message to a different DHCP server each time in the sequence in which DHCP servers were configured. You can run the **display dhcp relay** command to view DHCP server IP addresses in the **Server IP address** field to determine the sequence in which DHCP servers were configured.

Example

Enable DHCP server polling on the switch in the system view.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ip relay address cycle
```

6.3.91 ip route dhcp

Function

The **ip route dhcp** command configures a routing entry delivered by the DHCP server to a DHCP client.

The **undo ip route dhcp** command cancels the configuration.

By default, no routing entry is delivered by the DHCP server to a DHCP client.

Format

ip route *ip-address* { *mask* | *mask-length* } *interface-type interface-number* **dhcp** [*preference-value*]

undo ip route *ip-address* { *mask* | *mask-length* } *interface-type interface-number* **dhcp** [*preference-value*]

Parameters

Parameter	Description	Value
ip-address	Specifies the destination IP address.	The value is in dotted decimal notation.
mask	Specifies the mask of the IP address.	The value is in dotted decimal notation.

Parameter	Description	Value
mask-length	Specifies the mask length. The 32-bit mask is represented by consecutive 1s, and the mask in dotted decimal notation can be replaced by the mask length.	The value is an integer that ranges from 0 to 32.
interface-type interface-number	Specifies the type and number of the interface that forwards packets.	-
dhcp	Indicates that the DHCP client obtains routing entries using DHCP.	-
preference-value	Specifies the priority of the routing protocol.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **ip route dhcp** command is used on DHCP clients. After the **ip route** *ip-address* { *mask* | *mask-length* } *interface-type interface-number* **dhcp** [*preference-value*] command is run, a route with the gateway address as the next-hop IP address is automatically generated when a DHCP client obtains an IP address from the DHCP server through a DHCP request.

Example

Configure a routing entry to be obtained in DHCP mode on the DHCP client, and specify VLANIF100 as the outbound interface for forwarding packets and 30 as the routing protocol priority.

```
<HUAWEI> system-view
[HUAWEI] ip route 10.1.1.1 24 vlanif 100 dhcp 30
```

6.3.92 lease

Function

The **lease** command sets the lease for IP addresses in a global IP address pool.

The **undo lease** command restores the default lease of IP addresses in a global IP address pool.

By default, the lease of IP addresses is one day.

Format

lease { **day** *day* [**hour** *hour* [**minute** *minute*]] | **unlimited** }

undo lease

Parameters

Parameter	Description	Value
day *day*	Specifies the number of days in the IP address lease.	The value is an integer that ranges from 0 to 999. The default value is 1.
hour *hour*	Specifies the number of hours in the IP address lease.	The value is an integer that ranges from 0 to 23. The default value is 0.
minute *minute*	Specifies the number of minutes in the IP address lease.	The value is an integer that ranges from 0 to 59. The default value is 0.
unlimited	Indicates that the IP address lease is unlimited.	-

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. To meet different client requirements, DHCP supports dynamic, automatic, and static address assignment.

Different hosts require different IP address leases. For example, if some hosts such as a DNS server need to use certain IP addresses for a long time, run the **lease** command to set the IP address lease of the current global address pool to **unlimited**. If some hosts such as a portable computer just need to use temporary IP addresses, run the **lease** command to set the IP address lease of the current global address pool to the required time so that the expired IP addresses can be released and assigned to other clients.

When a DHCP client starts and 50% or 87.5% of its IP address lease has passed, the DHCP client sends a DHCP Request message to the DHCP server to renew the lease.

- If the IP address can be assigned to the client, the DHCP server informs the client that the IP address lease can be renewed.
- If the IP address can no longer be assigned to the client, the DHCP server informs the client that the IP address lease cannot be renewed. The client needs to request for another IP address.

You can run the **display ip pool** command to view information about the IP address lease. The values of the **lease** and **left** fields in the command output indicate the configured lease time and remaining lease time, respectively.

Prerequisites

A global IP address pool has been created using the **ip pool** command.

Precautions

Different IP address leases can be specified for different global address pools on a DHCP server. In a global address pool, all addresses have the same lease.

To specify the IP address lease for an interface address pool, run the **dhcp server lease** command.

If the IP address lease of an address pool is changed using this command, newly assigned IP addresses use the new IP address lease. IP addresses assigned before the change still use the original IP address lease before the lease is updated, and use the new lease after the lease is updated.

Example

Set the lease of a global address pool **global1** to 2 days 2 hours and 30 minutes.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] lease day 2 hour 2 minute 30
```

6.3.93 lock (IP address pool view)

Function

The **lock** command locks an IP address pool.

The **undo lock** restores the default configuration.

By default, no IP address pool is locked.

Format

lock

undo lock

Parameters

None

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

After the **lock** command is run, the specified IP address pool is locked and IP addresses in this address pool cannot be assigned to clients. When a DHCP server needs to be redeployed, you need to migrate address pools on the DHCP server to another DHCP server on the live network. To retain the addresses that have been assigned to clients from a global address pool, run the **lock** command to lock the global address pool. When new users get online after the address pool migration, they apply for IP addresses from a new address pool.

Example

Lock the IP address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] lock
```

6.3.94 logging (IP address pool view)

Function

The **logging** command enables the logging function during IP address allocation of the DHCP server in the IP address pool view.

The **undo logging** command disables the logging function during IP address allocation of the DHCP server in the IP address pool view.

By default, the logging function during IP address allocation of the DHCP server is disabled.

Format

logging [**allocation-fail** | **allocation-success** | **release** | **renew-fail** | **renew-success** | **detect-conflict** | **recycle-conflict**] *

undo logging [**allocation-fail** | **allocation-success** | **release** | **renew-fail** | **renew-success** | **detect-conflict** | **recycle-conflict**] *

Parameters

Parameter	Description	Value
allocation-fail	Displays logs when address allocation fails.	-
allocation-success	Displays logs when address allocation succeeds.	-
release	Displays logs when addresses are released.	-
renew-fail	Displays logs when address lease renewal fails.	-
renew-success	Displays logs when address lease renewal succeeds.	-
detect-conflict	Displays logs when address conflict occurs.	-
recycle-conflict	Displays logs when conflicting addresses are reclaimed.	-

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on a DHCP server. When the DHCP server allocates IP addresses to clients, it records address allocation information to facilitate routine maintenance and fault location. After the logging function during IP address allocation of the DHCP server is configured using the **logging** command, the DHCP server records logs about address allocation, conflict, lease renewal, and release.

Run the **display ip pool name** *ip-pool-name* command to check the status of the logging function during IP address allocation of the DHCP server.

Prerequisites

The global address pool has been created using the **ip pool (system view)** command.

Precautions

- With this logging function enabled, if a large number of DHCP clients request IP addresses from the DHCP server, the server frequently records logs. The server performance may therefore be affected.

- IP address allocation logs are recorded in the AM module. To view log information, the information center must be enabled. In addition, default settings for log output vary depending on various factors including the log level and output direction. For details, see Information Center Configuration in the *CLI-based Configuration - Device Management Configuration Guide*.

  For example, the level of logs indicating that an IP address is successfully allocated, an IP address is successfully renewed, and an IP address is successfully released is informational, and these logs are not recorded in the log buffer by default. You can run the **info-center source AM channel 4 log level informational** command to change the level of the logs to be recorded in the log buffer. You can then run the **display logbuffer** command to check the preceding logs.

Example

Enable the logging function during IP address allocation of the DHCP server in the IP address pool **pool1**.

```
<HUAWEI> system-view
[HUAWEI] ip pool pool1
[HUAWEI-ip-pool-pool1] logging
```

6.3.95 nbns-list

Function

The **nbns-list** command configures the NetBIOS server address for the DHCP client.

The **undo nbns-list** command deletes a configured NetBIOS server address.

By default, no NetBIOS server address is configured.

Format

nbns-list *ip-address* &<1-8>

undo nbns-list { *ip-address* | **all** }

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a NetBIOS server.	The value is in dotted decimal notation. A maximum of eight NetBIOS server addresses can be configured. These IP addresses are separated by spaces.
all	Deletes all NetBIOS server addresses.	-

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. Before hosts communicate with each other, a NetBIOS server needs to resolve the accessedNetBIOS hostname to an IP address. To enable hosts to communicate with each other, run the **nbns-list** command to configure NetBIOS server addresses. When assigning IP addresses to clients, a DHCP server also assigns the configured NetBIOS server addresses to clients. To configure NetBIOS server addresses for an interface address pool, run the **dhcp server nbns-list** command.

Precautions

In the IP address pool view and DHCP Option template view, a device can be configured with a maximum of eight NetBIOS server addresses respectively. The first assigned address functions as the primary address, and the other seven addresses function as secondary addresses.

Example

In the IP address pool view, set the IP address of the NetBIOS server to 192.168.1.1.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] nbns-list 192.168.1.1
```

In the DHCP Option template view, set the IP address of the NetBIOS server to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] nbns-list 10.1.1.1
```

6.3.96 netbios-type

Function

The **netbios-type** command configures the NetBIOS node type for the DHCP client.

The **undo netbios-type** command deletes a configured NetBIOS node type.

By default, no NetBIOS node type for the DHCP client is configured.

Format

netbios-type { **b-node** | **h-node** | **m-node** | **p-node** }

undo netbios-type

Parameters

Parameter	Description	Value
b-node	Indicates a node in broadcast mode. A b-node obtains the mapping between host names and IP addresses in broadcast mode.	-
h-node	Indicates a node in hybrid mode. An h-node is a b-type node enabled with the end-to-end communication mechanism.	-
m-node	Indicates a node in mixed mode. An m-node is a p-type node with some broadcast features.	-
p-node	Indicates a node in peer-to-peer mode. A p-node obtains the mapping between host names and IP addresses by communicating with a NetBIOS server.	-

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. When a DHCP client uses NetBIOS for communication, its host name needs to be mapped to an IP address, and the NetBIOS node type needs to be specified for it using the **netbios-type** command. When a DHCP server assigns an IP address to clients, it also sends the specified NetBIOS node type to clients.

Prerequisites

To specify the NetBIOS node type for a client in the interface address pool, run the **dhcp server netbios-type** command.

Example

In the IP address pool view, set the NetBIOS node type for the DHCP client to **b-node**.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] netbios-type b-node
```

In the DHCP Option template view, set the NetBIOS node type for the DHCP client to **b-node**.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] netbios-type b-node
```

6.3.97 network (IP address pool view)

Function

The **network** command sets a network segment address for a global address pool.

The **undo network** command restores the default network segment address.

By default, the range of IP addresses that can be dynamically allocated is not configured.

Format

network *ip-address* [**mask** { *mask* | *mask-length* }]

undo network

Parameters

Parameter	Description	Value
ip-address	Specifies a network segment address.	The value is in dotted decimal notation.
mask	Specifies the mask of the network segment address. If this parameter is not specified, the natural mask is used.	-
mask	Specifies the mask of the network segment address.	The value is in dotted decimal notation.
mask-length	Specifies the network mask length.	The value is an integer that ranges from 0 to 32.

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. Before a DHCP server assigns IP addresses to clients from a global address pool, run the **network** command to set a network segment address for the global address pool so that the DHCP server can select and assign IP addresses on this network segment to clients. When a DHCP server assigns an IP address to the client from the interface address pool, the network segment of the interface IP address is that of the interface address pool.

Precautions

- Each IP address pool can be configured with only one network segment. If the system needs multiple address segments, multiple IP address pools are required.
- The size of an address pool can be controlled by setting the mask length. The mask length is in reverse proportion to the address pool size.
- When configuring an address pool, ensure that IP addresses on the network address segment must be class A, B, or C IP addresses, and the mask cannot be set to 0 to 7, 31, or 32.
- If you need to assign IP addresses with a 16-bit mask in the network segment 10.1.1.0 to clients, the number of IP addresses in an IP address pool is 64K after the **network 10.1.1.0 mask 16** command is executed in the view of the IP address pool. If the number of IP addresses in the IP address pool is less than 64K, the **network 10.1.1.0 mask 16** command cannot be executed in the view of the IP address pool. In this case, perform the following operations:

  Run the following commands in the IP address pool view:

  ```
  [HUAWEI-ip-pool-test] ip pool test
  [HUAWEI-ip-pool-test] section 0 10.1.1.2 10.1.1.254  // The section command specifies the range of IP addresses to be allocated.
  [HUAWEI-ip-pool-test] network 10.1.1.1 mask 16  // The network command specifies the mask of IP addresses to be allocated using the mask parameter.
  ```

  Enable the DHCP server function on a specific interface.

  ```
  [HUAWEI-Vlanif10] ip address 10.1.1.1 16
  [HUAWEI-Vlanif10] dhcp select global
  ```
- The size of the IP address pool cannot be larger than 16K.

Example

Set the network segment address of the IP address pool **global1** to 192.168.1.0 and mask length to 24.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] network 192.168.1.0 mask 24
```

6.3.98 next-server

Function

The **next-server** command configures the IP address of a server for the DHCP client after the client automatically obtains the IP address.

The **undo next-server** command deletes a configured IP address of a server for the DHCP client after the client automatically obtains the IP address.

By default, no IP address of a server is configured for the DHCP client after the client automatically obtains the IP address.

Format

next-server *ip-address*

undo next-server

Parameters

Parameter	Description	Value
ip-address	Specifies a server IP address.	The value is in dotted decimal notation.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **next-server** command is used on DHCP servers. When assigning a client an IP address, a DHCP server can also assign the client an IP address of the server that provides network services for the client. For example, after obtaining IP addresses, clients such as IP phones need parameters such as the startup configuration file to work normally. You can run the **next-server** command to specify the server address used after a client obtains an IP address. The client then requests the configuration parameters from the specified server after obtaining an IP address.

If users use addresses in the interface address pool, run the **dhcp server next-server** command to specify the DHCP server IP address. If users use addresses in the global address pool, run the **next-server** command to specify the DHCP server IP address.

Precautions

- Only one IP address of a server that provides network services can be configured in each IP address pool view or DHCP Option template view. If the system needs multiple IP addresses of servers that provide network services, configure multiple IP address pools or DHCP Option templates.
- If you run the **next-server** command multiple times, only the latest configuration takes effect.

Example

In the IP address pool view, set the IP address of a server for the DHCP client after the client automatically obtains the IP address to 10.1.2.2.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] next-server 10.1.2.2
```

In the DHCP Option template view, set the IP address of a server for the DHCP client after the client automatically obtains the IP address to 10.1.2.2.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] next-server 10.1.2.2
```

6.3.99 option

Function

The **option** command configures the user-defined option that a DHCP server assigns to a DHCP client.

The **undo option** command deletes the user-defined option that a DHCP server assigns to a DHCP client.

By default, no user-defined option that a DHCP server assigns to a DHCP client is configured.

Format

option *code* [**sub-option** *sub-code*] { **ascii** *ascii-string* | **hex** *hex-string* | **cipher** *cipher-string* | **ip-address** *ip-address* &<1-8> }

undo option [*code* [**sub-option** *sub-code*]]

Parameters

Parameter	Description	Value
code	Specifies the code of a user-defined option.	The value is an integer that ranges from 1 to 254, except the values 1, 3, 6, 15, 44, 46, 50, 51, 52, 53, 54, 55, 57, 58, 59, 61, 82, 120, 121, and 184. **NOTE** There are well-known options and user-defined options. For details about well-known options, see RFC 2132. When the switch functions as a DHCP client, Option 148 can be used in an EasyDeploy scenario and is not recommended in other scenarios.
sub-option *sub-code*	Specifies the code of a user-defined sub-option.	The value is an integer that ranges from 1 to 254. For details about well-known options, see RFC 2132.
ascii *ascii-string*	Specifies the user-defined option code as an ASCII character string.	The value is a string of case-sensitive characters with spaces supported. If **sub-option** is not specified, the value is a string of 1 to 255 characters. If **sub-option** is specified, the value is a string of 1 to 253 characters.

Parameter	Description	Value
hex *hex-string*	Specifies the user-defined option code as a hexadecimal character string.	The value is a hexadecimal string with an even number of characters, for example, hh or hhhh. If **sub-option** is not specified, the value without spaces ranges from 1 to 254 characters; if **sub-option** is specified, the value without spaces ranges from 1 to 252. The value can be a combination of digits (0-9), uppercase letters (A-F), and lowercase letters (a-f).
cipher *cipher-string*	Specifies the user-defined option code as a ciphertext character string.	The value is a character string either in plain text or cipher text. ● The character string in plain text is a string of 1 to 64 characters. ● The character string in cipher text is a string of 32 to 108 characters. No matter whether the character string is entered in plain or cipher text, the character string is displayed in cipher text in the configuration file and in plain text in packets.
ip-address *ip-address*	Specifies the user-defined option code as an IP address.	The value is in dotted decimal notation.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. The option field in a DHCP packet carries control information and parameters. If a DHCP server is configured with options, when a DHCP client applies for an IP address, the client can obtain the configurations in the option field of the DHCP response packet from the DHCP server. To configure user-defined options for an interface address pool, run the **dhcp server option** command.

Precautions

- To ensure configuration accuracy, read the Request For Comments (RFC) before configuring options.
- When an option contains a password, the option code of the **ascii** or **hex** type is insecure. You are advised to set the option code type to **cipher**. For security purposes, a password must contain at least two types of the following: lowercase letters, uppercase letters, digits, and special characters. In addition, the password must consist of at least eight characters.
- Note the following if the **option** *code* [**sub-option** *sub-code*] { **ascii** *ascii-string* | **hex** *hex-string* | **cipher** *cipher-string* | **ip-address** *ip-address* &<1-8> } command is not executed for the first time:
  - If the new *code* is different from the existing *code*, both the new and existing configurations take effect.
  - If the new *code* is the same as the existing *code*, the following situations may occur:
    - When a *sub-code* is specified in the existing command, the new configuration overrides the existing configuration if the new and existing *sub-code*s are the same, and both the new and existing configurations take effect if the new and existing *sub-code*s are different. If no *sub-code* is specified in the new command, the new configuration overrides the existing configuration.
    - When no *sub-code* is specified in the existing command, the new configuration overrides the existing configuration.
- If the device functions as the DHCP server to assign IP addresses to APs, and the AC and APs are on different network segments, you need to configure the Option 43 field to specify the AC IP address for the APs. Otherwise, the APs cannot discover the AC. Run the **option 43** { **hex** *hex-string* | [**sub-option** 1 **hex** *hex-string* | **sub-option** 2 **ip-address** *ip-address* &<1-8> | **sub-option** 3 **ascii** *ascii-string*] } command to configure the device to specify the AC IP address for APs in one of the following methods:

  a. Run the **option 43 hex 031D3139322e3136382e3139342e35302c3139322e3136382e3139342e3534** command to configure the device to specify AC IP addresses 192.168.194.50 and 192.168.194.54 for APs. In this command, **03** indicates that the sub-option value of Option43 is an ASCII value; **1D** indicates that the length of IP addresses (192.168.194.50,192.168.194.54) including dots (.) and the comma (,) is 29, and multiple IP addresses are separated by the comma (,); **3139322e3136382e3139342e3530** indicates the ASCII value of 192.168.194.50; **2C** indicates the ASCII value of the comma (,); **3139322e3136382e3139342e3534** indicates the ASCII value of 192.168.194.54.

b. Run the **option 43 sub-option 1 hex C0A80001C0A80002** command to configure the device to specify AC IP addresses 192.168.0.1 and 192.168.0.2 for APs. In the command, **C0A80001** indicates the hexadecimal format of 192.168.0.1, and **C0A80002** indicates the hexadecimal format of 192.168.0.2.

c. Run the **option 43 sub-option 2 ip-address 192.168.0.1 192.168.0.2** command to configure the device to specify AC IP addresses 192.168.0.1 and 192.168.0.2 for APs.

d. Run the **option 43 sub-option 3 ascii 192.168.0.1,192.168.0.2** command to configure the device to specify AC IP addresses 192.168.0.1 and 192.168.0.2 for APs.

NOTE

If you need to configure multiple IP addresses when the option is specified as an ASCII character string, use commas (,) to separate the IP addresses.

If the AC and APs are on the same network segment, you do not need to configure the Option 43 field, and the APs can discover the AC in broadcast mode. After Option 43 is configured, the APs unicast Discover Request packets to the IP address carried in Option 43 to discover the AC. If the APs do not receive any Discovery Response packet after sending unicast Discovery Request packets, the APs then broadcast packets to discover the AC.

- When users on an enterprise's intranet use a proxy server to connect to the Internet, you need to configure proxy server parameters so that users can use browsers to access the network. The Web Proxy Auto-Discovery Protocol (WPAD) implements automatic configuration of these parameters. The administrator does not need to manually configure these parameters on each client. To implement the WPAD function, the administrator needs to deploy the configuration file of the proxy server in advance, and then run the **option 252 ascii** *ascii-string* command to specify the URL of the configuration file. The *ascii-string* parameter specifies the URL of the configuration file, in the format of https://*xxx*/proxy.pac. Set *ascii-string* according to the storage path of the configuration file. When a browser accesses the network, the browser requests the DHCP server to send the URL of the configuration file on the proxy server, and then downloads the configuration file to conduct automatic configuration. After the configuration is completed, the browser can access the network.

NOTE

The value of *ascii-string* cannot be enclosed in double quotation marks as "*ascii-string*". Otherwise, terminals cannot parse Option252.

Example

In the global address pool **global1**, configure Option64 to 0x11 (a hexadecimal number).

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] option 64 hex 11
```

In the DHCP Option template **template1**, configure Option64 to 0x11 (a hexadecimal number).

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] option 64 hex 11
```

6.3.100 option121

Function

The **option121** command configures the classless static route for the DHCP client.

The **undo option121** command deletes a configured classless static route.

By default, no classless static route is configured.

Format

option121 ip-address { *ip-address mask-length gateway-address* } &<1-8>

undo option121 [**ip-address** *ip-address mask-length gateway-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the destination IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer that ranges from 0 to 32.
gateway-address	Specifies the gateway address of a route.	The value is in dotted decimal notation.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **option121** command applies to only the DHCP server. The **option121** command configures Option 121 that defines a classless static route allocated to a client.

mask-length and *gateway-address* specify a classless static route. The **option121** command configures a maximum of eight classless static routes.

Precautions

- To configure multiple classless static routes, run the **option121** command repeatedly.
- The **undo option121** command will delete all classless static routes. To delete one classless static route, run the **undo option121 ip-address** *ip-address mask-length gateway-address* command.

Example

In the IP address pool view, configure classless static routes delivered by the DHCP server.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] option121 ip-address 10.10.10.10 24 10.11.11.11
```

In the DHCP Option template view, configure classless static routes delivered by the DHCP server.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] option121 ip-address 10.10.10.10 24 10.11.11.11
```

6.3.101 option125 vendor-specific

Function

The **option125 vendor-specific** command configures the vendor ID in Option 125 for a DHCP client.

The **undo option125 vendor-specific** command deletes the vendor ID in Option 125 for a DHCP client.

By default, no vendor ID is configured in Option 125.

Format

option125 vendor-specific *vendor-id*

undo option125 vendor-specific

Parameters

Parameter	Description	Value
vendor-id	Indicates the vendor ID, which is assigned by the IANA. 2011 indicates Huawei.	The value is an integer in the range from 1 to 4294967295.

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a DHCP client sends a DHCP Discover message carrying a vendor ID to a DHCP server, the DHCP server needs to exchange the vendor information with the client using Option 125. You can run the **option 125** [**sub-option** *sub-code*] **ascii** *ascii-string* command to configure the vendor ID in Option 125 delivered by a DHCP server to a client. However, it is complex to convert the vendor ID into an ASCII character string.

To simplify the configuration, you can run the **option125 vendor-specific** *vendor-id* command to specify the vendor ID in Option 125 of packets sent from a DHCP server to a client.

Prerequisites

1. A global address pool has been created using the **ip pool** command in the system view, and the IP address pool view is displayed.
2. Fields except **Vendor-ID** in Option 125 have been configured for the global address pool using the **option 125 ascii** *ascii-string* command. The **Vendor-ID** field in Option 125 occupies four bytes. Therefore, the *ascii-string* value is a string of 1 to 251 bytes.
3. (Optional) The **force insert option 125** command has been used to configure the DHCP server to insert the Option 125 field specified for the global address pool into the DHCP response packet sent from a DHCP server to a client. This resolves the problem in the following situation: The device functions as a DHCP server, and the DHCP request packet sent by a DHCP client does not carry Option 125. However, the DHCP client still expects the DHCP server to deliver Option 125 configured for the global address pool.

Precautions

This command and the **option 125 sub-option** *sub-code* **ascii** *ascii-string* command are mutually exclusive in an IP address pool.

Example

Configure the VLAN and vendor information in Option 125 in the IP address pool view.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] option 125 ascii id:vlan=10
[HUAWEI-ip-pool-global1] option125 vendor-specific 2011
```

6.3.102 option184

Function

The **option184** command configures the Option 184 field for the DHCP client.

The **undo option184** command deletes a configuration in the Option 184 field.

By default, no content in the Option 184 field is configured.

Format

option184 { **as-ip** *ip-address* | **fail-over** *ip-address dialer-string* | **ncp-ip** *ip-address* | **voice-vlan** *vlan-id* }

undo option184 [**as-ip** | **fail-over** | **ncp-ip** | **voice-vlan**]

Parameters

Parameter	Description	Value
ncp-ip *ip-address*	Specifies the IP address of the network call processor (NCP).	The value is in dotted decimal notation.
as-ip *ip-address*	Specifies the IP address of the backup NCP.	The value is in dotted decimal notation.
fail-over *ip-address*	Specifies the IP address in the failover route.	The value is in dotted decimal notation.
dialer-string	Specifies the dialer string.	The value is a string of 1 to 64 characters.
voice-vlan *vlan-id*	Specifies the ID of a voice VLAN.	The value is an integer that ranges from 1 to 4094.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

The **option184** command applies to only the DHCP server and configures Option 184 allocated by a DHCP server to a client in a global address pool.

Example

In the IP address pool view, configure the Option 184 field.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] option184 as-ip 192.168.1.10
```

In the DHCP Option template view, configure the Option 184 field.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] option184 as-ip 10.10.10.10
```

6.3.103 reset dhcp client statistics

Function

The **reset dhcp client statistics** command clears packet statistics about a DHCP client.

Format

reset dhcp client statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clear packet statistics about the DHCP client of the specified interface. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset dhcp client statistics** command is applicable to DHCP client. During DHCP troubleshooting, statistics about the packets sent and received within a specified period need to be checked. Therefore, before collecting packet statistics, run the **reset dhcp client statistics** command to clear the existing packet statistics. Then you can run the **display dhcp client statistics** command to check packet statistics about the DHCP client.

Precautions

The **reset dhcp client statistics** command can be run multiple times at any interval.

Example

Clear packet statistics about the DHCP client.

```
<HUAWEI> reset dhcp client statistics
```

6.3.104 reset dhcp relay statistics

Function

The **reset dhcp relay statistics** command clears message statistics on a DHCP relay agent.

Format

reset dhcp relay statistics [**server-group** *group-name*]

Parameters

Parameter	Description	Value
server-group *group-name*	Specifies the name of a DHCP server group.	The value is a string of 1 to 32 characters without spaces. A combination of digits, letters, underscores (_), and dots (.) is allowed.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to DHCP relay agents. Collecting statistics on the DHCP messages sent and received within a specified period helps you locate DHCP faults. Run the **reset dhcp relay statistics** [**server-group** *group-name*] command to clear original statistics on DHCP messages, and run the **display dhcp relay statistics** [**server-group** *group-name*] command to view packet statistics about the DHCP relay agent.

- Run the **reset dhcp relay statistics server-group** *group-name* command to clear message statistics on DHCP relay agents connected to DHCP servers in a specified DHCP server group. The DHCP server group name needs to be specified.
- Run the **reset dhcp relay statistics** command to clear message statistics on all DHCP relay agents besides DHCP relay agents connected to DHCP servers in the DHCP server group.

Precautions

The **reset dhcp relay statistics** command can be run multiple times at any interval.

Example

Clear message statistics on the DHCP relay agent.

```
<HUAWEI> reset dhcp relay statistics
```

6.3.105 reset dhcp server statistics

6.3.107 reset ip pool

Function

The **reset ip pool** command resets the IP address pool configured on the device.

Format

reset ip pool { **interface** *interface-name* | **name** *ip-pool-name* } { *start-ip-address* [*end-ip-address*] | **all** | **conflict** | **expired** | **used** }

Parameters

Parameter	Description	Value
interface *interface-name*	Specifies the name of the interface address pool to be reset, which is represented by the type and number of an interface.	The value is a string of 1 to 64 characters without spaces. A combination of digits, letters, underscores (_), and dots (.) is allowed.
name *ip-pool-name*	Specifies the name of the global address pool to be reset.	The value is a string of 1 to 64 characters without spaces. A combination of digits, letters, underscores (_), and dots (.) is allowed.
start-ip-address	Specifies the start IP address of the IP address pool to be reset.	The value is in dotted decimal notation.
end-ip-address	Specifies the end IP address of the IP address pool to be reset.	The value is in dotted decimal notation.
all	Indicates that all the IP addresses need to be reset.	-
conflict	Indicates that the conflicting IP addresses need to be reset.	-
expired	Indicates that the expired IP addresses need to be reset.	-
used	Indicates that the used IP addresses need to be reset.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset ip pool** command resets the IP addresses that cannot be released in an IP address pool. If an IP address conflict occurs because two clients use the same IP address, run the **reset ip pool** command to reset the specified IP address pool.

Precautions

If a user's IP address is within the IP address range specified when this command is run, the user cannot continue to use the IP address after this command is run, and needs to send an IP address application request again.

The address pool status cannot be restored after this command is run. Therefore, exercise caution when deciding to run this command.

User information cannot be restored after you clear it. Exercise caution when running the **reset ip pool** command. DHCP clients must release their old IP addresses before obtaining new IP addresses.

Follow-up Procedure

After the address pool is set to idle, the client can obtain an IP address from the global address pool.

Example

Reset the conflicting IP addresses in the IP address pool **mypool**.

```
<HUAWEI> reset ip pool name mypool conflict
```

6.3.108 section (IP address pool view)

Function

The **section** command configures an IP address range in an IP address pool.

The **undo section** command deletes a configured IP address range from an IP address pool.

By default, no IP address range is configured in an IP address pool.

Format

section *section-id start-address* [*end-address*]

undo section *section-id*

Parameters

Parameter	Description	Value
section-id	Specifies the ID of an address range in an IP address pool.	The value is an integer in the range from 0 to 255.

Parameter	Description	Value
start-address	Specifies the start IP address of the address range.	The value is in dotted decimal notation.
end-address	Specifies the end IP address of the address range. **NOTE** The end IP address must be greater than or equal to the start IP address. If the end IP address is not specified, the IP address range contains only one IP address.	The value is in dotted decimal notation.

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

An IP address pool consists of one or more IP address ranges. The IP addresses in the IP address ranges cannot overlap.

Example

Configure an IP address range 10.1.1.10 to 10.1.1.15 in the IP address pool **abc**, and set the ID of the IP address range to 0.

```
<HUAWEI> system-view
[HUAWEI] ip pool abc
[HUAWEI-ip-pool-abc] section 0 10.1.1.10 10.1.1.15
```

6.3.109 sip-server (IP address pool view)

Function

The **sip-server** command configures the SIP server IP address assigned to a DHCP client in a global address pool.

The **undo sip-server** command deletes the configured SIP server IP address assigned to a DHCP client in a global address pool.

By default, the SIP server IP address assigned to a DHCP client in a global address pool is not configured.

Format

sip-server { **ip-address** *ip-address* &<1-2> | **list** *domain-name* &<1-2> }

undo sip-server

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies an IP address for the SIP server.	The value is in dotted decimal notation.
list *domain-name*	Specifies the domain name of the SIP server.	The value is a string of 1 to 63 characters.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to the DHCP server. To enable DHCP clients to normally access the Internet, the DHCP server needs to specify the SIP server IP address in the address pool when assigning IP addresses to the clients.

Precautions

- A maximum of two SIP server addresses can be configured in each address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- Before specifying the IP address or name for a SIP server, ensure that the SIP server exists.
- If you run this command repeatedly, the latest configuration overrides the previous ones.

Example

Specify 192.168.1.1 as the IP address of the SIP server when addresses in the global address pool **global1** are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] sip-server ip-address 192.168.1.1
```

6.3.110 sname

Function

The **sname** command configures the name of the server from which the DHCP client obtains the startup configuration file.

The **undo sname** command deletes the configured name of the server from which the DHCP client obtains the startup configuration file.

By default, no name is configured for the server from which the DHCP client obtains the startup configuration file.

Format

sname *sname*

undo sname

Parameters

Parameter	Description	Value
sname	Specifies the name of the server where the DHCP client obtains the startup configuration file.	The value is a string of 1 to 63 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IP address pool view, DHCP Option template view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Besides assigning IP addresses, a DHCP server can also provide the required network configuration parameters, such as the startup configuration file name for the DHCP client. After the name of the server from which the DHCP client obtains the startup configuration file is configured using the **sname** command, the DHCP client obtains the startup configuration file from this server.

Precautions

Ensure that the route between the DHCP client and the file server from which the DHCP client obtains the startup configuration file is reachable.

Example

In the IP address pool view, configure the name of the server from which the DHCP client obtains the startup configuration file as **example**.

```
<HUAWEI> system-view
[HUAWEI] ip pool p1
[HUAWEI-ip-pool-p1] sname example
```

In the DHCP Option template view, configure the name of the server from which the DHCP client obtains the startup configuration file as **example**.

```
<HUAWEI> system-view
[HUAWEI] dhcp option template template1
[HUAWEI-dhcp-option-template-template1] sname example
```

6.3.111 static-bind

Function

The **static-bind** command binds an IP address in a global address pool to a MAC address of a client.

The **undo static-bind** command unbinds the IP address in a global address pool from a MAC address.

By default, the IP address in a global address pool is not bound to any MAC address.

Format

static-bind ip-address *ip-address* **mac-address** *mac-address* [**option-template** *template-name* | **description** *description*]

undo static-bind [**ip-address** *ip-address* | **mac-address** *mac-address*]

Parameters

Parameter	Description	Value
ip-address *ip-address*	Specifies the IP address to be bound. The IP address must be a valid IP address in the global address pool.	The value is in dotted decimal notation.
mac-address *mac-address*	Specifies the user MAC address.	The value is in H-H-H format. An H is a hexadecimal number of 1 to 4 digits.

Parameter	Description	Value
option-template *template-name*	Specifies the name of the DHCP Option template. To allocate network configuration parameters except IP addresses to static clients, specify the parameter. Before specifying the parameter, run the **dhcp option template** command to create a DHCP option template, and configure network parameters for static clients in the DHCP Option template view.	The name is a string of 1 to 31 case-sensitive characters without spaces.
description *description*	Specifies the user description.	The value is a string of 1 to 256 case-sensitive characters. It can contain spaces.

Views

IP address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **static-bind** command applies to DHCP servers. When planning a network, you need to allocate fixed IP addresses to some important hosts to ensure reliability. In this case, you can bind IP addresses in the address pool to the MAC addresses of these hosts. After the preceding configuration is complete, if the host of the MAC address to which the IP address is bound request an IP address from the DHCP server, the DHCP server finds the bound IP address based on the host's MAC address and allocates this IP address to the host, ensuring that the IP address obtained by the host is fixed.

You can run the **static-bind** command to bind an IP address in a global address pool to a MAC address.

You can run the **dhcp server static-bind** command to bind an IP address in an interface address pool to a MAC address.

Prerequisites

Network segment addresses that can be assigned from the global address pool have been configured using the **network (IP address pool view)** command.

Precautions

- Ensure that the bound IP address is not configured as the IP address that cannot be allocated using the **excluded-ip-address** command.
- IP addresses that are used can also be statically bound to MAC addresses or unbound from MAC addresses. When an IP address is statically bound to a MAC address, ensure that the MAC address to be bound is the same as the MAC address of the user who actually uses the IP address.
- The DHCP server preferentially allocates the IP address that has been statically bound to the client's MAC address.
- After an IP address is bound to a MAC address, the IP address does not expire. After an automatically allocated IP address is statically bound to a MAC address, the lease time of the IP address becomes unlimited. After the static binding between the IP address and the MAC address is deleted, the lease time of the IP address becomes the same as that configured in the address pool.

Example

Configure a DHCP server to assign a fixed IP address 192.168.1.10 in the global address pool **global1** to a host with the MAC address 00e0-fc96-e4c0.

```
<HUAWEI> system-view
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] network 192.168.1.10 mask 24
[HUAWEI-ip-pool-global1] static-bind ip-address 192.168.1.10 mac-address 00e0-fc96-e4c0
```

6.3.112 vpn-instance (global address pool view)

Function

The **vpn-instance** command binds an IP address pool to a VPN instance.

The **undo vpn-instance** command restores the default setting.

By default, an IP address pool is not bound to any VPN instance.

Format

vpn-instance *vpn-instance-name*

undo vpn-instance

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

Global address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command applies to DHCP servers. To apply DHCP services in a VPN instance, you need to run the **vpn-instance** command to bind the created IP address pool to the VPN instance.

Prerequisites

A VPN instance has been created using the **ip vpn-instance** command.

Precautions

- The VPN instance bound to the IP address pool on the DHCP server must be the same as the VPN instance bound to the DHCP server group on the DHCP relay agent; otherwise, users in the IP address pool cannot go online using this DHCP server group.
- If an IP address pool is bound to a VPN instance, IP addresses assigned from this address pool are VPN addresses.
- To bind an interface address pool to a VPN instance, run the **ip binding vpn-instance** command in the interface view.

Example

Bind the address pool **global1** to the VPN instance **example**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance example
[HUAWEI-vpn-instance-example] ipv4-family
[HUAWEI-vpn-instance-example-af-ipv4] quit
[HUAWEI-vpn-instance-example] quit
[HUAWEI] ip pool global1
[HUAWEI-ip-pool-global1] vpn-instance example
```

6.4 DHCP Policy VLAN Configuration Commands

6.4.1 Command Support

Only the following switch models support DHCP policy VLAN:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.4.2 dhcp policy-vlan generic

Function

The **dhcp policy-vlan generic** command configures the generic DHCP policy VLAN.

The **undo dhcp policy-vlan generic** command deletes the generic DHCP policy VLAN.

By default, the function of generic DHCP policy VLAN is disabled on the device.

Format

dhcp policy-vlan generic [**priority** *priority*]

undo dhcp policy-vlan generic

Parameters

Parameter	Description	Value
priority *priority*	Specifies the 802.1p priority of DHCP messages.	The value is an integer that ranges from 0 to 7. The default value is 0.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure three types of DHCP policy VLAN on the device at the same time. They are listed in descending order based on priorities as follows:

- DHCP policy VLAN based on MAC addresses
- DHCP policy VLAN based on interfaces
- Generic DHCP policy VLAN

On a network supporting VLAN assignment based on IP subnets, upon receiving an untagged packet from a host, a switch adds a VLAN ID to the packet based on the source IP address of the packet. A host that accesses the network for the first time does not have a valid IP address. Therefore, the switch cannot add the host to the VLAN and the host cannot obtain a valid IP address or network settings. To make the host obtain a valid IP address from the DHCP server, run the **dhcp policy-vlan generic** command to configure the generic policy VLAN.

Hosts that access the network for the first time apply the generic DHCP policy VLAN only when they cannot apply DHCP policy VLAN based on MAC addresses or interfaces.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

Precautions

If you run this command in multiple VLAN views, only the latest configuration takes effect.

Example

Configure the generic DHCP policy VLAN, associate DHCP packets that match no MAC address or interface to VLAN 100, and set the 802.1p priority of the packets to 5.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp policy-vlan generic priority 5
```

6.4.3 dhcp policy-vlan mac-address

Function

The **dhcp policy-vlan mac-address** command configures the MAC address-based DHCP policy VLAN.

The **undo dhcp policy-vlan mac-address** command deletes the MAC address-based DHCP policy VLAN.

By default, the function of DHCP policy VLAN based on MAC addresses is disabled on the device.

Format

dhcp policy-vlan mac-address *mac-address1* [**to** *mac-address2*] [**priority** *priority*]

undo dhcp policy-vlan mac-address *mac-address1* [**to** *mac-address2*]

Parameters

Parameter	Description	Value
mac-address1 [**to** *mac-address2*]	Specifies the MAC addresses of user hosts that access the network for the first time. - *mac-address1* specifies the start MAC address. - **to** *mac-address2* specifies the end MAC address. *mac-address2* must be greater than *mac-address1*. *mac-address2* and *mac-address1* specify the MAC address range. If **to** *mac-address2* is not specified, DHCP policy VLAN based on only the MAC address specified by *mac-address1* is configured.	*mac-address1* and *mac-address2* are in the format of H-H-H. An H contains one to four hexadecimal numbers. **NOTE** The range specified by *mac-address1* and *mac-address2* cannot contain multicast MAC addresses, broadcast MAC addresses, and all 0 address. The number of MAC addresses cannot exceed 512.
priority *priority*	Specifies the 802.1p priority of DHCP messages.	The value is an integer that ranges from 0 to 7. The default value is 0.

Usage Guidelines

Usage Scenario

You can configure three types of DHCP policy VLAN on the device at the same time. They are listed in descending order based on priorities as follows:

- DHCP policy VLAN based on MAC addresses
- DHCP policy VLAN based on interfaces
- Generic DHCP policy VLAN

On a network supporting VLAN assignment based on IP subnets, upon receiving an untagged packet from a host, a switch adds a VLAN ID to the packet based on the source IP address of the packet. A host that accesses the network for the first time does not have a valid IP address. Therefore, the switch cannot add the host to the VLAN and the host cannot obtain a valid IP address or network settings. To make the host obtain a valid IP address from the DHCP server, run the **dhcp policy-vlan mac-address** command to configure the MAC address-based DHCP policy VLAN.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

Precautions

If you run this command based on the same MAC address in multiple VLAN views, only the latest configuration takes effect.

Example

Configure the MAC address-based DHCP policy VLAN, associate DHCP packets from the host with the MAC address 00e0-fc01-0001 to VLAN 100, and set the 802.1p priority of the packets to 5.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp policy-vlan mac-address 1-1-1 priority 5
```

6.4.4 dhcp policy-vlan port

Function

The **dhcp policy-vlan port** command configures the interface-based DHCP policy VLAN.

The **undo dhcp policy-vlan port** command deletes the interface-based DHCP policy VLAN.

By default, the function of DHCP policy VLAN based on interfaces is disabled on the device.

Format

dhcp policy-vlan port *interface-type interface-number1* [**to** *interface-number2*] &<1-10> [**priority** *priority*]

undo dhcp policy-vlan port *interface-type interface-number1* [**to** *interface-number2*] &<1-10>

Parameters

Parameter	Description	Value
interface-type interface-number1 [**to** *interface-number2*] &<1-10>	Specifies the interface type and interface number. - *interface-type* specifies the type of an interface. - *interface-number1* specifies the number of the start interface. - **to** *interface-number2* specifies the number of the end interface. *interface-number2*must be greater than *interface-number1*. *interface-number2* and *interface-number1* specify the interface range. If **to** *interface-number2* is not specified, DHCP policy VLAN based on only the interface specified by *interface-number1* is configured. **NOTE** The interface cannot be a stack interface.	-
priority *priority*	Specifies the 802.1p priority of DHCP messages.	The value is an integer that ranges from 0 to 7. The default value is 0.

Usage Guidelines

Usage Scenario

You can configure three types of DHCP policy VLAN on the device at the same time. They are listed in descending order based on priorities as follows:

- DHCP policy VLAN based on MAC addresses

- DHCP policy VLAN based on interfaces
- Generic DHCP policy VLAN

On a network supporting VLAN assignment based on IP subnets, upon receiving an untagged packet from a host, a switch adds a VLAN ID to the packet based on the source IP address of the packet. A host that accesses the network for the first time does not have a valid IP address. Therefore, the switch cannot add the host to the VLAN and the host cannot obtain a valid IP address or network settings. To make the host obtain a valid IP address from the DHCP server, run the **dhcp policy-vlan port** command to configure the interface-based policy VLAN.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command in the system view.

Precautions

If you run this command on an interface in multiple VLAN views, only the latest configuration takes effect.

NOTE

The interface-based DHCP policy VLAN takes effect only for hybrid interfaces. If an interface is not hybrid, run the **port link-type hybrid** command to configure it as a hybrid interface.

Example

Configure the interface-based DHCP policy VLAN, associate DHCP packets received on GigabitEthernet0/0/1 with VLAN 100, and set the 802.1p priority of the packets to 5.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI--GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI--GigabitEthernet0/0/1] quit
[HUAWEI] dhcp enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] dhcp policy-vlan port gigabitethernet 0/0/1 priority 5
```

6.5 DNS Configuration Commands

6.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

6.5.2 display dns dynamic-host

Function

The **display dns dynamic-host** command displays dynamic DNS entries.

Format

display dns dynamic-host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays dynamic DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.
all	Displays all dynamic DNS entries, including both public and private DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public dynamic DNS entries are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display dns dynamic-host** command to view dynamic DNS entries and check whether domain names match the mapping entries.

Example

Display dynamic DNS entries.

```
<HUAWEI> display dns dynamic-host
No  Domain-name         IpAddress      TTL    Alias
1   www.example.com     10.1.1.1       3521
2   www.huawei.com     10.1.2.1       3000
```

Display dynamic DNS entries of the VPN instance vpn1.

```
<HUAWEI> display dns dynamic-host vpn-instance vpn1
No  Domain-name                        Alias                 IpAddress           TTL      VPN-Instance
1   www.example.com                                          10.1.3.1            3521     vpn1
2   www.huawei.com                                          10.1.4.1            3000     vpn1
```

Table 6-30 Description of the **display dns dynamic-host** command output

Item	Description
No	Number of a dynamic DNS entry.
Domain-name	Domain name.
IpAddress	IP addresses of the host.
TTL	Remaining lifetime of DNS entries (in seconds).
Alias	Alias of a host.
VPN-Instance	VPN instance name.

6.5.3 display dns domain

Function

The **display dns domain** command displays information about the domain name suffixes.

Format

display dns domain [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about domain name suffixes of a specified VPN instance.	The value must be an existing VPN instance name.
all	Displays information about all domain name suffixes, including both public and private domain name suffixes. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only information about public domain name suffixes is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display dns domain** command displays the configuration of domain name suffixes and the order in which they are configured.

Example

Display the list of domain name suffixes.

```
<HUAWEI> display dns domain
No                    Domain-name
1                    com
2                    net
```

Display the list of domain name suffixes of the VPN instance vpn1.

```
<HUAWEI> display dns domain vpn-instance vpn1
No          Domain-name         VPN-Instance
1           com.cn              vpn1
```

Table 6-31 Description of the **display dns domain** command output

Item	Description
No	Indicates the domain name suffix numbers, that is, the configuration sequence of domain name suffixes.
Domain-name	Indicates the configured domain name suffix. If there are multiple domain name suffixes in the list, during DNS resolution, the first suffix is added and sent to the DNS server. If the DNS server gives no response, the query message is resent; if the DNS server still gives no response, the query message is resent for a third time; if the DNS server still does not respond, the next suffix is added and sent to the DNS server for searching for the mapped address. The value is set using the **dns domain** command.
VPN-Instance	VPN instance name. The value is set using the **dns domain** command.

6.5.4 display dns server

Function

The **display dns server** command displays information about DNS servers.

Format

display dns server [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about DNS servers of a specified VPN instance.	The value must be an existing VPN instance name.
all	Displays information about all DNS servers, including both public and private DNS servers. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only information about public DNS servers is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring DNS server addresses, you can run the **display dns server** command to view the configuration and sequence of DNS servers.

Example

Display information about DNS servers.

```
<HUAWEI> display dns server
IPv4 Dns Servers :
Domain-server        IpAddress
    1               10.16.1.1
    2               10.17.1.1

IPv6 Dns Servers :
Domain-server        Ipv6Address                          (Interface Name)
    1               FC00:1::1
```

Display information about the DNS servers of the VPN instance vpn1.

```
<HUAWEI> display dns server vpn-instance vpn1
IPv4 Dns Servers :
Domain-server        IpAddress           VPN-Instance
    1               172.16.1.1          vpn1
    2               172.16.1.2          vpn1

IPv6 Dns Servers :
No configured servers.
```

Table 6-32 Description of the **display dns server** command output

Item	Description
IPv4 Dns Servers	IPv4 DNS server configuration.
Domain-server	DNS server number, indicating the order in which they were configured.
IpAddress	IP address of the DNS server. During DNS resolution, the first DNS server is used. If this server fails to resolve packets, the second DNS server is used. The value is set using the **dns server** command.
IPv6 Dns Servers	IPv6 DNS server configuration.
Ipv6Address	IPv6 address of the IPv6 DNS server. The value is set using the **dns server ipv6** command.
Interface Name	Interface name, which only corresponds to the local IPv6 link address. The value is set using the **dns server ipv6** command.
VPN-Instance	VPN instance name. The value is set using the **dns server** command.

6.5.5 display ip host

Function

The **display ip host** command displays the static DNS entries.

Format

display ip host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays static DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
all	Displays all static DNS entries, including both public and private static DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public static DNS entries are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **ip host** command to configure static DNS entries, you can run this command to check whether mappings between host names and IP addresses are correct. You can run the **display ip host** command to view static DNS entries.

Example

Display static DNS entries.

```
<HUAWEI> display ip host
Host                  Age        Flags  Address
www.3322.org          0          static 10.1.1.1
members.3322.org      0          static 10.1.2.1
checkip.dyndns.com    0          static 10.1.3.1
members.dyndns.org    0          static 10.1.4.1
```

Display static DNS entries of VPN instance vpn1.

```
<HUAWEI> display ip host vpn-instance vpn1
Host           Age         Flags      Address        VPN-Instance
RTB            0           static     10.1.5.1       vpn1
```

Table 6-33 Description of the **display ip host** command output

Item	Description
Host	Host name. The value is set using the **ip host** command.
Age	Aging time. The value 0 indicates a static DNS entry. Static entries are not aged out.
Flags	Status of the domain name. The value static indicates a static domain name.

Item	Description
Address	IP address mapping the domain name. The value is set using the **ip host** command.
VPN-Instance	VPN instance name. The value is set using the **ip host** command.

6.5.6 dns domain

Function

The **dns domain** command configures a domain name suffix.

The **undo dns domain** command deletes a domain name suffix.

By default, no domain name suffix is configured.

Format

dns domain *domain-name* [**vpn-instance** *vpn-instance-name*]

undo dns domain [*domain-name* [**vpn-instance** *vpn-instance-name*]]

Parameters

Parameter	Description	Value
domain-name	Specifies the suffix of a domain name.	The value is a string of 1 to 63 characters without spaces. A combination of digits, letters, underscores (_), hyphens (-), and dots (.) is allowed.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Many servers or hosts have the same suffix. In this case, you can configure domain name suffixes. For example, you can configure a suffix com.cn for the host whose domain name is huawei. When a DNS client accesses the host, it enters only "huawei" to send a query message to the DNS server. The DNS client automatically adds the suffix com.cn. Then the DNS server searches for the IP address mapped to "huawei.com.cn" first. If receiving no response, the DNS client sends a query message containing "huawei" to the DNS server to search for the mapped IP address.

Precautions

The switch supports a maximum of 10 domain name suffixes. To configure multiple domain name suffixes, you can run the **dns domain** command repeatedly.

If the name of the suffix to be deleted is specified, the specified suffix is deleted. Otherwise, all the suffixes are deleted.

If **vpn-instance** *vpn-instance-name* is specified, the specified domain name suffix can be used to search for the IP address corresponding to a domain name only when users access the domain name from the specified VPN instance.

Example

Configure a domain name suffix as com.cn.

```
<HUAWEI> system-view
[HUAWEI] dns domain com.cn
```

6.5.7 dns resolve

Function

The **dns resolve** command enables dynamic domain name resolution.

The **undo dns resolve** command disables dynamic domain name resolution.

By default, dynamic domain name resolution is disabled.

Format

dns resolve

undo dns resolve

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To obtain IP addresses mapping domain names using the DNS server, run the **dns resolve** command to enable dynamic domain name resolution on the device.

Example

Enable dynamic domain name resolution.

```
<HUAWEI> system-view
[HUAWEI] dns resolve
```

6.5.8 dns server

Function

The **dns server** command configures the IP address of a DNS server.

The **undo dns server** command deletes the IP address of a DNS server.

By default, no IP addresses of DNS servers are configured.

Format

dns server *ip-address* [**vpn-instance** *vpn-instance-name*]

undo dns server *ip-address* [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a DNS server.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During dynamic domain name resolution, the DNS client can send a query packet to the DNS server, requesting for the IP address of the specified domain name. The DNS client sends a domain name resolution request to the DNS servers according to the order in which they were configured. If the domain name resolution request on the first DNS server times out, the device sends the request to the second DNS server.

If **vpn-instance** *vpn-instance-name* is specified, the system sends domain name resolution requests only to the DNS server bound to the specified VPN instance.

Precautions

A maximum of six DNS server IP (IPv4 and IPv6) addresses can be configured on the switch.

Example

Configure two DNS servers with the IP addresses 172.16.1.1 and 10.10.10.10.

```
<HUAWEI> system-view
[HUAWEI] dns server 172.16.1.1
[HUAWEI] dns server 10.10.10.10
```

6.5.9 dns server source-ip

Function

The **dns server source-ip** command configures the source IP address for the DNS client to communicate with a server.

The **undo dns server source-ip** command deletes the source IP address for the DNS client to communicate with a server.

By default, no source IP address is configured for the DNS client to communicate with a server.

Format

dns server source-ip *ip-address* [**vpn-instance** *vpn-instance-name*]

undo dns server source-ip [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ip-address	Specifies the source IP address for the DNS client to communicate with a server.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When the DNS client communicates with a server, the administrator can specify a source IP address for the client to ensure the communication security. The route from the DNS server to the specified source IP address must be reachable. The DNS server uses the specified source IP address as the destination address and sends a DNS response packet to the client.

If **vpn-instance** *vpn-instance-name* is specified, the specified source IP address is used only when the device communicates with the DNS server bound to the specified VPN instance.

Example

Specify the source IP address 172.16.1.1 for the DNS client to communicate with a server.

```
<HUAWEI> system-view
[HUAWEI] dns server source-ip 172.16.1.1
```

6.5.10 ip host

Function

The **ip host** command configures a static DNS entry.

The **undo ip host** command deletes a static DNS entry.

By default, no static DNS entry is configured.

Format

ip host *host-name ip-address* [**vpn-instance** *vpn-instance-name*]

undo ip host *host-name* [*ip-address* [**vpn-instance** *vpn-instance-name*]]

Parameters

Parameter	Description	Value
host-name	Specifies the host name.	The value is a string of 1 to 255 case-sensitive characters without any space. The value must contain at least one letter, and can consist of letters, digits, hyphens (-), dots (.), and underscores (_).
ip-address	Specifies the IP address mapping the host name.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A static domain name resolution table is manually set up using the **ip host** command, describing the mappings between host names and IP addresses. In addition, some common host names are added to the table. Then, static host name resolution can be performed according to the static domain name resolution table. When requiring the IP address corresponding to a host name, the client first searches the static host name resolution table for the specified host name and obtains the corresponding IP address. In this manner, the efficiency of host name resolution is improved.

Precautions

The **ip host** command configures a maximum of 50 static DNS entries. Each host name can be mapped to only one IP address. When one host name is mapped to multiple IP addresses, only the latest configuration takes effect.

Example

Configure a static DNS entry.

```
<HUAWEI> system-view
[HUAWEI] ip host www.example.com 10.10.10.4
```

6.5.11 reset dns dynamic-host

Function

The **reset dns dynamic-host** command clears dynamic DNS entries.

Format

reset dns dynamic-host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears dynamic DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.
all	Clears all dynamic DNS entries, including both public and private DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public dynamic DNS entries are cleared.	-

2: Configuration level

Usage Guidelines

Usage Scenario

After confirming the action of deleting dynamic DNS entries, you can run the **reset dns dynamic-host** command to delete them.

Precautions

Dynamic DNS entries cannot be restored after being deleted. Confirm the action before you run the command.

Example

Delete all dynamic DNS entries.

```
<HUAWEI> reset dns dynamic-host all
```

6.6 mDNS Gateway Configuration Commands

6.6.1 Command Support

Only the following switch models support mDNS Gateway:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.6.2 display mdns gateway

Function

The **display mdns gateway** command displays the mDNS gateway configuration.

Format

display mdns gateway

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the mDNS gateway is configured, you can run the **display mdns gateway** command to view the mDNS gateway configuration.

Example

Display the mDNS gateway configuration.

```
<HUAWEI> display mdns gateway
mDNS Information:
--------------------------------------------------------------------------------
 mDNS Gateway Status         :  Enable
 mDNS Source IP              :  -
--------------------------------------------------------------------------------
 Gateway Probe Vlan   :  vlan50  vlan101
--------------------------------------------------------------------------------
```

Table 6-34 Description of the display mdns gateway command output

Item	Description
mDNS Gateway Status	mDNS gateway status: ● Enable ● Disable To enable the mDNS gateway, run the **mdns gateway enable** command.
mDNS Source IP	Source IP address in outgoing mDNS request packets when the mDNS gateway is configured to periodically discover services. To specify the source IP address in outgoing mDNS request packets when the mDNS gateway is configured to periodically discover services, run the **mdns source ip** command.
Gateway Probe Vlan	ID of the VLAN where the mDNS gateway is enabled to periodically discover services. To specify the ID of the VLAN where the mDNS gateway is enabled to periodically discover services, run the **mdns probe interval** command.

6.6.3 display mdns gateway statistics

Function

The **display mdns gateway statistics** command displays statistics on the mDNS gateway.

Format

display mdns gateway statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

During routine maintenance and fault location, you can run the **display mdns gateway statistics** command to view statistics on mDNS packets received and sent by the mDNS gateway in a given period of time.

To query statistics again, run the **reset mdns gateway statistics** command to clear existing statistics.

NOTICE

Cleared statistics on the mDNS gateway cannot be restored. Exercise caution when you use the **reset mdns gateway statistics** command.

Example

Display statistics on the mDNS gateway.

```
<HUAWEI> display mdns gateway statistics
mDNS Gateway Statistics:
------------------------------------
 Received        : 1120
  Query          : 411
  Response       : 707
  Discarded      : 29                    Query TimeOut : 22                    Bad source IP :
2
   Bad Pkt Length: 3
   Others        : 2
 Sent            : 681
  Query          : 678
  Response       : 3
```

Table 6-35 Description of the **display mdns gateway statistics** command output

Item	Description
Received	Number of mDNS packets received by the mDNS gateway.
Query	Number of mDNS query packets received by the mDNS gateway.
Response	Number of mDNS response packets received by the mDNS gateway.
Discarded	Number of mDNS packets discarded by the mDNS gateway. **NOTE** This field is displayed only when the value is not 0.
Query TimeOut	Number of packets that are discarded after being accumulated in a queue for more than 5 seconds.

Item	Description
Bad source IP	Number of unicast packets that are sent by untrusted mDNS relay agents and discarded by the mDNS gateway. **NOTE** This field is displayed only when the value of the **Discarded** field is not 0.
Bad Pkt Length	Number of mDNS packets discarded because the packet length exceeds the upper limit. **NOTE** This field is displayed only when the value of the **Discarded** field is not 0.
Others	Number of mDNS packets discarded because of other reasons. **NOTE** This field is displayed only when the value of the **Discarded** field is not 0.
Sent	Number of mDNS packets sent by the mDNS gateway.
Query	Number of mDNS query packets sent by the mDNS gateway.
Response	Number of mDNS response packets sent by the mDNS gateway.

6.6.4 display mdns group

Function

The **display mdns group** command displays mDNS group information.

Format

display mdns group [**name** *group-name* | **user-vlan** *vlan-id*]

Parameters

Parameter	Description	Value
name *group-name*	Displays mDNS group information with a specified name. If the mDNS group with the specified name is not created on the device, no information is displayed.	The mDNS group name must have been created.
user-vlan *vlan-id*	Displays mDNS group information with a specified user VLAN. If the specified user VLAN is not used any mDNS group, no information is displayed.	The user VLAN must have been created.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The device functioning as the mDNS gateway maintains service information lists of all service provisioning devices on a network, and it can use mDNS groups to isolate service resources to provide refined service management. You can run this command to check mDNS group information including the VLANs of the users and service provisioning devices added to the mDNS group.

If **name** *group-name* or **user-vlan** *vlan-id* is not specified in the command, the information about all mDNS groups is displayed.

Example

Display the information about all mDNS groups.

```
<HUAWEI> display mdns group
mDNS Group Information:
--------------------------------------------------------------------------------
 Group Name   :  group1
 User Vlan    :  10
 Service Vlan :  20  30

 Group Name   :  group2
 User Vlan    :  20  30
 Service Vlan :  20  40
--------------------------------------------------------------------------------
Total: 2
```

Table 6-36 Description of the **display mdns group** command output

Item	Description
Group Name	Name of an mDNS group. To configure the mDNS group name, run the **mdns group** command.
User Vlan	VLAN that users in an mDNS group belong to. To configure the VLAN that users in an mDNS group belong to, run the **user-vlan** command.
Service Vlan	VLAN that service provisioning devices in an mDNS group belong to. To configure the VLAN that service provisioning devices in an mDNS group belong to, run the **service-vlan** command.
Total	Number of mDNS groups that have been configured on the device.

6.6.5 display mdns service

Function

The **display mdns service** command displays service information recorded on the mDNS gateway.

Format

display mdns service { **all** [**verbose**] | **name** *name* | **vlan** *vlan-id* }

Parameters

Parameter	Description	Value
all	Displays all service information recorded on the mDNS gateway.	-
name *name*	Displays information about a specified service name recorded on the mDNS gateway.	The service name must have been created.

Parameter	Description	Value
vlan *vlan-id*	Displays service information provided by a specified service VLAN, which is recorded on the mDNS gateway. The VLAN ID indicates the VLAN that the service provisioning device belongs to.	The service VLAN must have been created.
verbose	Displays detailed service information recorded on the mDNS gateway. If this parameter is not specified, the summary of service information recorded on the mDNS gateway is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The device functioning as the mDNS gateway maintains service information lists of all service provisioning devices on a network. You can run this command to check service information recorded on the device.

NOTE

When a service name begins with a space or contains a question mark (?), the **name** parameter cannot be specified in this command.

Example

Display the summary of all services recorded on the mDNS gateway.

```
<HUAWEI> display mdns service all
MDNS Service Info:

Service name : Officejet Pro 8100 [C12FFA] (7)._printer._tcp.local
  SRV Info:
      Domain Name : HPC12FFA-156.local
      Port        : 515
      Vlan Id     : 200
  A Info:
      Domain Name : HPC12FFA-156.local
      IP Address  : 10.1.1.254
```

```
      Vlan Id     : 200
  TXT Info:
      Vlan Id     : 200
      Data Length : 297
Total service: 1
```

Display the details of all services recorded on the mDNS gateway.

```
<HUAWEI> display mdns service all verbose
MDNS Service Info:

Service name : Officejet Pro 8100 [C12FFA] (7)._printer._tcp.local
  SRV Info:
      Domain Name : HPC12FFA-156.local
      Port        : 515
      Vlan Id     : 10
      Cache Flush : 1
      Class       : 1
      TTL         : 120
      Aging Time  : 95
      Data Length : 264
      Priority    : 0
      Weight      : 0
  A Info:
      Domain Name : HPC12FFA-156.local
      IP Address  : 10.1.1.254
      Vlan Id     : 10
      Cache Flush : 1
      Class       : 1
      TTL         : 120
      Aging Time  : 115
  TXT Info:
      Vlan Id     : 10
      Data Length : 297
      Cache Flush : 1
      Class       : 1
      TTL         : 4500
      Aging Time  : 3400
      Text        : ***
Total service: 1
```

Table 6-37 Description of the **display mdns service** command output

Item	Description
MDNS Service Info	Service information recorded on the mDNS gateway.
Service name	Service name recorded on the mDNS gateway.
SRV Info	SRV type information, indicating service record information.
Domain Name	Domain name corresponding to the service name.
Port	Number of the port that provides the service.
A Info	A type information, indicating host record information.

Item	Description
IP Address	IP address corresponding to the domain name.
TXT Info	TXT type information, indicating the description of service record information.
Data Length	TXT data length.
PTR Info	PTR type information, indicating that information is searched reversely; that is, the service provisioning device is searched based on the service type. **NOTE** This field is displayed only when the **display mdns service** command is run in the diagnostic view.
Total	Number of services recorded on the mDNS gateway. ● When you query all service information or service information provided by a specified service VLAN recorded on the mDNS gateway, this field displays the total number of service names. ● When you query service information about a specified service name recorded on the mDNS gateway, this field displays the sum of the SRV Info, TXT Info, and PTR Info field values. Type A information and type AAAA information are excluded because they are not service information.
Cache Flush	Cache information about services. The value can be 0 or 1. ● The value 1 indicates that the information is cached information. ● The value 0 indicates that the information is not cached information.
Class	Service type. ● 1: indicates the Internet type. ● 255: indicates any type.
TTL	TTL of the service.

Item	Description
Aging Time	Time elapsed after the mDNS gateway records the service information, in seconds.
Priority	Service priority.
Weight	Service weight.
Text	Service text.
Vlan Id	Service VLAN ID, indicating the VLAN that the service provisioning device belongs to.

6.6.6 mdns gateway enable

Function

The **mdns gateway enable** command enables the mDNS gateway.

The **undo mdns gateway enable** command disables the mDNS gateway.

By default, the mDNS gateway is disabled.

Format

mdns gateway enable

undo mdns gateway enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Bonjour technology proposed by Apple uses mDNS. The destination multicast address of 224.0.0.251 used by mDNS is only valid in a Layer 2 broadcast domain. That is, information can be forwarded in a VLAN only, but cannot be forwarded across VLANs or Layer 3 devices. Run the **mdns gateway enable** command on the device to enable the mDNS gateway so that the device can discover services across VLANs or Layer 3. The mDNS gateway records all available service lists and responds to service requests from Bonjour-compliant terminals.

Precautions

The device cannot function as both mDNS relay and gateway. A protection failure will occur if the **mdns relay enable** and **mdns gateway enable** commands are both configured on the device.

Example

Enable the mDNS gateway.

```
<HUAWEI> system-view
[HUAWEI] mdns gateway enable
```

6.6.7 mdns group

Function

The **mdns group** command creates an mDNS group and displays the mDNS group view.

The **undo mdns group** command deletes the created mDNS group.

By default, no mDNS group is created.

Format

mdns group *group-name*

undo mdns group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of an mDNS group.	The value is a string of 1 to 31 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the mDNS gateway queries service information lists of all service provisioning devices when receiving an mDNS request packet from a user requesting for a service. The mDNS gateway then replies to the user with a message containing the service provisioning devices that can provide the service. All the service provisioning devices mapping the service are visible to the user; therefore, service resources cannot be isolated. You can configure an mDNS group on the mDNS gateway to implement service resource isolation and refined service management. After receiving an mDNS request packet from a user requesting for a service, the mDNS gateway queries the mDNS group based on the user VLAN. If the user VLAN is added to a certain mDNS group, the gateway queries and replies with the requested service from the service list provided by the service VLAN mapping the mDNS group. If no mDNS group is specified for the user VLAN or no service VLAN is configured in the mDNS group, the gateway queries and replies with the requested service from the service lists provided by all service VLANs.

Follow-up Procedure

- Run the **user-vlan** command to configure the user VLAN for the mDNS group.
- Run the **service-vlan** command to configure the service VLAN to provide services for the users in the mDNS group.

Precautions

The device supports a maximum of 4096 mDNS groups.

Example

Create an mDNS group named **group1**.

```
<HUAWEI> system-view
[HUAWEI] mdns group group1
```

6.6.8 mdns probe interval

Function

The **mdns probe interval** command enables the device to periodically discover services and sets the discovery interval.

The **undo mdns probe interval** command disables the device from periodically discovering services and deletes the discovery interval.

By default, the device is not enabled to periodically discover services and the discovery interval is not set.

Format

mdns probe interval *interval*

undo mdns probe interval

Parameters

Parameter	Description	Value
interval	Specifies the discovery interval.	The value is an integer that ranges from 60 to 38400, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on an mDNS gateway or mDNS relay. The mDNS gateway maintains service information lists of all service provisioning devices on the network. A service information list records the service name, service type, TTL, host name, and IP address of each service. The TTL is provided by a service provisioning device to the mDNS gateway, and represents the aging time of a service. If the mDNS gateway receives mDNS response packets from a service provisioning device within the aging time, the mDNS gateway updates its service information. If the mDNS gateway does not receive mDNS response packets from a service provisioning device within the aging time, the mDNS gateway deletes its service information. If an mDNS gateway already exists on the network, a service provisioning device connected to the network advertises service information to the mDNS gateway through the mDNS relay. If a service provisioning device already exists before an mDNS gateway connects to the network, the service provisioning device does not advertise service information to the mDNS gateway.

If the device works as an mDNS gateway, you can run the **mdns probe interval** command to enable the periodical service discovery function and set the service discovery interval. The device then sends a service query message at the specified interval, and updates the service information list after receiving a response message from the service provisioning device.

If the device works as an mDNS relay and the **mdns probe interval** command is run, the device sends a service query message at the specified interval to request available service update in its VLAN, and forwards the response message from the service provisioning device to the mDNS gateway, ensuring that service information lists on the mDNS gateway are updated immediately.

Precautions

When the device as the mDNS gateway and service provisioning device are located on different network segments, the mDNS relay but not the mDNS gateway needs to be configured to periodically update service lists.

Only the following types of services can be discovered:

- _services._dns-sd._udp.local
- _raop._tcp.local
- _airplay._tcp.local
- _printer._tcp.local
- _device-info._tcp.local
- _rfb._tcp.local
- _sftp-ssh._tcp.local
- _ssh._tcp.local
- _smb._tcp.local
- _afpovertcp._tcp.local
- _universal._sub._ipp._tcp.local

Example

Enable the device to periodically discover services in VLAN 100 and set the discovery interval to 150s.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mdns probe interval 150
```

6.6.9 mdns permit service-type

Function

The **mdns permit service-type** command configures the service type that can be recorded by an mDNS gateway.

The **undo mdns permit id** command cancels the configured service type that can be recorded by an mDNS gateway.

By default, an mDNS gateway can record all service types.

Format

mdns permit service-type *service-type* **id** *id*

undo mdns permit id *id*

Parameters

Parameter	Description	Value
service-type *service-type*	Specifies a service type.	The value can be any service type that service provider devices can provide. The value is a string of characters, including digits, case-insensitive letters, and special characters visible on the keyboard, such as underscores (_), periods (.), and hyphens (-).
id *id*	Specifies a service type ID.	The value is an integer that ranges from 0 to 99.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, an mDNS gateway records all service types on the network and generates a service list. Because a service list size is limited, some uncommonly used services occupy the list space, which may cause entries unable to be generated for commonly used services such as airplay and printer. To reduce the number of service entries in the service list, run the **mdns permit service-type** command. This command allows service entries to be generated for only the specified service type, reduces the number of service entries in the service list.

NOTE

- An mDNS gateway can be configured to record airplay and printer services (a maximum of 64 airplay and printer devices are allowed), meeting the requirements in high-density WLANs and enterprise office WLANs as well as the requirements in manufacturing, finance, and government sectors.
- An mDNS gateway can be configured to record airplay and printer services (a maximum of 256 airplay and printer devices are allowed), meeting the requirements in scenarios where the number of VLANs to which concurrent users belong is less than 36.

Example

Configure the service type that can be recorded by the mDNS gateway.

```
<HUAWEI> system-view
[HUAWEI] mdns permit service-type _raop._tcp.local id 0
[HUAWEI] mdns permit service-type _airplay._tcp.local id 1
```

```
[HUAWEI] mdns permit service-type _printer._tcp.local id 2
[HUAWEI] mdns permit service-type _device-info._tcp.local id 3
[HUAWEI] mdns permit service-type _rfb._tcp.local id 4
[HUAWEI] mdns permit service-type _sftp-ssh._tcp.local id 5
[HUAWEI] mdns permit service-type _ssh._tcp.local id 6
[HUAWEI] mdns permit service-type _smb._tcp.local id 7
[HUAWEI] mdns permit service-type _afpovertcp._tcp.local id 8
[HUAWEI] mdns permit service-type _universal._sub._ipp._tcp.local id 9
```

6.6.10 mdns source ip

Function

The **mdns source ip** command configures the source IP address in mDNS packets sent by the device that functions as an mDNS gateway or mDNS relay.

The **undo mdns source ip** command deletes the configuration of the source IP address in mDNS packets sent by the device.

By default, no source IP address is configured.

Format

mdns source ip *ip-address*

undo mdns source ip

Parameters

Parameter	Description	Value
ip-address	Specifies a source IP address.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure normal communication with user terminals and service provisioning devices, run this command to specify the source IP address in mDNS packets sent by the mDNS gateway or mDNS relay.

NOTE

When the device works as an mDNS relay, it is recommended that the IP address of the interface connecting the device to the mDNS gateway be used as the source IP address.

User terminals and service provisioning devices will ignore the source IP address of multicast mDNS packets received from the mDNS gateway or mDNS relay. As such, the source IP address configured by this command does not need to be on the same network segment as the user terminals or service provisioning devices.

When the device functions as an mDNS gateway, the configured source IP address in mDNS packets sent by the device applies to the following scenarios:

- When the mDNS gateway is enabled to periodically discover services, it encapsulates mDNS query packets with the source IP address configured by this command, so that it can receive response packets from service provisioning devices. If this command is not run to configure the source IP address, the mDNS gateway uses the IP address of the VLANIF interface corresponding to the VLAN where the periodic service discovery function is enabled as the source IP address of mDNS packets.
- If an mDNS relay is deployed, the mDNS gateway exchanges packets with the mDNS relay in unicast mode. When sending packets to the mDNS relay, the mDNS gateway uses the next-hop IP address of the outbound interface as the source IP address of the packets based on the routing table. If this command is configured, the device preferentially uses the configured IP address as the source IP address of packets.
- When receiving a request to discover services from a terminal, the mDNS gateway uses the IP address configured by this command as the source IP address of the response packet. If this command is not run to configure the source IP address, the mDNS gateway uses the IP address of the VLANIF interface corresponding to the VLAN to which the response packet belongs as the source IP address of the response packet.

When the device functions as an mDNS relay, the configured source IP address in mDNS packets sent by the device applies to the following scenarios:

- When the mDNS relay is enabled to periodically discover services, it encapsulates mDNS query packets with the source IP address configured by this command, so that it can receive response packets from service provisioning devices. If this command is not run to configure the source IP address, the mDNS relay uses the IP address of the VLANIF interface corresponding to the VLAN where the periodic service discovery function is enabled as the source IP address of mDNS packets.
- When the device acting as the mDNS relay forwards mDNS packets to an mDNS gateway, it uses the next-hop IP address of the outbound interface as the source IP address of packets based on the routing table. If this command is configured, the device preferentially uses the configured IP address as the source IP address of packets.

Precautions

When the device acting as an mDNS gateway is configured to periodically discover services, the device periodically sends mDNS query packets to all mDNS service provisioning devices in the VLAN, which are expected to return response packets. The destination IP address is the multicast address 224.0.0.251.

Before the mDNS service TTL expires, the mDNS gateway sends mDNS query packets to service provisioning devices that are expected to return response packets. If an mDNS service is advertised through an mDNS relay, the destination IP address of the query packets is the IP address of the mDNS relay. If an mDNS service is not advertised through an mDNS relay, the destination IP address is the multicast address 224.0.0.251.

When the device acting as an mDNS gateway receives mDNS requests from terminals and the requested services are available, the device returns mDNS response packets. If the mDNS request packets are forwarded through an mDNS relay, the destination IP address of the response packets is the IP address of the mDNS relay. If mDNS request packets are not forwarded through an mDNS relay, the destination IP address is the multicast address 224.0.0.251.

Example

Specify the source IP address of 10.1.1.1 in mDNS packets to be sent to periodically discover services and to be forwarded to the mDNS gateway by the device functioning as the mDNS relay.

```
<HUAWEI> system-view
[HUAWEI] mdns source ip 10.1.1.1
```

6.6.11 mdns whitelist source-ip

Function

The **mdns whitelist source-ip** command enables the trusted mDNS relay agent function and configures the IP address of the trusted mDNS relay agent.

The **undo mdns whitelist source-ip** command deletes the IP address of the trusted mDNS relay agent.

By default, the trusted mDNS relay agent function is disabled.

Format

mdns whitelist source-ip *ip-address*

undo mdns whitelist source-ip { **all** | *ip-address* }

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of the trusted mDNS relay agent.	The value is in dotted decimal notation.
all	Deletes IP addresses of all trusted mDNS relay agents.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Bogus mDNS relay agents may exist on the network and forge mDNS packets, threatening network security. To prevent this problem, run the **mdns whitelist source-ip** command on the device functioning as the mDNS gateway to enable the trusted mDNS relay agent function and configure the IP address of the trusted mDNS relay agent. The device then only processes unicast packets from the trusted mDNS relay agent, and discards unicast packets from untrusted mDNS relay agents. If the mDNS relay agent and mDNS gateway are on different network segments, you need to run the **mdns whitelist source-ip** *ip-address* command on the mDNS gateway to specify the IP address of the mDNS relay agent.

Example

Configure the IP address 192.168.1.1 for the trusted mDNS relay agent.

```
<HUAWEI> system-view
[HUAWEI] mdns whitelist source-ip 192.168.1.1
```

6.6.12 reset mdns gateway statistics

Function

The **reset mdns gateway statistics** command clears statistics on the mDNS gateway.

Format

reset mdns gateway statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

During routine maintenance and fault location, you can view statistics on mDNS packets received and sent by the mDNS gateway in a given period of time. Before viewing the statistics, run the **reset mdns gateway statistics** command to delete existing statistics. Then the mDNS gateway recollects statistics on received and sent mDNS packets. You can run the **display mdns gateway statistics** command to view statistics on mDNS packets received and sent by the mDNS gateway.

NOTICE

Cleared statistics on the mDNS gateway cannot be restored. Exercise caution when you use the **reset mdns gateway statistics** command.

Example

Clear statistics on the mDNS gateway.

```
<HUAWEI> reset mdns gateway statistics
```

6.6.13 service-vlan

Function

The **service-vlan** command configures service VLANs (that the service provisioning devices belong to) to provide services for users in an mDNS group.

The **undo service-vlan** deletes the service VLANs that provide services for users in an mDNS group.

By default, no service VLAN is configured to provide services for users in an mDNS group.

Format

service-vlan *vlan-id* &<1-32>

undo service-vlan { *vlan-id* &<1-32> | **all** }

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of the VLAN that the service provisioning devices belong to.	The value is an integer in the range from 1 to 4094.
all	Specifies all service VLANs.	-

Views

mDNS group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device functioning as an mDNS gateway maintains service information lists of all service provisioning devices on a network, and it can use mDNS groups to isolate service resources to provide refined service management. You can run the **service-vlan** command to configure service VLANs to provide services for users in the mDNS group. The users (specified using the **user-vlan** command in the mDNS group view) in the mDNS group can only obtain services from the service list provided by the service VLAN mapping the mDNS group.

Prerequisites

An mDNS group has been created using the **mdns group** command.

Precautions

- You can add at most 32 service VLANs to an mDNS group.
- You can add a service VLAN to multiple mDNS groups to provide services for the users in these groups.
- The service VLAN cannot be configured as a reserved VLAN for a stack.

Example

Configure the service provisioning devices in VLAN 10 to provide services for the mDNS group **group1**.

```
<HUAWEI> system-view
[HUAWEI] mdns group group1
[HUAWEI-mdns-group-group1] service-vlan 10
```

6.6.14 user-vlan (mDNS group view)

Function

The **user-vlan** command configures user VLANs for an mDNS group.

The **undo user-vlan** command deletes user VLANs for the mDNS group.

By default, no user VLAN is configured for an mDNS group.

Format

user-vlan *vlan-id* &<1-32>

undo user-vlan { *vlan-id* &<1-32> | **all** }

Parameters

Parameter	Description	Value
vlan-id	Specifies the ID of the VLAN that users belong to.	The value is an integer that ranges from 1 to 4094.
all	Specifies all user VLANs.	-

Views

mDNS group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The device functioning as the mDNS gateway maintains service information lists of all service provisioning devices on a network, and it can use mDNS groups to isolate service resources to provide refined service management. You can run the **user-vlan** command to configure user VLANs for an mDNS group. The intra-VLAN users who join the mDNS group can only obtain services from the service list provided by the service VLAN (specified using the **service-vlan** command) mapping the mDNS group.

Prerequisites

An mDNS group has been created using the **mdns group** command.

Precautions

- You can add at most 32 user VLANs to an mDNS group.
- A user VLAN can belong to only one mDNS group.
- If no mDNS group is specified for the user VLAN or no service VLAN is configured in the mDNS group, the gateway queries and replies with the requested service from the service lists provided by all service VLANs.

Example

Add the users in VLAN 10 to the mDNS group **group1**.

```
<HUAWEI> system-view
[HUAWEI] mdns group group1
[HUAWEI-mdns-group-group1] user-vlan 10
```

6.7 mDNS Relay Configuration Commands

6.7.1 Command Support

Only the following switch models support mDNS Relay:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.7.2 display mdns relay

Function

The **display mdns relay** command displays the mDNS relay configuration.

Format

display mdns relay

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the mDNS relay is configured, you can run the **display mdns relay** command to view the mDNS relay configuration.

Example

Display the mDNS relay configuration.

```
<HUAWEI> display mdns relay
MDNS Relay Information:
--------------------------------------------------------------------------------
 MDNS Gateway IP   :  10.1.1.2
 MDNS Source IP    :  192.168.1.1
--------------------------------------------------------------------------------
 Relay Enable Vlan :  vlan100
--------------------------------------------------------------------------------
 Relay Probe Vlan  :  vlan100
--------------------------------------------------------------------------------
```

Table 6-38 Description of the display mdns relay command output

Item	Description
MDNS Gateway IP	IP address of the mDNS gateway specified on the device as the mDNS relay. To specify the IP address of the mDNS gateway on the device as the mDNS relay, run the **mdns gateway ip** command.
MDNS Source IP	Source IP address in mDNS packets to be sent to periodically discover services and to be forwarded to the mDNS gateway by the device as the mDNS relay. To specify the source IP address in mDNS packets to be sent to periodically discover services and to be forwarded to the mDNS gateway by the device as the mDNS relay, run the **mdns source ip** command.
Relay Enable Vlan	ID of the VLAN where the mDNS relay is enabled. To enable the mDNS relay, run the **mdns relay enable** command.
Relay Probe Vlan	ID of the VLAN where the mDNS relay is enabled to periodically discover services. To specify the ID of the VLAN where the mDNS relay is enabled to periodically discover services, run the **mdns probe interval** command.

6.7.3 display mdns relay statistics

Function

The **display mdns relay statistics** command displays statistics on the mDNS relay.

Format

display mdns relay statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

During routine maintenance and fault location, you can run the **display mdns relay statistics** command to view statistics on mDNS packets received, sent and dropped by the mDNS relay in a given period of time.

To query statistics again, run the **reset mdns relay statistics** command to clear existing statistics.

NOTICE

Cleared statistics on the mDNS relay cannot be restored. Exercise caution when you use the **reset mdns relay statistics** command.

Example

Display statistics on the mDNS relay.

```
<HUAWEI> display mdns relay statistics
MDNS relay statistics:
------------------------------------
 Received  : 100
 Sent      : 100
 Dropped   : 0
  Bad Pkt Length : 0
  Other          : 0
------------------------------------
```

Table 6-39 Description of the display mdns relay statistics command output

Item	Description
Received	Number of mDNS packets received by the mDNS relay.
Sent	Number of mDNS packets sent by the mDNS relay.
Dropped	Number of mDNS packets dropped by the mDNS relay.
Bad Pkt Length	Number of mDNS packets discarded because the packet length exceeds the upper limit.
Other	Number of mDNS packets discarded because of other reasons.

6.7.4 mdns gateway ip

Function

The **mdns gateway ip** command specifies the IP address of the mDNS gateway on the device as the mDNS relay.

The **undo mdns gateway ip** command deletes the configured IP address of the mDNS gateway on the device as the mDNS relay.

By default, the IP address of the mDNS gateway is not specified on the device as the mDNS relay.

Format

mdns gateway ip *ip-address*

undo mdns gateway ip

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of the mDNS gateway.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The device as the mDNS relay needs to forward mDNS packets from Bonjour-compliant terminals or service provisioning devices to the mDNS gateway. After the **mdns gateway ip** command is used to specify the IP address of the mDNS gateway on the mDNS relay, the mDNS relay converts mDNS packets from Bonjour-compliant terminals or service provisioning devices into unicast packets and sends them to the mDNS gateway.

Example

Specify the IP address of the mDNS gateway as 10.1.1.1 on the device as the mDNS relay.

```
<HUAWEI> system-view
[HUAWEI] mdns gateway ip 10.1.1.1
```

6.7.5 mdns probe interval

Function

The **mdns probe interval** command enables the device to periodically discover services and sets the discovery interval.

The **undo mdns probe interval** command disables the device from periodically discovering services and deletes the discovery interval.

By default, the device is not enabled to periodically discover services and the discovery interval is not set.

Format

mdns probe interval *interval*

undo mdns probe interval

Parameters

Parameter	Description	Value
interval	Specifies the discovery interval.	The value is an integer that ranges from 60 to 38400, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is used on an mDNS gateway or mDNS relay. The mDNS gateway maintains service information lists of all service provisioning devices on the network. A service information list records the service name, service type, TTL, host name, and IP address of each service. The TTL is provided by a service provisioning device to the mDNS gateway, and represents the aging time of a service. If the mDNS gateway receives mDNS response packets from a service provisioning device within the aging time, the mDNS gateway updates its service information. If the mDNS gateway does not receive mDNS response packets from a service provisioning device within the aging time, the mDNS gateway deletes its service information. If an mDNS gateway already exists on the network, a service provisioning device connected to the network advertises service information to the mDNS gateway through the mDNS relay. If a service provisioning device already exists before an mDNS gateway connects to the network, the service provisioning device does not advertise service information to the mDNS gateway.

If the device works as an mDNS gateway, you can run the **mdns probe interval** command to enable the periodical service discovery function and set the service discovery interval. The device then sends a service query message at the specified interval, and updates the service information list after receiving a response message from the service provisioning device.

If the device works as an mDNS relay and the **mdns probe interval** command is run, the device sends a service query message at the specified interval to request available service update in its VLAN, and forwards the response message from the service provisioning device to the mDNS gateway, ensuring that service information lists on the mDNS gateway are updated immediately.

Precautions

When the device as the mDNS gateway and service provisioning device are located on different network segments, the mDNS relay but not the mDNS gateway needs to be configured to periodically update service lists.

Only the following types of services can be discovered:

- _services._dns-sd._udp.local
- _raop._tcp.local
- _airplay._tcp.local
- _printer._tcp.local
- _device-info._tcp.local
- _rfb._tcp.local
- _sftp-ssh._tcp.local
- _ssh._tcp.local
- _smb._tcp.local
- _afpovertcp._tcp.local
- _universal._sub._ipp._tcp.local

Example

Enable the device to periodically discover services in VLAN 100 and set the discovery interval to 150s.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mdns probe interval 150
```

6.7.6 mdns relay enable

Function

The **mdns relay enable** command enables the mDNS relay.

The **undo mdns relay enable** command disables the mDNS relay.

By default, the mDNS relay is disabled.

Format

mdns relay enable

undo mdns relay enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Bonjour technology proposed by Apple uses mDNS. The destination multicast address of 224.0.0.251 used by mDNS is only valid in a Layer 2 broadcast domain. That is, information can be forwarded in a VLAN only, but cannot be forwarded across VLANs or Layer 3 devices. The mDNS relay and mDNS gateway solution implements service discovery across Layer 3. The device can function as the mDNS relay to forward mDNS packets exchanged between Bonjour-compliant terminals or service provisioning devices and mDNS gateway, implementing service discovery across Layer 3. The **mdns relay enable** command enables the mDNS relay.

Precautions

The device cannot function as both mDNS relay and gateway. A protection failure will occur if the **mdns relay enable** and **mdns gateway enable** commands are both configured on the device.

Example

Enable the mDNS relay.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] mdns relay enable
```

6.7.7 mdns source ip

Function

The **mdns source ip** command configures the source IP address in mDNS packets sent by the device that functions as an mDNS gateway or mDNS relay.

The **undo mdns source ip** command deletes the configuration of the source IP address in mDNS packets sent by the device.

By default, no source IP address is configured.

Format

mdns source ip *ip-address*

undo mdns source ip

Parameters

Parameter	Description	Value
ip-address	Specifies a source IP address.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure normal communication with user terminals and service provisioning devices, run this command to specify the source IP address in mDNS packets sent by the mDNS gateway or mDNS relay.

NOTE

When the device works as an mDNS relay, it is recommended that the IP address of the interface connecting the device to the mDNS gateway be used as the source IP address.

User terminals and service provisioning devices will ignore the source IP address of multicast mDNS packets received from the mDNS gateway or mDNS relay. As such, the source IP address configured by this command does not need to be on the same network segment as the user terminals or service provisioning devices.

When the device functions as an mDNS gateway, the configured source IP address in mDNS packets sent by the device applies to the following scenarios:

- When the mDNS gateway is enabled to periodically discover services, it encapsulates mDNS query packets with the source IP address configured by this command, so that it can receive response packets from service provisioning devices. If this command is not run to configure the source IP address, the mDNS gateway uses the IP address of the VLANIF interface corresponding to the VLAN where the periodic service discovery function is enabled as the source IP address of mDNS packets.
- If an mDNS relay is deployed, the mDNS gateway exchanges packets with the mDNS relay in unicast mode. When sending packets to the mDNS relay, the mDNS gateway uses the next-hop IP address of the outbound interface as the source IP address of the packets based on the routing table. If this command

is configured, the device preferentially uses the configured IP address as the source IP address of packets.

- When receiving a request to discover services from a terminal, the mDNS gateway uses the IP address configured by this command as the source IP address of the response packet. If this command is not run to configure the source IP address, the mDNS gateway uses the IP address of the VLANIF interface corresponding to the VLAN to which the response packet belongs as the source IP address of the response packet.

When the device functions as an mDNS relay, the configured source IP address in mDNS packets sent by the device applies to the following scenarios:

- When the mDNS relay is enabled to periodically discover services, it encapsulates mDNS query packets with the source IP address configured by this command, so that it can receive response packets from service provisioning devices. If this command is not run to configure the source IP address, the mDNS relay uses the IP address of the VLANIF interface corresponding to the VLAN where the periodic service discovery function is enabled as the source IP address of mDNS packets.
- When the device acting as the mDNS relay forwards mDNS packets to an mDNS gateway, it uses the next-hop IP address of the outbound interface as the source IP address of packets based on the routing table. If this command is configured, the device preferentially uses the configured IP address as the source IP address of packets.

Precautions

When the device acting as an mDNS gateway is configured to periodically discover services, the device periodically sends mDNS query packets to all mDNS service provisioning devices in the VLAN, which are expected to return response packets. The destination IP address is the multicast address 224.0.0.251.

Before the mDNS service TTL expires, the mDNS gateway sends mDNS query packets to service provisioning devices that are expected to return response packets. If an mDNS service is advertised through an mDNS relay, the destination IP address of the query packets is the IP address of the mDNS relay. If an mDNS service is not advertised through an mDNS relay, the destination IP address is the multicast address 224.0.0.251.

When the device acting as an mDNS gateway receives mDNS requests from terminals and the requested services are available, the device returns mDNS response packets. If the mDNS request packets are forwarded through an mDNS relay, the destination IP address of the response packets is the IP address of the mDNS relay. If mDNS request packets are not forwarded through an mDNS relay, the destination IP address is the multicast address 224.0.0.251.

Example

Specify the source IP address of 10.1.1.1 in mDNS packets to be sent to periodically discover services and to be forwarded to the mDNS gateway by the device functioning as the mDNS relay.

```
<HUAWEI> system-view
[HUAWEI] mdns source ip 10.1.1.1
```

6.7.8 reset mdns relay statistics

Function

The **reset mdns relay statistics** command clears statistics on the mDNS relay.

Format

reset mdns relay statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

During routine maintenance and fault location, you can view statistics on mDNS packets received and sent by the mDNS relay in a given period of time. Before viewing the statistics, run the **reset mdns relay statistics** command to delete existing statistics. Then the mDNS relay recollects statistics on received and sent mDNS packets. You can run the **display mdns relay statistics** command to view statistics on mDNS packets received and sent by the mDNS relay.

NOTICE

Cleared statistics on the mDNS relay cannot be restored. Exercise caution when you use the **reset mdns relay statistics** command.

Example

Clear statistics on the mDNS relay.

```
<HUAWEI> reset mdns relay statistics
```

6.8 UDP Helper Configuration Commands

6.8.1 Command Support

Only the following switch models support UDP helper:

S5720I-SI, S5735-S, S5735-L, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.8.2 display udp-helper port

Function

The **display udp-helper port** command displays the configured UDP ports to which packets need to be relayed on the device.

Format

display udp-helper port

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the configured UDP ports to which packets need to be relayed, run this command. If the UDP helper function is not enabled, the system displays the following information:

```
Info: Udp-helper has not been enabled, please enable udp-helper first.
```

Example

Display the UDP ports to which packets need to be relayed.

```
<HUAWEI> display udp-helper port
Udp-Port-Number       Description
-------------------------------------------------------------
      1              TCP Port Service Multiplexer
     37              Time
     49              Login Host Protocol
     53              Domain Name Server
     69              Trivial File Transfer
    137              NETBIOS Name Service
    138              NETBIOS Datagram Service
```

Table 6-40 Description of the **display udp-helper port** command output

Item	Description
Udp-Port-Number	UDP ports to which packets need to be relayed. UDP ports are classified into the following types: ● Well-known port: The well-known port numbers range from 0 to 1023. These ports are used by standard TCP/UDP protocols. ● Registered port: The registered port numbers range from 1024 to 49151. They are vendor-specific ports. ● Dynamic/Static port: The dynamic or static port numbers range from 49152 to 65535. These ports can be used as required and may conflict on a network. To configure the UDP ports, run the **udp-helper port** command.
Description	UDP port description.

6.8.3 display udp-helper server

Function

The **display udp-helper server** command displays the VLANIF interface, destination server address, and number of relayed UDP packets.

Format

display udp-helper server [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type* *interface-number*	Displays statistics about UDP broadcast packets relayed on the specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	The interface type must be VLANIF.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays statistics about packets relayed by UDP helper. The statistics help you monitor the UDP helper function.

If no parameter is specified, statistics about relayed packets on all VLANIF interfaces are displayed.

NOTE

This command collects statistics on only the packets forwarded by the UDP helper server. Successful packet forwarding depends on the reachable route.

Example

Display statistics about relayed packets on VLANIF 100.

```
<HUAWEI> display udp-helper server interface vlanif 100
vlan-interface       Server-Ip                packet-num
Vlanif100          10.10.10.10                         0
```

Table 6-41 Description of the **display udp-helper server** command output

Item	Description
vlan-interface	VLANIF interface on which UDP packets are relayed.

Item	Description
Server-Ip	Destination server address. You can run the **udp-helper server** command to set the destination server address.
packet-num	Number of packets sent to the destination server.

6.8.4 reset udp-helper packet

Function

The **reset udp-helper packet** command clears statistics about packets relayed by UDP helper.

Format

reset udp-helper packet

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

This command clears statistics about packets relayed by UDP helper. Before collecting packet statistics in a certain period, run this command to clear existing statistics first.

NOTICE

UDP helper statistics cannot be restored after being cleared. Exercise caution when you run the **reset udp-helper packet** command.

Example

Clear statistics about packets relayed by UDP helper.

```
<HUAWEI> reset udp-helper packet
Warning: This command will delete the packet statistics of udp-helper.Continue?[Y/N]y
```

6.8.5 udp-helper enable

Function

The **udp-helper enable** command enables the UDP Helper function.

The **undo udp-helper enable** command disables the UDP Helper function.

By default, the UDP Helper function is disabled.

Format

udp-helper enable

undo udp-helper enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hosts on an enterprise intranet may need to obtain the network configuration or resolve host names by sending UDP broadcast packets to the server. If the host and the server are located in different broadcast domains, broadcast packets cannot reach the server and the host cannot obtain the configuration from the server. The switch provides the UDP Helper function to solve this problem. UDP Helper can relay the UDP broadcast packets with specified destination ports. It converts the broadcast packets into unicast packets and sends the unicast packets to the specified destination servers.

The packets that can be forwarded by UDP Helper must meet the following requirements:

- The destination MAC address is the broadcast MAC address (ffff-ffff-ffff).
- The Time-to-Live (TTL) is larger than 1.
- The protocol type is UDP.
- The destination port is a specified UDP port.

Precautions

UDP helper enables a device to relay DHCP packets destined for UDP port 67 (that is, DHCP packets sent to the DHCP server).

However, a UDP helper-enabled device cannot relay DHCP packets destined for UDP port 68 (that is, DHCP packets sent to the DHCP client). To relay this type of DHCP packets, you must enable the DHCP relay function.

After the UDP Helper function is enabled, the switch relays broadcast packets destined for the following UDP ports by default.

Protocol	UDP Port Number
Trivial File Transfer Protocol (TFTP)	69
Domain Name System (DNS)	53
Time Service	37
NetBIOS Name Service (NetBIOS-NS)	137
NetBIOS Datagram Service (NetBIOS-DS)	138
Terminal Access Controller Access Control System (TACACS)	49

After UDP Helper is disabled, all specified UDP ports and default ports are canceled.

NOTE

After the UDP Helper function is enabled, the switch automatically relays the UDP broadcast packets on six default ports. If you want to relay the packets on only one default port, run the **undo udp-helper port** { **dns** | **netbios-ds** | **netbios-ns** | **tacacs** | **tftp** | **time** } command to disable packet relay on other five ports.

Example

Enable UDP Helper.

```
<HUAWEI> system-view
[HUAWEI] udp-helper enable
```

6.8.6 udp-helper port

Function

The **udp-helper port** command specifies the UDP ports to which UDP broadcast packets are relayed.

The **undo udp-helper port** command deletes the UDP ports to which packets are relayed.

By default, no UDP port is specified. After UDP helper is enabled, the switch relays broadcast packets destined for ports 37, 49, 53, 69, 137, and 138 by default.

Format

udp-helper port { *port-number* | **dns** | **netbios-ds** | **netbios-ns** | **tacacs** | **tftp** | **time** }

undo udp-helper port { *port-number* | **dns** | **netbios-ds** | **netbios-ns** | **tacacs** | **tftp** | **time** }

Parameters

Parameter	Description	Value
port-number	Specifies the UDP ports to which packets are relayed.	The value is an integer that ranges from 1 to 65535, excluding 68.
dns	Relays the UDP broadcast packets sent by DNS. The UDP port number is 53.	-
netbios-ds	Relays the UDP broadcast packets sent by NetBIOS-DS. The UDP port number is 138.	-
netbios-ns	Relays the UDP broadcast packets sent by NetBIOS-NS. The UDP port number is 137.	-
tacacs	Relays the UDP broadcast packets sent by TACACS. The UDP port number is 49.	-
tftp	Relays the UDP broadcast packets sent by TFTP. The UDP port number is 69.	-
time	Relays the UDP broadcast packets sent by time service. The UDP port number is 37.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After UDP helper is enabled and the UDP ports are specified, the switch relays the received UDP broadcast packets destined for the specified ports.

Precautions

The **udp-helper port** command takes effect globally. That is, if the switch is configured to relay packets destined for a UDP port, all the interfaces configured with the destination server address will relay such packets.

UDP helper enables a device to relay DHCP packets destined for UDP port 67 (that is, DHCP packets sent to the DHCP server).

However, a UDP helper-enabled device cannot relay DHCP packets destined for UDP port 68 (that is, DHCP packets sent to the DHCP client). To relay this type of DHCP packets, you must enable the DHCP relay function.

The switch supports a maximum of 16 UDP ports.

Example

Configure the switch to relay the broadcast packets destined for UDP port 100.

```
<HUAWEI> system-view
[HUAWEI] udp-helper enable
[HUAWEI] udp-helper port 100
```

6.8.7 udp-helper server

Function

The **udp-helper server** command configures the destination server to which UDP packets are relayed.

The **undo udp-helper server** command deletes the destination server to which UDP packets are relayed.

By default, no destination server is configured for UDP Helper.

Format

udp-helper server *ip-address*

undo udp-helper server [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a destination server. The IP address can be a unicast address or a subnet broadcast address, but cannot be 255.255.255.255. Otherwise, the configuration fails.	The value is in dotted decimal notation.

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If UDP Helper is enabled and the destination server is configured on an interface, when the interface receives the UDP broadcast packets destined for the specified port, it converts the broadcast packets into unicast packets with the destination address *ip-address* and sends them to the specified server.

Precautions

- A maximum of 20 destination servers can be configured on an interface. If multiple destination servers are configured on an interface, the switch converts the broadcast packets into unicast packets and sends them to all these servers.
- When specifying the IP address of a destination server, ensure that the switch has a reachable route to the network segment where the destination server is located. If no route is reachable, packets cannot be forwarded.
- When the **undo udp-helper server** command is used without parameter specified, all the configured destination servers on the interface are deleted.

Example

Configure destination server 10.1.1.2 on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] udp-helper server 10.1.1.2
```

6.9 IP Performance Optimization Configuration Commands

6.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

6.9.2 clear ip df

Function

The **clear ip df** command enables fragmentation for outgoing control-plain IP packets on an interface.

The **undo clear ip df** command disables fragmentation for outgoing control-plain IP packets on an interface.

By default, fragmentation for outgoing control-plain IP packets on an interface is disabled.

Format

clear ip df

undo clear ip df

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IP header contains a Don't Fragment (DF) bit to identify whether packet fragmentation is allowed. Commonly, if the DF bit of a packet is set to 1, the packet cannot be fragmented. When the remote device or intermediate forwarding device receives IP packets, if it checks the packet length and discards packets whose length is longer than the Maximum Transmission Unit (MTU) on the interface, network communication is interrupted. You can run the **clear ip df** command to enable fragmentation for outgoing control-plane IP packets so that packets with the DF bit set to 1 are fragmented based on the MTU value on the interface.

After fragmentation for outgoing control-plain IP packets is enabled on an interface, the device sets the Don't Fragment (DF) field to 0 and fragments IP packets that meet the following conditions:

- The value of the DF field in the IP packet header is 1.
- The packet length is larger than the MTU value of the interface that sends the packets.

Precautions

This command takes effect only for the control-plain packets but not for the forwarding-plain packets.

Example

Enable fragmentation for outgoing IP packets on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] clear ip df
```

Enable fragmentation for outgoing IP packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] clear ip df
```

6.9.3 discard { ra | rr | srr | ts }

Function

The **discard { ra | rr | srr | ts }** command configures the device to discard the packets that contain the route alert option, route record option, source route option, or timestamp option on interfaces.

The **undo discard { ra | rr | srr | ts }** command configures the device to process the packets that contain the route alert option, route record option, source route option, or timestamp option on interfaces.

By default, the device processes packets sent to the CPU based on route options contained in these packets.

Format

discard { ra | rr | srr | ts }

undo discard { ra | rr | srr | ts }

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IP packets can carry route options including the route alert option (**ra**), route record option (**rr**), source route option (**srr**), and timestamp option (**ts**).

These route options are used to diagnose network paths and temporarily transmit special services. These options, however, may be used by attackers to spy on the network structure for initiating attacks. This degrades network security and device performance. To solve this problem, you can run the **discard { ra | rr | srr | ts }** command to configure the device to discard the IP packets that contain the route options.

Precautions

The **discard { ra | rr | srr | ts }** command only takes effect for the packets on inbound interfaces.

The **discard { ra | rr | srr | ts }** command only takes effect for packets sent to the CPU. For packets that are not sent to the CPU, the device processes and forwards them using the same method of processing packets without route options regardless of whether the **discard { ra | rr | srr | ts }** command is configured or not.

Example

Configure the device to discard the packets that contain the route alert option on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] discard ra
```

Configure the device to discard the packets that contain the route alert option on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] discard ra
```

6.9.4 display icmp statistics

Function

The **display icmp statistics** command displays ICMP traffic statistics.

Format

display icmp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view information about ICMP packet sending and receiving, run the **display icmp statistics** command.

Example

Display ICMP traffic statistics.

```
<HUAWEI> display icmp statistics
  Input: bad formats          0          bad checksum            0
         echo                10         destination unreachable 0
         source quench        0          redirects               0
         echo reply          25         parameter problem       0
         timestamp request    0          information request     0
         mask requests        0          mask replies            0
         time exceeded        0          timestamp reply         0
         Mping request        0          Mping reply             0
  Output:echo                25          destination unreachable 0
         source quench        0          redirects               0
         echo reply          10         parameter problem       0
         timestamp request    0          information reply       0
         mask requests        0          mask replies            0
         time exceeded        0          timestamp reply         0
         Mping request        0          Mping reply             0
```

Table 6-42 Description of the **display icmp statistics** command output

Item	Description
Input	Received packets.
Output	Sent packets.
bad formats	Number of packets in incorrect format.
bad checksum	Number of packets with checksum errors.
echo	Number of echo request packets.
destination unreachable	Number of unreachable packets.
source quench	Number of source quench packets.
redirects	Number of redirection packets.
echo reply	Number of echo reply packets.

Item	Description
parameter problem	Number of packets with incorrect parameters.
timestamp request	Number of timestamp request packets.
information request	Number of information request packets.
information reply	Number of information reply packets.
mask requests	Number of mask request packets.
mask replies	Number of mask reply packets.
time exceeded	Number of expired packets.
timestamp reply	Number of timestamp reply packets.
Mping requests	Number of multicast ping request packets.
Mping reply	Number of multicast ping reply packets.

6.9.5 display ip interface

Function

The **display ip interface** command displays the IP configuration and statistics on interfaces. The statistics include the number of packets and bytes received and sent by interfaces, number of multicast packets sent and received by interfaces, and number of broadcast packets received, sent, forwarded, and discarded by interfaces.

The **display ip interface brief** command displays brief information about interface IP addresses, including the IP address, subnet mask, physical status, link-layer protocol status, and number of interfaces in different states.

Format

display ip interface [*interface-type interface-number*]

display ip interface brief [*interface-type* [*interface-number*] | **slot** *slot-id* [**card** *card-number*]]

display ip interface brief [*interface-type*] &<1-8>

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. If no interface is specified, IP configuration and statistics about all interfaces are displayed.	-

Parameter	Description	Value
brief	Displays brief information, including the IP address, subnet mask, physical status, link-layer protocol status, and number of interfaces in different states.	-
slot *slot-id*	Displays the IP configuration and statistics of interfaces on the specified slot. If the slot number is not specified, brief information related to the IP addresses of the interfaces on all interface boards and main control boards is displayed.	-
card *card-number*	Displays the IP configuration and statistics of interfaces on specified card.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ip interface brief** command to view the following information:

- IP configurations of all interfaces
- IP configurations of interfaces of the specified type and a specified interface
- IP configurations of interfaces that have IP addresses

This command, however, cannot display the IP configurations of Layer 2 interfaces or Eth-Trunk member interfaces.

NOTE

- You can run the **display interface description** command to view the interface description.
- You can run the **display interface** command to view detailed information about the running status and statistics on the interface.
- Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support sub-interfaces.

Example

Display IP information about VLANIF15.

```
<HUAWEI> display ip interface vlanif 15
Vlanif15 current state : UP
Line protocol current state : UP
The Maximum Transmit Unit : 1500 bytes
input packets : 766390, bytes : 41540847, multicasts : 681817
```

```
output packets : 242239, bytes : 14679482, multicasts : 172333
Directed-broadcast packets:
 received packets:            0, sent packets:            0
 forwarded packets:           0, dropped packets:           0
Internet Address is 10.1.1.119/24
Broadcast address : 10.1.1.255
TTL being 1 packet number:    164035
TTL invalid packet number:          0
ICMP packet input number:          0
  Echo reply:                     0
  Unreachable:                    0
  Source quench:                  0
  Routing redirect:               0
  Echo request:                   0
  Router advert:                  0
  Router solicit:                 0
  Time exceed:                    0
  IP header bad:                  0
  Timestamp request:              0
  Timestamp reply:                0
  Information request:            0
  Information reply:              0
  Netmask request:                0
  Netmask reply:                  0
  Unknown type:                   0
```

Table 6-43 Description of the **display ip interface** command output

Item	Description
Vlanif15 current state	Physical status of the interface: ● UP: indicates that the interface is physically Up. ● DOWN: indicates that the interface is physically Down. ● Administratively down: indicates that the administrator has run the **shutdown (interface view)** command on the interface.
Line protocol current state	Link layer protocol status of the interface: ● UP: The link layer protocol of the interface is running properly. ● DOWN: The link layer protocol of the interface is Down or no IP address is configured on the interface.
The Maximum Transmit Unit	MTU of the interface. The default MTU of an Ethernet interface or a serial interface is 1500 bytes. Packets longer than the MTU are fragmented before being transmitted. If fragmentation is not allowed, the packets are discarded.
input packets : 766390, bytes : 41540847, multicasts : 681817	Total number of packets, bytes, and multicast packets received by the interface.

Item	Description
output packets : 242239, bytes : 14679482, multicasts : 172333	Total number of packets, bytes, and multicast packets sent by the interface.
Directed-broadcast packets	Number of packets broadcast on the interface directly.
received packets	Total number of received packets.
sent packets	Total number of sent packets.
forwarded packets	Total number of forwarded packets.
dropped packets	Total number of discarded packets.
Internet Address is	IP address assigned to the interface and mask length.
Broadcast address	Broadcast address of the interface.
TTL being 1 packet number	Number of packets with TTL 1.
TTL invalid packet number	Number of packets with invalid TTL.
ICMP packet input number	Number of received ICMP packets.
Echo reply	Number of Echo Reply packets.
Unreachable	Number of Destination Unreachable packets.
Source quench	Number of Source Quench packets.
Routing redirect	Number of Redirect packets.
Echo request	Number of Echo Request packets.
Router advert	Number of Router Advertisement packets.
Router solicit	Number of Router Solicitation packets.
Time exceed	Number of Time Exceeded packets.
IP header bad	Number of IP header error packets.
Timestamp request	Number of Timestamp Request packets.
Timestamp reply	Number of Timestamp Reply packets.
Information request	Number of Information Request packets.
Information reply	Number of Information Reply packets.
Netmask request	Number of Address Mask Request packets.
Netmask reply	Number of Address Mask Reply packets.
Unknown type	Number of unknown packets.

Display brief IP information about VLANIF15.

```
<HUAWEI> display ip interface brief vlanif 15
*down: administratively down
^down: standby
(l): loopback
(s): spoofing
(E): E-Trunk down
Interface                     IP Address/Mask      Physical   Protocol
Vlanif15                      10.1.1.119/24        up         up
```

Table 6-44 Description of the **display ip interface brief** command output

Item	Description
*down:	Reason why an interface is physically Down. Administratively down indicates that the administrator has run the **shutdown** command on the interface.
^down	^down: indicates that the interface is a backup interface.
(l): loopback	The letter "l" refers to loopback.
(s): spoofing	The letter "s" refers to spoofing.
(E): E-Trunk down	Indicates that the Eth-Trunk is Down because of the protocol negotiation on the E-Trunk.
Interface	Interface type and number.
IP Address/Mask	IP address and mask of an interface.
Physical	Physical status of an interface: ● Up: indicates that the interface is physically Up. (l) indicates that the loopback function is configured on the interface. ● Down: indicates that the interface becomes faulty. ● *down: indicates that the administrator has run the **shutdown (interface view)** command on the interface. (l) indicates that the loopback function is configured on the interface. ● !down: indicates that the FIB module is suspended. In this case, the link protocol status of the interface is Down.

Item	Description
Protocol	Link protocol status of the interface: - Up: indicates that the link protocol of the interface is running properly. (s) indicates that the link protocol status of the interface is Up when this interface is created and has no IP address configured. This is an inherent attribute of an interface. When this interface is configured with an IP address, (s) is still displayed. - Down: indicates that the link protocol of the interface fails or no IP address is configured on the interface. (l) indicates that the loopback function is configured on the interface.

6.9.6 display ip forwarding status

Function

The **display ip forwarding status** command displays whether IPv4 Layer 3 unicast forwarding is enabled on a switch.

Format

display ip forwarding status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check whether IPv4 Layer 3 unicast forwarding is enabled on a switch.

Example

Display whether IPv4 Layer 3 unicast forwarding is enabled on the switch.

```
<HUAWEI> display ip forwarding status
Current IP forwarding status: Open
```

Table 6-45 Description of the **display ip forwarding status** command output

Item	Description
Current IP forwarding status	Whether IPv4 Layer 3 unicast forwarding is enabled: ● Open: The function is enabled. ● Closed: The function is disabled. To configure IPv4 Layer 3 unicast forwarding, run the **ip forwarding disable** command.

6.9.7 display ip socket

Function

The **display ip socket** command displays information about the created IPv4 sockets.

Format

display ip socket [**monitor**] [**task-id** *task-id* **socket-id** *socket-id* | **socket-type** *socket-type*]

Parameters

Parameter	Description	Value
monitor	Displays information about the socket monitor. Information about the socket monitor is displayed together with information about the socket.	-
task-id *task-id*	Displays socket information of the task with a specified ID.	The value must be an existing task ID.
socket-id *socket-id*	Displays information about the socket with a specified ID.	The value must be an existing socket ID.
socket-type *socket-type*	Displays information about a socket of a specified type.	The value is an integer. **Table 6-46** shows the value range.

Table 6-46 Value range of **socket-type** *socket-type*

Value	Description
1	TCP socket
2	UDP socket
3	RAWIP socket
4	RAWLINK socket

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A socket monitor monitors and records each connection. A RawLink also monitors interfaces. The socket monitor records specific protocol events that occur during operations. In addition, it logs information in the disk space.

The socket monitor is similar to a black box of the system. It records specific events that happen during system operations. When the system fails, you can use information recorded by the socket monitor to locate faults.

You can also set the filtering rules, such as the task ID, socket ID, and socket type so that only the information matching the rules is displayed. This reduces information output and helps you locate faults accurately and efficiently.

Example

Display information about the IP sockets.

```
<HUAWEI> display ip socket monitor
SOCK_STREAM:
Task = VTYD(30), socketid = 1, Proto = 6,
LA = 0.0.0.0:23, FA = 0.0.0.0:0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_KEEPALIVE SO_LINGER SO_REUSEPORT SO_SENDVPNID(23553)
SO_SETKEEPALIVE SO_SETACL,
socket state = SS_PRIV SS_ASYNC
                        Socket Monitor:
Asyn Que status:
 read = 0, write = 0, connect = 0, close = 0,
 peer close = 0, accept = 0, keep alive down = 0,
 cram time = 0000-00-00 00:00:00+08:00, lost msg= 0, msg type=0x00000000;
Nothing else has been captured!
SOCK_DGRAM:
Task = DHCP(54), socketid = 2, Proto = 17,
LA = 0.0.0.0:67, FA = 0.0.0.0:0,
sndbuf = 9216, rcvbuf = 41600, sb_cc = 0, rb_cc = 0,
socket option = SO_BROADCAST SO_REUSEPORT SO_UDPCHECKSUM SO_SENDVPNID(14849),
socket state = SS_PRIV
                        Socket Monitor:
Statistics:
```

```
 input packets = 6,recv packets = 6,output packets = 0;
Rcvbuf status:
 cram time = 0000-00-00 00:00:00+00:00, full times = 0,dropped packets = 0;
Asyn Que status:
 read = 0, write = 0, connect = 0, close = 0,
 peer close = 0, accept = 0, keep alive down = 0,
 smb input = 0, smb output = 0, smooth over = 0,
 cram time = 0000-00-00 00:00:00+00:00, lost msg = 0, msg type = 0x00000000;
```

Display the information about the IP socket with the task ID as 23 and socket ID as 1.

```
<HUAWEI> display ip socket monitor task-id 23 socket-id 1
Task = RSVP(23), socketid = 1, Proto = 46,
LA = 0.0.0.0, FA = 0.0.0.0,
sndbuf = 4194304, rcvbuf = 4194304, sb_cc = 0, rb_cc = 0,
socket option = 0,
socket state = SS_PRIV SS_NBIO SS_ASYNC
                        Socket Monitor:
Statistics:
 input packets = 0,recv packets = 0,output packets = 0;
Rcvbuf status:
 cram time = 00H00M00S: full times = 0,dropped packets = 0;
Asyn Que status:
 read = 0, write = 0, connect = 0, close = 0,
 peer close = 0, accept = 0, keep alive down = 0,
 smb input = 0, smb output = 0, smooth over = 0,
 cram time = 00H00M00S, lost msg = 0, msg type = 0x00000000;
```

Display information about the IP socket with the socket type as TCP.

```
<HUAWEI> display ip socket monitor socket-type 1
SOCK_STREAM:
Task = VTYD(30), socketid = 1, Proto = 6,
LA = 0.0.0.0:23, FA = 0.0.0.0:0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_KEEPALIVE SO_REUSEPORT SO_SENDVPNID(14849)
SO_SETKEEPALIVE,
socket state = SS_PRIV SS_ASYNC
                        Socket Monitor:
Asyn Que status:
 read = 0, write = 0, connect = 0, close = 0,
 peer close = 0, accept = 0, keep alive down = 0,
 cram time = 0000-00-00 00:00:00+00:00, lost msg= 0, msg type=0x00000000;
Nothing else has been captured!
```

Table 6-47 Description of the **display ip socket** command output

Item	Description
SOCK_STREAM	Socket types. There are the following socket types: ● SOCK_STREAM ● SOCK_DGRAM ● SOCK_RAWLINK ● SOCK_RAWIP
Task	Type and ID of the task that invokes the socket. For example, Task = VTYD(30) indicates that the task named VTYD uses the socket, with the task ID being 30.
socketid	Socket ID.

Item	Description
Proto	Protocol number.
LA	Local address/port number.
FA	Remote address/port number.
sndbuf	Maximum socket send buffer size. The value is in bytes.
rcvbuf	Maximum socket receive buffer size. The value is in bytes.
sb_cc	Number of sent packets. The value is in bytes and is valid only when TCP caches data packets.
rb_cc	Number of received packets. The value is in bytes.

Item	Description
socket option	Set socket options. There are the following socket options: - SO_DEBUG: indicates that debugging is enabled. - SO_ACCEPTCONN: indicates that the socket is the server and is responsible for monitoring. - SO_REUSEADDR: indicates that addresses are overlapped. After the option is set, multiple identical addresses can be bound to an interface. - SO_KEEPALIVE: indicates that the keepalive timer starts after a TCP connection is set up. - SO_DONTROUTE: indicates that a socket must choose the direct route to the destination when setting up a connection. - SO_BROADCAST: indicates that an interface can send broadcast packets. - SO_REUSEPORT: indicates that interfaces are overlapped. After the option is set, multiple identical interfaces can be bound to the local interface. This option is often set on servers. - SO_UDPCHECKSUM: indicates that the socket calculates the checksum of UDP packets. - SO_SENDVPNID: indicates an exclusive option for VPNs. - SO_SETKEEPALIVE: indicates that the keepalive timer starts after a TCP connection is set up. - SO_SETACL: indicates that an ACL can be configured on the interface. - SO_USELOOPBACK: indicates that a socket can use a loopback interface to receive or send data. - SO_LINGER: indicates the time for closing a TCP connection. If the time is not set to 0, a TCP connection is closed after the timer expires. If the time is set to 0, a TCP connection is closed immediately.

Item	Description
	- SO_OOBINLINE: indicates out-band data. When receiving data, a socket processes the out-band data first. - SO_SENDDATAIF: indicates that a socket uses the specified interface to receive or send data. - SO_SENDDATAIF_DONTSETTTL: indicates that a socket uses the specified interface to receive or send data but does not set the TTL value. - SO_SETSRCADDR: indicates that a socket sets the source address of outgoing packets. - SO_SENDBY_IF_NEXTHOP: indicates that a socket sets the outbound interface and next hop address of outgoing packets.

Item	Description
socket state	Socket status. There are the following socket states: ● SS_NOFDREF: indicates that the socket ID is deleted. ● SS_ISCONNECTED: indicates that a TCP connection is set up. ● SS_ISCONNECTING: indicates that a TCP connection is being set up. ● SS_ISDISCONNECTING: indicates that a TCP connection is being closed. ● SS_CANTSENDMORE: indicates that a socket cannot send data. ● SS_CANTRCVMORE: indicates that a socket cannot receive data. ● SS_RCVMARK: indicates that a socket sets the receiving option in the received packet. ● SS_NBIO: indicates that the type of a socket is non-blocking. ● SS_ISCONFIRMING: indicates that the upper-layer application will complete processing a connection. ● SS_BLOCKING: indicates that congestion occurs during packet receiving and sending. ● SS_RECALL: indicates that the message notification method is set by an asynchronous socket. ● SS_PRIV: indicates the option transferred from the Unix. The option is invalid in the current socket. ● SS_ASYNC: indicates the status identifier of an asynchronous socket.
Asyn Que status	Current asynchronous queue status.
read	Number of messages read by the asynchronous queue.
write	Number of messages written by the asynchronous queue.
connect	Number of connection messages in the asynchronous queue.
close	Number of messages about closed connections in the asynchronous queue.

Item	Description
peer close	Number of messages about connections closed by the remote end in the asynchronous queue.
accept	Number of messages received by the asynchronous queue.
keep alive down	Number of keepalivedown messages in the asynchronous queue.
cram time	Time for the asynchronous queue to become full.
lost msg	Number of asynchronous messages discarded by the asynchronous queue.
msg type	Current asynchronous message type.
smb input	Number of times of notifying the application layer to read received packets on the backup board.
smb output	Number of times of notifying the application layer to read sent packets on the backup board.
smooth over	Number of times of notifying the application layer that the smoothing is over.

6.9.8 display ip socket register-port

Function

The **display ip socket register-port** command displays non-well-known port numbers that have been assigned to services on the device.

Format

display ip socket register-port

Parameters

None

Views

All views

Default Level

3: Management level

Usage Guidelines

As defined in RFC standards, port numbers larger than 1024 are non-well-known port numbers and can be assigned to desired services, such as NQA and SSH services. However, a non-well-known port number can be assigned to only one service on the same device. If you assign a non-well-known port number to two or more services, this port number takes effect for only the latest configured service. As a result, the other services using this port number will fail.

Before you assign a non-well-known port number to a service, run the **display ip socket register-port** command to check non-well-known port numbers that have been assigned to other services, preventing service failures caused by conflicts of non-well-known port numbers.

Example

Display non-well-known port numbers that have been assigned to services on the device.

```
<HUAWEI> display ip socket register-port
Port      Task        Type
5247      CWP_FWD     UDP4
31009     MPLSFW      UDP4
38514     INFO        UDP4
60000     EZOP        UDP4
65030     ipfpm       UDP4
65531     CWP_FWD     UDP4
65532     CWP_FWD     UDP4
65533     CWP_FWD     UDP4
65534     CWP_FWD     UDP4
3232      mdt         UDP6
3503      MPLSFW      UDP6
3784      BFD         UDP6
4784      BFD         UDP6
5246      CWP_FWD     UDP6
5247      CWP_FWD     UDP6
31009     MPLSFW      UDP6
38514     INFO        UDP6
60000     EZOP        UDP6
65531     CWP_FWD     UDP6
65532     CWP_FWD     UDP6
65533     CWP_FWD     UDP6
65534     CWP_FWD     UDP6
```

Table 6-48 Description of the **display ip socket register-port** command output

Item	Description
Port	Non-well-known port number that has been assigned to a service.
Task	Name of the task to which a non-well-known port number is assigned.
Type	Port type, including TCP and UDP.

6.9.9 display ip statistics

Function

The **display ip statistics** command displays IP traffic statistics.

Format

display ip statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

IP traffic statistics include statistics about received packets (including discarded packets that carry source-route options), sent packets, fragmented packets, and reassembled packets. If a large number of bad protocol and no route fields is displayed in the command output, the device receives a large volume of IP packets of unknown protocol types and IP packets for which no routes can be found. In this situation, the device may be attacked by the connected devices.

Example

Display IP traffic statistics.

```
<HUAWEI> display ip statistics
 Input:     sum                263482      local               263473
            bad protocol            0      bad format               1
            bad checksum            0      bad options              0
            discard srr             0      discard rr               0
            discard ra              0      discard ts               0
            TTL exceeded            0
 Output:    forwarding              0      local               303399
            dropped             56479      no route               225
 Fragment:  input                   0      output                   0
            dropped                 0
            fragmented              0      couldn't fragment        0
 Reassembling:sum                   0      timeouts                 0
```

Table 6-49 Description of the **display ip statistics** command output

Item	Description
Input	Received packets.
sum	Total number of packets.

Item	Description
local	Number of packets sent to the upper-layer protocol.
bad protocol	Number of received IP packets of unknown protocol types. The protocol field in the IP header cannot be identified by the upper-layer protocol.
bad format	Number of packets in incorrect format.
bad checksum	Number of packets with checksum errors.
bad options	Number of packets with incorrect options.
discard srr	Number of discarded packets with source route options.
discard rr	Indicates the number of packets that are received and then discarded because of record-route options.
discard ra	Indicates the number of packets that are received and then discarded because of alert-route options.
discard ts	Indicates the number of packets that are received and then discarded because of time stamps options.
TTL exceeded	Number of packets discarded because the TTL expires.
Output	Sent packets.
forwarding	Number of forwarded packets.
local	Number of generated packets.
dropped	Number of discarded packets.
no route	Number of packets for which no correct route can be found, including the packets sent and forwarded by the local device.
Fragment	Number of packet fragments.
input	Number of received fragments.
output	Number of sent fragments.
dropped	Number of discarded fragments.
fragmented	Number of successfully fragmented packets.
couldn't fragment	Number of packets that cannot be fragmented.

Item	Description
Reassembling:sum	Number of successfully reassembled fragments.
timeouts	Number of expired fragments.

6.9.10 display load-balance mode

Function

The **display load-balance mode** command displays the load balancing mode on a switch.

Format

display load-balance mode [**packet** | **flow** | **slot** *slot-number*]

Parameters

Parameter	Description	Value
packet	Displays information about the switch adopting the per packet load balancing mode.	-
flow	Displays information about the switch adopting the per flow load balancing mode.	-
slot *slot-number*	Specifies the ID of a slot. After the slot ID is specified, the load balancing mode on a specified switch is displayed.	The value is an integer. It has a fixed value of 0 in a non-stack scenario, and depends on the device configuration in a stack scenario.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display load-balance mode packet** or the **display load-balance mode flow** command displays information about the switch adopting the specified load balancing mode.

The **display load-balance mode slot** *slot-number* command displays the load balancing mode on a specified switch.

If neither the slot ID nor load balancing mode is specified in the **display load-balance mode** command, by default, load balancing mode on the switch is displayed.

Example

Display the load balancing modes on the switch.

```
<HUAWEI> display load-balance mode
load-balance flow slot 0
```

Table 6-50 Description of the **display load-balance mode** command output

Item	Description
load-balance	Load balancing mode: ● packet: per packet load balancing ● flow: per flow load balancing
slot	Slot ID.

6.9.11 display network status

Function

Running the **display network status** command, you can check the network status of a device.

Format

display network status { **all** \| **tcp** \| **udp** \| **port** *port-number* }

Parameters

Parameter	Description	Value
all	Displays all the network information.	-
tcp	Displays TCP.	-

Parameter	Description	Value
udp	Displays UDP.	-
port *port-number*	Specifies the number of an interface.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display network status** command to check the network status, such as the running ports and services on the network. For example, when you find that a port is being used by an unknown module during a security scan, run the **display network status** command to check out the module.

Example

Display all information about the network status.

```
<HUAWEI> display network status all
Proto Task/SockId Local Addr&Port          Foreign Addr&Port        State
TCP   VTYD/1      0.0.0.0:23               0.0.0.0:0                Listening
TCP   HTTP/2      0.0.0.0:80               0.0.0.0:0                Listening
TCP   HTTP/1      0.0.0.0:443              0.0.0.0:0                Listening
TCP   VTYD/59     192.168.50.166:23        10.135.19.141:60445      Established
TCP6  VTYD/2      ::->23                   ::->0                    Listening
UDP   AGNT/1      0.0.0.0:161              0.0.0.0:0
UDP   SLAG/1      0.0.0.0:1025             0.0.0.0:0
UDP   RDS /1      0.0.0.0:1812             0.0.0.0:0
UDP   CMRE/1      0.0.0.0:65311            0.0.0.0:0
UDP6  AGT6/1      ::->161                  ::->0
UDP6  RDS /2      ::->1812                 ::->0
```

Table 6-51 Description of the **display network status** command output

Item	Description
Proto	Protocol

Item	Description
Task/SockId	Task and Socket ID - VTYD: Process login requests of all users. - HTTP: Transfer hypertext from WWW servers to local browsers - AGNT: Implement the IPv4 SNMP protocol. - SLAG: Implement E-Trunk. - RDS: Implement the RADIUS protocol, manage the protocol state machine, and maintain protocol databases. - CMRE: Register with the iMaster NCE-Campus for authentication and establishes NETCONF transmission channels. - AGT6: Implement the IPv6 SNMP protocol.
Local Addr&Port	Local IP address and Port number
Foreign Addr&Port	Remote IP address and Port number
State	Connection status

6.9.12 display priority

Function

Using the **display priority** command, you can view the 802.1p priority and DSCP priority that are set in the system.

Format

display priority { **8021p** | **dscp** }

Parameters

Parameter	Description	Value
8021p	Displays the 802.1p priority.	-
dscp	Displays the DSCP priority.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays the 802.1p priority and DSCP priority that are set in the system.

The **display priority** command displays information only after the **set priority** command is executed to set the 802.1p priority or DSCP priority.

Example

Set the DSCP priority to 10, and display the DSCP priority set in the system.

```
<HUAWEI> system-view
[HUAWEI] set priority dscp 10
[HUAWEI] quit
<HUAWEI> display priority dscp
 The dscp priority is 10
```

6.9.13 display rawip statistics

Function

The **display rawip statistics** command displays RawIP traffic statistics.

Format

display rawip statistics [**verbose**]

Parameters

Parameter	Description	Value
verbose	Displays detailed RawIP traffic statistics based on the ICMP, RSVP, OSPF, and Others protocols.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The statistics about RawIP packets include the number of sent RawIP packets and the number of received RawIP packets.

RSVP, OSPF, and ICMP packets are encapsulated into RawIP packets to be sent. During the ping operation, for example, you can run the **display rawip statistics** command to view the number of RawIP packets sent by the local device to check whether the abnormality on the network is caused by abnormal sending and receiving of RawIP packets.

If you want to diagnose problems and monitor information of specific applications, configure **verbose** in the **display rawip statistics** command to display application-specific RawIP packet statistics. The applications can be ICMP, RSVP, OSPF, and others.

Precautions

The number of packets received by a switch includes the number of forwarded packets, packets sent to the upper layer, and discarded packets.

RawIP traffic statistics are collected based on the well-known protocol number. The protocol number is identified by the protocol field in the IP packet header.

- The protocol number of ICMP statistics is 1.
- The protocol number of OSPF statistics is 89.
- The protocol number of RSVP statistics is 46.
- Statistics about packets with other protocol numbers are collected into the Others field.

Example

View the statistics about RawIP packets.

```
<HUAWEI> display rawip statistics
Received packets:
  dropped packets because the socket buffer is full   : 0
  dropped packets because no matching socket is found : 0

Sent packets:
  dropped packets : 0
```

Table 6-52 Description of the **display rawip statistics** command output

Item	Description
Received packets	Indicates the number of received packets.
dropped packets because the socket buffer is full	Indicates the number of RawIP packets that are discarded because the socket buffer is full.
dropped packets because no matching socket is found	Indicates the number of RawIP packets that are discarded because the socket of the receiver does not match with that of the sender.
Sent packets	Indicates the number of sent packets.
dropped packets	Indicates the number of discarded packets.

6.9.14 display tcp statistics

Function

The **display tcp statistics** command displays TCP traffic statistics.

Format

display tcp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command displays TCP traffic statistics including different types of received and sent packets. For example, duplicate received packets and packets with checksum errors. In addition, connection-related statistics are displayed, for example, times of accepted connections, the number of retransmitted packets, and the number of keepalive packets.

Most of the preceding statistics are expressed in number of packets, and some of them are expressed in number of bytes.

Example

Display TCP traffic statistics.

```
<HUAWEI> display tcp statistics
Received packets:
     Total: 0
     Total(64bit high-capacity counter): 0
     packets in sequence: 0 (0 bytes)
     window probe packets: 0, window update packets: 0
     checksum error: 0, offset error: 0, short error: 0

     duplicate packets: 0 (0 bytes), partially duplicate packets: 0 (0 bytes)
     out-of-order packets: 0 (0 bytes)
     packets of data after window: 0 (0 bytes)
     packets received after close: 0

     ACK packets: 0 (0 bytes)
     duplicate ACK packets: 0, too much ACK packets: 0

Sent packets:
    Total: 0
     Total(64bit high-capacity counter): 0
     urgent packets: 0
     control packets: 0 (including 0 RST)
     window probe packets: 0, window update packets: 0
```

```
    data packets: 0 (0 bytes),    data packets retransmitted: 0 (0 bytes)
    ACK-only packets: 0 (0 delayed)

Other information:
    Retransmitted timeout: 0, connections dropped in retransmitted timeout: 0
    Keep alive timeout: 0, keep alive probe: 0,     Keep alive timeout, so connections disconnected : 0
    Initiated connections: 0,     accepted connections: 0, established connections: 0
    Closed connections: 0 (    dropped: 0, initiated dropped: 0)
    Packets dropped with MD5 authentication: 0
    Packets permitted with MD5 authentication: 0
    Send Packets permitted with Keychain authentication: 0
    Receive Packets permitted with Keychain authentication: 0
    Receive Packets Dropped with Keychain authentication: 0
```

Table 6-53 Description of the **display tcp statistics** command output

Item	Description
Received packets	Statistics about received packets.
Total	Total number of packets.
Total (64bit high-capacity counter)	Total number of packets, using the 64-bit counter.
packets in sequence (bytes)	Number of bytes in the packets that arrive in order.
window probe packets	Number of window probe packets.
window update packets	Number of window update packets.
checksum error	Number of packets with checksum errors.
offset error	Number of packets with offset errors.
short error	Number of packets whose length is too short.
duplicate packets (bytes)	Number of bytes in the duplicate packets.
partially duplicate packets (bytes)	Number of bytes in partially duplicate packets.
out-of-order packets (bytes)	Number of bytes in the out-of-order packets.
packets of data after window (bytes)	Number of bytes in the packets whose size is greater than the window size.
packets received after close	Number of packets that arrive after a connection is closed.
ACK packets (bytes)	Number of acknowledged packets, in bytes.
duplicate ACK packets	Number of re-acknowledged packets.
too much ACK packets	Number of acknowledged packets with no data sent.

Item	Description
Sent packets	Number of sent packets.
urgent packets	Number of urgent packets.
control packets (RST)	Number of control packets (RST packets).
data packets	Number of data packets.
data packets retransmitted (0 bytes)	Number of bytes in the retransmitted packets.
ACK only packets (delayed)	Number of acknowledged packets that are delayed.
Other information	Other information.
Retransmitted timeout	Timeout interval of the retransmission timer.
connections dropped in retransmitted timeout	Number of connections discarded because the number of retransmission times exceeds the threshold.
Keep alive timeout	Timeout interval of the keepalive timer.
keep alive probe	Number of sent keepalive packets.
Keep alive timeout, so connections disconnected	Number of connections discarded because keepalive probe fails.
Initiated connections	Number of initiated connections.
accepted connections	Number of accepted connections.
established connections	Number of established connections.
Closed connections (dropped, initiated dropped)	Number of closed connections (number of discarded packets after a connection is set up or before a connection is set up).
Packets dropped with MD5 authentication	Number of packets that fail to pass MD5 authentication.
Packets permitted with MD5 authentication	Number of packets that pass MD5 authentication.
Send Packets permitted with Keychain authentication	Number of sent packets that carry keychain options.
Receive Packets permitted with Keychain authentication	Number of received packets that pass keychain authentication.
Receive Packets Dropped with Keychain authentication	Number of received packets that fail to pass keychain authentication.

6.9.15 display tcp status

Function

The **display tcp status** command displays current TCP connection status.

Format

display tcp status [[**task-id** *task-id*] [**socket-id** *socket-id*] | [**local-ip** *ip-address*] [**local-port** *local-port-number*] [**remote-ip** *ip-address*] [**remote-port** *remote-port-number*]]

Parameters

Parameter	Description	Value
task-id *task-id*	Displays the TCP connection status of the task with a specified ID.	The value must be an existing task ID.
socket-id *socket-id*	Displays the TCP connection status of the socket with a specified ID.	The value must be an existing socket ID.
local-ip *ip-address*	Displays the TCP connection status of a specified local IP address.	The value is in dotted decimal notation.
local-port *local-port-number*	Displays the TCP connection status of a specified local port ID.	The value must be an existing local port ID.
remote-ip *ip-address*	Displays the TCP connection status a specified remote IP address.	The value is in dotted decimal notation.
remote-port *remote-port-number*	Displays the TCP connection status of a specified remote port ID.	The value must be an existing remote port ID.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The transmission control protocol defined in RFC 793 ensures high reliability of transmission between hosts. TCP provides reliable and connection-oriented services in full duplex mode. Run the **display tcp status** command to monitor the TCP connection status. The following information is displayed.

- ID of the TCP task control block.
- ID of the IPv4 TCP task and socket.
- Local IPv4 address and port ID.
- Remote IPv4 address and port ID.
- ID of the VPN instance to which the TCP connection belongs.
- IPv4 TCP connection status.

You can set filtering rules based on the Task ID, socket ID, IP address and port number of the local device, and IP address and port number of the remote device so that only the information matching the rules is displayed. This prevents unnecessary information from being displayed and helps you locate faults accurately and efficiently.

Precautions

The command output is null if there is no TCP connection.

Example

Display the TCP connection status on the local device.

```
<HUAWEI> display tcp status
TCPCB    Tid/Soid Local Add:port        Foreign Add:port      VPNID  State
0a5d560c 30 /1    0.0.0.0:23            0.0.0.0:0             14849 Listening
```

Display the status of the TCP connection originated from the local IP address 0.0.0.0 and port 23.

```
<HUAWEI> display tcp status local-ip 0.0.0.0 local-port 23
TCPCB    Tid/Soid Local Add:port        Foreign Add:port      VPNID  State
0a5d560c 30 /1    0.0.0.0:23            0.0.0.0:0             14849 Listening
```

Table 6-54 Description of the **display tcp status** command output

Field	Description
TCPCB	ID of the TCP task control block.
Tid/Soid	Task ID and socket ID.
Local Add: port	IP address and port number of the local device. If the value of Local Add is 0.0.0.0, TCP connections of all IP addresses are monitored. If the value of port is 0, the TCP connection of all ports is monitored.

Field	Description
Foreign Add: port	IP address and port number of the remote device. If the value of Foreign Add is 0.0.0.0, the TCP connection of all IP addresses is monitored. If the value of port is 0, TCP connections of all ports are monitored.
VPNID	ID of the VPN instance to which the TCP connection belongs. ● -1: indicates all VPNs. ● 0: indicates the public VPN. ● Other values: indicates the private VPN. The VPNID is defined by users.
State	TCP connection status: ● Closed: indicates that the TCP connection is closed. ● Listening: indicates that the TCP connection is being monitored. ● Syn_Rcvd: indicates that a packet with the SYN flag is received. ● Syn_Sent: indicates that a SYN packet is sent. ● Established: indicates that the TCP connection has been set up. ● Close_Wait: indicates that a user sends a packet with the FIN flag to the server to close the TCP connection in Established state. The server then sends an ACK packet to the user after receiving the packet and enters the Close_Wait state. ● Fin_Wait1: indicates that a user sends a packet with the FIN flag to the server to close the TCP connection and enter this state. ● Fin_Wait2: indicates that a user receives an ACK packet that responds to the sent packet with the FIN flag. ● Time_Wait: indicates that TCP enters this state after the TCP connection is closed. When TCP has been in Time_Wait state two times the lifetime of the longest packets, records about the closed connection are deleted. ● Closing: indicates that the user and server close the TCP connection simultaneously.

6.9.16 display udp statistics

Function

The **display udp statistics** command displays UDP traffic statistics.

Format

display udp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command displays UDP traffic statistics including different types of received and sent packets. For example, packets with checksum errors. In addition, connection-related statistics are displayed, for example, the number of broadcast packets. The preceding statistics are expressed in number of packets.

Example

Display UDP traffic statistics.

```
<HUAWEI> display udp statistics
Received packets:
    Total: 0
    Total(64bit high-capacity counter): 0
    checksum error: 0
    shorter than header: 0
    data length larger than packet: 0
    unicast(no socket on port): 0
    broadcast/multicast(no socket on port): 0
    not delivered, input socket full: 0
    input packets missing pcb cache: 0

Sent packets:
    Total: 0
    Total(64bit high-capacity counter): 0
```

Table 6-55 Description of the **display udp statistics** command output

Item	Description
Received packet: Total Total (64bit high-capacity counter)	Total number of received UDP packets. Total number of received UDP packets (using the 64-bit counter).
checksum error	Number of packets with checksum errors.
shorter than header	Number of packets whose length is shorter than the packet header.

Item	Description
data length larger than packet	Number of packets whose data length is greater than the packet length.
unicast (no socket on port)	Number of unicast packets.
broadcast/multicast (no socket on port)	Number of broadcast and multicast packets.
not delivered, input socket full	Number of packets that are not sent out because the socket buffer is full.
input packets missing pcb cache	Number of sent packets that are not found in the PCB cache.
Sent packets: Total Total (64bit high-capacity counter)	Total number of sent UDP packets. Total number of sent UDP packets (using the 64-bit counter).

6.9.17 drop illegal-dst-ip enable

Function

The **drop illegal-dst-ip enable** command enables the device to discard IP packets with invalid destination IP addresses and record logs.

The **undo drop illegal-dst-ip enable** command disables the device from discarding IP packets with invalid destination IP addresses and recording logs.

By default, a device is disabled from discarding IP packets with invalid destination IP addresses and recording logs.

Format

drop illegal-dst-ip enable

undo drop illegal-dst-ip enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The following three types of IP addresses are invalid destination IP addresses and should not be used on the network:

- IP address with all 0s, that is, 0.0.0.0
- IP addresses with a network ID of 127, that is, 127.0.0.0 to 127.255.255.255
- Class E IP addresses except 255.255.255.255, that is, 240.0.0.0 to 255.255.255.254

After the **drop illegal-dst-ip enable** command is run on a device, the device discards the IP packets destined to invalid IP addresses and reports statistics about the discarded packets through logs. This reduces the device burden and prevents these packets from occupying network bandwidth.

NOTE

- Devices of the following models will discard IP packets destined to 0.0.0.0, 127.0.0.0 to 127.255.255.255, and 240.0.0.0 to 255.255.255.254 only after this function is configured:

  S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S
- Devices of other models discard the IP packet destined to an IP address that does not match any routing entry. Since there is no routing entry matching 0.0.0.0, 127.0.0.0 to 127.255.255.255, or 240.0.0.0 to 255.255.255.254, devices will discard IP packets destined to these IP addresses by default.

Example

Enable the device to discard IP packets with invalid destination IP addresses and record logs.

```
<HUAWEI> system-view
[HUAWEI] drop illegal-dst-ip enable
```

6.9.18 drop illegal-ip disable

Function

The **drop illegal-ip disable** command disables a device from discarding IPv4 and IPv6 packets sourced from the all-zero address.

The **undo drop illegal-ip disable** command enables a device to discard IPv4 and IPv6 packets sourced from the all-zero address.

By default, the function of discarding IPv4 and IPv6 packets sourced from the all-zero address is enabled.

NOTE

The **drop illegal-ip disable** and **undo drop illegal-ip disable** commands are supported only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S. The other device models discard IPv4 and IPv6 packets sourced from the all-zero address by default, and this function cannot be disabled on those models.

Format

drop illegal-ip disable

undo drop illegal-ip disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

IPv4 and IPv6 packets sourced from the all-zero address are typical attack packets. You can run the **undo drop illegal-ip disable** command to enable a device to discard these packets.

Example

Enable a device to discard IPv4 and IPv6 packets sourced from the all-zero address.

```
<HUAWEI> system-view
[HUAWEI] undo drop illegal-ip disable
```

6.9.19 icmp blackhole unreachable send

Function

The **icmp blackhole unreachable send** command enables the switch to send a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv4 blackhole route.

The **undo icmp blackhole unreachable send** command disables the switch from sending a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv4 blackhole route.

By default, the switch is disabled from sending a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv4 blackhole route.

Format

icmp blackhole unreachable send

undo icmp blackhole unreachable send

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If static IPv4 blackhole routes are configured on the switch configured with the user access and authentication function, when a user goes offline, only the IPv4 blackhole route corresponding to the user's address segment exists on the switch. When a tracert packet matches the IPv4 blackhole route, the switch discards the packet. As a result, an initiator cannot detect that the user has gone offline.

After you run the **icmp blackhole unreachable send** command, the switch sends a Destination Unreachable ICMP packet to an initiator, notifying the initiator that the user has gone offline if a user goes offline and a tracert packet matches the IPv4 blackhole route.

Example

Enable the switch to send a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv4 blackhole route.

```
<HUAWEI> system-view
[HUAWEI] icmp blackhole unreachable send
```

6.9.20 icmp host-unreachable send

Function

The **icmp host-unreachable send** command enables the switch to send ICMP Host Unreachable packets.

The **undo icmp host-unreachable send** command disables the switch from sending ICMP Host Unreachable packets.

By default, the function of sending ICMP Host Unreachable packets is enabled.

Format

icmp host-unreachable send

undo icmp host-unreachable send

Parameters

None

Views

System view, interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

ICMP error packets contain network information, such as network connectivity, host reachability, and route availability. ICMP error packets are ultimately returned to the sender because the sender is the logical receiver of the ICMP error packets. The sender learns about the error types from the ICMP error packets, and then determines how to retransmit the data.

The Destination Unreachable packets facilitate network control and management. However, the inherent defects of the ICMP protocol make the routing devices and hosts be prone to attacks. Therefore, sending the ICMP Destination Unreachable packets has the following defects:

- The ICMP packets increase traffic volume and burden the network devices.
- If a device receives a large number of malicious attack packets and needs to return ICMP error packets, the device is busy handling ICMP packets, and the device performance is degraded.
- The ICMP Destination Unreachable packets indicate that the destination is unreachable. If there are malicious attacks, user terminals cannot normally use the network.

After you run the **undo icmp host-unreachable send** command, the device does not send ICMP Host Unreachable packets externally. This prevents the peer device from processing a large number of ICMP packets.

Precautions

The **icmp host-unreachable send** command can be run in the system view or interface view.

- After the function of sending ICMP Host Unreachable packets is disabled in the system view, all interfaces do not send ICMP Host Unreachable packets. Even if the function is enabled on an interface, the interface does not send ICMP Host Unreachable packets.
- After the function of sending ICMP Host Unreachable packets is enabled in the system view, all interfaces send ICMP Host Unreachable packets because the function is enabled on all interfaces by default. You can run the **undo icmp host-unreachable send** command in interface view to disable the function on a specified interface.

If the function of sending ICMP Host Unreachable packets is disabled, the switch does not send ICMP Host Unreachable packets in any situations.

This command needs to be configured on the inbound interface of ICMP packets in the interface view.

Example

Enable the switch to send ICMP Host Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] icmp host-unreachable send
```

Enable VLANIF100 to send ICMP Host Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] icmp host-unreachable send
```

Enable GE0/0/1 to send ICMP Host Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] icmp host-unreachable send
```

6.9.21 icmp port-unreachable send

Function

The **icmp port-unreachable send** command enables the device to send ICMP Port Unreachable packets.

The **undo icmp port-unreachable send** command disables the device from sending ICMP Port Unreachable packets.

By default, the device sends ICMP Port Unreachable packets.

Format

icmp port-unreachable send

undo icmp port-unreachable send

Parameters

None

Views

System view, interface view

2: Configuration level

Usage Guidelines

Usage Scenario

ICMP error packets contain network information, such as network connectivity, host reachability, and route availability. ICMP error packets are ultimately returned to the sender because the sender is the logical receiver of the ICMP error packets. The sender learns about the error types from the ICMP error packets, and then determines how to retransmit the data.

The Destination Unreachable packets facilitate network control and management. However, the inherent defects of the ICMP protocol make the routing devices and hosts be prone to attacks. Therefore, sending the ICMP Destination Unreachable packets has the following defects:

- The ICMP packets increase traffic volume and burden the network devices.
- If a device receives a large number of malicious attack packets and needs to return ICMP error packets, the device is busy handling ICMP packets, and the device performance is degraded.
- The ICMP Destination Unreachable packets indicate that the destination is unreachable. If there are malicious attacks, user terminals cannot normally use the network.

After you run the **undo icmp port-unreachable send** command, the device does not send ICMP Port Unreachable packets externally. This prevents the peer device from processing a large number of ICMP packets.

Precautions

The **icmp port-unreachable send** command can be run in the system view or interface view.

- After the function of sending ICMP Port Unreachable packets is disabled in the system view, all interfaces do not send ICMP Port Unreachable packets. Even if the function is enabled on an interface, the interface does not send ICMP Port Unreachable packets.
- After the function of sending ICMP Port Unreachable packets is enabled in the system view, all interfaces send ICMP Port Unreachable packets because the function is enabled on all interfaces by default. You can run the **undo icmp port-unreachable send** command in interface view to disable the function on a specified interface.

If the function of sending ICMP Port Unreachable packets is disabled, the switch does not send ICMP Port Unreachable packets in any situations.

Example

Enable the device to send ICMP Port Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] icmp port-unreachable send
```

Enable the device to send ICMP Port Unreachable packets on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] icmp port-unreachable send
```

Enable the device to send ICMP Port Unreachable packets on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] icmp port-unreachable send
```

6.9.22 icmp protocol-unreachable send

Function

The **icmp protocol-unreachable send** command enables the function of sending ICMP Protocol Unreachable packets.

The **undo icmp protocol-unreachable send** command disables the function of sending ICMP Protocol Unreachable packets.

By default, the function of sending ICMP Protocol Unreachable packets is enabled.

Format

icmp protocol-unreachable send

undo icmp protocol-unreachable send

Parameters

Usage Guidelines

ICMP error packets contain network information, such as network connectivity, host reachability, and route availability. ICMP error packets are ultimately returned to the sender because the sender is the logical receiver of the ICMP error packets. The sender learns about the error types from the ICMP error packets, and then determines how to retransmit the data.

The Destination Unreachable packets facilitate network control and management. However, the inherent defects of the ICMP protocol make the routing devices and hosts be prone to attacks. Therefore, sending the ICMP Destination Unreachable packets has the following defects:

- The ICMP packets increase traffic volume and burden the network devices.
- If a device receives a large number of malicious attack packets and needs to return ICMP error packets, the device is busy handling ICMP packets, and the device performance is degraded.
- The ICMP Destination Unreachable packets indicate that the destination is unreachable. If there are malicious attacks, user terminals cannot normally use the network.

After you run the **icmp protocol-unreachable send** command, the device does not send ICMP Protocol Unreachable packets externally. This prevents the peer device from processing a large number of ICMP packets.

Example

Enable the function of sending ICMP Protocol Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] icmp protocol-unreachable send
```

6.9.23 icmp receive

Function

The **icmp receive** command enables a switch to receive ICMP packets with the local IP address as the destination IP address.

The **undo icmp receive** command disables a switch from receiving ICMP packets with the local IP address as the destination IP address.

By default, switches are enabled to receive ICMP packets with the local IP address as the destination IP address.

Format

icmp { **type** *icmp-type* **code** *icmp-code* | **name** *icmp-name* | **all** } **receive**

undo icmp { **type** *icmp-type* **code** *icmp-code* | **name** *icmp-name* | **all** } **receive**

Parameters

Parameter	Description	Value
type *icmp-type*	Specifies the type number of an ICMP packet.	The value is an integer ranging from 0 to 255.
code *icmp-code*	Specifies the code of an ICMP packet.	The value is an integer ranging from 0 to 255.

Parameter	Description	Value
name *icmp-name*	Specifies the name of an ICMP packet.	The value is a string of case-insensitive characters, with spaces not supported. The value can be any of the following: ● echo ● echo-reply ● fragmentneed-dfset ● host-redirect ● host-tos-redirect ● host-unreachable ● information-reply ● information-request ● net-redirect ● net-tos-redirect ● net-unreachable ● parameter-problem ● port-unreachable ● protocol-unreachable ● reassembly-timeout ● source-quench ● source-route-failed ● timestamp-reply ● timestamp-request ● ttl-exceeded
all	Specifies all ICMP packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- On secure networks, the device can normally receive ICMP packets. In the case of heavy traffic on the network, if hosts or ports are frequently unreachable, the device will receive a large number of ICMP packets, which causes heavier traffic burdens over the network and degrades the performance of the device.

- On insecure networks, network attackers often use ICMP error packets to probe on the internal structure of the network.

To improve network performance or enhance security, run the **undo icmp receive** command to disable switches from receiving ICMP packets with the local IP address as the destination IP address.

After network performance improves, you can run the **icmp receive** command to enable switches to receive ICMP packets with the local IP address as the destination IP address.

Precautions

After the **undo icmp receive** command is run, the device no longer process ICMP packets of a certain type, causing the host to fail to ping the device.

Example

Disable the switch from receiving ICMP packets with the local IP address as the destination IP address whose type number is 3 and code number is 1.

```
<HUAWEI> system-view
[HUAWEI] undo icmp type 3 code 1 receive
```

6.9.24 icmp redirect send

Function

The **icmp redirect send** command enables the switch to send ICMP redirect packets.

The **undo icmp redirect send** command disables the switch from sending ICMP redirect packets.

The function of sending ICMP Redirect packets is enabled.

Format

icmp redirect send

undo icmp redirect send

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

ICMP error packets contain network information, such as network connectivity, host reachability, and route availability. ICMP error packets are ultimately returned to the sender because the sender is the logical receiver of the ICMP error packets. The sender learns about the error types from the ICMP error packets, and then determines how to retransmit the data.

ICMP Redirect packets are a type of ICMP error packets.

When a host starts, there may be only one default route to the gateway in its routing table. In the following situations, the device functions as a gateway to send an ICMP Redirect packet to the source host, requesting the host to select another next hop address for subsequent packet forwarding:

- The interface that receives the data packet is the same as the interface used to forward the packet.
- The device needs to forward a received packet. After looking up the routing table, the device finds that the next hop IP address is on the same network segment with the destination address of the packet.

After the device sends ICMP Redirect packets to the host that has only a few routes, the host can enrich the routing table and find out the optimal route.

The ICMP error packets facilitate network control and management. However, the inherent defects of the ICMP protocol make the routing devices and hosts be prone to attacks. Therefore, sending the ICMP error packets has the following defects:

- The ICMP packets increase traffic volume and burden the network devices.
- If a device receives a large number of malicious attack packets and needs to return ICMP error packets, the device is busy handling ICMP packets, and the device performance is degraded.
- The ICMP Redirect function increases the number of routes in the host's routing table. When many routes are added, the host performance will be degraded.

You need to decide whether to enable ICMP Redirect packet sending according to network situation.

Precautions

The command is used on the interface that receives ICMP packets.

Example

Enable VLANIF100 to send ICMP Redirect packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] icmp redirect send
```

Enable GE0/0/1 to send ICMP Redirect packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] icmp redirect send
```

6.9.25 icmp time-exceed

Function

The **icmp time-exceed** command specifies the format of ICMP Time Exceeded packets.

The **undo icmp time-exceed** command restores the default format of ICMP Time Exceeded packets.

By default, ICMP Time Exceeded packets carry extension headers in compliant mode and original datagrams are of variable length.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

icmp time-exceed { **extension** { **compliant** | **non-compliant** } | **classic** }

undo icmp time-exceed

Parameters

Parameter	Description	Value
extension	Indicates that ICMP Time Exceeded packets carry extension headers.	-
compliant	Indicates that ICMP Time Exceeded packets carry extension headers in compliant mode and original datagrams are of variable length.	-
non-compliant	Indicates that ICMP Time Exceeded packets carry extension headers in non-compliant mode and original datagrams are of fixed length.	-
classic	Indicates that ICMP Time Exceeded packets do not carry extension headers.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When using the **tracert** command to check the network connectivity, you can run the **icmp time-exceed** command to specify the format of ICMP Time Exceeded packets.

- When the **icmp time-exceed** command carry the parameter **extension compliant**, ICMP Time Exceeded packets carry extension headers in compliant mode and original datagrams are of variable length. ICMP Time Exceeded packets carry as many original datagrams as possible. Lengths of original datagrams carried in ICMP Time Exceeded packets are recorded in ICMP headers.
- When the **icmp time-exceed** command carry the parameter **extension non-compliant**, ICMP Time Exceeded packets carry extension headers in non-compliant mode and original datagrams are of fixed length. If the length of original datagrams is less than 128 bytes, the system automatically fills the length to 128 bytes.
- When the **icmp time-exceed** command carry the parameter **classic**, ICMP Time Exceeded packets do not carry extension headers.

Example

Configure ICMP Time Exceeded packets to carry extension headers in compliant mode.

```
<HUAWEI> system-view
[HUAWEI] icmp time-exceed extension compliant
```

6.9.26 icmp ttl-exceeded drop

Function

The **icmp ttl-exceeded drop** command enables the device to discard the ICMP packets whose TTL values are 1.

The **undo icmp ttl-exceeded drop** command disables the device from discarding the ICMP packets whose TTL values are 1.

By default, the function of discarding ICMP packets with TTL values of 1 is disabled on the device.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

icmp ttl-exceeded drop { **slot** *slot-id* | **all** }

undo icmp ttl-exceeded drop { **slot** *slot-id* | **all** }

Parameters

Parameter	Description	Value
slot *slot-id*	Indicates the slot ID.	The value is determined based on the device configuration.
all	Indicates all the devices. This parameter is used when you need to enable all the devices to discard or disable all the devices from discarding the ICMP packets whose TTL values are 1.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

TTL is a field in an IP packet that limits the lifespan of the IP packet on the network. The TTL value is set by the sender, and is reduced by 1 every time the packet passes a device. If a forwarding device receives an IP packet of which the TTL is 0 and the destination address is not the local address, the device discards this packet and returns an ICMP packet to the sender.

ICMP packets are encapsulated into IP packets. When receiving an ICMP packet of which the destination address is not the local address and the TTL value is 1, the device discards the packet and returns an ICMP Time Exceeded.

When receiving a packet of which the TTL value is 1, the switch sends the packet to the CPU. The **tracert** function implements hop-by-hop detection using the packets with TTL value 1. If an attacker sends a large number of IP packets with TTL value 1 to a target device, the CPU of the target device is busy handling these IP packets and returns ICMP Destination Unreachable packets. Therefore, the CPU usage becomes high.

If a switch is configured to discard the ICMP packets with TTL value 1, the pressure on the switch can be reduced and network attacks can be prevented.

Precautions

After the function is enabled on the device, the **tracert** command does not take effect.

Example

Enable the device to discard the ICMP packets whose TTL values are 1.

```
<HUAWEI> system-view
[HUAWEI] icmp ttl-exceeded drop slot 0
```

6.9.27 icmp ttl-exceeded send

Function

The **icmp ttl-exceeded send** command enables an interface to send ICMP Time Exceeded packets.

The **undo icmp ttl-exceeded send** command disables an interface from sending ICMP Time Exceeded packets.

By default, an interface is enabled to send ICMP Time Exceeded packets.

Format

icmp ttl-exceeded send

undo icmp ttl-exceeded send

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If the destination address of a received IP packet is not the local address and the TTL value is 1, a timeout error occurs. In this situation, the device discards the packet and returns an ICMP Time Exceeded packet to the source.

When replying with an ICMP Time Exceeded packet, an interface adds its IP address as the source IP address in the ICMP Time Exceeded packet, exposing the interface itself to attackers. In addition, after being attacked, the interface replies with numerous ICMP Time Exceeded packets, consuming CPU resources and degrading system performance. To resolve these problems, run the **undo icmp ttl-exceeded send** command to disable the interface from replying with ICMP Time Exceeded packets.

Example

Enable VLANIF100 to send ICMP Time Exceeded packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] icmp ttl-exceeded send
```

Enable GE0/0/1 to send ICMP Time Exceeded packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] icmp ttl-exceeded send
```

6.9.28 icmp unreachable drop

Function

The **icmp unreachable drop** command enables the function of discarding ICMP Destination Unreachable packets.

The **undo icmp unreachable drop** command disables the function of discarding the ICMP Destination Unreachable packets.

By default, the function of discarding ICMP Destination Unreachable packets is disabled.

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

icmp unreachable drop

undo icmp unreachable drop

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

ICMP error packets contain network information, such as network connectivity, host reachability, and route availability. ICMP error packets are ultimately returned to the sender because the sender is the logical receiver of the ICMP error packets. The sender learns about the error types from the ICMP error packets, and then determines how to retransmit the data.

The Destination Unreachable packets facilitate network control and management. However, the inherent defects of the ICMP protocol make the routing devices and hosts be prone to attacks. Therefore, sending the ICMP Destination Unreachable packets has the following defects:

- The ICMP packets increase traffic volume and burden the network devices.
- If a device receives a large number of malicious attack packets and needs to return ICMP error packets, the device is busy handling ICMP packets, and the device performance is degraded.
- The ICMP Destination Unreachable packets indicate that the destination is unreachable. If there are malicious attacks, user terminals cannot normally use the network.

The switch sends ICMP Destination Unreachable packets to the CPU for processing. When a large number of such packets are received, the CPU may be overloaded. To reduce the number of ICMP packets on the network, you can enable the switch to discard ICMP Destination Unreachable packets. After the configuration, the workload on the switch is reduced and malicious attacks can be prevented.

Example

Enable the function of discarding ICMP Destination Unreachable packets.

```
<HUAWEI> system-view
[HUAWEI] icmp unreachable drop
```

6.9.29 icmp with-options drop

Function

The **icmp with-options drop** command enables the device to discard ICMP packets that carry options.

The **undo icmp with-options drop** command disables the device from discarding ICMP packets that carry options.

By default, the function of discarding ICMP packets with TTL values of 1 is disabled on the device.

Format

icmp with-options drop { **slot** *slot-id* | **all** }

undo icmp with-options drop { **slot** *slot-id* | **all** }

NOTE

Only the S5720I-SI, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, S5735S-S, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
slot *slot-id*	The value is an integer. It must be the slot ID of the device that is inserted into the chassis.	The value is determined based on the device configuration.
all	Indicates all the stacking devices. This parameter is used when you need to enable all the devices to discard or disable all the devices from discarding the ICMP packets that carry options.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When the **ping -r** command is run to detect network connectivity, the IP packet is forwarded by Layer 3 routing devices. Every Layer 3 device fills its own IP address into the option field of the IP packet. When the IP packet reaches the destination, the ICMP Echo Reply packet should contain the IP addresses of all passing devices, including the devices on the forward and return paths. When the ping program receives the reply packet, it can display the IP addresses of all passing Layer 3 devices.

If the length of IP packet encapsulating the ICMP packet exceeds the interface MTU, this IP packet is fragmented. Only the IP header of the first fragment includes the option field. The fragment carrying the option field is sent to the protocol stack and processed by the CPU.

When malicious attacks are initiated using ICMP packets, the device needs to process a large number of fragments carrying the option field, so the forwarding performance of the device degrades. To reduce impact on the forwarding performance and prevent ICMP packet attacks, you can enable the device to discard the ICMP fragments carrying option fields.

Example

Enable the device to discard the ICMP packets that carry options.

```
<HUAWEI> system-view
[HUAWEI] icmp with-options drop slot 0
```

6.9.30 icmp-reply fast

Function

The **icmp-reply fast** command enables the fast ICMP reply function.

The **undo icmp-reply fast** command disables the fast ICMP reply function.

By default, the fast ICMP reply function is enabled.

Format

icmp-reply fast

undo icmp-reply fast

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The ping program is used to check network connectivity. If two hosts cannot ping each other, they cannot set up a connection. The ping program uses the ICMP protocol. It encapsulates ICMP Echo Request packets into IP packets, and sends the packets to the destination host. The destination host returns an ICMP Echo Reply packet to the source host. If the source host receives a reply within a certain period, the source host considers that the destination host is reachable.

In normal situations, after an interface receives an ICMP Echo Request packet, this packet is sent to the protocol stack and handled by the CPU.

After fast ICMP reply is enabled, if an interface receives an ICMP Echo Request packet of which the destination address is the local address, the packet is not sent to the protocol stack for handing by the CPU, but handled by the physical interface. This improves forwarding performance of the device.

Precautions

The fast ICMP reply function is not supported for fragmented packets, packets with IP options, and MPLS-encapsulated packets.

On the S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, fast ICMP reply is not supported for packets whose TTL is 1.

A switch does not support fragmentation of the ICMP Echo Reply packets processed based on the fast ICMP reply mechanism to be sent to the remote end. The packets will not be discarded even if their length is greater than the MTU of the outbound interface.

For the S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6720S-S, S6735-S, S6720-EI, S6720S-EI:

- The fast ICMP reply function does not take effect on VBDIF interfaces.
- When a routed main interface (supporting Layer 2 and Layer 3 mode switching) is bound to a VPN instance, the fast ICMP reply function does not take effect on the interface.
- When a sub-interface is bound to a VPN instance, the fast ICMP reply function does not take effect on the interface.
- After VLAN mapping is configured, the VLANIF interface corresponding to the mapped VLAN does not support the fast ICMP reply function.

For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, after fast ICMP reply is enabled, the ping detection cannot be blocked by the blacklist. This is because after the fast ICMP reply function is enabled, the ICMP Echo Request packets received on an interface of the device are not sent to the protocol stack or processed by the CPU. Instead, the interface directly processes the packets.

Example

Enable the fast ICMP reply function.

```
<HUAWEI> system-view
[HUAWEI] icmp-reply fast
```

6.9.31 ip error-packet-check disable

Function

The **ip error-packet-check disable** command disables the IP packet checking function.

The **undo ip error-packet-check disable** command enables the IP packet checking function.

By default, the IP packet checking function is enabled.

NOTE

Only following model switches support this function:

S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S6720S-S, S5735S-H, S5736-S

Format

ip error-packet-check disable

undo ip error-packet-check disable

Parameters

None

Views

Ethernet interface view, GE interface view, MultiGE interface view, XGE interface view, port group view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the link type of an interface is QinQ or the VLAN mapping or VLAN stacking function is configured on the interface, the system checks IP packets so that the device cannot transparently transmit IP error packets. In addition, during Layer 2 forwarding, devices cannot transparently transmit packets with the same source and destination IP addresses. To enable the device to transparently transmit IP error packets, you can run the **ip error-packet-check disable** command to disable the IP packet checking function.

Precautions

When the IP packet checking function is disabled, the IP subnet-based VLAN assignment, policy-based VLAN assignment, and IPv6 over IPv4 tunnel functions do not take effect. Therefore, confirm your action before disabling this function.

Example

Disable the IP packet checking function on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] ip error-packet-check disable
```

6.9.32 ip forward-broadcast

Function

Using the **ip forward-broadcast** command, you can enable an interface to forward directed broadcast packets.

Using the **undo ip forward-broadcast** command, you can disable an interface from forwarding directed broadcast packets.

By default, disable the interface from forwarding directed broadcast packets.

Format

ip forward-broadcast [**acl** *acl-number*]

undo ip forward-broadcast

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of an ACL.	The value is an integer that ranges from 2000 to 3999. - The number of a basic ACL ranges from 2000 to 2999. - The number of an advanced ACL ranges from 3000 to 3999.

Views

VE sub-interface view, VBDIF interface view, VLANIF interface view, Ethernet interface view, MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Directed broadcast packets are sent to a specified network. In the destination IP address of a directed broadcast packet, the network number is that of the specified network and the host number is all 1s.

Hackers use directed broadcast packets to attack networks, which threatens the network security. Therefore, directed broadcast packets are isolated by Layer 3 switches in normal cases. However, in some scenarios, the device needs to receive or forward these directed broadcast packets. For example, when Wake on LAN (WOL) is configured on a PC, the command can be run to enable the interface to forward directed broadcast packets. (WOL enables a PC in dormancy or shutdown state to wake up from dormancy state to running state or turn from shutdown state to power-on state through the instruction from the peer of the network.)

The device can also be enabled to receive and forward a certain type of directed broadcast packets based on ACLs. For example, if the basic ACL is used, run the **acl (system view)** and **rule (basic ACL view)** commands to define the directed broadcast packets to be received and forwarded as **permit**, and then run the **ip forward-broadcast** command to bind this ACL.

Only broadcast packets that match the permit action defined in the ACL are forwarded. Broadcast packets that match the deny action defined in the ACL or do not match any ACL rules are not forwarded.

Precautions

By default, the device identifies directed broadcast packets as malformed packets, and intercepts and discards them because the attack defense function of malformed packets is enabled on the device. In this case, the interface on the device cannot forward the directed broadcast packets.

To solve this problem, use either of the following methods:

- Run the **anti-attack abnormal disable** command to disable the attack defense function of malformed packets. However, after this command is configured, other malformed packets will not be intercepted and discarded, which brings certain security risks. Use this command with caution.
- Run the **anti-attack disable** command to disable all attack defense functions. However, after this command is configured, not only malformed packets but also fragmented, tcp-syn, udp-flood, and icmp-flood attack packets will not be intercepted and discarded, which brings certain security risks. Use this command with caution.

This command does not apply to VPN scenarios, IP address unnumbered scenarios, and scenarios of conflicts between host routes and subnet broadcast routes due to network segment overlapping.

Example

Enable VLANIF100 to forward directed broadcast packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip forward-broadcast
```

Enable GE0/0/1 to forward directed broadcast packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip forward-broadcast
```

6.9.33 ip forwarding converge normal

Function

The **ip forwarding converge normal** command disables the device to perform Layer 2 forwarding for IP traffic during ring network switchover.

The **undo ip forwarding converge** command enables the device from performing Layer 2 forwarding for IP traffic during ring network switchover.

By default, the device is enabled from performing Layer 2 forwarding for IP traffic during ring network switchover.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ip forwarding converge normal

undo ip forwarding converge

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device deployed with the ring network protocols (STP, RSTP, MSTP, SEP, ERPS, RRPP, VBST, and Smart Link) performs link switchover due to a link fault, the ARP entries need to be learned again. This deteriorates the Layer 3 convergence performance of IP traffic. If the device is enabled to perform Layer 2 forwarding for IP traffic during the switchover, the convergence performance can be improved. By default, the device is enabled from performing Layer 2 forwarding for IP traffic during ring network switchover.

Precautions

After the device is enabled to perform Layer 2 forwarding for IP traffic, it will forward the IP traffic in broadcast mode during ring network switchover. Therefore, the IP traffic increases within a short time.

Example

Disable the device from performing Layer 2 forwarding for IP traffic during ring network switchover.

```
<HUAWEI> system-view
[HUAWEI] ip forwarding converge normal
```

6.9.34 ip forwarding disable

Function

The **ip forwarding disable** command disables IPv4 Layer 3 unicast forwarding on a switch.

The **undo ip forwarding disable** command enables IPv4 Layer 3 unicast forwarding on a switch.

By default, IPv4 Layer 3 unicast forwarding is enabled on a switch.

Format

ip forwarding disable

undo ip forwarding disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run this command to disable IPv4 Layer 3 unicast forwarding on a switch.

After IPv4 Layer 3 unicast forwarding is disabled on a switch, the IPv4 routing function becomes ineffective on the switch, and the switch cannot forward Layer 3 packets based on the IPv4 routing table and FIB table.

Precautions

Running this command on a switch disables IPv4 Layer 3 packet forwarding at the hardware layer and CPU software layer.

Example

Disable IPv4 Layer 3 unicast forwarding on the switch.

```
<HUAWEI> system-view
[HUAWEI] ip forwarding disable
Warning: This operation will close IPv4 forwarding function and affect IPv4 traffic forwarding. Continue?
[Y/N]:y
```

6.9.35 ip ttl-expired drop

Function

The **ip ttl-expired drop** command enables the switch to discard IP packets with expired TTL.

The **undo ip ttl-expired drop** command disables the switch from discarding IP packets with expired TTL.

By default, the function of discarding IP packets with expired TTL is disabled.

Format

ip ttl-expired drop

undo ip ttl-expired drop

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

TTL is a field in an IP packet that limits the lifespan of the IP packet on the network. The TTL value is set by the sender, and is reduced by 1 every time the packet passes a device. If a forwarding device receives an IP packet of which the TTL is 0 and the destination address is not the local address, the device discards this packet.

If a device receives many IP packets with TTL value 1, the device may undergo an attack. Run the **ip ttl-expired drop** command to enable the device to discard the IP packets with expired TTL. Then the device discards the packets with TTL value 1, but does not send them to the CPU.

Precautions

After the **ip ttl-expired drop** command is run, some packets that have the TTL value 1 but need to be processed by the CPU are also discarded. Therefore, after the attack is removed, run the **undo ip ttl-expired drop** command to disable the device from discarding the IP packets with expired TTL.

Example

Enable the switch to discard IP packets with expired TTL.

```
<HUAWEI> system-view
[HUAWEI] ip ttl-expired drop
```

6.9.36 ip verify source-address

Function

The **ip verify source-address** command enables an interface to check validity of source IP addresses of received packets.

The **undo ip verify source-address** command disables an interface from checking validity of source IP addresses of received packets.

By default, an interface does not check validity of source IP addresses of received packets.

Format

ip verify source-address

undo ip verify source-address

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Configuring source IP address verification enables an interface to check validity of source IP addresses of received packets. Packets with invalid addresses are discarded, which improves the network security.

The following IP addresses are illegal source addresses:

- Addresses with all 0s or 1s
- Multicast addresses (class D addresses)
- Class E addresses
- Loopback addresses that are not generated on local hosts (in 127.x.x.x format)
- Broadcast addresses of classes A, B, and C
- Subnet broadcast addresses that are on the same network segment as the address of the inbound interface

The interface only checks validity of source IP addresses of the packets that need to be forwarded to the CPU, and does not check validity of source IP addresses of the packets that will be directly forwarded according to the FIB table.

If the mask in the IP address of the received packet is of 31 bits, the receiver considers it as a valid source address without checking the broadcast address of the subnet.

Run the **display this** command in the interface view to check configuration of checking validity of source IP addresses.

Example

Enable VLANIF100 to check validity of source IP addresses of received packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ip verify source-address
```

Enable GE0/0/1 to check validity of source IP addresses of received packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip verify source-address
```

6.9.37 ipv4 destination-unreachable drop

Function

The **ipv4 destination-unreachable drop** command enables the function of discarding IP packets that match no routing entry.

The **undo ipv4 destination-unreachable drop** command disables the function of discarding IP packets that match no routing entry.

By default, the function of discarding IP packets that match no routing entry is enabled.

Format

ipv4 destination-unreachable drop

undo ipv4 destination-unreachable drop

NOTE

Only the S5720I-SI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the switch receives an IP packet that matches no routing entry in the local routing table, it sends the packet to the CPU. If a lot of IP packets match no routing entry because of an attack or incorrect network configuration, the CPU is busy. To prevent this problem, run the **ipv4 destination-unreachable drop** command to configure the switch to discard these packets.

Precautions

If you run the **ipv4 destination-unreachable drop** command, the switch does not respond to ICMP error packets when a route fails to match the routing policies. To enable the switch to respond to these ICMP packets, you need to run the **undo ipv4 destination-unreachable drop** command.

On the S6720-EI, S6735-S, and S6720S-EI, when both the **ipv4 destination-unreachable drop** command and the traffic policy command are run, both the drop action and the redirection action take effect. The ICMP redirection packets are discarded because the drop action has a higher priority than the redirection action. This leads to a redirection failure for ICMP packets. To make the redirection action for ICMP packets effective, run the **undo ipv4 destination-unreachable drop** command to disable the drop action. However, disabling the drop action will degrade the attack defense performance of the system. You must configure the two actions properly according to the network requirements.

For the S6720-EI, S6735-S and S6720S-EI, if the resource allocation mode is set to **enhanced-ipv4** or **ipv4-ipv6 6:1** using the **assign resource-mode** command, the **ipv4 destination-unreachable drop** command does not take effect.

Example

Enable the function of discarding IP packets that match no routing entry.

```
<HUAWEI> system-view
[HUAWEI] ipv4 destination-unreachable drop
```

6.9.38 ipv4 fragment enable

Function

The **ipv4 fragment enable** command enables fragmentation for outgoing forwarding-plain IP packets.

The **undo ipv4 fragment enable** command disables fragmentation for outgoing forwarding-plain IP packets.

By default, fragmentation for outgoing forwarding-plain IP packets is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ipv4 fragment enable

undo ipv4 fragment enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, only packets on the control plane can be fragmented according to the MTU on an interface. Packets on the forwarding plane can be forwarded normally without limited by the MTU. When the remote device or intermediate forwarding device receives IP packets, if it checks the packet length and discards packets whose length is longer than the MTU on the interface, network communication is interrupted. For the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, you can run the **ipv4 fragment enable** command to enable fragmentation for outgoing forwarding-plane IP packets so that packets on the forwarding plane are fragmented based on the MTU on the interface.

Precautions

Before configuring the **ipv4 fragment enable** command, set a proper MTU. If the MTU is small, there may be many fragments of IP packets, causing the Layer 3 forwarding performance of IP packets to deteriorate.

Example

Enable fragmentation for outgoing IP packets.

```
<HUAWEI> system-view
[HUAWEI] ipv4 fragment enable
```

6.9.39 ipv6 destination-unreachable drop

Function

The **ipv6 destination-unreachable drop** command enables the switch to discard the packets that do not match IPv6 routing entries.

The **undo ipv6 destination-unreachable drop** command disables the switch from discarding the packets that do not match IPv6 routing entries.

By default, the device discards the packets that do not match IPv6 routing entries.

Format

ipv6 destination-unreachable drop

undo ipv6 destination-unreachable drop

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, the device sends the IPv6 packets that do not match routing entries to the CPU for processing. If many IPv6 packets do not match routing entries because of an attack or improper network configurations, the CPU is busy. To prevent this situation, run the **ipv6 destination-unreachable drop** command to configure the switch to discard these packets.

Precautions

If the **ipv6 destination-unreachable drop** command is used and a traffic policy with the redirect action is configured, both the drop action and the redirect action take effect. Because the drop action has a higher priority than the redirect action, ICMPv6 Redirect packets are discarded. This leads to a redirection failure. To make the redirect action take effect, run the **undo ipv6 destination-unreachable drop** command to disable the drop action. However, disabling the drop action will degrade the attack defense performance of the system. You must configure the two actions properly according to network requirements.

After the **ipv6 destination-unreachable drop** command is used, the switch does not respond to the ICMPv6 Error packets caused when IPv6 packets do not match routing entries until the drop action is disabled.

For the S6720-EI, S6735-S and S6720S-EI, if the resource allocation mode is set to **enhanced-ipv4** or **ipv4-ipv6 6:1** using the **assign resource-mode** command, the **ipv6 destination-unreachable drop** command does not take effect.

Example

Configure the switch to discard the packets that do not match IPv6 routing entries.

```
<HUAWEI> system-view
[HUAWEI] undo ipv6 destination-unreachable drop
```

6.9.40 ipv6 with-options drop

Function

The **ipv6 with-options drop** command enables the switch to discard IPv6 packets destined for the switch and containing specified extension headers.

The **undo ipv6 with-options drop** command disables the switch from discarding IPv6 packets destined for the switch and containing specified extension headers.

By default, the switch is disabled from discarding IPv6 packets destined for the switch and containing specified extension headers.

Format

ipv6 with-options drop

undo ipv6 with-options drop

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

IPv6 packets may contain the following extension headers:

- Routing header: An IPv6 source node uses this header to specify the intermediate nodes that a packet must pass through on the way to its destination.
- Fragment header: The length of IPv6 packets to be forwarded cannot exceed the maximum transmission unit (MTU) specified on interfaces of devices along the forwarding path. When the packet length exceeds the MTU, the packet needs to be fragmented. In IPv6, the fragment header is used by an IPv6 source node to send a packet larger than the MTU. Fragmentation in IPv6 is performed only by source nodes, not by intermediate nodes along the path a packet traverses.
- Destination options header: This header carries information that only the destination node of a packet processes.

Malicious attacks can be initiated using these IPv6 extension headers. For example, the routing header can be used to specify a node that packets must pass through. The fragment header can be used to set the MTU to a small value on the source node, leading to a large number of data fragments. The destination options header can specify destination devices to process IPv6 packets. If attackers send a large number of such IPv6 packets to the switch, the switch is busy handling these packets, degrading the forwarding performance. To prevent malicious network attacks and reduce impact on the forwarding performance, you can enable the switch to discard IPv6 packets destined for the switch and containing specified extension headers.

Example

Enable the switch to discard IPv6 packets destined for the switch and containing specified extension headers.

```
<HUAWEI> system-view
[HUAWEI] ipv6 with-options drop
```

6.9.41 load-balance (system view)

Function

The **load-balance** command configures a load balancing mode for public IP packet forwarding.

The **undo load-balance** command restores the load balancing mode for public IP packet forwarding to the default configuration.

By default, flow-based load balancing is used for public IP packet forwarding

Format

load-balance { **flow** | **packet** } [**all** | **slot** *slot-id*]

undo load-balance packet [**all** | **slot** *slot-id*]

Parameters

Parameter	Description	Value
flow	Indicates flow-based load balancing.	-
packet	Indicates packet-based load balancing.	-
all	In a stack, the configuration is applied to all devices in the stack. On a stand-alone switch, the configuration is applied to the local device.	-
slot *slot-id*	Indicates that the configuration is applied to the device with the specified stack ID.	The value is an integer. It has a fixed value of 0 in a non-stack scenario, and depends on the device configuration in a stack scenario.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Scenario

If flow-based load balancing is used, the hash algorithm is used to calculate a value for selecting a link to forward packets. The value is calculated based on the protocol type, source IP address, destination IP address, source port number, and destination port number.

If packet-based load balancing is used, packets are forwarded through different links. Packet-based load balancing can be implemented only for packets forwarded by the CPU such as protocol packets.

Precautions

The **load-balance** command takes effect on packets delivered by the local device and IP/MPLS packets processed by the CPU.

Example

Configure packet-based load balancing for public IP packet forwarding.

```
<HUAWEI> system-view
[HUAWEI] load-balance packet
```

6.9.42 load-balance vpn

Function

The **load-balance vpn** command configures a load balancing mode for private IP packet forwarding.

The **undo load-balance vpn** command restores the load balancing mode for private IP packet forwarding to the default configuration.

By default, packet-based load balancing is used for private IP packet forwarding

Format

load-balance { **flow** | **packet** } **vpn**

undo load-balance flow vpn

Parameters

Parameter	Description	Value
flow	Indicates flow-based load balancing.	-
packet	Indicates packet-based load balancing.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Scenario

If flow-based load balancing is used, the hash algorithm is used to calculate a value for selecting a link to forward packets. The value is calculated based on the protocol type, source IP address, destination IP address, source port number, and destination port number.

If packet-based load balancing is used, packets are forwarded through different links. Packet-based load balancing can be implemented only for packets forwarded by the CPU such as protocol packets.

Precautions

The **load-balance vpn** command takes effect on packets delivered by the local device and IP/MPLS packets processed by the CPU.

Example

Configure flow-based load balancing for private IP packet forwarding.

```
<HUAWEI> system-view
[HUAWEI] load-balance flow vpn
```

6.9.43 management-port icmp-reply fast disable

Function

The **management-port icmp-reply fast disable** command disables the fast ICMP reply function on the management Ethernet port.

The **undo management-port icmp-reply fast disable** command enables the fast ICMP reply function on the management Ethernet port.

By default, the fast ICMP reply function is enabled on the management Ethernet port.

NOTE

The following models support this command: S5731-H, S5731S-H, S5731-S, S5731S-S, S5732-H, S5735-S, S5735-S-I, S5735S-H, S5735-L, S5736-S, S6730-H, S6730S-H, S6730-S, S6730S-S, S6735-S, S6720-EI, S6720S-S, S6720S-EI.

Format

management-port icmp-reply fast disable

undo management-port icmp-reply fast disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The ping program is used to check network connectivity. If two hosts cannot ping each other, they cannot set up a connection. The ping program uses the ICMP protocol. It encapsulates ICMP Echo Request packets into IP packets, and sends the packets to the destination host. The destination host returns an ICMP Echo Reply packet to the source host. If the source host receives a reply within a certain period, the source host considers that the destination host is reachable.

In normal situations, after the management Ethernet port of a device receives an ICMP Echo Request packet, this packet is sent to the protocol stack and handled by the CPU.

After fast ICMP reply is enabled, if the management Ethernet port receives an ICMP Echo Request packet of which the destination address is the local address, the packet is not sent to the protocol stack for handing by the CPU, but handled by the management Ethernet port. This improves forwarding performance of the device.

Precautions

The fast ICMP reply function is not supported for fragmented packets, packets with IP options, and MPLS-encapsulated packets.

Example

Enable the fast ICMP reply function on the management Ethernet port.

```
<HUAWEI> system-view
[HUAWEI] undo management-port icmp-reply fast disable
```

6.9.44 reset ip socket monitor

Function

The **reset ip socket monitor** command clears information in a socket monitor.

Format

reset ip socket monitor [**task-id** *task-id* **socket-id** *socket-id*]

Parameters

Parameter	Description	Value
task-id *task-id*	Clears information about the task with a specified ID in the socket monitor.	The value must be an existing task ID.
socket-id *socket-id*	Clears information about the socket with a specified ID in the socket monitor.	The value must be an existing socket ID.

Views

User view

Default Level

3: Management level

Usage Guidelines

A socket monitor monitors and records each connection. A RawLink monitor also monitors interfaces. The socket monitor records specific protocol events that occur during operations and logs information in the disk space.

You can specify the task ID and socket ID for deleting information about the socket monitor that meets the filtering condition.

Example

Clear information in a socket monitor.

```
<HUAWEI> reset ip socket monitor
```

6.9.45 reset ip socket pktsort

Function

The **reset ip socket pktsort** command resets statistics on the dual receive buffer of the socket.

Format

reset ip socket pktsort task-id *task-id* **socket-id** *socket-id*

Parameters

Parameter	Description	Value
task-id *task-id*	Specifies the ID of a task.	The value must be an existing task ID.
socket-id *socket-id*	Specifies the ID of a socket.	The value must be an existing socket ID.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command clears statistics on the dual receive buffer of the socket and restarts the count. Therefore, confirm your action before running the command.

Example

Reset statistics on the dual receive buffer of the socket with the task ID of 2 and the socket ID of 6.

```
<HUAWEI> reset ip socket pktsort task-id 2 socket-id 6
```

6.9.46 reset ip statistics

Function

The **reset ip statistics** command clears IP traffic statistics on an interface.

Format

reset ip statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and ID of an interface. If no optional parameter is specified, all the IP statistics will be deleted.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

To collect IP traffic statistics on an interface in a period of time, you must clear the existing traffic statistics and collect IP statistics after a period of time. Run the **display ip statistics** command to display information.

If no parameter is specified, the command clears IP traffic statistics on all boards.

Example

Clear IP statistics on all interfaces.

```
<HUAWEI> reset ip statistics
```

Clear IP statistics on VLANIF10.

```
<HUAWEI> reset ip statistics interface vlanif 10
```

6.9.47 reset rawip statistics

Function

The **reset rawip statistics** command clears RawIP packet statistics.

Format

reset rawip statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You need to clear the existing statistics about RawIP packets before using the **display rawip statistics** command to view the statistics about RawIP packets in a specified period.

The **reset rawip statistics** command clears RawIP packet statistics. Confirm your action before running this command.

Example

Clear RawIP packet statistics.

```
<HUAWEI> reset rawip statistics
```

6.9.48 reset tcp statistics

Function

The **reset tcp statistics** command deletes TCP traffic statistics.

Format

reset tcp statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To delete TCP packet statistics, run the **reset tcp statistics** command. To view TCP packet statistics, run the **display tcp statistics** [**verbose**] command. The command output contains the number of sent packets, the number of received packets, or the number of TCP packets for each protocol (verbose). You can run the **reset tcp statistics** command to delete existing statistics and then run the **display tcp statistics** command to collect statistics. The statistics help you check whether TCP packet counts are correct or help you diagnose faults.

Precautions

The **reset tcp statistics** command deletes TCP traffic statistics. Confirm your action before running this command.

Example

Delete TCP traffic statistics.

```
<HUAWEI> reset tcp statistics
```

6.9.49 reset udp statistics

Function

The **reset udp statistics** command deletes UDP traffic statistics.

Format

reset udp statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To delete UDP packet statistics, run the **reset udp statistics** command. To view UDP packet statistics, run the **display udp statistics** [**verbose**] command. The command output contains the number of sent packets, the number of received packets, or the number of UDP packets for each protocol (verbose). You can run the **reset udp statistics** command to delete existing statistics and then run the **display udp statistics** command to collect statistics. The statistics help you check whether UDP packet counts are correct or help you diagnose faults.

Precautions

The **reset udp statistics** command deletes UDP traffic statistics. Confirm your action before running this command.

Example

Delete UDP traffic statistics.

```
<HUAWEI> reset udp statistics
```

6.9.50 set priority

Function

The **set priority** command sets the 802.1p priority or DSCP priority of packets.

The **undo set priority** command cancels the settings of the 802.1p priority or DSCP priority of packets.

By default, the 802.1p priority or DSCP priority of packets is not set.

Format

set priority 8021p *8021p-number*

undo set priority 8021p

set priority dscp *dscp-number* [**if-match acl** *acl-number*]

undo set priority dscp [**if-match acl** *acl-number*]

NOTE

Only the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support **if-match acl** *acl-number*.

Parameters

Parameter	Description	Value
8021p *8021p-number*	Specifies the 802.1p priority of packets.	The value is an integer that ranges from 0 to 7. A larger value indicates a higher priority.
dscp *dscp-number*	Specifies the DSCP priority of packets. This parameter takes effect only for IPv4 packets.	The value is an integer that ranges from 0 to 63.
if-match acl *acl-number*	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3999.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **set priority** command to set the 802.1p priority or DSCP priority of packets sent by the switch.

To change the DSCP priority of protocol packets that meet specified characteristics and are sent by the switch, you can use an ACL to match these packets.

Precautions

This command takes effect only for IPv4 but not for IPv6.

If the packet priority has been specified in the protocol, the **set priority 8021p** command does not take effect.

If you use ACLs to match packets whose DSCP priority is to be changed, you can specify up to eight ACLs, each of which supports a maximum of 32 rules. The following fields can be matched:

- ICMP packets: source IP address, destination IP address, protocol number, icmp-type, icmp-code, fragment, precedence, tos, dscp, ttl-expired, vpn-instance, and time-range
- TCP packets: source IP address, destination IP address, protocol number, source port, destination port, tcp-flag, fragment, precedence, tos, dscp, ttl-expired, vpn-instance, and time-range
- UDP packets: source IP address, destination IP address, protocol number, source port, destination port, fragment, precedence, tos, dscp, ttl-expired, vpn-instance, and time-range
- Other protocol packets: source IP address, destination IP address, protocol number, fragment, precedence, tos, dscp, ttl-expired, vpn-instance, and time-range

The switch cannot use ACL-based matching to change the DSCP priority of the following protocol packets:

- Protocol packets that are not sent from the protocol stack, such as fast ICMP reply packets and NetStream packets
- Protocol packets whose priority can be configured using a command (for example, you can run the **tos** command to set the priority of NQA packets)

Example

Set the DSCP priority to 10.

```
<HUAWEI> system-view
[HUAWEI] set priority dscp 10
```

6.9.51 tcp min-mss

Function

The **tcp min-mss** command sets the minimum value of maximum segment size (MSS) for a TCP connection.

The **undo tcp min-mss** command restores the default minimum value of the MSS for a TCP connection.

The default minimum MSS value for a TCP connection is 216 bytes.

Format

tcp min-mss *mss-value*

undo tcp min-mss

Parameters

Parameter	Description	Value
mss-value	Specifies the minimum MSS value for a TCP connection.	The value ranges from 32 bytes to 1500 bytes. By default, the value is 216 bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To establish a TCP connection, the MSS value is negotiated, which indicates the maximum length of packets that the local device can receive. The TCP client on a network may send a request packet for establishing a TCP connection carrying a small MSS value. For example, the MSS value is 1. After the TCP server receives the request packet carrying the MSS value, the TCP connection is established. The TCP client then may send large numbers of requests to the server by an application, causing the TCP server to generate large numbers of reply packets. This may burden the TCP server or network, causing denial of service (DoS) attacks. To resolve this problem, run the **tcp min-mss** command to set the minimum MSS value for a TCP connection. This configuration prevents a server from receiving packets carrying a small MSS value.

Precautions

The minimum MSS value configured using this command is not the negotiation parameter value carried in the MSS option. The negotiation parameter value carried in the MSS option of packets sent by the local device is calculated based on the MTU value.

The minimum MSS value configured using the **tcp min-mss** command must be less than the maximum MSS value configured using the **tcp max-mss** command.

If the **tcp min-mss** command is run more than once in the same view, the latest configuration overrides the previous one.

Configure the parameters under the guidance of the technical personnel.

Example

Set the minimum MSS value for a TCP connection to 512 bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp min-mss 512
```

6.9.52 tcp max-mss

Function

The **tcp max-mss** command configures the maximum Maximum Segment Size (MSS) value for a TCP connection.

The **undo tcp max-mss** command deletes the maximum MSS value of a TCP connection.

By default, the maximum MSS value is not configured for TCP connections.

Format

tcp max-mss *mss-value*

undo tcp max-mss

Parameters

Parameter	Description	Value
mss-value	Specifies the maximum MSS value for a TCP connection.	The value is an integer ranging from 32 to 9600, in bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To establish a TCP connection, the MSS value is negotiated, which indicates the maximum length of packets that the local device can receive. This length is the TCP payload length, excluding that of the TCP header. If the path MTU is unavailable on one end of a TCP connection, this end cannot adjust the TCP packet size based on the MTU. As a result, this end may send TCP packets that are longer than the MTUs on intermediate devices, which will discard these packets. To prevent this problem, run the **tcp max-mss** command on either end of a TCP connection to set the maximum MSS value of TCP packets. Then the MSS value negotiated by both ends will not exceed this maximum MSS value, and accordingly TCP packets sent from both ends will not be longer than this maximum MSS value and can travel through the intermediate network.

Precautions

The maximum MSS value configured using the **tcp max-mss** command must be greater than the minimum MSS value configured using the **tcp min-mss** command.

Example

Set the maximum MSS value for a TCP connection to 1024 bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp max-mss 1024
```

6.9.53 tcp send-trap bind-port

Function

The **tcp send-trap bind-port** command configures a TCP port number list.

The **undo tcp send-trap bind-port** command restores the default TCP port number list.

By default, no TCP port number list is configured.

Format

tcp send-trap bind-port { *port-number* } &<1-10>

undo tcp send-trap bind-port { { *port-number* } &<1-10> | **all** }

Parameters

Parameter	Description	Value
port-number	Specifies a TCP port number.	The value is an integer in the range from 1 to 65535.
all	Indicates all TCP port numbers in a TCP port number list.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you need to pay special attention to some TCP port numbers, you can run this command to add them to a TCP port number list. If port numbers in a TCP port number list are bound to services or an attempt is made to bind such numbers to services, the device sends an event alarm so that you can monitor the TCP port numbers.

Precautions

When the **undo tcp send-trap bind-port all** command is run, the system prompts you for confirmation.

Example

Configure a TCP port number list.

```
<HUAWEI> system-view
[HUAWEI] tcp send-trap bind-port 20 21 23 80
```

6.9.54 tcp timer fin-timeout

Function

The **tcp timer fin-timeout** command configures the value of the TCP FIN-Wait timer.

The **undo tcp timer fin-timeout** command restores the default value of the TCP FIN-Wait timer.

By default, the value of the TCP FIN-Wait timer is 675s.

Format

tcp timer fin-timeout *interval*

undo tcp timer fin-timeout

Parameters

Parameter	Description	Value
interval	Specifies the value of the TCP FIN-Wait timer.	The value is an integer that ranges from 76 to 3600, in seconds. The default value is 675s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When a TCP connection changes from FIN_WAIT_1 to FIN_WAIT_2, the TCP FIN-Wait timer is started. If no response packet is received after the TCP FIN-Wait timer expires, the TCP connection is closed.

If you run this command in the same view for multiple times, only the last configuration takes effect.

You are advised to configure this parameter under the supervision of technical support personnel.

Example

Set the value of the TCP FIN-Wait timer to 400s.

```
<HUAWEI> system-view
[HUAWEI] tcp timer fin-timeout 400
```

6.9.55 tcp timer syn-timeout

Function

The **tcp timer syn-timeout** command configures the value of the TCP SYN-Wait timer.

The **undo tcp timer syn-timeout** command restores the default value of the TCP SYN-Wait timer.

By default, the value of the TCP SYN-Wait timer is 75s.

Format

tcp timer syn-timeout *interval*

undo tcp timer syn-timeout

Parameters

Parameter	Description	Value
interval	Specifies the value of the TCP SYN-Wait timer.	The value is an integer ranging from 2 to 600, in seconds. The default value is 75s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When an SYN packet is sent, the TCP SYN-Wait timer is started. If no response packet is received after the TCP SYN-Wait timer expires, the TCP connection is closed.

If you run this command in the same view for multiple times, only the last configuration takes effect.

You are advised to configure this parameter under the supervision of technical support personnel.

Example

Set the value of the TCP SYN-Wait timer to 100s.

```
<HUAWEI> system-view
[HUAWEI] tcp timer syn-timeout 100
```

6.9.56 tcp window

Function

The **tcp window** command configures the size of the receive or send buffer of a connection-oriented socket.

The **undo tcp window** command restores the default size of the receive or send buffer of a connection-oriented socket.

By default, the size of the receive or send buffer of a connection-oriented socket is 8k bytes.

Format

tcp window *window-size*

undo tcp window

Parameters

Parameter	Description	Value
window-size	Specifies the size of the receive or send buffer of a connection-oriented socket.	The value is an integer that ranges from 1 to 32, in k bytes. The default value is 8k bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If you run this command in the same view for multiple times, only the last configuration takes effect.

You are advised to configure this parameter under the supervision of technical support personnel.

Example

Set the size of the receive or send buffer of a connection-oriented socket to 3K bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp window 3
```

6.10 Basic IPv6 Configuration Commands

6.10.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

6.10.2 display default-parameter tcp6

Function

The **display default-parameter tcp6** command displays the default values of all configurable parameters on the TCP6 module.

Format

display default-parameter tcp6

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display default-parameter tcp6** command displays the default values of all configurable parameters on the TCP6 module.

Example

Display the default values of all configurable parameters on the TCP6 module.

```
<HUAWEI> display default-parameter tcp6
---------------------------------
  SYN Timeout Value(sec) : 75
  FIN Timeout Value(sec) : 600
  Window Size(KBytes)    : 8
---------------------------------
```

Table 6-56 Description of the display default-parameter tcp6 command output

Item	Description
SYN Timeout Value(sec)	TCP SYN-Wait timer value. To configure this parameter, run the **tcp ipv6 timer syn-timeout** command.
FIN Timeout Value(sec)	TCP FIN-Wait timer value. To configure this parameter, run the **tcp ipv6 timer fin-timeout** command.
Window Size(KBytes)	TCP6 slide window size. To configure this parameter, run the **tcp ipv6 window** command.

6.10.3 display icmpv6 statistics

Function

The **display icmpv6 statistics** command displays ICMPv6 traffic statistics.

Format

display icmpv6 statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Indicates the ICMPv6 traffic statistics on the specified interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display icmpv6 statistics** command to view ICMPv6 packet statistics, including statistics about received and sent ICMPv6 error packets and statistics about four types of ICMPv6 packets (RS, RA, NS, and NA packets) used in the neighbor discovery mechanism.

When you ping an IPv6 address from a device, run the **display icmpv6 statistics** command on the device to check whether the total number of sent and received packets is correct.

Precautions

The total number of packets received by the device includes the number of packets forwarded, number of packets delivered to upper-layer network devices, and number of packets discarded.

Example

Display ICMPv6 traffic statistics on the device.

```
<HUAWEI> display icmpv6 statistics interface vlanif 100
ICMPv6 protocol:

 Sent packets:
  Total              : 2
  Unreached          : 0          Prohibited          : 0
  Hop count exceeded : 0          Parameter problem   : 0
  Too big            : 0          Echoed              : 0
  Echo replied       : 0          Router solicit      : 0
  Router advert      : 0          Neighbor solicit    : 1
  Neighbor advert    : 1          Redirected          : 0
  Rate limited       : 0          Cert path advert    : 0

 Received packets:
  Total              : 0          Format error        : 0
  Checksum error     : 0          Too short           : 0
  Bad code           : 0          Bad length          : 0
  Unknown info type  : 0          Unknown error type  : 0
  Unreached          : 0          Prohibited          : 0
  Hop count exceeded : 0          Parameter problem   : 0
  Too big            : 0          Echoed              : 0
  Echo replied       : 0          Router solicit      : 0
  Router advert      : 0          Neighbor solicit    : 0
  Neighbor advert    : 0          Redirected          : 0
  Rate limited       : 0          Cert path solicit   : 0
```

Table 6-57 Description of the display icmpv6 statistics command output

Item	Description
ICMPv6 protocol	ICMPv6 packet statistics.
Sent packets	Statistics about sent ICMPv6 packets.
Total	Total number of sent packets.
Unreached	Total number of sent ICMPv6 Destination Unreachable packets.
Prohibited	Total number of sent ICMPv6 Administratively Prohibited Unreachable packets.
Hop count exceeded	Total number of sent ICMPv6 packets whose hops exceed the limit.
Parameter problem	Total number of sent ICMPv6 Parameter Problem packets.

Item	Description
Too big	Total number of sent ICMPv6 Packet Too Big packets.
Echoed	Total number of sent ICMPv6 Echo Request packets.
Echo replied	Total number of sent ICMPv6 Echo Reply packets.
Router solicit	Total number of sent Router Solicitation (RS) packets.
Router advert	Total number of sent Router Advertisement (RA) packets.
Neighbor solicit	Total number of sent Neighbor Solicitation (NS) packets.
Neighbor advert	Total number of sent Neighbor Advertisement (NA) packets.
Redirected	Total number of sent ICMPv6 Redirect packets.
Rate limited	Total number of ICMPv6 packets that fail to be sent because of the rate limit.
Cert path advert	Total number of sent CPS packets. This parameter is not supported currently and displayed as 0.
Received packets	Statistics about received ICMPv6 packets.
Total	Total number of received packets.
Format error	Total number of received ICMPv6 packets with format errors.
Checksum error	Total number of received ICMPv6 packets with checksum errors.
Too short	Total number of received ICMPv6 packets that are too short.
Bad code	Total number of received ICMPv6 packets with code errors.
Bad length	Total number of received ICMPv6 packets with packet length errors.
Unknown info type	Total number of received ICMPv6 packets with an unknown information type.
Unknown error type	Total number of received ICMPv6 packets with an unknown error type.
Unreached	Total number of received ICMPv6 Destination Unreachable packets.

Item	Description
Prohibited	Total number of received ICMPv6 Administratively Prohibited Unreachable packets.
Hop count exceeded	Total number of received ICMPv6 packets whose hops exceed the limit.
Parameter problem	Total number of received ICMPv6 Parameter Problem packets.
Too big	Total number of received ICMPv6 packets that are oversized.
Echoed	Total number of received ICMPv6 Echo Request packets.
Echo replied	Total number of received ICMPv6 Echo Reply packets.
Router solicit	Total number of received RS packets.
Router advert	Total number of received RA packets.
Neighbor solicit	Total number of received NS packets.
Neighbor advert	Total number of received NA packets.
Redirected	Total number of received ICMPv6 Redirect packets.
Rate limited	Total number of ICMPv6 packets that fail to be received because of the rate limit.
Cert path solicit	Total number of received CPA packets. This parameter is not supported currently and displayed as 0.

6.10.4 display ipv6 attack-source overlapping-fragment

Function

The **display ipv6 attack-source overlapping-fragment** displays source information about overlapping fragment attacks.

Format

display ipv6 attack-source overlapping-fragment

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the device suffers from overlapping fragment attacks, the administrator can run this command to view source information about attack packets. Source information includes the source and destination IP addresses of the packets, interface receiving the packets, source VLAN, source CE VLAN, and VPN to which the packets belongs. The administrator can take proper actions on the attack source.

Example

Display source information about overlapping fragment attacks.

```
<HUAWEI> display ipv6 attack-source overlapping-fragment
Attack-source overlapping fragment table:

------------------------------------------------------------------------------
  Source IP           : FC00::1
  Destination IP      : FC00::2
  Interface name      : Vlanif2
  VPN name            :
  VLAN                : 0                          CEVLAN: 0
  Attacked time       : 2011-09-29 01:01:28
------------------------------------------------------------------------------

Total: 1
```

Table 6-58 Description of the display ipv6 attack-source overlapping-fragment command output

Item	Description
Source IP	Source IPv6 address of an overlapping fragment attack packet.
Destination IP	Destination IPv6 address of the overlapping fragment attack packet.
Interface name	Interface that receives the overlapping fragment attack packet.
VPN name	Name of the VPN to which the overlapping fragment attack packet belongs.
VLAN	VLAN to which the overlapping fragment attack packet belongs.
CEVLAN	CE VLAN to which the overlapping fragment attack packet belongs.
Attacked time	Duration of the overlapping fragment attack.
Total	Number of pieces of source information about overlapping fragment attacks.

6.10.5 display ipv6 interface

Function

The **display ipv6 interface** command displays IPv6 information on an interface.

Format

display ipv6 interface [*interface-type interface-number* | **brief**]

Parameters

Parameter	Description	Value
interface-type interface-number	Displays IPv6 information on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number. If no interface is specified, IPv6 information on all interfaces configured with IPv6 addresses is displayed.	-
brief	Displays brief information about the interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Before running this command, ensure that the interface is configured with an IPv6 address. If no IPv6 address is assigned to the interface, no interface information is displayed.

Example

Display IPv6 information on VLANIF 2.

```
<HUAWEI> display ipv6 interface vlanif 2
Vlanif2 current state : DOWN
IPv6 protocol current state : DOWN
IPv6 is enabled, link-local address is FE80::200:1FF:FE04:5D00 [TENTATIVE]
  Global unicast address(es):
    FC00::1, subnet is FC00::/64 [TENTATIVE]
  Joined group address(es):
    FF02::1:FF00:1
```

```
  FF02::1:FF04:5D00
  FF02::2
  FF02::1
MTU is 1500 bytes
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND retransmit interval is 1000 milliseconds
ND stale time is 1200 seconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisement max interval 600 seconds, min interval 200 seconds
ND router advertisements live for 1800 seconds
ND router advertisements hop-limit 64
ND default router preference medium
Hosts use stateless autoconfig for addresses
```

Table 6-59 Description of the **display ipv6 interface** command output

Item	Description
Vlanif2 current state	Current physical status of VLANIF 2. ● UP: enabled ● DOWN: disabled
IPv6 protocol current state	Current protocol status of the interface. ● UP: enabled ● DOWN: disabled
IPv6 is enabled	IPv6 is enabled.
link-local address	Link-local address on the interface. After an IPv6 address is configured on the interface, the system automatically assigns a link-local address for the interface. To manually configure a link-local address for an interface, run the **ipv6 address link-local** command.
Global unicast address(es)	Global unicast address configured on the interface. To configure a global unicast address for an interface, run the **ipv6 address** command.
Joined group address(es)	Addresses of all multicast groups that the interface joins.
TENTATIVE	When the interface is in DOWN state, the IPv6 address is TENTATIVE.
MTU	MTU of the interface. To configure the MTU for an interface, run the **ipv6 mtu** command.
ND DAD is enabled	NS packets are sent when the system performs Duplicate Address Detection (DAD).

Item	Description
number of DAD attempts	Number of times duplicate address detection is performed.
ND reachable time	Neighbor reachable time.
ND retransmit interval	Retransmission interval of NS packets.
ND stale time	Aging time of ND entries in STALE state.
ND advertised reachable time	Reachable time of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND advertised retransmit interval	Retransmission interval of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisement max interval 600 seconds, min interval 200 seconds	Maximum and minimum interval of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisements live for	Router lifetime in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisements hop-limit	Hop limit of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND default router preference	Default route priority in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
Hosts use stateless autoconfig for addresses	Hosts obtain IPv6 addresses by means of stateless auto-configuration. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.

Display brief IPv6 information about all interfaces.

```
<HUAWEI> display ipv6 interface brief
*down: administratively down
(l): loopback
(s): spoofing
Interface                 Physical             Protocol
LoopBack0                   up                   up(s)
[IPv6 Address] Unassigned
Vlanif2                   down                 down
[IPv6 Address] 2001:db8:1::1 [TENTATIVE]
```

Table 6-60 Description of the **display ipv6 interface brief** command output

Item	Description
*down	Reason that interface is physically Down. **administratively down** indicates that the network administrator has executed the **shutdown (interface view)** command on the interface.
(l)	This interface is enabled with the loopback function.
(s)	This interface is enabled with the spoofing function.
Interface	Name of an interface.
Physical	Physical status of the interface.
Protocol	Link layer protocol status of the interface.
IPv6 Address	IPv6 address configured for the interface. If no IPv6 address is assigned to the interface, this field displays Unassigned.
TENTATIVE	When the interface is in Down state, the IPv6 address is TENTATIVE.

6.10.6 display ipv6 interface tunnel

Function

The **display ipv6 interface tunnel** command displays IPv6 information on a tunnel interface.

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display ipv6 interface tunnel *interface-number*

Parameters

Parameter	Description	Value
interface-number	Displays the tunnel interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ipv6 interface tunnel** command displays IPv6 information on a tunnel interface.

Example

Display IPv6 information on Tunnel1.

```
<HUAWEI> display ipv6 interface tunnel 1
Tunnel1 current state : UP
IPv6 protocol current state : DOWN
IPv6 is enabled, link-local address is FE80::2E0:9FF:FE87:7890 [TENTATIVE]
  Global unicast address(es):
    FC00:1::1, subnet is FC00:1::/64 [TENTATIVE]
  Joined group address(es):
    FF02::1:FF87:7890
    FF02::1:FF00:1
    FF02::2
    FF02::1
  MTU is 1500 bytes
  ND reachable time is 30000 milliseconds
  ND retransmit interval is 1000 milliseconds
  ND stale time is 1200 seconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisement max interval 600 seconds, min interval 200 seconds
  ND router advertisements live for 1800 seconds
  ND router advertisements hop-limit 64
  ND default router preference medium
  Hosts use stateless autoconfig for addresses
```

Table 6-61 Description of the **display ipv6 interface tunnel** command output

Item	Description
Tunnel1 current state	Current status of the tunnel interface: ● UP: enabled ● DOWN: disabled When working properly, an IPv6 over IPv4 tunnel is in Up state.

Item	Description
IPv6 protocol current state	Current status of the link layer protocol: - UP: enabled - DOWN: disabled When working properly, an IPv6 over IPv4 tunnel is in Up state.
IPv6 is enabled	IPv6 is enabled.
link-local address	Link-local address on the interface. After an IPv6 address is configured on the interface, the system automatically assigns a link-local address for the interface. To manually configure a link-local address for an interface, run the **ipv6 address link-local** command.
Global unicast address(es)	IPv6 global unicast address. To configure an IPv6 global unicast address, run the **ipv6 address** command.
Joined group address(es)	Addresses of multicast groups that the interface joins.
TENTATIVE	When the interface is in DOWN state, the IPv6 address is TENTATIVE.
MTU	MTU of the interface. To configure the MTU of the interface, run the **ipv6 mtu** command.
ND reachable time	Reachable time of ND packets.
ND retransmit interval	Interval for retransmitting ND packets.
ND stale time	Time period for the neighbor to keep the STALE state.
ND advertised reachable time	Reachable time of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND advertised retransmit interval	Retransmission interval of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.

Item	Description
ND router advertisement max interval 600 seconds, min interval 200 seconds	Maximum and minimum interval of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisements live for	Router lifetime in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisements hop-limit	Hop limit of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND default router preference	Default route priority in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
Hosts use stateless autoconfig for addresses	Hosts obtain IPv6 addresses by means of stateless auto-configuration. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.

6.10.7 display ipv6 nd track

Function

The **display ipv6 nd track** command displays information about the changes in the outbound interfaces of ND entries on VLANIF interfaces.

Format

display ipv6 nd track

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If the outbound interfaces of ND entries learned by a VLANIF interface change, traffic is intermittently interrupted. To keep track of the outbound interface changes, run the **display ipv6 nd track** command to display the change time.

Prerequisites

A VLANIF interface has ND entries, and their outbound interfaces have changed.

Precautions

After the **display ipv6 nd track** command is run, the following types of changes are displayed:

- The outbound interface of a dynamic ND entry learned by the VLANIF interface changes to another interface.
- The outbound interface of a static ND entry configured on the VLANIF interface is changed to another interface.
- A dynamic or static ND entry on the VLANIF interface is deleted.

The following types of changes are not displayed:

- ND entries on a non-VLANIF interface change.
- A new ND entry is learned.
- A new static ND entry is configured.

Example

Display information about the changes in the outbound interfaces of ND entries on VLANIF interfaces.

```
<HUAWEI> display ipv6 nd track
Operate Flag : Modify
IPv6-Address : 2001:db8::1
MAC-Address  : 00e0-fc12-3456
VLAN         : 1000
Old-Port     : GE0/0/1
New-Port     : GE0/0/11
System-Time  : 2017-10-19 12:10:12

Operate Flag : Modify
IPv6-Address : 2001:db8:2::2
MAC-Address  : 00e0-fc12-3456
VLAN         : 1000
Old-Port     : GE0/0/1
New-Port     : GE0/0/11
System-Time  : 2017-09-19 12:13:12

Operate Flag : Delete
IPv6-Address : 2001:db8:3::3
MAC-Address  : 00e0-fc12-3455
VLAN         : 300
Old-Port     : GE0/0/2
New-Port     :
System-Time  : 2017-08-19 12:12:12
```

Table 6-62 Description of the **display ipv6 nd track** command output

Item	Description
Operate Flag	Operation flag. - Modify: indicates that the outbound interface changes. - Delete: indicates that the ND entry is deleted.
IPv6-Address	IPv6 address of the ND entry.
MAC-Address	MAC address of the ND entry.
VLAN	VLAN ID of the VLANIF interface.
Old-Port	Original outbound interface of the ND entry.
New-Port	New outbound interface of the ND entry.
System-Time	Time when the outbound interface changed.

6.10.8 display ipv6 neighbors

Function

The **display ipv6 neighbors** command displays information about neighbor entries.

Format

display ipv6 neighbors [*ipv6-address* | [**vid** *vid*] *interface-type interface-number* | **vpn-instance** *vpn-instance-name*]

display ipv6 neighbors [*interface-type interface-number* [**vid** *vid* [**cevid** *cevid*]]]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support **cevid** *cevid*.

Parameters

Parameter	Description	Value
ipv6-address	Displays neighbor entries of a specified IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Parameter	Description	Value
vid *vid*	Displays neighbor entries of a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Displays neighbor entries on a specified interface.	-
vpn-instance *vpn-instance-name*	Displays neighbor entries of a specified VPN instance.	The value must be an existing VPN instance name.
cevid *cevid*	Specifies the inner tag.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ipv6 neighbors** command displays information about dynamic and static ND entries. The information helps you:

- Check whether the local routing device has learned MAC addresses from neighbors.
- Check the neighbor status of the local routing device, including neighbor unreachable, neighbor reachable, or unknown.

You can run one of the following commands as required:

- To view neighbor entries based on the neighbor IPv6 address, run the **display ipv6 neighbors** [*ipv6-address*] command.
- To view neighbor entries based on the neighbor interface number, run the **display ipv6 neighbors** *interface-type interface-number* command.

  To view neighbor entries on a VLANIF interface, run the **display ipv6 neighbors** [[**vid** *vlan-id*] *interface-type interface-number*] command or the **display ipv6 neighbors** [*interface-type interface-number* [**vid** *vid* [**cevid** *cevid*]]] command.
- To view the neighbor entry on a sub-interface for QinQ VLAN tag termination or Dot1q VLAN tag termination, run the **display ipv6 neighbors** [*interface-type interface-number* [**vid** *vid* [**cevid** *cevid*]]] command.

If no parameter is specified, the **display ipv6 neighbors** command displays all neighbor entries.

Example

Display neighbor entries of IPv6 address FC00::2.

```
<HUAWEI> display ipv6 neighbors fc00::2
------------------------------------------------------------------------------
IPv6 Address : FC00::2
Link-layer   : 00e0-fc89-fe6e          State : STALE
Interface    : GE0/0/1                 Age   : 00h19m12s
VLAN         : -                     CEVLAN: -
VPN name     :                         Is Router: FALSE
------------------------------------------------------------------------------
Total: 1        Dynamic: 1          Static: 0
```

Display neighbor entries on a specified interface.

```
<HUAWEI> display ipv6 neighbors vlanif 11
------------------------------------------------------------------------------
IPv6 Address : FC00::3
Link-layer   : 0001-0001-0012                   State : INCMP
Interface    : GE0/0/1                          Age   : 00h19m12s
VLAN         : 11                             CEVLAN: -
VPN name     : v1                               Is Router: TRUE

------------------------------------------------------------------------------
Total: 1       Dynamic: 0       Static: 1
```

View the neighbor entries on the QinQ termination sub-interface GE0/0/1.1.

```
<HUAWEI> display ipv6 neighbors gigabitethernet 0/0/1.1 vid 1 cevid 1
------------------------------------------------------------------------------
IPv6 Address : 2001:db8::2
Link-layer   : 00e0-3602-8100                   State : REACH
Interface    : GE0/0/1.1                        Age   : -
VLAN         : 1                              CEVLAN: 1
VPN name     :                                Is Router: TRUE
------------------------------------------------------------------------------
Total: 1       Dynamic: 0       Static: 1
```

Table 6-63 Description of the **display ipv6 neighbors** command output

Item	Description
IPv6 Address	IPv6 address of a neighbor.
Link-layer	Link layer address (MAC address) of the neighbor.

Item	Description
State	Status of a neighbor entry: - INCMP: indicates that the neighbor is unreachable. When the address is being resolved, the link layer address of the neighbor is not detected. If resolution succeeds, the neighbor entry is in REACH state. - REACH: indicates that the neighbor is reachable within a specified period. By default, the neighbor is reachable within 30s. If the period expires and the entry remains unused, the neighbor entry is in STALE state. - STALE: indicates that whether the neighbor is reachable is unknown. The entry remains unused within a specified period. By default, the neighbor is reachable within 30s. A device does not detect neighbor reachability unless it needs to send packets to a neighbor. - DELAY: indicates that whether the neighbor is reachable is unknown. A device has sent a packet to a neighbor. If the device does not receive any response from the neighbor within the specified period, the neighbor entry is in PROBE state. - PROBE: indicates that whether the neighbor is reachable is unknown. A device has sent a packet to a neighbor to detect whether the neighbor is reachable. If the device receives a response from the neighbor within a specified period, the neighbor entry is in REACH state. Otherwise, the neighbor entry is in INCMP state.
Interface	Name of the interface to which the neighbor entry belongs.
Age	Aging time of the neighbor entry: - The aging time of static entries is displayed as "-". - The aging time of dynamic entries is the time that the reachable state lasts. "#" indicates non-reachable (only for dynamic entries).
VLAN	ID of the VLAN to which the neighbor belongs.
CEVLAN	ID of the CEVLAN to which a neighbor belongs. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this parameter.
VPN name	Name of a VPN instance to which the neighbor belongs.

Item	Description
Is Router	Whether an NA packet carries the R flag: - If the NA packet carries the R flag, "TRUE" is displayed. In this case, the neighbor is a routing device. - If the NA packet carries no R flag, "FALSE" is displayed. In this case, the neighbor may be a PC or a routing device that sends an NA packet carrying no R flag.
Total	Number of total neighbor entries.
Dynamic	Number of dynamic neighbor entries.
Static	Number of static neighbor entries.

6.10.9 display ipv6 pathmtu

Function

The **display ipv6 pathmtu** command displays information about PMTU entries.

Format

display ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] { *ipv6-address* | **all** | **dynamic** | **static** }

Parameters

Parameter	Description	Value
ipv6-address	Displays PMTU entries that match a specified IPv6 address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
all	Displays all PMTU entries.	-
dynamic	Displays all dynamic PMTU entries.	-
static	Displays all static PMTU entries.	-
vpn-instance *vpn-instance-name*	Displays PMTU entries of a specified IPv6 VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If the MTU on the outbound interface of an intermediate routing device is smaller than the MTU of the source host, the path MTU (PMTU) discovery mechanism determines the maximum size of packets that can be transmitted on a path.

The **display ipv6 pathmtu** command displays information about dynamic and static PMTU entries. The device then fragments packets into a size smaller than the PMTU and forwards the fragmented packets.

Precautions

If no PMTU is set using the **ipv6 pathmtu** command, no static PMTU entry is displayed after the **display ipv6 pathmtu** command is run.

If a static PMTU entry is displayed, the remaining lifetime displays "-".

Example

Display all PMTU entries.

```
<HUAWEI> display ipv6 pathmtu all
IPv6 Destination Address               ZoneID PathMTU LifeTime(M) Type    FF
FC00::2                                0      1500    -           Static  NO
-------------------------------------------------------------------------------
Total: 1      Dynamic: 0     Static: 1
```

Table 6-64 Description of the display ipv6 pathmtu command output

Item	Description
IPv6 Destination Address	Destination IPv6 address.
ZoneID	Zone ID.
PathMTU	PMTU of an IPv6 address. To configure the PMTU for an IPv6 address, run the **ipv6 pathmtu** command.
LifeTime(M)	Remaining lifetime, in minutes. The update interval is 1 minute. This field displays "-" for static entries.

Item	Description
Type	Type of the PMTU entry: - Dynamic: dynamic entries - Static: static entries (configured through CLI)
FF	Fragmentation flag: - YES: Packets are fragmented, and a fragment header is added to a packet. - NO: Packets are not fragmented.
Total	Total number of PMTU entries.
Dynamic	Number of dynamic PMTU entries.
Static	Number of static PMTU entries.

6.10.10 display ipv6 socket

Function

The **display ipv6 socket** command displays information about IPv6 sockets.

Format

display ipv6 socket [**socktype** *socket-type* | **task-id** *task-id* **socket-id** *socket-id*]

Parameters

Parameter	Description	Value
socktype *socket-type*	Specifies the type of a socket. The value can be: - 1: indicates SOCK_STREAM, corresponding to the TCP-based socket. - 2: indicates SOCK_DGRAM, corresponding to the UDP-based socket. - 3: indicates SOCK_RAW, corresponding to the RawIP-based socket.	The value is an integer that ranges from 1 to 3.
socket-id *socket-id*	Specifies the socket ID.	The value is an integer that ranges from 1 to 131072.

Parameter	Description	Value
task-id *task-id*	Specifies the task ID.	The value is an integer and the range depends on the task configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To locate a fault, you can use this command to view detailed information about sockets of all types or a specified type.

Precautions

If there is no socket information, no information is displayed.

If no parameter is specified, this command displays information about all types of sockets.

Example

Display information about all types of sockets.

```
<HUAWEI> display ipv6 socket
SOCK_STREAM:
Task = VTYD(102), socketid = 3, Proto = 6,
LA = ::->22, FA = ::->0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_REUSEADDR SO_KEEPALIVE SO_LINGER SO_SETACL6 SO_
SETKEEPALIVE SO_ZONEID(-1),
socket state = SS_PRIV SS_ASYNC

Task = VTYD(102), socketid = 2, Proto = 6,
LA = ::->23, FA = ::->0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_KEEPALIVE SO_LINGER SO_REUSEPORT SO_SETACL6 SO_
SETKEEPALIVE SO_ZONEID(-1),
socket state = SS_PRIV SS_ASYNC

SOCK_DGRAM:
Task = TRAP(105), socketid = 2, Proto = 17,
LA = ::->49152, FA = ::->0,
sndbuf = 9216, rcvbuf = 42080, sb_cc = 0, rb_cc = 0,
socket option = SO_ZONEID(-1),
socket state = SS_PRIV

Task = AGT6(106), socketid = 1, Proto = 17,
LA = ::->161, FA = ::->0,
sndbuf = 17941, rcvbuf = 42080, sb_cc = 0, rb_cc = 0,
socket option = SO_ZONEID(-1),
socket state = SS_PRIV SS_ASYNC
```

```
Task = RDS(123), socketid = 2, Proto = 17,
LA = ::->1812, FA = ::->0,
sndbuf = 9216, rcvbuf = 42080, sb_cc = 0, rb_cc = 0,
socket option = SO_ZONEID(-1),
socket state = SS_PRIV SS_RECALL

SOCK_DGRAM:
SOCK_RAW:
```

Display information about the socket with socket type 1.

```
<HUAWEI> display ipv6 socket socktype 1
SOCK_STREAM:
Task = VTYD(102), socketid = 3, Proto = 6,
LA = ::->22, FA = ::->0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_REUSEADDR SO_KEEPALIVE SO_LINGER SO_SETACL6 SO_
SETKEEPALIVE SO_ZONEID(-1),
socket state = SS_PRIV SS_ASYNC

Task = VTYD(102), socketid = 2, Proto = 6,
LA = ::->23, FA = ::->0,
sndbuf = 8192, rcvbuf = 8192, sb_cc = 0, rb_cc = 0,
socket option = SO_ACCEPTCONN SO_KEEPALIVE SO_LINGER SO_REUSEPORT SO_SETACL6 SO_
SETKEEPALIVE SO_ZONEID(-1),
socket state = SS_PRIV SS_ASYNC
```

Table 6-65 Description of the **display ipv6 socket** command output

Item	Description
SOCK_STREAM	One type of socket. Sockets are classified into the following types: ● SOCK_STREAM ● SOCK_DGRAM ● SOCK_RAW
Task = VTYD	Type and ID of the task that invokes the socket. For example, **Task = VTYD(48)** shows that the task named VTYD uses the socket, with task ID 48.
socketid	Socket ID.
Proto	Protocol ID.
LA	Local address and local port number.
FA	Remote address and remote port number.
sndbuf	Upper limit of the send buffer, in bytes.
rcvbuf	Upper limit of the receive buffer, in bytes.
sb_cc	Total number of sent bytes.
rb_cc	Total number of received bytes.
socket option	Socket option that has been set.
socket state	Socket status.

6.10.11 display ipv6 statistics

Function

The **display ipv6 statistics** command displays IPv6 traffic statistics.

Format

display ipv6 statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays IPv6 traffic statistics on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display ipv6 statistics** command to view statistics on received and sent IPv6 packets.

During packet transmission, if the source node has fragmented packets, you can run this command to view the total number of IPv6 packets that are successfully fragmented and the total number of fragmented packets that have been sent, and then check whether the number of fragmented packets received by the destination node is correct.

Precautions

The total number of packets received by the device includes the number of forwarded packets, number of packets delivered by the routing device to the upper layer, and number of discarded packets.

Example

Display IPv6 traffic statistics on the device.

```
<HUAWEI> display ipv6 statistics
IPv6 Protocol:

 Sent packets:
  Total             : 0
  Local sent out     : 0         Forwarded          : 0
  Raw packets        : 0         Discarded          : 0
  Fragmented         : 0         Fragments          : 0
  Fragments failed   : 0         Multicast          : 0

 Received packets:
  Total             : 0         Local host         : 0
  Hop count exceeded : 0         Header error       : 0
  Too big            : 0         Routing failed     : 0
  Address error      : 0         Protocol error     : 0
  Truncated          : 0         Option error       : 0
  Fragments          : 0         Reassembled        : 0
  Reassembly timeout : 0         Multicast          : 0
  Fragments overlap  : 0
  Extension header:
    Hop-by-hop options   : 0              Mobility header       : 0
    Destination options  : 0              Routing header        : 0
    Fragment header      : 0              Authentication header : 0
    Encapsulation header : 0              No header             : 0
    TLV length error     : 0              Header length error   : 0
    Unknown header type  : 0              Unknown TLV type      : 0
```

Table 6-66 Description of the **display ipv6 statistics** command output

Item	Description
Sent packets	Statistics about sent packets.
Total	Total number of sent packets.
Local sent out	Total number of packets sent by the local device.
Forwarded	Number of forwarded packets.
Raw packets	Total number of packets sent through the raw socket, such as ping or tracert packets.
Discarded	Total number of discarded packets.
Fragmented	Total number of IPv6 packets that are successfully fragmented.
Fragments	Total number of sent fragmented packets.
Fragments failed	Total number of IPv6 packets that fail to be fragmented.
Multicast	Total number of sent multicast packets.
Received packets	Statistics about received packets.
Total	Total number of received packets.

Item	Description
Local host	Total number of packets received by the local device.
Hop count exceeded	Total number of packets whose hops exceed the upper limit.
Header error	Total number of packets with incorrect packet header.
Too big	Total number of received packets that fail to be forwarded because of excessive size.
Routing failed	Total number of packets that fail to be routed.
Address error	Total number of packets with incorrect IP addresses.
Protocol error	Total number of packets with the incorrect protocol.
Truncated	Total number of packets discarded because the actual packet length is shorter than that specified in the packet length field.
Option error	Total number of packets that carry incorrect options.
Fragments	Total number of received fragmented packets.
Reassembled	Total number of packets that are successfully reassembled.
Reassembly timeout	Total number of packets that fail to be reassembled due to timeout.
Multicast	Total number of received multicast packets.
Fragments overlap	Total number of received fragmented packets that are overlapped.
Extension Header	Total number of the IPv6 extension headers.
Hop-by-Hop Options	Total number of the hop-by-hop options headers.
Mobility Header	Total number of the mobility headers.
Destination Options	Total number of the destination options headers.

Item	Description
Routing Header	Total number of the routing options headers.
Fragment Header	Total number of the fragment headers.
Authentication Header	Total number of the authentication headers.
Encapsulation Header	Total number of the encapsulation headers.
No header	Total number of the packets without headers.
TLV Length error	Total number of the extension headers in which the TLV length field is wrong.
Header Length error	Total number of the extension headers in which the length field is wrong.
Unknown header type	Total number of the unknown extension header types.
Unknown TLV type	Total number of the unknown TLV types.

6.10.12 display nd optimized-passby status

Function

The **display nd optimized-passby status** command displays whether the device is configured not to send NS packets destined for other devices to the CPU and whether the configuration takes effect.

Format

display nd optimized-passby status interface vlanif *vlanif-id* **slot** *slot-id*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interface vlanif *vlanif-id*	Displays whether the device is configured not to send NS packets destined for other devices to the CPU and whether the configuration takes effect on a specified VLANIF interface.	The value is an integer and the value range depends on the range of existing VLANIF interfaces. You can enter ? to obtain the range of VLANIF interface numbers.
slot *slot-id*	Displays whether the device is configured not to send NS packets destined for other devices to the CPU and whether the configuration takes effect in a specified slot.	The value must be set according to the device configuration.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an interface receives a large number of NS packets whose destination IPv6 addresses are different from the IPv6 address of this interface and sends these NS packets to the CPU for processing, the CPU usage is high and the CPU cannot process services properly.

To prevent this issue, you can configure the device to directly forward NS packets destined for other devices without sending them to the CPU. This improves the device's capability of defending against packet attacks.

When the device is configured not to send NS packets destined for other devices to the CPU, the configuration does not take effect if a conflict configuration exists on the device. You can use the **display nd optimized-passby status** command to check whether the device is configured not to send NS packets destined for other devices to the CPU and whether the configuration takes effect. For details about conflict configurations, see **nd optimized-passby enable**.

Example

Display whether the device is configured not to send NS packets destined for other devices to the CPU and whether the configuration takes effect on VLANIF 100.

```
<HUAWEI> display nd optimized-passby status interface Vlanif 100 slot 0
Current configuration: Enable
Actual          status: Inactive
Inactive        Reason: The interface protocol status is down.
```

Table 6-67 Description of the **display nd optimized-passby status** command output

Item	Description
Current configuration	Whether the device is configured not to send NS packets destined for other devices to the CPU. - Enable: The device is configured not to send NS packets destined for other devices to the CPU. - Disable: The device is configured to send NS packets destined for other devices to the CPU.
Actual status	Whether the configuration of disabling the device from sending NS packets destined for other devices to the CPU takes effect. - Inactive - Active
Inactive Reason	Conflict configuration.

6.10.13 display nd optimized-reply statistics

Function

The **display nd optimized-reply statistics** command displays statistics on optimized ND Reply packets.

Format

display nd optimized-reply statistics [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID.	The value is an integer. It has a fixed value of 0 in a non-stack scenario, and depends on the device configuration in a stack scenario.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check statistics on optimized ND Reply packets after the optimized ND reply function is enabled on the device.

Example

Display statistics on optimized ND Reply packets.

```
<HUAWEI> display nd optimized-reply statistics
Slot          Received           Processed            Dropped
---------------------------------------------------------------
0                  11                 9                 7
```

Table 6-68 Description of the display nd optimized-reply statistics command output

Item	Description
Slot	Stack ID.
Received	Number of ND Request packets entering the processing procedure of the optimized ND reply function.
Processed	Number of optimized ND Reply packets.
Dropped	Number of ND Request packets discarded. **NOTE** When the optimized ND reply function is enabled, the device does not optimize the responses to the ND Request packets whose destination IPv6 address is not the IPv6 address of a local interface on the switch.

6.10.14 display nd optimized-reply status

Function

The **display nd optimized-reply status** command displays the status of the optimized ND reply function.

Format

display nd optimized-reply status

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the status of the optimized ND reply function.

Example

Check the status of the optimized ND reply function.

```
<HUAWEI> display nd optimized-reply status
Current configuration:Disable
Actual          status:Inactive
Related configuration:
   nd optimized-reply disable
```

Table 6-69 Description of the display nd optimized-reply status command output

Item	Description
Current configuration	Configuration of the optimized ND reply function. - Enable - Disable To set this field, run the **nd optimized-reply disable** command.
Actual status	Status of the optimized ND reply function. - Active - Inactive
Related configuration	Configuration that results in the invalid optimized ND reply function. If the optimized ND reply function has taken effect, this field is not displayed.

6.10.15 display rawip ipv6 statistics

Function

The **display rawip ipv6 statistics** command displays Raw IPv6 packet statistics.

Format

display rawip ipv6 statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display rawip ipv6 statistics** command to view Raw IPv6 packet statistics, including:

- Statistics about received and sent Raw IPv6 packets
- Statistics about discarded Raw IPv6 packets

Example

Display Raw IPv6 packet statistics.

```
<HUAWEI> display rawip ipv6 statistics
 Received packets:
     total: 20
     packets sent for external pre processing: 0
     packets for which checksum has to be calculated: 0
     packets with invalid checksum : 0
     dropped packets due to socket buffer is full: 0
     dropped packets due to no matching socket: 20
     dropped multicast packets due to no matching socket: 0
 Sent packets:
     total (excluding ICMP6 packets): 0
```

Table 6-70 Description of the display rawip ipv6 statistics command output

Item	Description
total	Total number of received and sent packets.
packets sent for external pre processing	Number of received Raw IPv6 packets for external preprocessing.
packets for which checksum has to be calculated	Number of received Raw IPv6 packets for which checksum has been calculated.
packets with invalid checksum	Number of discarded Raw IPv6 packets with checksum errors.
dropped packets due to socket buffer is full	Number of Raw IPv6 packets that are discarded because the socket buffer is full.

Item	Description
dropped packets due to no matching socket	Number of discarded Raw IPv6 packets that do not match the receiving socket.
dropped multicast packets due to no matching socket	Number of discarded Raw IPv6 packets destined to a multicast address that do not match the receiving socket.

6.10.16 display tcp ipv6 authentication-statistics

Function

The **display tcp ipv6 authentication-statistics** command displays authentication statistics of a specified TCP6 connection.

Format

display tcp ipv6 authentication-statistics src-ip *src-ip* **src-port** *src-port* **dest-ip** *dest-ip* **dest-port** *dest-port*

Parameters

Parameter	Description	Value
src-ip *src-ip*	Specifies the source IPv6 address.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.
src-port *src-port*	Specifies the source port.	The value is an integer that ranges from 0 to 65535.
dest-ip *dest-ip*	Specifies the destination IPv6 address.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.
dest-port *dest-port*	Specifies the destination port.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display tcp ipv6 authentication-statistics** command to view authentication statistics of a specified TCP6 connection, including:

- Number of TCP6 packets with MD5 Option
- Number of TCP6 packets with Enhanced Authentication Option

Example

Display authentication statistics of a specified TCP6 connection.

```
<HUAWEI> display tcp ipv6 authentication-statistics src-ip fc00::1 src-port 3456 dest-ip fc00::5 dest-port 5678
MD5 Signature Option (MSO)is enabled |
 Enhanced Authentication Option (EAO)is enabled
Received packets:
     total: 0
     packets received with MSO: 0
     packets received with EAO: 0
     packets dropped due to MD5 authentication failure: 0
     packets dropped due to absence of MSO: 0
     packets dropped due to presence of MSO: 0
     packets dropped due to MAC authentication failure: 0
     packets dropped due to absence of active receive key: 0
     packets dropped due to invalid receive algorithm id: 0
     packets dropped due to absence of EAO: 0

Sent packets:
     total: 0
     packets sent with MSO: 0
     packets sent with EAO: 0
     packets not sent due to absence of active send key: 0
```

Table 6-71 Description of the **display tcp ipv6 authentication-statistics** command output

Item	Description
total (received packets)	Total number of received and discarded TCP6 packets.
packets received with MSO	Total number of received TCP6 packets with MD5 Option.
packets received with EAO	Total number of received TCP6 packets with Enhanced Authentication Option.
packets dropped due to MD5 authentication failure	Total number of TCP6 packets discarded due to MD5 authentication failure.
packets dropped due to absence of MSO	Total number of TCP6 packets discarded due to absence of MD5 Option.
packets dropped due to presence of MSO	Total number of TCP6 packets discarded due to presence of MD5 Option.

Item	Description
packets dropped due to MAC authentication failure	Total number of TCP6 packets discarded due to MAC authentication failure.
packets dropped due to absence of active receive key	Total number of TCP6 packets discarded due to absence of active receive key.
packets dropped due to invalid receive algorithm id	Total number of TCP6 packets discarded due to invalid receive algorithm ID.
packets dropped due to absence of EAO	Total number of TCP6 packets discarded due to absence of Enhanced Authentication Option.
total (sent packets)	Total number of sent and unsent TCP6 packets.
packets sent with MSO	Total number of sent TCP6 packets with MD5 Option.
packets sent with EAO	Total number of sent TCP6 packets with Enhanced Authentication Option.
packets not sent due to absence of active send key	Total number of TCP6 packets discarded due to absence of active send key.

6.10.17 display tcp ipv6 statistics

Function

The **display tcp ipv6 statistics** command displays TCP6 traffic statistics.

Format

display tcp ipv6 statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can check the network connection status according to the items in the command output, for example:

- Established connections: indicates the number of established connections, helping you determine whether to continue deploying services such as BGP services or adjust the load.
- Duplicate ACK packets: indicates whether the device is attacked by unknown ACK packets. If the device receives a large number of unknown ACK packets, the device may be attacked.
- Out-of-order packets: allows you to check network performance. If the network is in poor condition, a lot of out-of-order packets are generated.

Precautions

- The total number of received packets includes the number of forwarded packets, number of packets delivered to the upper layer, and number of discarded packets.
- Before running this command to view TCP6 statistics within a specified period, run the **reset tcp ipv6 statistics** command to clear existing statistics.

Example

Display TCP6 packet statistics.

```
<HUAWEI> display tcp ipv6 statistics
Received packets:
    total: 0
    total(64bit high-capacity counter): 0
    packets in sequence: 0 (0 bytes)
    window probe packets: 0
    window update packets: 0
    checksum error: 0
    offset error: 0
    short error: 0
    duplicate packets: 0 (0 bytes)
    partially duplicate packets: 0 (0 bytes)
    out-of-order packets: 0 (0 bytes)
    packets with data after window: 0 (0 bytes)
    packets after close: 0
    ACK packets: 0 (0 bytes)
    duplicate ACK packets: 0
    too much ACK packets: 0
    packets dropped due to MD5 authentication failure: 0
    packets dropped due to absence of MSO: 0
    packets dropped due to presence of MSO: 0
    packets received with MD5 Signature Option: 0

Sent packets:
    total: 0
    urgent packets: 0
    total(64bit high-capacity counter): 0
    control packets: 0 (including 0 RST)
    window probe packets: 0
    window update packets: 0
    data packets: 0 (0 bytes)
    data packets retransmitted: 0 (0 bytes)
    ACK only packets: 0 (0 delayed)
    packets sent with MD5 Signature Option: 0

Other Statistics:
    retransmitted timeout: 0
    connections dropped in retransmitted timeout: 0
    keepalive timeout: 0
    keepalive probe: 0
```

```
    keepalive timeout, so connections disconnected: 0
    initiated connections: 0
    accepted connections: 0
    established connections: 0
    closed connections: 1 (dropped: 0, initiated dropped: 0)
```

Table 6-72 Description of the **display tcp ipv6 statistics** command output

Item	Description
Received packets: total	Total number of received packets.
packets in sequence	Number of packets received in sequence.
window probe packets	Number of received window probe packets.
window update packets	Number of received window update packets.
checksum error	Number of received packets received with invalid checksum.
offset error	Number of received packets with incorrect TCP header length.
short error	Number of received packets with total length shorter than the set value in the packet header.
duplicate packets	Number of received duplicate packets.
partially duplicate packets	Number of received partially duplicate packets.
out-of-order packets	Number of received out-of-order packets.
packets with data after window	Number of received packets exceeding the receive window.
packets after close	Number of packets received after the connection is closed.
ACK packets	Number of received ACK packets.
duplicate ACK packets	Number of received duplicate ACK packets.
too much ACK packets	Number of received ACK packets with too large ACK values.
Sent packets: total	Total number of sent packets.
urgent packets	Number of sent packets with the urgent pointer.
control packets	Number of sent control packets.
window probe packets	Number of sent window probe packets.

Item	Description
window update packets	Number of sent window update packets.
data packets	Number of sent data packets.
data packets retransmitted	Number of retransmitted data packets.
ACK only packets	Number of sent ACK only packets.
Other Statistics	Other statistics.
retransmitted timeout	Number of retransmission timeout packets.
connections dropped in retransmitted timeout	Number of disconnected connections during the retransmission timeout.
keepalive timeout	Number of Keepalive timeouts.
keepalive probe	Number of Keepalive probes.
keepalive timeout, so connections disconnected	Number of connections disconnected due to Keepalive timeout.
initiated connections	Number of initiated connections.
accepted connections	Number of accepted connections.
established connections	Number of established connections.
closed connections	Number of closed connections.
dropped	Number of disconnected connections.
initiated dropped	Number of initiated and disconnected connections.

6.10.18 display tcp ipv6 status

Function

The **display tcp ipv6 status** command displays the status of all TCP6 connections.

Format

display tcp ipv6 status [**local-ip** *ipv6-address*] [**local-port** *local-port-number*] [**remote-ip** *ipv6-address*] [**remote-port** *remote-port-number*]

display tcp ipv6 status [**task-id** *task-id* [**sock-id** *sock-id*]]

Parameters

Parameter	Description	Value
local-ip *ipv6-address*	Displays the TCP6 connection status of the specified IPv6 address. *ipv6-address* specifies the IPv6 address of the local device.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.
remote-ip *ipv6-address*	Displays the TCP6 connection status of the specified IPv6 address. *ipv6-address* specifies the IPv6 address of the remote device.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.
local-port *local-port-number*	Displays the TCP6 connection status of the specified port number. *local-port-number* specifies the port number of the local device.	The value is an integer that ranges from 0 to 65535.
remote-port *remote-port-number*	Displays the TCP6 connection status of the specified port number. *remote-port-number* specifies the port number of the remote device.	The value is an integer that ranges from 0 to 65535.
task-id *task-id*	Displays the status of the TCP6 connection with the specified task ID. *task-id* specifies the task ID.	The value is an integer that ranges from 1 to 200.
sock-id *sock-id*	Displays the TCP6 connection status with the specified socket ID. *sock-id* specifies the socket ID.	The value is an integer that ranges from 1 to 131072.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display tcp ipv6 status** command to view all valid TCP6 control blocks, including the following information:

- TCP6 socket ID
- Local IPv6 address and port number
- Remote IPv6 address and port number
- TCP6 connection status
- VPN ID

To view the status of all valid TCP6 connections, run the **display tcp ipv6 status** [**local-ip** *ipv6-address*] [**local-port** *local-port-number*] [**remote-ip** *ipv6-address*] [**remote-port** *remote-port-number*] command.

To view the status of the TCP6 connection with a specified socket ID, run the **display tcp ipv6 status** [**task-id** *task-id* [**sock-id** *sock-id*]] command.

Precautions

If there is no TCP connection, no information is displayed.

Example

Display the status of TCP6 connections.

```
<HUAWEI> display tcp ipv6 status
* - MD5 Authentication is enabled.
TCP6CB   TID/SoID  Local Address       Foreign Address      State        VPNID
0be58fa8 102/3     ::->22              ::->0                Listening    0
0d109448 102/2     ::->23              ::->0                Listening    0
```

Table 6-73 Description of the **display tcp ipv6 status** command output

Item	Description
TCP6CB	Address of a TCP6 control block, in hexadecimal notation.
TID/SoID	Task ID and socket ID.
Local Address	Local IPv6 address and port number.
Foreign Address	Remote IPv6 address and port number.

Item	Description
State	Status of a TCP6 connection: - Closed: indicates that the TCP connection is closed. - Listening: indicates that the TCP connection is being listened on. - Syn_Rcvd: indicates that a TCP packet with the SYN flag is received. - Syn_Sent: indicates that a TCP packet with the SYN flag is sent. - Established: indicates that the TCP connection has been set up. - Close_Wait: indicates that a user host sends a packet with the FIN flag to the server, requesting the server to close the TCP connection in Established state. The server then sends an ACK packet to the user host after receiving the packet and enters the Close_Wait state. - Fin_Wait1: indicates that a user host sends a packet with the FIN flag to the server, requesting the server to close the TCP connection and enters the Fin_Wait1 state. - Fin_Wait2: indicates that a user host receives an ACK packet in a response to the sent packet with the FIN flag and enters the Fin_Wait2 state. - Time_Wait: indicates that TCP enters this state after the TCP connection is closed. When TCP has been in Time_Wait state two times the longest packet lifetime, records about the closed connection are deleted. - Closing: indicates that the two ends close the TCP connection simultaneously. - LAST_ACK: indicates that the local end waits for acknowledging the TCP connection teardown request sent to the remote end.
VPNID	VPN ID.

6.10.19 display this ipv6 interface

Function

The **display this ipv6 interface** command displays IPv6 information on the current interface.

Format

display this ipv6 interface

Parameters

None

Views

Interface view

Default Level

1: Monitoring level

Usage Guidelines

After an IPv6 address is configured in the interface view, you can run the **display this ipv6 interface** command to check IPv6 information on the interface.

Example

Display IPv6 information on VLANIF10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] display this ipv6 interface
Vlanif10 current state : UP
IPv6 protocol current state : UP
IPv6 is enabled, link-local address is FE80::2E0:4AFF:FE3D:9801 [TENTATIVE]
  Global unicast address(es):
    FC00::1, subnet is FC00::/64 [TENTATIVE]
  Joined group address(es):
    FF02::1:FF00:1
    FF02::1:FF3D:9801
    FF02::2
    FF02::1
  MTU is 1500 bytes
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND retransmit interval is 1000 milliseconds
  ND stale time is 1200 seconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisement max interval 600 seconds, min interval 200 seconds
  ND router advertisements live for 1800 seconds
  ND router advertisements hop-limit 64
  ND default router preference medium
  Hosts use stateless autoconfig for addresses
```

Display IPv6 information on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00:1::1 64
[HUAWEI-GigabitEthernet0/0/1] display this ipv6 interface
GigabitEthernet0/0/1 current state : DOWN
IPv6 protocol current state : DOWN
IPv6 is enabled, link-local address is FE80::225:9EFF:FEF4:ABCD
[TENTATIVE]
  Global unicast address(es):
    FC00:1::1, subnet is FC00:1::/64 [TENTATIVE]
  Joined group address(es):
    FF02::1:FF00:1
    FF02::1:FFF4:ABCD
    FF02::2
    FF02::1
  MTU is 1500 bytes
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND retransmit interval is 1000 milliseconds
  ND stale time is 1200 seconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisement max interval 600 seconds, min interval 200 seconds
  ND router advertisements live for 1800 seconds
  ND router advertisements hop-limit 64
  ND default router preference medium
  Hosts use stateless autoconfig for addresses
```

Table 6-74 Description of the **display this ipv6 interface** command output

Item	Description
Vlanif10 current state	Current physical status of VLANIF 10. - UP: enabled - DOWN: disabled
GigabitEthernet0/0/1 current state	Current physical status of GigabitEthernet0/0/1. - UP: enabled - DOWN: disabled
IPv6 protocol current state	Current protocol status of the interface. - UP: enabled - DOWN: disabled
link-local address	Link-local address on the interface. After an IPv6 address is configured on the interface, the system automatically assigns a link-local address for the interface. To manually configure a link-local address for an interface, run the **ipv6 address link-local** command.

Item	Description
Global unicast address(es)	Global unicast address configured on the interface. To configure a global unicast address for an interface, run the **ipv6 address** command.
Joined group address(es)	Addresses of all multicast groups that the interface joins.
TENTATIVE	When the interface is in DOWN state, the IPv6 address is TENTATIVE. When the IPv6 address is duplicate with another, this field is DUPLICATE. In normal cases, this field is not displayed.
MTU	MTU of the interface. To configure the MTU for an interface, run the **ipv6 mtu** command.
ND DAD is enabled	Duplicate address detection (DAD) has been enabled.
number of DAD attempts	Number of times duplicate address detection is performed.
ND reachable time	Neighbor reachable time.
ND retransmit interval	Retransmission interval.
ND stale time	Aging time of ND entries in STALE state.
ND advertised reachable time	Reachable time of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND advertised retransmit interval	Retransmission interval of NA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisement max interval 600 seconds, min interval 200 seconds	Maximum and minimum interval of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND router advertisements live for	Router lifetime in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.

Item	Description
ND router advertisements hop-limit	Hop limit of RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
ND default router preference	Default route priority in RA packets. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.
Hosts use stateless autoconfig for addresses	Hosts obtain IPv6 addresses by means of stateless auto-configuration. **NOTE** This field is displayed only after the **undo ipv6 nd ra halt** command is executed on the interface.

6.10.20 display udp ipv6 statistics

Function

The **display udp ipv6 statistics** command displays UDP6 packet statistics.

Format

display udp ipv6 statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The User Datagram Protocol (UDP) is a simple protocol that exchanges packets on the Internet. You can run the **display udp ipv6 statistics** command to view statistics about sent and received UDP6 packets.

Precautions

The total number of packets received by the device includes the number of forwarded packets, number of packets delivered by the device to the upper layer, and number of discarded packets.

Example

Display UDP6 packet statistics.

```
<HUAWEI> display udp ipv6 statistics
Received packets:
     total: 0
     total(64bit high-capacity counter): 0
     checksum error: 0
     shorter than header: 0
     invalid message length: 0
     no socket on port: 0
     no multicast port: 0
     not delivered, input socket full: 0
     input packets missing pcb cache: 0
     packets sent for external pre processing: 1

Sent packets:
     total: 0
     total(64bit high-capacity counter): 0
```

Table 6-75 Description of the display udp ipv6 statistics command output

Item	Description
Received packets	Number of received packets.
total	Total number of received and sent packets.
checksum error	Total number of packets with invalid checksum.
shorter than header	Total number of UDP6 packets with the length shorter than the packet header.
invalid message length	Total number of packets whose data length is longer than the packet length.
no socket on port	Number of packets without corresponding sockets on the interface.
no multicast port	Number of received packets carrying nonexistent multicast interfaces.
not delivered, input socket full	Number of unprocessed packets when the buffer is full.
input packet missing pcb cache	Number of received packets failing to find the PCB cache.
packets sent for external pre processing	Number of received packets for external preprocessing.
Sent packets	Number of sent packets.

6.10.21 eth-trunk (tunnel interface view)

Function

The **eth-trunk** command associates a specified tunnel interface with an Eth-Trunk interface enabled with service loopback.

The **undo eth-trunk** command disassociates a specified tunnel interface from an Eth-Trunk interface enabled with service loopback.

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

eth-trunk *trunk-id*

undo eth-trunk

Parameters

Parameter	Description	Value
trunk-id	Specifies the ID of an Eth-Trunk interface associated with the tunnel interface.	S5720I-SI, S5735-S, S500, S5735-S-I, and S5735S-S: The value ranges from 0 to 119. S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S: The value ranges from 0 to 127. S5735S-H, S5736-S, and S6720S-S: The value ranges from 0 to 249.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Before associating a specified tunnel interface with an Eth-Trunk interface, run the **service type tunnel** command to enable service loopback on the Eth-Trunk interface.

Example

Associate Tunnel1 with the Eth-Trunk interface enabled with service loopback.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] eth-trunk 1
```

6.10.22 ipv6

Function

The **ipv6** command enables the device to forward IPv6 unicast packets, including sending and receiving local IPv6 packets.

The **undo ipv6** command disables the device from forwarding IPv6 unicast packets.

By default, a device is disabled from forwarding IPv6 unicast packets.

Format

ipv6

undo ipv6

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You must run the **ipv6** command in the system view before performing IPv6 configurations.

NOTE

The **undo ipv6** command disables the device from forwarding IPv6 unicast packets. Therefore, confirm your action before running this command.

When system resources are insufficient, the **ipv6** command does not take effect and an alarm is generated. The alarm ID is 1.3.6.1.4.1.2011.5.25.227.2.1.7.

Example

Enable the device to forward IPv6 unicast packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
```

Disable the device from forwarding IPv6 unicast packets.

```
<HUAWEI> system-view
[HUAWEI] undo ipv6
Warning: This operation will interrupt all IPv6 services. Continue?[Y/N]:y
```

6.10.23 ipv6 address

Function

The **ipv6 address** command configures a site-local address or global unicast address for an interface.

The **ipv6 address** *dhcpv6-prefix* command configures an IPv6 address bound to the DHCPv6 PD prefix for an interface.

The **undo ipv6 address** command deletes a global unicast address from an interface.

The **undo ipv6 address** *dhcpv6-prefix* command deletes the IPv6 address bound to the DHCPv6 PD prefix for an interface.

By default, no global unicast address is configured for an interface.

By default, no IPv6 address bound to the DHCPv6 PD prefix is configured for an interface.

Format

ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* }

ipv6 address *dhcpv6-prefix* { *ipv6-address prefix-length* | *ipv6-address/prefix-length* }

undo ipv6 address [*ipv6-address prefix-length* | *ipv6-address/prefix-length*]

undo ipv6 address *dhcpv6-prefix*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of an interface.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.

Parameter	Description	Value
prefix-length	Specifies the prefix length of an IPv6 address. An IPv6 address with a 128-bit prefix can be configured only on a loopback interface.	The value is an integer that ranges from 1 to 128.
dhcpv6-prefix	Specifies the prefix assigned to a DHCPv6 PD client.	The value must be an existing prefix assigned to a DHCPv6 PD client.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A global unicast address is similar to an IPv4 public network address. Global unicast addresses are used on the links that can be summarized, and are provided for the Internet Service Providers (ISPs). These addresses allow route prefix summarization, limiting global routing entries. A global unicast address consists of a 48-bit route prefix managed by carriers, a 16-bit subnet ID managed by local nodes, and a 64-bit interface ID.

The switch is required to function as a DHCPv6 PD client and obtain an IPv6 address prefix from the DHCPv6 PD server. You can run the **ipv6 address** *dhcpv6-prefix* { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } command to configure an IPv6 address is bound to the DHCPv6 PD prefix. After you run this command, the switch uses the prefix assigned to the DHCPv6 PD client and the IPv6 address to form an RA prefix for the interface only when the switch functions as a DHCPv6 PD client and obtains a prefix. The prefix must be a 64-digit number. If not, the host cannot use this prefix for automatic assignment of IPv6 addresses.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

The following conditions are prohibited for different interfaces on the same switch:

- The IPv6 addresses are the same.
- The network prefixes of the IPv6 addresses are the same. For example, if the IPv6 address of interface A is 2001:db8::1/12 and its network prefix is 200::

and the IPv6 address of interface B is 2001:db8::1/127 and its network prefix is 2001:db8::, the configuration succeeds. If the IPv6 address of interface B is also 2002:db8::1/12 and its network prefix is also 200::, the configuration fails.

A maximum of 10 global unicast addresses can be configured for an interface.

An IPv6 address with a 128-bit prefix can be configured only on a loopback interface.

The following IPv6 addresses cannot be configured for an interface:

- Loopback address (::1/128)
- Unspecified address (::/128)
- Multicast address
- IPv4-mapped IPv6 address (0:0:0:0:0:FFFF:IPv4-address)

A 128-bit IPv6 address has two formats:

- X:X:X:X:X:X:X:X

  In this format, a 128-bit IPv6 address is written as eight groups of four hexadecimal digits (0 to 9, A to F), where each group is separated by a colon (:). Every X represents a group of hexadecimal numbers.
- X:X:X:X:X:X:d.d.d.d

  In this format, "X:X:X:X:X:X" represent the high-order six groups of numbers, and each X stands for 16 bits that are represented by four hexadecimal characters. "d.d.d.d" represents the low-order four groups of numbers, and each d stands for 8 bits that are represented by decimal numbers. "d.d.d.d" stands for a standard IPv4 address.

An IPv6 address has two parts:

- Network prefix: corresponds to the network ID of an IPv4 address. It is of n bits.
- Interface identifier: corresponds to the host ID of an IPv4 address. It is of 128-n bits.

If the **ipv6 address** command has been run to configure an IPv6 address for an interface, but no link-local address is configured for the interface, the system generates a link-local address for the interface.

If no parameter (IPv6 address or prefix length) is specified in the **undo ipv6 address** command, running the **undo ipv6 address** command deletes all IPv6 addresses.

Example

Configure a global unicast address for VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address fc00::1/64
```

Configure a global unicast address for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00::1/64
```

Configure an IPv6 address bound to the DHCPv6 PD prefix for VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address prefix1 ::1:0:0:0:1/64
```

6.10.24 ipv6 address anycast

Function

The **ipv6 address anycast** command configures an IPv6 anycast address.

The **undo ipv6 address** command deletes an IPv6 anycast address.

By default, no IPv6 anycast address is configured.

Format

ipv6 address { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } **anycast**

undo ipv6 address [*ipv6-address prefix-length* | *ipv6-address/prefix-length*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies an IPv6 address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 1 to 128.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An anycast address identifies a group of interfaces, which usually belong to different nodes. Packets sent to an anycast address are delivered to the nearest interface that is identified by the anycast address, depending on the routing protocols.

To implement communication between a 6to4 network and a local (native) IPv6 network using a 6to4 tunnel, configure an anycast address with prefix 2002:c058:6301:: for the tunnel interface of a 6to4 relay agent. If an anycast address is used, you need to configure the same address for the tunnel interfaces of all devices. In this manner, the number of addresses is reduced.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

If no parameter is specified in the **undo ipv6 address** command, all IPv6 addresses except link-local addresses are deleted.

An anycast address cannot be used as the source address of a packet. Therefore, a global unicast address must be configured when a device needs to send packets.

An IPv6 address with a 128-bit prefix can be configured only on a loopback interface.

Example

Configure anycast address 2002:c058:6301::/48 for VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address 2002:c058:6301:: 48 anycast
```

Configure anycast address 2002:c058:6301::/48 for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address 2002:c058:6301:: 48 anycast
```

6.10.25 ipv6 address auto global

Function

The **ipv6 address auto global** command enables a device to generate an IPv6 global address through stateless autoconfiguration.

The **undo ipv6 address auto global** command disables a device from generating an IPv6 global address through stateless autoconfiguration.

By default, the device is disabled from generating an IPv6 global address through stateless autoconfiguration.

Format

ipv6 address auto global [**default**]

undo ipv6 address auto global

Parameters

Parameter	Description	Value
default	Indicates that the device learns the default route.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **ipv6 address auto global** command is run, a device automatically generates an IPv6 global unicast address on the interface that receives a RA packet. The generated IPv6 address contains the address prefix in the received RA packet and interface identifier of the device. If the device does not receive RA packets, the device can only automatically configure a link-local address to interconnect with local nodes.

After the **ipv6 address auto global default** command is run, a device generates an IPv6 address based on the received RA packet and learns the source address in the RA packet. The device then uses the source IPv6 address as the next hop address of the default IPv6 route.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

After the **ipv6 address auto global** command is run, if an interface receives a new RA packet, a new IPv6 address is generated for the interface based on the received RA packet, but the default routes learned by the interface are not deleted.

If an interface has been configured with an IPv6 address, the original IPv6 address is not deleted after the interface receives an RA packet and generates a new IPv6 address. If the interface receives no RA packet and the generated IPv6 address expires, the interface deletes the generated IPv6 address and uses the original IPv6 address.

A device learns a maximum of three default routes based on RA packets. New routes cannot override the existing three routes, and extra routes will be discarded. If multiple default routes have the same priority, packets are forwarded in load balancing mode.

Example

Enable a device to generate an IPv6 global address through stateless autoconfiguration on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address auto global
```

Enable a device to generate an IPv6 global address through stateless autoconfiguration on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto global
```

6.10.26 ipv6 address auto link-local

Function

The **ipv6 address auto link-local** command configures an interface to automatically generate a link-local address.

The **undo ipv6 address auto link-local** command deletes the automatically generated link-local address on a specified interface.

By default, no link-local address is automatically generated on an interface.

Format

ipv6 address auto link-local

undo ipv6 address auto link-local

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Link-local addresses are used for communications between link-local nodes in either the neighbor discovery or stateless auto-configuration process. A packet with a link-local address set to a source or destination address will not be forwarded to another link. That is, link-local addresses are valid only on local links.

After the **ipv6 address auto link-local** command is run, a device uses the link-local address prefix FE80::/10 (1111 1110 10) and IEEE EUI-64 interface identifier go generate a link-local address for an interface. An IEEE EUI-64 interface identifier is converted from an interface link layer address, for example a MAC address.

1. The hexadecimal number FFFE (1111 1111 1111 1110 in binary) is inserted in the middle of a MAC address.
2. The U/L bit (the leftmost seventh bit) is set to 1.
3. The interface ID in EUI-64 format then is obtained.

After an interface automatically obtains a link-local address, it can implement neighbor discovery and automatically configure a global unicast address or a unique local address.

Prerequisites

Before running this command, run the **ipv6 enable** command in the interface view to enable the IPv6 function.

Precautions

Only a single link-local address can be assigned to each interface. If an automatically allocated link-local address has already been configured on an interface, running the **ipv6 address link-local** command will overwrite the existing link-local address.

The **undo ipv6 address auto link-local** command can only delete a link-local address that is automatically generated by an interface. To delete a manually configured link-local address, run the **undo ipv6 address link-local** command.

Example

Configure VLANIF2 to automatically generate a link-local address.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 address auto link-local
```

Configure GE0/0/1 to automatically generate a link-local address.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto link-local
```

6.10.27 ipv6 address eui-64

Function

The **ipv6 address eui-64** command configures a site-local address or global unicast address in EUI-64 format for an interface.

The **undo ipv6 address eui-64** command deletes a site-local address or global unicast address in EUI-64 format from an interface.

By default, no site-local address or global unicast address in EUI-64 format is configured for an interface.

Format

ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **eui-64**

undo ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **eui-64**

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of an interface.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 1 to 128.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In IPv6, any IPv6 unicast address needs an interface identifier. The interface identifier is globally unique, similar to a 48-bit MAC address.

The interface identifier of an IPv6 host address uses the IEEE EUI-64 format. A 64-bit interface identifier is generated based on an existing MAC address; therefore, such an interface identifier is globally unique. These 64-bit interface identifiers are globally valid for addressing and uniquely identify each network interface.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

The following conditions are prohibited for different interfaces on the same switch:

- The IPv6 addresses are the same.
- The network prefixes of the IPv6 addresses are the same. For example, if the IPv6 address of interface A is 2001:db8::1/12 and its network prefix is 200:: and the IPv6 address of interface B is 2001:db8::1/127 and its network prefix is 2001:db8::, the configuration succeeds. If the IPv6 address of interface B is also 2002:db8::1/12 and its network prefix is also 200::, the configuration fails.

A maximum of 10 global unicast addresses can be configured for an interface.

The following IPv6 addresses in EUI-64 format cannot be configured for an interface:

- Loopback address (::1/128)
- Unspecified address (::/128)
- Multicast address
- IPv4-mapped IPv6 address (0:0:0:0:0:FFFF:IPv4-address)

The **ipv6 address** command is used to specify a 128–bit IPv6 address. Using the **ipv6 address eui-64** command, you can specify the high-order 64 bits of an IPv6 address. The low-order 64 bits of an IPv6 address are automatically generated in the EUI-64 format. Even when the low-order 64 bits are manually specified, the automatically generated ones will override them.

Example

Configure an IPv6 address in EUI-64 format for VLANIF 2.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 address fc00::1/64 eui-64
```

Configure an IPv6 address in EUI-64 format for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00::1/64 eui-64
```

6.10.28 ipv6 address link-local

Function

The **ipv6 address link-local** command manually configures a link-local address for a specified interface.

The **undo ipv6 address link-local** command deletes the manually configured link-local address on an interface.

By default, no link-local address is configured for an interface.

Format

ipv6 address *ipv6-address* **link-local**

undo ipv6 address *ipv6-address* **link-local**

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of an interface.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X. When a link-local address is being configured, the prefix of the specified IPv6 address must match FE80::/10.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Link-local addresses are used for the communication between nodes on the same local link in neighbor discovery or stateless autoconfiguration. The packet with a link-local address being the source or destination address will not be forwarded to other links. That is, link-local addresses are valid only on local links.

You can run the **ipv6 address link-local** command to manually configure a link-local address for an interface.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

Avoid changing link-local addresses.

You can configure multiple IPv6 addresses but only one link-local address for an interface.

The link-local address configured using the **ipv6 address link-local** command will override the link-local address automatically generated by the system.

The **undo ipv6 address link-local** command deletes only the link-local address manually configured for an interface. To delete the automatically generated link-local address, run the **undo ipv6 address auto link-local** command.

If an interface is being unbound from the VPN instance that has IPv6 address family enabled, the system displays a message, indicating that this command cannot be run.

The following IPv6 addresses cannot be configured for an interface:

- Loopback address (::1/128)
- Unspecified address (::/128)
- Multicast address

Example

Manually configure a link-local address for VLANIF 2.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 address fe80::1 link-local
```

Manually configure a link-local address for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fe80::1 link-local
```

6.10.29 ipv6 enable (interface view)

Function

The **ipv6 enable** command enables the IPv6 function on an interface.

The **undo ipv6 enable** command disables the IPv6 function on an interface.

By default, the IPv6 function is disabled on an interface.

Format

ipv6 enable

undo ipv6 enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can perform IPv6 configurations on an interface only when the interface has the IPv6 function enabled.

Prerequisites

The **ipv6** command has been run in the system view.

Follow-up Procedure

Configure IPv6 addresses and ND parameters. ND parameters include the M flag, O flag, RA halt flag, interval for sending RA packets, lifetime of RA packets, interval for sending NS packets, DAD counts, period during which the IPv6 neighbor keeps reachable, prefix carried in the RA packet, and static ND entries.

Precautions

After the IPv6 function is disabled on an interface, IPv6 configurations on the interface are deleted.

- After the IPv6 function is disabled on an interface, IPv6 addresses of the interface are deleted and IPv6 commands cannot be configured on the interface.
- After the IPv6 function is disabled on an interface, IS-IS IPv6 and RIPng are disabled on the interface. That is, the **isis ipv6 enable** and **ripng enable** commands become ineffective.

When system resources are insufficient, the **ipv6 enable** command does not take effect and an alarm is generated. The alarm ID is 1.3.6.1.4.1.2011.5.25.227.2.1.22.

Example

Enable the IPv6 function on VLANIF10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
```

Enable the IPv6 function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
```

6.10.30 ipv6 icmp-error

Function

The **ipv6 icmp-error** command sets the rate limit for sending ICMPv6 error packets.

The **undo ipv6 icmp-error** command restores the default rate limit for sending ICMPv6 error packets.

By default, the size of the token buckets is 10 and the limit rate is 100 milliseconds.

Format

ipv6 icmp-error { **bucket** *bucket-size* | **ratelimit** *interval* } *

undo ipv6 icmp-error

Parameters

Parameter	Description	Value
bucket *bucket-size*	Specifies the maximum number of tokens the bucket can hold.	The value is an integer that ranges from 1 to 200. The default value is 10, which is recommended.
ratelimit *interval*	Specifies the interval for placing tokens into the bucket.	The value is an integer that ranges from 0 to 2147483647, in milliseconds. The default value is 100, which is recommended.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a network is not attacked, a routing device can correctly send ICMPv6 error packets to notify other devices of exceptions in packet transmission. If an attacker frequently sends ICMPv6 packets to network devices, the network devices will be busy responding with ICMPv6 packets. This affects system throughput and CPU usage. To prevent the system from sending a great number of ICMPv6 packets, run the **ipv6 icmp-error** command to limit the rate at which ICMPv6 packets are sent.

The token bucket algorithm is used to count ICMPv6 packets. One token represents an ICMPv6 error packet. The system places tokens into the virtual bucket at a certain interval until the number of tokens in the bucket reaches the upper limit. Once the number of ICMPv6 packets exceeds the maximum number of tokens that the bucket can contain, excess packets are discarded. You can limit the rate at which ICMPv6 packets are sent by setting the bucket size and the interval for placing tokens into the bucket.

Precautions

If you run the **ipv6 icmp-error** command multiple times, only the latest configuration takes effect.

If the interval for placing tokens into the bucket is 0, there is no limit on the interval.

Example

Set the rate limit for sending ICMPv6 error packets to 100.

```
<HUAWEI> system-view
[HUAWEI] ipv6 icmp-error ratelimit 100
```

Set the bucket size of ICMPv6 to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6 icmp-error bucket 50
```

Set the rate limit for sending ICMPv6 error packets to 100 and the bucket size to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6 icmp-error bucket 50 ratelimit 100
```

6.10.31 ipv6 icmp blackhole unreachable send

Function

The **ipv6 icmp blackhole unreachable send** command enables the switch to send a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv6 blackhole route.

The **undo ipv6 icmp blackhole unreachable send** command disables the switch from sending a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv6 blackhole route.

By default, the switch is disabled from sending a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv6 blackhole route.

Format

ipv6 icmp blackhole unreachable send

undo ipv6 icmp blackhole unreachable send

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If static IPv6 blackhole routes are configured on the switch configured with the user access and authentication function, when a user goes offline, only the IPv6 blackhole route corresponding to the user's address segment exists on the switch. When a tracert packet matches the IPv6 blackhole route, the switch discards the packet. As a result, an initiator cannot detect that the user has gone offline.

After you run the **ipv6 icmp blackhole unreachable send** command, the switch sends a Destination Unreachable ICMP packet to an initiator, notifying the initiator that the user has gone offline if a user goes offline and a tracert packet matches the IPv6 blackhole route.

Pre-configuration Tasks

Static IPv6 blackhole routes have been configured on the switch.

Example

Enable the switch to send a Destination Unreachable ICMP packet to an initiator when a tracert packet matches an IPv6 blackhole route.

```
<HUAWEI> system-view
[HUAWEI] ipv6 icmp blackhole unreachable send
```

6.10.32 ipv6 icmp port-unreachable send

Function

The **ipv6 icmp port-unreachable send** command enables an interface to send ICMPv6 Port Unreachable messages.

The **undo ipv6 icmp port-unreachable send** command disables the function.

By default, the enabling status of the function that the interface sends ICMPv6 Port Unreachable messages is the same as that of the function that the system sends ICMPv6 Port Unreachable messages.

Format

ipv6 icmp port-unreachable send

undo ipv6 icmp port-unreachable send

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a router receives a TCP6/UDP6 packet but cannot find the corresponding socket entry, the router replies with an ICMPv6 Port Unreachable message. This ICMPv6 error message carries the IPv6 address of the router as its source IPv6 address, which exposes the IPv6 address of the router and brings security risks. If the router is attacked by flooding packets, the router keeps replying with ICMPv6 Port Unreachable messages, causing high CPU usage and affecting device performance. To address this problem, run the **undo ipv6 icmp port-unreachable send** command on the inbound interface of ICMPv6 packets to disable the transmission of ICMPv6 Port Unreachable message.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Example

Enable VLANIF100 to send ICMPv6 Port Unreachable messages.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 icmp port-unreachable send
```

Enable interface GE0/0/1 to send ICMPv6 Port Unreachable messages.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 icmp port-unreachable send
```

6.10.33 ipv6 icmp hop-limit-exceeded send

Function

The **ipv6 icmp hop-limit-exceeded send** command enables an interface to send ICMPv6 Hop Limit Exceeded messages.

The **undo ipv6 icmp hop-limit-exceeded send** command disables the function.

By default, the enabling status of the function that the interface sends ICMPv6 Hop Limit Exceeded messages is the same as that of the function that the system sends ICMPv6 Hop Limit Exceeded messages.

Format

ipv6 icmp hop-limit-exceeded send

undo ipv6 icmp hop-limit-exceeded send

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If a router receives a packet with a hop limit of 1, it replies with an ICMPv6 Hop Limit Exceeded message. This ICMPv6 error message carries the IPv6 address of the router as its source IPv6 address, which exposes the IPv6 address of the router and brings security risks. If the router is attacked by flooding packets, the router keeps replying with ICMPv6 Hop Limit Exceeded messages, causing high CPU usage and affecting device performance. To address this problem, run the **undo ipv6 icmp hop-limit-exceeded send** command on the inbound interface of ICMPv6 packets to disable the transmission of ICMPv6 Hop Limit Exceeded messages.

Example

Disable VLANIF100 from sending ICMPv6 Hop Limit Exceeded messages.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ipv6 icmp hop-limit-exceeded send
```

Disable interface GE0/0/1 from sending ICMPv6 Hop Limit Exceeded messages.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] undo ipv6 icmp hop-limit-exceeded send
```

6.10.34 ipv6 icmp receive

Function

The **ipv6 icmp receive** command enables the system to receive ICMPv6 messages with the local address as the destination address.

The **undo ipv6 icmp receive** command disables the system from receiving ICMPv6 messages with the local address as the destination address.

By default, the system receives ICMPv6 messages with the local address as the destination address.

Format

ipv6 icmp { *icmpv6-type icmpv6-code* | *icmpv6-name* | **all** } **receive**

undo ipv6 icmp { *icmpv6-type icmpv6-code* | *icmpv6-name* | **all** } **receive**

Parameters

Parameter	Description	Value
icmpv6-type	Specifies the type of ICMPv6 messages.	The value is an integer in the range from 0 to 255.
icmpv6-code	Specifies the code of ICMPv6 messages.	The value is an integer in the range from 0 to 255.
icmpv6-name	Specifies the name of ICMPv6 messages.	ICMPv6 messages are classified into the following types: ● echo: Echo packet ● echo-reply: Echo Reply packet ● err-header-field: Packet with an error header ● frag-time-exceeded: Fragmentation Timeout packet ● hop-limit-exceeded: Packet whose hop count exceeds the limit ● host-admin-prohib: Packet that is rejected by a host ● host-unreachable: ICMPv6 Host Unreachable packet ● neighbor-advertisement: Neighbor Advertisement packet ● neighbor-solicitation: Neighbor Solicitation packet ● network-unreachable: ICMPv6 Network Unreachable packet ● packet-too-big: Packet Too Big packet ● port-unreachable: ICMPv6 Port Unreachable packet ● redirect: Redirected packets ● router-advertisement: Router Advertisement packet ● router-solicitation: Router Solicitation packet ● unknown-ipv6-opt: Error packet with unknown options ● unknown-next-hdr: Error packet with unknown next header
all	Indicates all ICMPv6 messages.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In normal cases, a switch can properly receive ICMPv6 messages. However, when network traffic load is heavy, host unreachable or port unreachable events frequently occur, the switch receives a large number of ICMPv6 messages, which burdens the network and degrades device performance. In addition, attackers usually use ICMPv6 error messages to probe the internal network topology.

To improve network performance and security, run the **undo ipv6 icmp receive** command to disable the system from receiving ICMPv6 Echo Reply packets, Host Unreachable packets, and Port Unreachable packets with the local address as the destination address.

Precautions

When the network is in good performance again, you can run the **ipv6 icmp receive** command to enable the system to receive ICMPv6 messages with the local address as the destination address.

After the **undo ipv6 icmp receive** command is run, main interfaces are disabled from processing these ICMPv6 messages. In addition, the system does not collect statistics on these messages that are received but collects statistics on discarded messages.

Example

Disable the system from receiving ICMPv6 Echo packets with the local address as the destination address.

```
<HUAWEI> system-view
[HUAWEI] undo ipv6 icmp echo receive
```

6.10.35 ipv6 icmp send

Function

The **ipv6 icmp send** command enables the system to send ICMPv6 packets.

The **undo ipv6 icmp send** command disables the system from sending ICMPv6 packets.

By default, the system is enabled to send ICMPv6 packets.

Format

ipv6 icmp { *icmpv6-type icmpv6-code* | *icmpv6-name* | **all** } **send**

undo ipv6 icmp { *icmpv6-type icmpv6-code* | *icmpv6-name* | **all** } **send**

Parameters

Parameter	Description	Value
icmpv6-type	Specifies the type of ICMPv6 packets.	The value is an integer that ranges from 0 to 255.
icmpv6-code	Specifies the code of ICMPv6 packets.	The value is an integer that ranges from 0 to 255.
icmpv6-name	Specifies the name of ICMPv6 packets.	ICMPv6 packets are classified into the following types: ● echo: Echo packet ● echo-reply: Echo Reply packet ● err-header-field: Packet with an error header ● frag-time-exceeded: Fragmentation Timeout packet ● hop-limit-exceeded: Packet whose hop count exceeds the limit ● host-admin-prohib: Packet that is rejected by a host ● host-unreachable: ICMPv6 Host Unreachable packet ● neighbor-advertisement: Neighbor Advertisement packet ● neighbor-solicitation: Neighbor Solicitation packet ● network-unreachable: ICMPv6 Network Unreachable packet ● packet-too-big: Packet Too Big packet ● port-unreachable: ICMPv6 Port Unreachable packet ● redirect: Redirected packets ● router-advertisement: Router Advertisement packet ● router-solicitation: Router Solicitation packet ● unknown-ipv6-opt: Error packet with unknown options ● unknown-next-hdr: Error packet with unknown next header

Parameter	Description	Value
all	Indicates all ICMPv6 packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network is in good performance, routing devices can send or receive ICMPv6 packets. However, when network traffic load is heavy, host unreachable or port unreachable events frequently occur, the routing devices send a large number of ICMPv6 packets, which burdens the network and degrades the performance of the routing devices. In addition, attackers may use ICMPv6 error packets to probe the internal network topology.

To improve network performance and security, run the **undo ipv6 icmp send** command to disable the system from sending ICMPv6 packets.

Precautions

When the network is in good performance again, you can run the **ipv6 icmp send** command to enable the system to send ICMPv6 packets.

Example

Disable the system from sending all ICMPv6 packets.

```
<HUAWEI> system-view
[HUAWEI] undo ipv6 icmp all send
```

6.10.36 ipv6 icmp too-big-rate-limit

Function

The **ipv6 icmp too-big-rate-limit** command enables a device to limit oversized ICMPv6 error packets.

The **undo ipv6 icmp too-big-rate-limit** command disables a device from limiting oversized ICMPv6 error packets.

By default, a device limit oversized ICMPv6 error packets.

Format

ipv6 icmp too-big-rate-limit

undo ipv6 icmp too-big-rate-limit

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When a host sends a large number of packets in a path with a small MTU, it may receive a large number of ICMPv6 error packets, affecting the processing of valid packets. This command limits the number of ICMPv6 error packets, ensuring host performance.

Example

Enable the device to limit oversized ICMPv6 error packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6 icmp too-big-rate-limit
```

6.10.37 ipv6 mtu

Function

The **ipv6 mtu** command sets the MTU on the interface for sending IPv6 packets.

The **undo ipv6 mtu** command restores the default MTU of IPv6 packets on an interface.

By default, the MTU of IPv6 packets on an interface is 1500 bytes.

NOTE

For the S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H, this command does not take effect on the IPv6 packets matching ND entries. That is, the MTU of IPv6 packets matching ND entries on the devices is always 1500 bytes.

Format

ipv6 mtu *mtu*

undo ipv6 mtu

Parameters

Parameter	Description	Value
mtu	Specifies the MTU value.	- For GE interfaces, GE sub-interfaces, XGE interfaces, XGE sub-interfaces, MultiGE interfaces, MultiGE sub-interfaces, 25GE interfaces, 25GE sub-interfaces, tunnel interfaces, and VLANIF interfaces, the value is an integer that ranges from 1280 to 9600, in bytes. - For other interfaces, the value is an integer that ranges from 1280 to 1500, in bytes. The default value is 1500.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the traffic processing capability of a link connecting the source and destination ends changes, you can use this command to set the MTU of IPv6 packets on an interface. If the packet length is larger than the IPv6 MTU of the interface, the system fragments the packet based on the configured MTU value before forwarding the packet.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

The directly-connected interfaces must be configured with the same IPv6 MTU values.

Example

Set the MTU of IPv6 packets on VLANIF2 to 1280 bytes.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 mtu 1280
```

Set the MTU of IPv6 packets on GE0/0/1 to 1280 bytes.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 mtu 1280
```

6.10.38 ipv6 nd autoconfig managed-address-flag

Function

The **ipv6 nd autoconfig managed-address-flag** command sets the M flag of stateful autoconfiguration in an RA packet.

The **undo ipv6 nd autoconfig managed-address-flag** command deletes the M flag of stateful autoconfiguration in an RA packet.

By default, the "managed address configuration" flag (M flag) is not set in the RA message.

Format

ipv6 nd autoconfig managed-address-flag

undo ipv6 nd autoconfig managed-address-flag

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- If the M flag is set, a host obtains an IPv6 address through stateful autoconfiguration.
- If the M flag is not set, a host uses stateless autoconfiguration to obtain an IPv6 address, that is, the host generates an IPv6 address based on the prefix information in the RA packet.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

After the **ipv6 nd autoconfig managed-address-flag** command is run, a host can obtain configurations (excluding an IPv6 address) such as the router lifetime, neighbor reachable time, retransmission interval, and PMTU by means of stateful autoconfiguration even if the **ipv6 nd autoconfig other-flag** command is not run.

After the **display ipv6 interface** command is run, the command output shows that the attached hosts obtain IPv6 addresses through stateful autoconfiguration or stateless autoconfiguration.

Example

Set the M flag of stateful autoconfiguration in an RA packet on VLANIF2.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 nd autoconfig managed-address-flag
```

Set the M flag of stateful autoconfiguration in an RA packet on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd autoconfig managed-address-flag
```

6.10.39 ipv6 nd autoconfig other-flag

Function

The **ipv6 nd autoconfig other-flag** command sets the "other configuration" flag (O flag) of stateful autoconfiguration in an RA packet.

The **undo ipv6 nd autoconfig other-flag** command deletes the O flag of stateful autoconfiguration in an RA packet.

By default, the O flag is not set in the RA packet.

Format

ipv6 nd autoconfig other-flag

undo ipv6 nd autoconfig other-flag

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- If the O flag is set, a host uses stateful autoconfiguration to obtain other configuration parameters (excluding an IPv6 address), including the router lifetime, neighbor reachable time, retransmission interval, and PMTU.
- If the O flag is not set, a host uses stateless autoconfiguration to obtain other configuration parameters, including the router lifetime, neighbor reachable time, retransmission interval, and PMTU. That is, the host obtains other configuration parameters through the RA packet advertised by routers.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Example

Set the O flag of stateful autoconfiguration on VLANIF2.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 2
[HUAWEI-Vlanif2] ipv6 enable
[HUAWEI-Vlanif2] ipv6 nd autoconfig other-flag
```

Set the O flag of stateful autoconfiguration on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd autoconfig other-flag
```

6.10.40 ipv6 nd dad attempts

Function

The **ipv6 nd dad attempts** command sets the number of times NS packets are sent when the system performs Duplicate Address Detection (DAD).

The **undo ipv6 nd dad attempts** command restores the default value.

By default, the number of times NS packets are sent when the system performs DAD is 1.

Format

ipv6 nd dad attempts *value*

undo ipv6 nd dad attempts

Parameters

Parameter	Description	Value
value	Specifies the number of times NS packets are sent when the system performs DAD.	The value is an integer that ranges from 0 to 600. The default value is 1, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you configure an IPv6 address (a global unicast address or a link-local address) for an interface, check whether other interfaces connected to this interface have used the IPv6 address to be configured to prevent address conflicts. The default number of detection times is recommended. If there is a long link delay, you can increase the number of detection times. When a loopback address is configured for an interface, the loopback address may fail the address conflict detection. In this case, you can set the number of detection times to 0 to disable detection, allowing the loopback address to be used.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

If the number of times NS packets are sent when the system performs DAD is set 0, DAD is prohibited.

If the physical link connected to an interface fails, DAD cannot be performed on the interface.

If the **ipv6 nd dad attempts** command has been run, running the **ipv6 nd ra** command will change the number of configured detection times.

DAD transmits node configuration variables. The system automatically determines the time to send neighbor request messages while DAD is performed to detect a tentative unicast IPv6 address.

Example

Set the number of times NS packets are sent when the system performs DAD to 20 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd dad attempts 20
```

Set the number of times NS packets are sent when the system performs DAD to 20 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd dad attempts 20
```

6.10.41 ipv6 nd hop-limit

Function

The **ipv6 nd hop-limit** command sets hop limit for IPv6 unicast packets initially sent by a device.

The **undo ipv6 nd hop-limit** command restores the hop limit for IPv6 unicast packets to the default value.

By default, the IPv6 unicast packets initially sent by a device can travel 64 hops.

Format

ipv6 nd hop-limit *limit*

undo ipv6 nd hop-limit

Parameters

Parameter	Description	Value
limit	Specifies the hop limit.	The value is an integer that ranges from 1 to 255. The default value is 64, which is recommended.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A hop limit on a device provides the following functions:

- Limiting the number of hops through which IPv6 unicast packets are allowed to travel.

- Functioning as a parameter in an RA packet to help a host automatically configure a hop limit (a limit on the number of hops through which IPv6 unicast packets initially sent by a host are allowed to travel).

Precautions

The hop limit for unicast packets is set using the **ipv6 nd hop-limit** command in the system view.

The hop limit for RA packets depends on the configuration of the **ipv6 nd hop-limit** command in the system view and the configuration of the **ipv6 nd ra hop-limit** command in the interface view.

- If the hop limit for RA packets is not set in the interface view or in the system view, the hop limit for RA packets is 64 by default.
- If the hop limit for RA packets is not set in the interface view, the value set using the **ipv6 nd hop-limit** command in the system view is used as the hop limit for RA packets.
- If the **ipv6 nd ra hop-limit** command is run in the interface view, the configuration in the interface view takes effect, no matter whether the hop limit is set in the system view.

The hop limit set for IPv6 unicast packets is the same as that set for RA packets. In the following cases, however, the hop limit for IPv6 unicast packets is 64, while the hop limit for RA packets is 0.

- No hop limit is set for IPv6 unicast packets. The default value takes effect.
- The **undo ipv6 nd hop-limit** command is run to restore the default hop limit set for IPv6 unicast packets.

After a host receives an RA packet with the hop limit of 0, it sets its hop limit to the default value 64, consistent with the default hop limit on the device.

Example

Set the hop limit for IPv6 unicast packets initially sent by a device to 100.

```
<HUAWEI> system-view
[HUAWEI] ipv6 nd hop-limit 100
```

6.10.42 ipv6 nd learning strict

Function

The **ipv6 nd learning strict** command enables IPv6 neighbor discovery (ND) strict learning.

The **undo ipv6 nd learning strict** command disables IPv6 ND strict learning.

By default, IPv6 ND strict learning is disabled.

Format

In the system view:

ipv6 nd learning strict

undo ipv6 nd learning strict

In the interface view:

ipv6 nd learning strict { **force-disable** | **force-enable** | **trust** }

undo ipv6 nd learning strict

Parameters

Parameter	Description	Value
force-disable	Disables IPv6 ND strict learning forcibly.	-
force-enable	Enables IPv6 ND strict learning forcibly.	-
trust	Inherits the global setting of IPv6 ND strict learning.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, Eth-Trunk sub-interface view, system view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a device uses neighbor advertisement (NA) packets to establish neighbor entries. Run the **ipv6 nd learning strict** command to enable IPv6 ND strict learning. After you enable IPv6 ND strict learning on a device, the device uses NA packets only in response to neighbor solicitation (NS) packets to establish neighbor entries.

Prerequisites

Before using the **ipv6 nd learning strict** command to enable IPv6 neighbor discovery (ND) strict learning on an interface, ensure that the IPv6 function has been enabled on the interface using the **ipv6 enable** command.

Precautions

Before running this command in an Eth-Trunk view, run the **undo portswitch** command to switch the Eth-Trunk to a Layer 3 interface. For the models supporting switching between Layer 2 and Layer 3 modes, see **portswitch**.

After you run the **ipv6 nd learning strict** command on a device, the device synchronizes fake entries. Synchronizing a large number of fake entries affects device performance. Therefore, you are advised to use the command only for protocol consistency tests.

Example

Enable IPv6 ND strict learning globally.

```
<HUAWEI> system-view
[HUAWEI] ipv6 nd learning strict
```

Enable IPv6 ND strict learning on VLANIF 100 forcibly.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd learning strict force-enable
```

6.10.43 ipv6 nd link-local-entry-learn enable

Function

The **ipv6 nd link-local-entry-learn enable** command enables the device to learn the ND entry containing the link-local address of a peer interface.

The **undo ipv6 nd link-local-entry-learn enable** command disables the device from learning the ND entry containing the link-local address of a peer interface.

By default, the device is disabled from learning the ND entry containing the link-local address of a peer interface.

Format

ipv6 nd link-local-entry-learn enable

undo ipv6 nd link-local-entry-learn enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

By default, on a network where IPv6 routes are learnt through RIPng, a device can learn the link-local address of a peer interface only through packets. If a device does not learn the link-local address of a peer interface but needs to forward a packet with the next hop being this address, the packet will be lost.

The **ipv6 nd link-local-entry-learn enable** command helps solve this issue. With this command run on a device on a RIPng network, the device learns the ND entry containing the link-local address of a peer interface, when it learns the ND entry containing the global unicast address of the peer interface. If you do not require this function, you are advised to disable this function to reduce the memory occupied by ND entries.

Example

Enable the device to learn the ND entry containing the link-local address of a peer interface.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ipv6 nd link-local-entry-learn enable
```

6.10.44 ipv6 nd neighbor-limit

Function

The **ipv6 nd neighbor-limit** command configures the maximum number of dynamic neighbor entries that can be learned by an interface.

The **undo ipv6 nd neighbor-limit** command restores the default maximum number of dynamic neighbor entries that can be learned by an interface.

By default, the maximum of dynamic neighbor entries that an interface can learn is 212 for the S300, 1748 for the S500, 1000 for the SS1720GW-E, S1720GWR-E, S5720-LI, and S5720S-LI, 1024 for the S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, and S5735S-L-M, 2048 for the S5720I-SI, and 3072 for the S5735-S, S5735-S-I, and S5735S-S, 8192 for the S5731-S, S5731S-S, and 64000 for the 65536 for the S5731S-H and S5731-H, 10240 for the S5735S-H, S5736-S and 49152 for the S6720-EI, S6735-S and S6720S-EI, and 32768 for the S5732-H, S6730-S, S6730-H, S6730S-H, and S6730S-S.

Format

ipv6 nd neighbor-limit *limit-number*

undo ipv6 nd neighbor-limit

Parameters

Parameter	Description	Value
limit-number	Specifies the maximum number of dynamic neighbor entries that can be learned by a specified interface.	The value is an integer. ● The value ranges from 2 to 212 for the S300. ● The value ranges from 2 to 1748 for the S500. ● The value ranges from 2 to 1000 for the SS1720GW-E, S1720GWR-E, S5720-LI, and S5720S-LI. ● The value ranges from 2 to 1024 for the S2730S-S, S5735-L-I, S5735-L1,S5735-L, S5735S-L, S5735S-L1, and S5735S-L-M. ● The value ranges from 2 to 2048 for the S5720I-SI. ● The value ranges from 2 to 3072 for the S5735-S, S5735-S-I, and S5735S-S. ● The value ranges from 2 to 8192 for the S5731-S, and S5731S-S. ● The value ranges from 2 to 65536 for the S5731S-H and S5731-H. ● The value ranges from 2 to 10240 for the S5735S-H, S5736-S. ● The value ranges from 2 to 49152 for the S6720-EI, S6735-S and S6720S-EI. ● The value ranges from 2 to 32768 for the S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H.

Views

VLANIF interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an interface learns too many neighbor entries, the processing load for the device will be increased and the performance of the device will be degraded. You can run the **ipv6 nd neighbor-limit** command to configure the maximum number of dynamic neighbor entries that can be learned by a specified interface.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command.

Example

Set the maximum number of dynamic neighbor entries that can be learned by the VLANIF100 interface to 10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd neighbor-limit 10
```

6.10.45 ipv6 nd ns multicast-enable

Function

The **ipv6 nd ns multicast-enable** command enables a termination sub-interface to send NS multicast packets.

The **undo ipv6 nd ns multicast-enable** command disables a termination sub-interface from sending NS multicast packets.

By default, a termination sub-interface is disabled from sending NS multicast packets.

NOTE

Only S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ipv6 nd ns multicast-enable

undo ipv6 nd ns multicast-enable

Parameters

None

Views

GE sub-interface view, XGE sub-interface view, MultiGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view, Eth-Trunk sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A termination sub-interface can send NS multicast packets to actively learn ND entries or respond to NS packets to passively learn ND entries.

When a termination sub-interface needs to send multicast NS packets to learn ND entries but there is no corresponding ND entry, you need to run this command to enable a termination sub-interface to send NS multicast packets.

Prerequisites

Run the **ipv6 enable** command in the sub-interface view to enable IPv6 on a termination sub-interface.

Run the **dot1q termination vid** command in the sub-interface view to set the single VLAN ID for Dot1q termination. Or run the **qinq termination pe-vid ce-vid** command in the sub-interface view to configure a QinQ termination sub-interface to terminate double VLAN tags.

Precautions

- If this command is not run on the termination sub-interface, the system discards the NS multicast packets.
- If this command is run on the termination sub-interface, the system tags an NS multicast packet and forwards it through the termination sub-interface.

Sending multicast NS packets consumes CPU resources. Therefore, when the CPU performance of the system is rather low, you are advised not to enable a termination sub-interface to send NS multicast packets to actively learn ND entries but to respond to NS packets to passively learn ND entries.

VLAN termination sub-interfaces cannot be created on a VCMP client. You can run the **vcmp role** command to configure the role for a switch in a VCMP domain.

Example

Enable the Dot1q termination sub-interface GigabitEthernet0/0/1.1 to send NS multicast packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type hybrid
[HUAWEI-GigabitEthernet0/0/1] quit
[HUAWEI] interface gigabitethernet 0/0/1.1
[HUAWEI-GigabitEthernet0/0/1.1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1.1] dot1q termination vid 100
[HUAWEI-GigabitEthernet0/0/1.1] ipv6 nd ns multicast-enable
```

6.10.46 ipv6 nd ns retrans-timer

Function

The **ipv6 nd ns retrans-timer** command sets the interval for sending NS packets.

The **undo ipv6 nd ns retrans-timer** command restores the interval for sending NS packets to the default value.

By default, the interval for sending NS packets is 1000 ms.

Format

ipv6 nd ns retrans-timer *interval*

undo ipv6 nd ns retrans-timer

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending NS packets.	The value is an integer that ranges from 1000 to 4294967295, in milliseconds. The default value is 1000 milliseconds, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting the interval for sending NS packets provides the following functions:

- Controlling the interval at which a local routing device detects neighbor reachability.
- Controlling the interval at which a local routing device performs DAD.
- Functioning as a parameter in an RA packet to instruct hosts to specify this interval as their own interval for sending NS packets.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

Frequently sending NS packets causes high CPU usage, which affects the system performance. Therefore, you are advised to set the interval for sending NS packets to a larger value. The default interval, 1000 milliseconds, is recommended.

If you run the **ipv6 nd ns retrans-timer** command multiple times, only the latest configuration takes effect.

The interval for sending NS packets is the same as that for sending RA packets. In the following cases, however, the interval for sending NS packets is the default value1000 ms, while the interval for sending RA packets is 0 ms.

- No interval for sending NS packets is set. The default value takes effect.
- The **undo ipv6 nd ns retrans-timer** command is run to restore the interval for sending NS packets to the default value.

After a host receives an RA packet of which the sending interval is 0 ms from a device, the host sets the interval for sending NS packet to 1000 ms, the same as that on the device.

Example

Set the interval for sending NS packets to 10000 milliseconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ns retrans-timer 10000
```

Set the interval for sending NS packets to 10000 milliseconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ns retrans-timer 10000
```

6.10.47 ipv6 nd nud reachable-time

Function

The **ipv6 nd nud reachable-time** command sets the IPv6 neighbor reachable time.

The **undo ipv6 nd nud reachable-time** command restores the IPv6 neighbor reachable time to the default value.

By default, the IPv6 neighbor reachable time is 30000 ms.

Format

ipv6 nd nud reachable-time *value*

undo ipv6 nd nud reachable-time

Parameters

Parameter	Description	Value
value	Specifies the IPv6 neighbor reachable time.	The value is an integer that ranges from 1 to 3600000, in milliseconds. The default value is 30000 ms, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting the IPv6 neighbor reachable time provides the following functions:

- Controlling the aging time of neighbor entries on a local routing device.
- Being a parameter in an RA packet to enable a host to configure the neighbor reachable time.

Each RA packet sent by a routing device carries the neighbor reachable time. This allows all nodes along the same link to use the same neighbor reachable time.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

A shorter neighbor reachable time enables a routing device to detect neighbor reachability more quickly. However, this consumes more network bandwidth and CPU resources. Therefore, a short neighbor reachable time is not recommended on an IPv6 network. The default value, 30000 ms, is recommended.

If you run the **ipv6 nd nud reachable-time** command multiple times, only the latest configuration takes effect.

The neighbor reachable time set on a routing device is the same as that carried in an RA packet. In the following cases, however, the neighbor reachable time set on a routing device is the default value 30000 ms while the neighbor reachable time carried in the RA packet is 0 millisecond:

- No neighbor reachable time is set on the routing device. The default value takes effect.
- The **undo ipv6 nd nud reachable-time** command is run to restore the neighbor reachable time to the default value.

After a host receives an RA packet in which the neighbor reachable time is 0 ms, the host sets the neighbor reachable time to 30000 ms, the same as that on the device.

Example

Set the neighbor reachable time to 10000 ms on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd nud reachable-time 10000
```

Set the neighbor reachable time to 10000 ms on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd nud reachable-time 10000
```

6.10.48 ipv6 nd proxy inner-access-vlan enable

Function

The **ipv6 nd proxy inner-access-vlan enable** command enables intra-VLAN ND proxy on a VLANIF interface.

The **undo ipv6 nd proxy inner-access-vlan enable** command disables intra-VLAN ND proxy on a VLANIF interface.

By default, intra-VLAN ND proxy is disabled.

Format

ipv6 nd proxy inner-access-vlan enable

undo ipv6 nd proxy inner-access-vlan enable

Parameters

None

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Application Scenario

On an IPv6 network, if port isolation is configured in a VLAN, users in the VLAN cannot communicate with each other. Configure intra-VLAN ND proxy on the VLAN-associated interface to enable Layer 3 communication among users.

Prerequisites

In the VLANIF interface view:

1. Run the **ipv6 enable** command to enable the IPv6 function.
1. Run the **ipv6 address** command to configure an IPv6 address for the interface. The IPv6 address must be in the same network segment as the IPv6 addresses of all hosts in the VLAN.

Example

Enable intra-VLAN ND proxy on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address fc00::1/64
[HUAWEI-Vlanif100] ipv6 nd proxy inner-access-vlan enable
```

6.10.49 ipv6 nd proxy inter-access-vlan enable

Function

The **ipv6 nd proxy inter-access-vlan enable** command enables inter-VLAN ND proxy on a VLANIF interface.

The **undo ipv6 nd proxy inter-access-vlan enable** command disables inter-VLAN ND proxy on a VLANIF interface.

By default, inter-VLAN ND proxy is disabled.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S supports this command.

Format

ipv6 nd proxy inter-access-vlan enable

undo ipv6 nd proxy inter-access-vlan enable

Parameters

None

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Application Scenario

In a VLAN aggregation scenario on an IPv6 network, if hosts in different sub-VLANs need to communicate at Layer 3, enable inter-VLAN ND proxy on the VLANIF interface corresponding to the super-VLAN. In this way, all sub-VLANs in the super-VLAN are reachable to each other.

Prerequisites

In the VLANIF interface view:

1. Run the **ipv6 enable** command to enable the IPv6 function.
2. Run the **ipv6 address** command to configure an IPv6 address for the interface. The IPv6 address must be in the same network segment as the IPv6 addresses of all sub-VLAN hosts.

Example

Configure inter-VLAN ND proxy on VLANIF 30, the VLANIF interface corresponding to super-VLAN 30.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 30
[HUAWEI-Vlanif30] ipv6 enable
[HUAWEI-Vlanif30] ipv6 address fc00::1/64
[HUAWEI-Vlanif30] ipv6 nd proxy inter-access-vlan enable
```

6.10.50 ipv6 nd ra

Function

The **ipv6 nd ra** command sets the interval for sending Router Advertisement packets.

The **undo ipv6 nd ra** command restores the interval for sending RA packets to the default value.

By default, the maximum interval is 600s and the minimum interval is 200s.

NOTE

If *min-interval* is not specified, the minimum interval varies depending on the maximum interval specified by *max-interval* (the minimum is 1/3 of the maximum). If *min-interval* is specified, the minimum interval is the value configured.

Format

ipv6 nd ra { **max-interval** *maximum-interval* | **min-interval** *minimum-interval* }

undo ipv6 nd ra { **max-interval** | **min-interval** }

Parameters

Parameter	Description	Value
max-interval *maximum-interval*	Specifies the maximum interval for sending RA packets.	The value is an integer that ranges from 4 to 1800, in seconds. The default value is 600 seconds, which is recommended. The maximum interval cannot be less than the minimum interval.
min-interval *minimum-interval*	Specifies the minimum interval for sending RA packets.	The value is an integer that ranges from 3 to 1350, in seconds. The default value is 200 seconds, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A routing device periodically sends RA packets. An RA packet carries both the IPv6 address prefix and the flag of stateful address autoconfiguration.

You can run the **ipv6 nd ra** command to change the interval for sending RA packets. To reduce the number of RA messages being transmitted on a link, you can set a longer interval. To speed up router discovery, you can set a shorter interval.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

Running the **ipv6 nd ra** command changes the interval for sending RA packets during DAD. Therefore, you are advised to use the default interval, that is, the maximum value is 600s and the minimum value is 200s.

If the **ipv6 nd ra** command is run multiple times, the latest configuration takes effect.

The interval for sending RA packets cannot be longer than the lifetime of the RA packets. The default lifetime of the RA packets is 1800s and, you can run the **ipv6 nd ra router-lifetime** command to change the value.

The actual interval for sending RA packets is a random value between *min-interval* and *max-interval*.

Example

Set the maximum interval for sending RA packets to 1000s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ra max-interval 1000
```

Set the maximum interval for sending RA packets to 1000s on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra max-interval 1000
```

Set the minimum interval for sending RA packets to 300s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ra min-interval 300
```

Set the minimum interval for sending RA packets to 300s on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra min-interval 300
```

6.10.51 ipv6 nd ra dns-server

Function

The **ipv6 nd ra dns-server** command configures a DNS server address for RA packets.

The **undo ipv6 nd ra dns-server** command deletes the DNS server address configured for RA packets.

By default, RA packets do not contain a DNS server address.

Format

ipv6 nd ra dns-server *ipv6-address* [*valid-lifetime*]

undo ipv6 nd ra dns-server [*ipv6-address* [*valid-lifetime*]]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a DNS server.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
valid-lifetime	Specifies a valid lifetime.	The value is an integer ranging from 1 to 4294967295, in seconds. The default value is three times the maximum interval for advertising RA packets. The maximum interval for advertising RA packets can be configured using the **ipv6 nd ra max-interval** *maximum-interval* command.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a scenario where IPv6 ND stateless address auto-configuration is used or DHCPv6 is not configured, run the **ipv6 nd ra dns-server** command to configure a DNS server address for RA packets so that the host can implement the DNS service using the DNS server address in RA packets.

Prerequisites

The IPv6 function has been enabled on an interface using the **ipv6 enable** command in the interface view.

Precautions

A maximum of eight DNS server addresses can be configured for the RA packets transmitted on the same interface.

Example

Configure a DNS server address for the RA packets transmitted on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra dns-server 2001:db8:1::2 1000
```

6.10.52 ipv6 nd ra dns-suffix

Function

The **ipv6 nd ra dns-suffix** command sets a DNS suffix in RA packets.

The **undo ipv6 nd ra dns-suffix** command deletes the DNS suffix configured for RA packets.

By default, RA packets do not contain a DNS suffix.

Format

ipv6 nd ra dns-suffix *domain-suffix* [*valid-lifetime*]

undo ipv6 nd ra dns-suffix [*domain-suffix* [*valid-lifetime*]]

Parameters

Parameter	Description	Value
domain-suffix	Specifies a DNS suffix.	The value is a string of 1 to 64 characters and can contain digits, letters, hyphens (-), underscores (_), and periods (.), but not spaces.

Parameter	Description	Value
valid-lifetime	Specifies a valid lifetime.	The value is an integer ranging from 1 to 4294967295, in seconds. The default value is three times the maximum interval for advertising RA packets. The maximum interval for advertising RA packets can be configured using the **ipv6 nd ra max-interval** *maximum-interval* command.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To allow a host use a DNS domain name with a suffix upon receipt of RA packets, run the **ipv6 nd ra dns-suffix** command to configure a DNS suffix for RA packets.

Prerequisites

The IPv6 function has been enabled on an interface using the **ipv6 enable** command in the interface view.

Precautions

Only one DNS suffix can be configured for the RA packets transmitted on the same interface. If the **ipv6 nd ra dns-suffix** command is run more than once for the same interface, the latest configuration overrides the previous one.

Example

Configure a DNS suffix for the RA packets transmitted on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra dns-suffix example.com 1000
```

6.10.53 ipv6 nd ra halt

Function

The **ipv6 nd ra halt** command disables the system from sending RA packets.

The **undo ipv6 nd ra halt** command enables the system to send RA packets.

By default, the system is disabled from sending RA packets.

Format

ipv6 nd ra halt

undo ipv6 nd ra halt

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- When a device is connected to a host, it periodically sends RA packets to the host. An RA packet carries the IPv6 address prefix and flag information of stateful autoconfiguration. You can run the **undo ipv6 nd ra halt** command to enable the device to send RA packets.
- When a device is connected to another device, that is, there is no host on the network, sending RA packets is not required. The default configuration is recommended.

Prerequisites

The IPv6 function has been enabled in the interface view using the **ipv6 enable** command.

Precautions

After the **ipv6 nd ra halt** command is run, the device does not send RA packets. In such a case, the hosts on the network cannot periodically receive information about updated IPv6 prefixes.

You can run the **display icmpv6 statistics** command to check whether a local device has sent RA packets.

Example

Disable VLANIF100 from sending RA packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ra halt
```

Disable GE0/0/1 from sending RA packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
```

```
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra halt
```

6.10.54 ipv6 nd ra hop-limit

Function

The **ipv6 nd ra hop-limit** command sets the hop limit for RA packets.

The **undo ipv6 nd ra hop-limit** command restores the hop limit for RA packets to the default value.

By default, the hop limit for RA packets is 64.

Format

ipv6 nd ra hop-limit *limit*

undo ipv6 nd ra hop-limit

Parameters

Parameter	Description	Value
limit	Specifies the hop limit for RA packets.	The value is an integer that ranges from 0 to 255. The default value is 64, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

As a parameter in an RA packet, the hop limit enables a host to automatically configure a hop limit (a limit on the number of hops through which IPv6 unicast packets initially sent by a host are allowed to travel).

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

After this command is run on the switch, the device discards the RA packet whose hop limit is different from its configuration.

- If the **ipv6 nd ra hop-limit** command is run on an interface, the hop limit for RA packets is determined by the interface configuration.
- If the **ipv6 nd ra hop-limit** command is not run on an interface, the hop limit for RA packets is determined by the hop limit configured using the **ipv6 nd hop-limit** command.

Example

Set the hop limit for RA packets sent by VLANIF100 to 126.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ra hop-limit 126
```

Set the hop limit for RA packets sent by GE0/0/1 to 126.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra hop-limit 126
```

6.10.55 ipv6 nd ra preference

Function

The **ipv6 nd ra preference** command configures the default router priority value in the RA packets.

The **undo ipv6 nd ra preference** command restores the default router priority value in RA packets to be the default value.

By default, the router priority of RA packets is medium.

Format

ipv6 nd ra preference { **high** | **medium** | **low** }

undo ipv6 nd ra preference

Parameters

Parameter	Description	Value
high	Specifies the default router priority to be high.	-
medium	Specifies the default router priority to be medium.	-
low	Specifies the default router priority to be low.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If there are multiple switches on the links connected to a host, the host needs to select suitable switches based on different destination addresses of the packets to be forwarded. Each switch advertises its default router priority and specific route information to the host so that the host can enhance its own capability of selecting suitable forwarding switches based on different IP addresses of the packets to be forwarded.

After receiving an RA message that contains the default router priority, the host updates its own default router list. If the host does not have any route to select when sending packets to other devices, the host will search the updated router list for the switch with the highest priority. If the switch with the highest priority becomes faulty, the host selects another switch in descending order of priority.

To set a default router priority in RA messages, run the **ipv6 nd ra preference** command. This setting allows the switch with the highest priority to function as the gateway for hosts.

Prerequisites

Before running this command, run the **ipv6 enable** command on the interface view to enable the IPv6 function.

By default, the switch does not advertise RA packets. Therefore, to allow the default router priority to be advertised to the host, you need to run the **undo ipv6 nd ra halt** command to enable the function of advertising RA packets for the device.

Precautions

If the system is deleting the binding relationship between an interface and an IPv6 address family VPN instance, you are prompted not to run the **ipv6 nd ra preference** command.

Example

Configure the default router priority value in RA packets on VLANIF100 to be high.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ipv6 nd ra halt
[HUAWEI-Vlanif100] ipv6 nd ra preference high
```

Configure the default router priority value in RA packets on GE0/0/1 to be high.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
```

```
[HUAWEI-GigabitEthernet0/0/1] undo ipv6 nd ra halt
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra preference high
```

6.10.56 ipv6 nd ra prefix

Function

The **ipv6 nd ra prefix** command configures the prefix in an RA packet.

The **undo ipv6 nd ra prefix** command deletes the prefix in an RA packet.

By default, an RA packet carries only the address prefix configured using the **ipv6 address** command.

Format

ipv6 nd ra prefix { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } *valid-lifetime preferred-lifetime* [**no-autoconfig**] [**off-link**]

undo ipv6 nd ra prefix { *ipv6-address prefix-length* | *ipv6-address/prefix-length* }

ipv6 nd ra prefix default no-advertise

undo ipv6 nd ra prefix default no-advertise

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address carried in the RA packet.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 0 to 128. You can calculate the IPv6 prefix carried in the RA packet based on the IPv6 address and prefix length. When stateless autoconfiguration is used, specify the length of address prefix as 64; otherwise, the address will be invalid and RA packets are discarded.

Parameter	Description	Value
valid-lifetime	Specifies the valid lifetime of the prefix. The valid lifetime decides the prefix on-link status.	The value is an integer that ranges from 0 to 4294967295, in seconds.
preferred-lifetime	Specifies the preferred lifetime of the prefix. The length of time in seconds (relative to the time the packet is sent) that addresses generated from the prefix via stateless address autoconfiguration remain preferred. The preferred lifetime cannot be larger than the valid lifetime.	The value is an integer that ranges from 0 to 4294967295, in seconds.
no-autoconfig	Deletes the A-Flag. If **no-autoconfig** is specified, a configured prefix cannot be used in stateless address allocation. A-Flag indicates the autonomous address configuration in the prefix option of RA packet.	-
off-link	Specifies the L-Flag. If **off-link** is specified, indicates that this prefix can be used for on-link determination. When **off-link** is not specified, the advertisement makes no statement about on-link or off-link properties of the prefix. In other words, if the L flag is not set a host MUST NOT conclude that an address derived from the prefix is off-link. That is, it MUST NOT update a previous indication that the address is on-link.	-
default no-advertise	Specifies that RA packets do not carry the default prefix generated based on the interface IPv6 address.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a prefix has been configured using the **ipv6 nd ra prefix** command, the device advertises both prefixes configured using the **ipv6 nd ra prefix** and **ipv6 address** commands.

By default, RA packets carry the default prefix generated based on the interface IPv6 address. If the default setting is not required, run the **ipv6 nd ra prefix default no-advertise** command.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

After a host receives the RA packet with the prefix configured using the **ipv6 nd ra prefix** command, the host updates the local prefix information.

The prefix configured using the **ipv6 nd ra prefix** command cannot be fe80:: (prefix of a link-local address), ff00:: (prefix of a multicast address), :: (prefix of an unspecified address), or the prefix that has been used by another interface (including the interface address prefix and prefix carried in RA packets).

The prefix configuring using the **ipv6 nd ra prefix** command takes precedence over the default prefix generated based on the interface IPv6 address. An RA message can carry a maximum of 10 prefixes. If exactly 10 prefixes have been manually configured, the default prefix will not be carried.

In the DHCPv6 stateful address autoconfiguration scenario, the lifetime of the PD prefixes advertised in RA packets is the default value defined in DHCPv6. If the prefixes in RA packets remain unchanged, you can run the **ipv6 nd ra prefix** command to configure static prefixes and specify their lifetime. If the prefixes in RA packets change, you need to specify the lifetime of the changed prefixes.

Example

Configure the prefix in the RA packet on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ipv6 nd ra halt
[HUAWEI-Vlanif100] ipv6 nd ra prefix fc00:1::100 128 1000 400 no-autoconfig
[HUAWEI-Vlanif100] ipv6 nd ra prefix fc00:2::100 64 1000 400 off-link
```

Configure the prefix in the RA packet on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6

```

6.10.57 ipv6 nd ra route-information

Function

The **ipv6 nd ra route-information** command configures route information in RA packets.

The **undo ipv6 nd ra route-information** command deletes route information in RA packets.

By default, there is no route information in RA packets.

Format

ipv6 nd ra route-information *ipv6-address prefix-length* **lifetime** *route-lifetime* [**preference** { **high** | **medium** | **low** }]

undo ipv6 nd ra route-information *ipv6-address prefix-length*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address.	The prefix is a 32-bit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 0 to 128.
lifetime *route-lifetime*	Specifies the lifetime of a route.	The value is an integer ranging from 0 to 4294967295, in seconds.
preference	Specifies the priority of a route.	-
high	Specifies the route priority to be high.	-
medium	Specifies the route priority to be medium.	-
low	Specifies the route priority to be low.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An RA packet includes route information. The switch sends the specified routes to the hosts on the local network segment by using this information. The hosts can send packets by using these routes.

When receiving the RA packets carrying route information, a host updates its routing table. When sending the RA packets to another device, a host queries the routing table and selects proper route for sending packets.

Prerequisites

Before running this command, run the **ipv6 enable** command on the interface view to enable the IPv6 function of an interface.

By default, the switch does not send RA packets. Therefore, to send the routes to the host, you need to run the **undo ipv6 nd ra halt** command to enable the function of advertising RA packets for the device.

Precautions

A maximum of 17 route options are supported on each interface.

When this command is to be run, the value of *ipv6-address* cannot be a loopback address.

Example

Configure the route information of RA packets on VLANIF100: The lifetime of the route with the destination address of 2001:db8::2/64 is 1550 seconds, and the priority of this route is high.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ipv6 nd ra halt
[HUAWEI-Vlanif100] ipv6 nd ra route-information 2001:db8::2 64 lifetime 1550 preference high
```

Configure the route information of RA packets on GE0/0/1: The lifetime of the route with the destination address of 2001:db8::2/64 is 1550 seconds, and the priority of this route is high.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] undo ipv6 nd ra halt
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra route-information 2001:db8::2 64 lifetime 1550 preference
high
```

6.10.58 ipv6 nd ra router-lifetime

Function

The **ipv6 nd ra router-lifetime** command sets the lifetime of RA packets.

The **undo ipv6 nd ra router-lifetime** command restores the lifetime of RA packets to the default value.

By default, the lifetime of an RA packet is 1800s.

Format

ipv6 nd ra router-lifetime *ra-lifetime*

undo ipv6 nd ra router-lifetime

Parameters

Parameter	Description	Value
ra-lifetime	Specifies the lifetime of RA packets.	The value is an integer and can be 0 or ranges from 4 to 9000, in seconds. The default value is 1800 seconds, which is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device adds the lifetime value to an RA packet before sending the RA packet to the host on the local network segment.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

If a host receives an RA packet with the lifetime field being 0, the host does not add the address of the switch to its default router table.

The lifetime of the RA packets cannot be smaller than the interval for sending RA packets. By default, the maximum interval for sending RA packets is 600s and the minimum interval is 200s. You can run the **ipv6 nd ra** command to set the interval. If the set lifetime value of the RA packets is smaller than the set interval for sending RA packets, the system displays an error. In such a case, you need to reset the lifetime value.

Example

Set the lifetime of the RA packets on VLANIF100 to 1000s.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd ra router-lifetime 1000
```

Set the lifetime of the RA packets on GE0/0/1 to 1000s.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd ra router-lifetime 1000
```

6.10.59 ipv6 nd stale-timeout

Function

The **ipv6 nd stale-timeout** command sets the aging time of ND entries in STALE state.

The **undo ipv6 nd stale-timeout** command restores the aging time of ND entries in STALE state to the default value.

By default, the aging time of ND entries in STALE state is 1200s.

Format

ipv6 nd stale-timeout *timeout-value*

undo ipv6 nd stale-timeout

Parameters

Parameter	Description	Value
timeout-value	Specifies the aging time of ND entries in STALE state.	The value is an integer that ranges from 60 to 172800, in seconds. The default value is 1200s, which is recommended.

Views

System view, Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The STALE state of an ND entry indicates that whether the neighbor is reachable is unknown. A device does not detect the neighbor reachability unless packets need to be sent to a neighbor.

The aging time of ND entries in STALE state is configurable. To quickly clear invalid ND entries, set the aging time to a smaller value using the **ipv6 nd stale-timeout** command. This speeds up entry aging.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

If the aging time is not configured on an interface, the aging time configured in system view is used for the interface. If the aging time is configured on an interface, the interface configuration takes effect.

After the **ipv6 nd stale-timeout** command is run, the status of ND entries can be updated after the aging time of ND entries in STALE state expires. That is, the new aging time configuration takes effect after the last aging time expires.

The system checks the validity of ND entries after the aging time of ND entries in STALE state expires. If the neighbor is reachable, the ND entry status changes to REACH; otherwise, the ND entry is deleted.

Example

Set the aging time of ND entries in STALE state to 3600s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 nd stale-timeout 3600
```

Set the aging time of ND entries in STALE state to 3600s on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 nd stale-timeout 3600
```

6.10.60 ipv6 neighbor

Function

The **ipv6 neighbor** command configures static neighbor entries.

The **undo ipv6 neighbor** command deletes static neighbor entries.

By default, no static neighbor entry is configured.

Format

VLANIF interface view:

ipv6 neighbor *ipv6-address mac-address* **vid** *vlan-id interface-type interface-number*

undo ipv6 neighbor *ipv6-address*

Ethernet interface view, Eth-Trunk interface view, Ethernet sub-interface view, and Eth-Trunk sub-interface view:

ipv6 neighbor *ipv6-address mac-address* [**vid** *vlan-id* [**cevid** *cevid*]]

undo ipv6 neighbor *ipv6-address*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the command in Ethernet interface view and Ethernet sub-interface view.

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a static neighbor entry.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
mac-address	Specifies the MAC address of a static neighbor entry.	The value is in the H-H-H format. An H contains one to four hexadecimal numbers.
vid *vlan-id*	Specifies the ID of the outer VLAN to which the interface belongs.	The value is an integer that ranges from 1 to 4094.
cevid *cevid*	Specifies the ID of the inner VLAN to which the interface belongs.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Specifies the interface type and number of a physical interface.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To filter invalid packets, you can create static neighbor entries, binding the destination IPv6 addresses of these packets to nonexistent MAC addresses.

Prerequisites

The IPv6 function has been enabled on the interface using the **ipv6 enable** command in the interface view.

Precautions

A neighbor entry enters the REACHABLE state after being created, indicating that the interface connected to this neighbor is Up.

The static neighbor entries overwrite the neighbor entries dynamically learnt by device. That is, static neighbor entries are of higher priorities than dynamically learnt neighbor entries.

If the IPv6 address or MAC address specified in the **ipv6 neighbor** command is incorrect, communication with this neighbor fails.

Example

Configure static neighbor entries on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 neighbor fc00::1 00e0-fc12-3456 vid 2 gigabitethernet 0/0/1
```

Configure static neighbor entries on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 neighbor fc00::1 00e0-fc12-3456
```

6.10.61 ipv6 packet-too-big drop

Function

The **ipv6 packet-too-big drop** configures the switch to discard packets with the length larger than the IPv6 MTU of the outbound interface, and enables IPv6 PMTU discovery.

The command **undo ipv6 packet-too-big drop** restores the default policy for processing packets with the length larger than the IPv6 MTU of the outbound interface.

By default, the switch properly forwards packets with the length larger than the IPv6 MTU of the outbound interface and IPv6 PMTU discovery is disabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

ipv6 packet-too-big drop

undo ipv6 packet-too-big drop

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch functions as an intermediate node on an IPv6 network, you can configure the **ipv6 packet-too-big drop** command to discard packets with the length larger than the IPv6 MTU of the outbound interface and enable IPv6 PMTU discovery.

In an IPv4 network, oversized packets need to be fragmented. When a transit device receives a packet exceeding the maximum transmission unit (MTU) size of its outbound interface from a source node, the transit device fragments the packet before forwarding it to the destination node. In an IPv6 network, however, only the source node can fragment packets, which reducing pressure on transit devices. When an interface on a transit device receives a packet whose size exceeds the MTU, the transit device discards the packet and sends an ICMPv6 Packet Too Big message to the source node. The ICMPv6 Packet Too Big message contains the MTU value of the outbound interface. The source node fragments the packet based on the MTU and resends the packet, increasing traffic overhead. The Path MTU Discovery protocol dynamically discovers the MTU value of each link on the transmission path, reducing excessive traffic overhead.

The PMTU Discovery protocol is implemented through ICMPv6 Packet Too Big messages. A source node first uses the MTU of its outbound interface as the PMTU and sends a probe packet. If a smaller PMTU exists on the transmission path, the transit device sends a Packet Too Big message to the source node. The Packet Too Big message contains the MTU value of the outbound interface on the transit device. After receiving this message, the source node changes the PMTU value to the received MTU value and sends packets based on the new MTU. This process repeats until packets are sent to the destination address. The source node obtains the PMTU of the destination address.

Precautions

The switch supports IPv6 MTU discovery, but does not support IPv6 packet fragmentation when it functions as an intermediate node. IPv6 packets can be fragmented only on source nodes.

Example

Configure the switch to discard packets with the length larger than the IPv6 MTU of the interface, and enable IPv6 PMTU discovery.

```
<HUAWEI> system-view
[HUAWEI] ipv6 packet-too-big drop
Warning: This operation will affect IPv6 traffic forwarding. Continue? [Y/N]:y
```

6.10.62 ipv6 pathmtu

Function

The **ipv6 pathmtu** command sets the PMTU for a specified destination IPv6 address.

The **undo ipv6 pathmtu** command deletes the PMTU for a specified destination IPv6 address.

Format

ipv6 pathmtu *ipv6-address* [**vpn-instance** *vpn-instance-name*] [*path-mtu*]

undo ipv6 pathmtu *ipv6-address* [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address for which a PMTU is to be set. **NOTE** The link-local address does not take effect.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
vpn-instance *vpn-instance-name*	Specifies the name of an IPv6 VPN instance for which a PMTU is to be set.	The value must be an existing VPN instance name.
path-mtu	Specifies the path MTU, that is, the maximum size of IPv6 packets allowed to be sent along the path.	The value is an integer that ranges from 1280 to 10000, in bytes. The default value is 1500, which is recommended.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A PMTU is used to determine the proper size of packets to be transmitted along the path from a source to a destination. Usually, a device fragments and forwards packets based on the dynamically learnt PMTU. Packets that are sent using this PMTU do not need to be fragmented during transmission. This reduces pressure on routing devices and optimizes network resource utilization to obtain the maximum throughput.

In some special cases, however, to protect devices on the network and avoid large-size packet attacks, you can run the **ipv6 pathmtu** command to set a static PMTU for the specified destination IPv6 address to control the maximum size of packets that can be transmitted between the source and the destination.

Precautions

On the path along which packets are transmitted, a node discards the received packets if its MTU is smaller than the PMTU of the received packets. Therefore, in most cases, dynamic PMTU learning is recommended unless there are security vulnerabilities on the network. You can use the default PMTU value instead of running the **ipv6 pathmtu** command to set a static PMTU.

Example

Set the PMTU of a specified IPv6 destination address to 1300 bytes.

```
<HUAWEI> system-view
[HUAWEI] ipv6 pathmtu fc00::12 1300
```

Set the PMTU of the address fc00::1 of the IPv6 VPN instance to 1600 bytes.

```
<HUAWEI> system-view
[HUAWEI] ipv6 pathmtu fc00::1 vpn-instance vpn6 1600
```

6.10.63 ipv6 pathmtu age

Function

The **ipv6 pathmtu age** command sets the aging time of dynamic PMTU entries.

The **undo ipv6 pathmtu age** command restores the aging time of dynamic PMTU entries to the default value.

By default, the aging time of dynamic PMTU entries is 10 minutes.

Format

ipv6 pathmtu age *age-time*

undo ipv6 pathmtu age

Parameters

Parameter	Description	Value
age-time	Specifies the aging time of dynamic specified PMTU entries.	The value is an integer that ranges from 10 to 100, in minutes. The default value is 10 minutes, which is recommended.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The lifetime of a dynamic PMTU entry can be changed by setting an aging time for dynamic PMTU entries.

To slow down PMTU aging, run the **ipv6 pathmtu age** command to set the aging time of dynamic PMTU entries to a larger value.

Precautions

This command changes only the aging time of dynamic PMTUs but not static PMTUs because static PMTU entries never age.

The priority of a static PMTU is higher than that of a dynamic PMTU. If the static PMTU exists, the dynamic PMTU does not take effect.

The aging time for the PMTU is valid only for the dynamic PMTU entries generated after this configuration, instead of the PMTU entries generated before this configuration.

Example

Set the aging time of dynamic PMTU entries to 40 minutes.

```
<HUAWEI> system-view
[HUAWEI] ipv6 pathmtu age 40
```

6.10.64 nd optimized-passby enable

Function

The **nd optimized-passby enable** command configures the device not to send NS packets destined for other devices to the CPU.

The **undo nd optimized-passby enable** command configures the device to send NS packets destined for other devices to the CPU.

By default, a device does not send NS packets destined for other devices to the CPU.

Format

nd optimized-passby enable

undo nd optimized-passby enable

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an interface receives a large number of NS packets whose destination IPv6 addresses are different from the IPv6 address of this interface and sends these NS packets to the CPU for processing, the CPU usage is high and the CPU cannot process services properly.

To prevent this issue, you can configure the device to directly forward NS packets destined for other devices without sending them to the CPU. This improves the device's capability of defending against packet attacks.

Precautions

If the **nd snooping enable** is executed in system view, or if IPv6 protocol is **Down** on the VLANIF interface, the configuration of disabling the device from sending NS packets destined for other devices to the CPU does not take effect on the VLANIF interface.

Example

Configure the device to send NS packets destined for other devices to the CPU.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo nd optimized-passby enable
```

6.10.65 nd optimized-reply disable

Function

The **nd optimized-reply disable** command disables the optimized ND reply function.

The **undo nd optimized-reply disable** command enables the optimized ND reply function.

By default, the optimized ND reply function is enabled.

Format

nd optimized-reply disable

undo nd optimized-reply disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a stack functions as an access gateway, it receives a large number of ND Request packets that request the switch to reply with its local interface MAC address. If all these ND Request packets are sent to the master switch, the CPU usage of the master switch increases, and other services are affected.

The optimized ND reply function addresses this issue. After this function is enabled, the switch receiving an ND Request packet returns an ND Reply packet if the ND Request packet is destined for a local interface on the switch of the stack, and discards the ND Request packet if the packet is not destined for a local interface on the switch of the stack.

By default, the optimized ND reply function is enabled. After receiving an ND Request packet, the switch checks whether an ND entry corresponding to the source IPv6 address of the ND Request packet exists.

- If the corresponding ND entry exists and the packet information is the same as the saved ND entry information, the switch performs optimized ND reply to this ND Request packet.
- If the corresponding ND entry exists but the packet information differs from the saved ND entry information, the switch does not perform optimized ND reply to this ND Request packet.
- If the corresponding ND entry does not exist, the switch does not perform optimized ND reply to this ND Request packet.

Precautions

- The optimized ND reply function takes effect for ND Request packets sent by wireless users.

- The optimized ND reply function takes effect for ND Request packets received on VLANIF interfaces and VBDIF interfaces enabled with IPv6. VLANIF interfaces of Group VLANs and Separate VLANs in MUX VLANs, VLANIF interfaces of mapped VLANs, and VLANIF interfaces of super-VLANs do not perform optimized ND reply.
- If the number of global unicast IPv6 addresses on a VLANIF interface or VBDIF interface enabled with IPv6 exceeds 1, the switch does not perform optimized ND reply for NS packets received on this interface.
- If the ND snooping function is enabled on a switch, the switch does not perform optimized ND reply to received ND Request packets.
- The switch does not perform optimized ND reply to the following received packets:
  - NS packets with the source IPv6 address :: (that is, Duplicate Address Detection packets)
  - Packets with IPv6 extension headers

Example

Disable the optimized ND reply function.

```
<HUAWEI> system-view
[HUAWEI] nd optimized-reply disable
```

6.10.66 nd trap hash-conflict enable

Function

The **nd trap hash-conflict enable** command enables the trap function for hash conflicts of ND entries.

The **undo nd trap hash-conflict enable** command disables the trap function for hash conflicts of ND entries.

By default, the trap function for hash conflicts of ND entries is enabled.

Format

nd trap hash-conflict enable

undo nd trap hash-conflict enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

After the trap function for hash conflicts of ND entries is configured, the switch sends traps when a hash conflict of ND entries occurs so that you can obtain the status of ND entries promptly. ND entry resources are key resources on the switch. Monitoring the ND entry status effectively ensures proper running of the switch.

To improve the IPv6 forwarding performance, the switch saves ND entries using hash links. When multiple ND entries obtain the same key based on the hash algorithm, the ND entries cannot be saved. This is a hash conflict of ND entries.

When a hash conflict of ND entries occurs, the switch has available ND entry space but cannot save ND entries. The switch cannot forward IPv6 traffic matching the ND entries with a hash conflict.

You can enable the trap function for hash conflicts of ND entries to detect hash conflicts of ND entries promptly.

Example

Enable the trap function for hash conflicts of ND entries.

```
<HUAWEI> system-view
[HUAWEI] nd trap hash-conflict enable
```

6.10.67 nd trap hash-conflict history

Function

The **nd trap hash-conflict history** command sets the number of traps reported within each interval when a hash conflict of ND entries occurs.

The **undo nd trap hash-conflict history** command restores the default number of traps reported within each interval when a hash conflict of ND entries occurs.

By default, a switch reports a maximum of 10 traps within each interval when a hash conflict of ND entries occurs.

Format

nd trap hash-conflict history *history-number*

undo nd trap hash-conflict history

Parameters

Parameter	Description	Value
history-number	Specifies the number of traps reported within each interval when a hash conflict of ND entries occurs.	The value is an integer that ranges from 10 to 30. The default value is 10.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the trap function for hash conflicts of ND entries is enabled, the switch reports a maximum of 10 traps within 60 seconds by default. Each trap contains an IPv6 address that has a hash conflict.

If hash conflicts of more than 10 ND entries occur within an interval, traps for the eleventh and following ND entries that have hash conflicts cannot be reported. To solve this problem, you can run the **nd trap hash-conflict history** command to set the number of traps reported within each interval when a hash conflict of ND entries occurs.

Precautions

If you run this command multiple times, only the latest configuration takes effect.

Example

Configure the switch to report a maximum of 15 traps within each interval when a hash conflict of ND entries occurs.

```
<HUAWEI> system-view
[HUAWEI] nd trap hash-conflict history 15
```

6.10.68 nd trap hash-conflict interval

Function

The **nd trap hash-conflict interval** command sets the interval at which the switch reports traps when a hash conflict of ND entries occurs.

The **undo nd trap hash-conflict interval** command restores the default interval at which the switch reports traps when a hash conflict of ND entries occurs.

By default, a switch reports traps at an interval of 60 seconds when a hash conflict of ND entries occurs.

Format

nd trap hash-conflict interval *interval-time*

undo nd trap hash-conflict interval

Parameters

Parameter	Description	Value
interval-time	Specifies the interval at which the switch reports traps when a hash conflict of ND entries occurs.	The value is an integer that ranges from 30 to 3600, in seconds. The default value is 60.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the trap function for hash conflicts of ND entries is enabled, the switch reports a maximum of 10 traps within 60 seconds by default. Each trap contains an IPv6 address that has a hash conflict.

If the trap report interval is set to a small value, the switch reports traps for hash conflicts of ND entries more promptly. When many hash conflicts of ND entries occur, the switch reports a lot of traps.

If the trap report interval is set to a large value, the switch reports traps for hash conflicts of ND entries less promptly. When many hash conflicts of ND entries occur, the switch suppresses traps to be reported.

You can run the **nd trap hash-conflict interval** command to adjust the trap report interval based on actual requirements.

Precautions

If you run this command multiple times, only the latest configuration takes effect.

Example

Configure the switch to report traps at an interval of 90 seconds when a hash conflict of ND entries occurs.

```
<HUAWEI> system-view
[HUAWEI] nd trap hash-conflict interval 90
```

6.10.69 nd-miss message-cache disable

Function

The **nd-miss message-cache disable** command disables the ND Miss message sending function.

The **undo nd-miss message-cache disable** command enables the ND Miss message sending function.

By default, the ND Miss message sending function is enabled.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

nd-miss message-cache disable

undo nd-miss message-cache disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If a user sends an IPv6 packet with an irresolvable destination IPv6 address to the device (that is, if the device has a route to the destination IPv6 address of the IPv6 packet but has no ND entry matching the next hop of the route), the device generates an ND Miss message. By default, the device sends the ND Miss messages to the CPU. This improves the efficiency of processing the ND Miss messages.

When the ND Miss message sending function is enabled, a device cannot reply to ICMPv6 host unreachable packets. To enable the device to reply to ICMPv6 host unreachable packets, you can run the **nd-miss message-cache disable** command to disable the ND Miss message sending function.

Example

Disable the ND Miss message sending function.

```
<HUAWEI> system-view
[HUAWEI] nd-miss message-cache disable
```

6.10.70 reset ipv6 attack-source overlapping-fragment

Function

The **reset ipv6 attack-source overlapping-fragment** command clears statistics on overlapping fragment attack packets.

Format

reset ipv6 attack-source overlapping-fragment

Parameters

None

Views

User view

Default Level

2: Configuration level

Usage Guidelines

After overlapping fragment attack packets are processed manually, run the **reset ipv6 attack-source overlapping-fragment** command to clear statistics on overlapping fragment attack packets.

Example

Clear statistics on IPv6 overlapping fragment attack packets.

```
<HUAWEI> reset ipv6 attack-source overlapping-fragment
```

6.10.71 reset ipv6 neighbors

Function

The **reset ipv6 neighbors** command clears neighbor entries.

Format

reset ipv6 neighbors { **all** | **dynamic** | **static** | **vid** *vlan-id* [*interface-type interface-number*] | *interface-type interface-number* [**dynamic** | **static**] }

Parameters

Parameter	Description	Value
all	Clears neighbor entries on all interfaces.	-
dynamic	The first **dynamic** indicates that dynamic neighbor entries on all interfaces are cleared. The second **dynamic** indicates that dynamic neighbor entries on the current interface are cleared.	-

Parameter	Description	Value
static	The first **static** indicates that static neighbor entries on all interfaces are cleared. The second **static** indicates that static neighbor entries on the current interface are deleted.	-
vid *vlan-id*	Clears neighbor entries of a specified VLAN.	The value is an integer that ranges from 1 to 4094.
interface-type interface-number	Clears all neighbor entries on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of neighbor entries exceeds the upper limit, run the **reset ipv6 neighbors** command to clear excessive neighbor entries.

Precautions

The **reset ipv6 neighbors** command clears specified neighbor entries, which affects IPv6 packet forwarding. Therefore, confirm your action before running this command.

Example

Clear all neighbor entries on all interfaces.

```
<HUAWEI> reset ipv6 neighbors all
Warning: This operation will delete all static and dynamic IPv6 ND entries and the configurations of all
static IPv6 ND. Continue?[Y/N]:y
```

Clear all neighbor entries on the specified interface VlANIF 10.

```
<HUAWEI> reset ipv6 neighbors vlanif 10
```

6.10.72 reset ipv6 pathmtu

Function

The **reset ipv6 pathmtu** command clears PMTU entries.

Format

reset ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] { **all** | **dynamic** | **static** }

Parameters

Parameter	Description	Value
all	Clears all PMTU entries in the cache.	-
dynamic	Clears all dynamic PMTU entries in the cache.	-
static	Clears all static PMTU entries in the cache.	-
vpn-instance *vpn-instance-name*	Clears all PMTU entries of a specified IPv6 VPN instance.	The value must be an existing VPN instance name.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To collect statistics on PMTU entries within a specified period, use the **reset ipv6 pathmtu** command to clear the existing statistics on PMTU entries before running the **display ipv6 pathmtu** command to check information about PMTU entries.

Precautions

The **reset ipv6 pathmtu all** command clears all PMTU entries. Therefore, confirm your action before running this command.

Example

Clear all PMTU entries.

```
<HUAWEI> reset ipv6 pathmtu all
Warning: This operation will reset all static and dynamic IPv6 PMTU entries, and clear the configurations of
all static IPv6 PMTU, continue?[Y/N]:y
```

6.10.73 reset ipv6 socket pktsort

Function

The **reset ipv6 socket pktsort** command clears statistics on the dual receive buffer of an IPv6 socket.

Format

reset ipv6 socket pktsort task-id *task-id* **socket-id** *socket-id*

Parameters

Parameter	Description	Value
task-id *task-id*	Specifies the ID of a task.	The value is an integer and the range depends on the task configuration.
socket-id *socket-id*	Specifies the ID of a socket.	The value is an integer that ranges from 1 to 131072.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command clears statistics on the dual receive buffer of an IPv6 socket and the count restarts. Therefore, confirm your action before running this command.

Example

Clear statistics on the dual receive buffer of the IPv6 socket with the task ID 2 and the socket ID 4.

```
<HUAWEI> reset ipv6 socket pktsort task-id 2 socket-id 4
```

6.10.74 reset ipv6 statistics

Function

The **reset ipv6 statistics** command clears IPv6 traffic statistics.

Format

reset ipv6 statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To collect IPv6 traffic statistics within a specified period, clear the existing IPv6 traffic statistics before running the **display ipv6 statistics** command to display IPv6 traffic statistics.

Precautions

The **reset ipv6 statistics** command clears the specified IPv6 traffic statistics. Therefore, confirm your action before running this command.

Example

Clear IPv6 traffic statistics.

```
<HUAWEI> reset ipv6 statistics
```

6.10.75 reset nd optimized-reply statistics

Function

The **reset nd optimized-reply statistics** command clears statistics on optimized ND Reply packets.

Format

reset nd optimized-reply statistics [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	Specifies the stack ID.	The value is an integer. It has a fixed value of 0 in a non-stack scenario, and depends on the device configuration in a stack scenario.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Before collecting statistics on optimized ND Reply packets on the device, you can run the **reset nd optimized-reply statistics** command to clear statistics on optimized ND Reply packets of the device.

Example

Clears statistics on optimized ND Reply packets.

```
<HUAWEI> reset nd optimized-reply statistics
```

6.10.76 reset rawip ipv6 statistics

Function

The **reset rawip ipv6 statistics** command clears all Raw IPv6 packet statistics.

Format

reset rawip ipv6 statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You need to run this command to clear the existing statistics on Raw IPv6 packets before running the **display rawip ipv6 statistics** command to view statistics on Raw IPv6 packets in a specified period.

The **reset rawip ipv6 statistics** command clears statistics on Raw IPv6 packets. Therefore, confirm your action before running this command.

Example

Clear all Raw IPv6 packet statistics.

```
<HUAWEI> reset rawip ipv6 statistics
```

6.10.77 reset tcp ipv6 authentication-statistics

Function

The **reset tcp ipv6 authentication-statistics** command clears authentication statistics of a specified TCP6 connection.

Format

reset tcp ipv6 authentication-statistics src-ip *src-ip* **src-port** *src-port* **dest-ip** *dest-ip* **dest-port** *dest-port*

Parameters

Parameter	Description	Value
src-ip *src-ip*	Specifies the source IPv6 address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
src-port *src-port*	Specifies the source port.	The value is an integer that ranges from 0 to 65535.
dest-ip *dest-ip*	Specifies the destination IPv6 address.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
dest-port *dest-port*	Specifies the destination port.	The value is an integer that ranges from 0 to 65535.

Usage Guidelines

The **reset tcp ipv6 authentication-statistics** command clears authentication statistics of a TCP6 connection. Therefore, confirm your action before running this command.

Example

Clear authentication statistics of a TCP6 connection.

```
<HUAWEI> reset tcp ipv6 authentication-statistics src-ip fc00:1::1 src-port 3456 dest-ip fc00:3::5 dest-port 5678
```

6.10.78 reset tcp ipv6 statistics

Function

The **reset tcp ipv6 statistics** command clears TCP6 packet statistics.

Format

reset tcp ipv6 statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To delete TCP6 packet statistics displayed using the **display tcp ipv6 statistics** command, run the **reset tcp ipv6 statistics** command. The TCP6 packet statistics include the number of both sent and received packets, the number of discarded packets, the number of redirected packets, the threshold-crossing status of TCP6 connections, network attack status, and network quality. You can run the **reset tcp ipv6 statistics** command to delete existing statistics and then run the **display tcp ipv6 statistics** command to collect statistics. The statistics help you check whether TCP6 packet counts are correct or help you diagnose faults.

Precautions

The **reset tcp ipv6 statistics** command clears TCP6 packet statistics. Therefore, confirm your action before running this command.

Example

Clear TCP6 packet statistics.

```
<HUAWEI> reset tcp ipv6 statistics
```

6.10.79 reset udp ipv6 statistics

Function

The **reset udp ipv6 statistics** command clears UDP6 packet statistics.

Format

reset udp ipv6 statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To delete UDP6 packet statistics displayed using the **display udp ipv6 statistics** command, run the **reset udp ipv6 statistics** command. The statistics include the number of both the sent and received packets, the number of discarded packets, and the number of redirected packets. You can run the **reset udp ipv6 statistics** command to delete existing statistics and then run the **display udp ipv6 statistics** command to collect statistics. The statistics help you check whether UDP6 packet counts are correct or help you diagnose faults.

The **reset udp ipv6 statistics** command clears UDP6 packet statistics. Therefore, confirm your action before running this command.

Example

Clear UDP6 packet statistics.

```
<HUAWEI> reset udp ipv6 statistics
```

6.10.80 segment-routing ipv6 head pop

Function

The **segment-routing ipv6 head pop** command enables SRv6 packet decapsulation.

The **undo segment-routing ipv6 head pop** command disables SRv6 packet decapsulation.

By default, SRv6 packet decapsulation is disabled.

NOTE

This command is supported only on the following models:

S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, S6730S-S

Format

segment-routing ipv6 head pop

undo segment-routing ipv6 head pop

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Segment Routing over IPv6 (SRv6) is designed to forward IPv6 packets on a network through source routing. SRv6 is based on the IPv6 forwarding plane. With SRv6, a segment routing header (SRH) is added to IPv6 packets. If the downstream device of a switch cannot process SRv6 packets, run the **segment-routing ipv6 head pop** command on the switch to enable SRv6 packet decapsulation and then configure MQC- or ACL-based redirection. In this case, the switch will forward the decapsulated IPv6 packets to the downstream device.

The following actions are taken to decapsulate SRv6 packets:

- Change the value in the **Next Header** field in the IPv6 header to the value in the **Next Header** field in the SRH.
- Change the value in the **Destination Address** field in the IPv6 header to the first IPv6 address (that is, segment list [0]) in the SRH.
- Remove the SRH from the packet.
- Subtract the SRH length from the **Payload Length** field in the IPv6 header.

Follow-up Procedure

Configure MQC- or ACL-based redirection to redirect decapsulated packets to other devices.

Precautions

After the **segment-routing ipv6 head pop** command is run, SRv6 packets cannot be mirrored or sampled, or sent to the CPU.

Example

Enable SRv6 packet decapsulation.

```
<HUAWEI> system-view
[HUAWEI] segment-routing ipv6 head pop
```

6.10.81 service type tunnel

Function

The **service type tunnel** command enables service loopback on an Eth-Trunk interface to loop service packets back to tunnel interfaces.

The **undo service type tunnel** command disables service loopback on an Eth-Trunk interface.

By default, service loopback is disabled on an Eth-Trunk interface.

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

service type tunnel

undo service type tunnel

Parameters

None

Views

Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To forward packets using tunnel interfaces, you need to bind the tunnel interfaces to an Eth-Trunk interface. Before binding the tunnel interfaces to the Eth-Trunk interface, run the **service type tunnel** command to enable service loopback on the Eth-Trunk interface to loop service packets back to tunnel interfaces.

Precautions

After being configured as a service loopback interface, an Eth-Trunk interface can only be used to loop service packets back to tunnel interfaces.

A device can be configured with only one service loopback interface.

You cannot configure both the **service type tunnel** command and the URPF function on the same Eth-Trunk.

On an Eth-Trunk enabled with the service loopback function, the STP function is automatically disabled. After the service loopback function is disabled on the Eth-Trunk, the STP function is automatically enabled.

- The configurations allowed on an Eth-Trunk to be configured as a loopback interface include **description**, **enable snmp trap updown**, **jumboframe enable**, **mixed-rate link enable**, **qos phb marking enable**, **set flow-stat interval**, **shutdown**, **local-preference enable**, **traffic-policy (interface view)**, and **trust**. If other configurations exist on the Eth-Trunk, the Eth-Trunk cannot be configured as a loopback interface.
- After an Eth-Trunk is configured as a loopback interface, the Eth-Trunk supports only the following configurations: **authentication open ucl-policy enable**, **description**, **enable snmp trap updown**, **jumboframe enable**, **mixed-rate link enable**, **qos phb marking enable**, **set flow-stat interval**, **shutdown**, **local-preference enable**, **statistic enable (interface view)**, **traffic-policy (interface view)**, **vcmp disable**, and **trust**.
- Before running the **undo service type tunnel** command, delete all the member interfaces of the Eth-Trunk interface on the device.

After the Eth-Trunk interface is configured as the service loopback interface, other service configurations cannot be performed on the Eth-Trunk interface by invoking the MIB through the NMS. Otherwise, the service loopback interface function or the service configurations delivered through the MIB may be invalid.

Example

Enable service loopback on the interface **Eth-Trunk 0**.

```
<HUAWEI> system-view
[HUAWEI] interface eth-trunk 0
[HUAWEI-Eth-Trunk0] service type tunnel
```

6.10.82 tcp ipv6 max-mss

Function

The **tcp ipv6 max-mss** command sets the maximum value of Maximum Segment Size (MSS) for a TCP6 connection.

The **undo tcp ipv6 max-mss** command deletes the maximum MSS value of a TCP6 connection.

By default, the maximum MSS value is not configured for TCP6 connections.

Format

tcp ipv6 max-mss *mss-value*

undo tcp ipv6 max-mss

Parameters

Parameter	Description	Value
mss-value	Specifies the maximum MSS value for a TCP6 connection.	The value is an integer ranging from 32 to 9600, in bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To establish a TCP6 connection, the MSS value is negotiated, which indicates the maximum length of packets that the local device can receive. If the path MTU is unavailable on one end of a TCP6 connection, this end cannot adjust the TCP6 packet size based on the MTU. As a result, this end may send TCP6 packets that are longer than the MTUs on intermediate devices, which will discard these packets. To prevent this problem, run the **tcp ipv6 max-mss** command on either end of a TCP6 connection to set the maximum MSS value of TCP6 packets. Then the MSS value negotiated by both ends will not exceed this maximum MSS value, and accordingly TCP6 packets sent from both ends will not be longer than this maximum MSS value and can travel through the intermediate network.

Precautions

The maximum MSS value configured using the **tcp ipv6 max-mss** command must be greater than the minimum MSS value configured using the **tcp ipv6 min-mss** command.

Example

Set the maximum MSS value for a TCP6 connection to 1024 bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp ipv6 max-mss 1024
```

6.10.83 tcp ipv6 min-mss

Function

The **tcp ipv6 min-mss** command sets the minimum value of maximum segment size (MSS) for a TCP6 connection.

The **undo tcp ipv6 min-mss** command restores the default minimum value of the MSS for a TCP6 connection.

The default minimum MSS value for a TCP6 connection is 216 bytes.

Format

tcp ipv6 min-mss *mss-value*

undo tcp ipv6 min-mss

Parameters

Parameter	Description	Value
mss-value	Specifies the minimum MSS value for a TCP6 connection.	The value ranges from 32 bytes to 1500 bytes. By default, the value is 216 bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To establish a TCP6 connection, the MSS value is negotiated, which indicates the maximum length of packets that the local device can receive. The TCP6 client on a network may send a request packet for establishing a TCP6 connection carrying a small MSS value. For example, the MSS value is 1. After the TCP6 server receives the request packet carrying the MSS value, the TCP6 connection is established. The TCP6 client then may send large numbers of requests to the server by an application, causing the TCP6 server to generate large numbers of reply packets. This may burden the TCP6 server or network, causing denial of service (DoS) attacks. To resolve this problem, run the **tcp ipv6 min-mss** command to set the minimum MSS value for a TCP6 connection. This configuration prevents a server from receiving packets carrying a small MSS value.

Precautions

The minimum MSS value configured using the **tcp ipv6 min-mss** command must be less than the maximum MSS value configured using the **tcp ipv6 max-mss** command.

If the **tcp ipv6 min-mss** command is run more than once in the same view, the latest configuration overrides the previous one.

Configure the parameters under the guidance of the technical personnel.

Example

Set the minimum MSS value for a TCP6 connection to 512 bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp ipv6 min-mss 512
```

6.10.84 tcp ipv6 timer fin-timeout

Function

The **tcp ipv6 timer fin-timeout** command sets the value of the TCP6 FIN-Wait timer.

The **undo tcp ipv6 timer fin-timeout** command restores the default value of the TCP6 FIN-Wait timer.

By default, the value of the TCP6 FIN-Wait timer is 600s.

Format

tcp ipv6 timer fin-timeout *interval*

undo tcp ipv6 timer fin-timeout

Parameters

Parameter	Description	Value
interval	Specifies the value of the TCP6 FIN-Wait timer.	The value is an integer that ranges from 76 to 3600, in seconds. The default value is 600s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a TCP6 connection changes from FIN_WAIT_1 to FIN_WAIT_2, the TCP FIN-Wait timer is started. If the local device does not receive a packet with the FIN flag after the TCP6 FIN-Wait timer expires, the TCP6 connection is closed.

Precautions

If you run the **tcp ipv6 timer fin-timeout** command multiple times, only the latest configuration takes effect.

You are advised to use this command under the supervision of technical support personnel.

Example

Set the value of the TCP6 FIN-Wait timer to 800s.

```
<HUAWEI> system-view
[HUAWEI] tcp ipv6 timer fin-timeout 800
```

6.10.85 tcp ipv6 timer syn-timeout

Function

The **tcp ipv6 timer syn-timeout** command sets the value of the TCP6 SYN-Wait timer.

The **undo tcp ipv6 timer syn-timeout** command restores the default value of the TCP6 SYN-Wait timer.

By default, the value of the TCP6 SYN-Wait timer is 75s.

Format

tcp ipv6 timer syn-timeout *interval*

undo tcp ipv6 timer syn-timeout

Parameters

Parameter	Description	Value
interval	Specifies the value of the TCP6 SYN-Wait timer.	The value is an integer that ranges from 2 to 600, in seconds. The default value is 75s.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an SYN packet is sent, the TCP6 SYN-Wait timer is started. If no response packet is received when the TCP6 SYN-Wait timer expires, the TCP6 connection is closed.

Precautions

If you run the **tcp ipv6 timer syn-timeout** command multiple times, only the latest configuration takes effect.

You are advised to use this command under the supervision of technical support personnel.

Example

Set the value of the TCP6 SYN-Wait timer to 100s.

```
<HUAWEI> system-view
[HUAWEI] tcp ipv6 timer syn-timeout 100
```

6.10.86 tcp ipv6 window

Function

The **tcp ipv6 window** command sets the size of the packet receive or send buffer of a connection-oriented socket.

The **undo tcp ipv6 window** command restores the default size of the packet receive or send buffer of a connection-oriented socket.

By default, the size of the packet receive or send buffer of a connection-oriented socket is 8K bytes.

Format

tcp ipv6 window *window-size*

undo tcp ipv6 window

Parameters

Parameter	Description	Value
window-size	Specifies the size of the packet receive or send buffer of a connection-oriented socket.	The value is an integer that ranges from 1 to 32, in K bytes. The default value is 8K bytes.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command changes the default size of the packet receive or send buffer. The device uses the default size to establish a TCP6 session.

Precautions

If you run the **tcp ipv6 window** command multiple times, only the latest configuration takes effect.

You are advised to use this command under the supervision of technical support personnel.

Example

Set the size of the packet receive or send buffer of a connection-oriented socket to 4K bytes.

```
<HUAWEI> system-view
[HUAWEI] tcp ipv6 window 4
```

6.11 DHCPv6 Configuration Commands

6.11.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

Layer 3 Ethernet interface, VLANIF interface, and sub-interface all support the DHCPv6 function.

6.11.2 address prefix

Function

The **address prefix** command configures the network prefix and lifetime in the IPv6 address pool view.

The **undo address prefix** command deletes the network prefix and lifetime that are configured in the IPv6 address pool view.

By default, no network prefix and lifetime are configured in the IPv6 address pool view.

Format

address prefix *ipv6-prefix/ipv6-prefix-length* [**eui-64**] [**life-time** { *valid-lifetime* | **infinite** } { *preferred-lifetime* | **infinite** }]

address prefix *ipv6-prefix/ipv6-prefix-length* [**eui-64**] [**life-time preferred-lifetime days** *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]] **valid-lifetime days** *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]]

address prefix *ipv6-prefix/ipv6-prefix-length* [**lock**]

undo address prefix *ipv6-prefix/ipv6-prefix-length* [**lock**]

Parameters

Parameter	Description	Value
ipv6-prefix/ipv6-prefix-length	Specifies the network prefix and prefix length.	*ipv6-prefix*: The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X. *ipv6-prefix-length*: The value is an integer that ranges from 1 to 128.
eui-64	Generates the interface ID based on the user MAC address according to the EUI-64 specifications. This method can be used to allocate addresses only when the client DUID type is LL or LLT.	-
life-time	Specifies the network prefix lifetime.	-
valid-lifetime	Specifies the valid lifetime.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 172800, that is two days.
preferred-lifetime	Specifies the preferred lifetime. The preferred lifetime cannot exceed the valid lifetime.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 86400, that is one day.
infinite	Sets the lifetime to infinite. When the preferred lifetime is set to infinite, the valid lifetime must be set to infinite.	-

Parameter	Description	Value
preferred-lifetime days *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]	Specifies the preferred lifetime of the IPv6 prefix. The time must be no less than 1 minute.	- *days*: indicates days. The value is an integer that ranges from 0 to 1999. - *hours*: indicates hours. The value is an integer that ranges from 0 to 23. - *minutes*: indicates minutes. The value is an integer that ranges from 0 to 59. - *seconds*: indicates seconds. The value is an integer that ranges from 0 to 59.
valid-lifetime days *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]	Specifies the valid lifetime of the IPv6 prefix. The time must be no less than 1 minute and cannot be less than the preferred lifetime.	- *days*: indicates days. The value is an integer that ranges from 0 to 1999. - *hours*: indicates hours. The value is an integer that ranges from 0 to 23. - *minutes*: indicates minutes. The value is an integer that ranges from 0 to 59. - *seconds*: indicates seconds. The value is an integer that ranges from 0 to 59.
lock	Locks the address prefix.	-

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device functions as a DHCPv6 server, run the **address prefix** command to configure the network prefix in an IPv6 address pool. If IPv6 addresses in an

IPv6 address pool have been assigned to DHCPv6 clients, only the value of life-time can be modified.

Precautions

If no DHCPv6 relay agent exists between the DHCPv6 server and client, the length of the network prefix configured to the DHCPv6 server address pool must be longer than or equal to the prefix length of IPv6 addresses of Layer 3 interfaces on the DHCPv6 server.

Idle addresses or prefixes are assigned to DHCPv6 clients from the IPv6 address pool. Reserved addresses, conflicted addresses, and used addresses cannot be assigned to DHCPv6 clients. Reserved addresses include unspecified addresses, multicast addresses, loopback addresses, link-local addresses, NSAP addresses, and anycast addresses (defined in RFC 2526).

Prerequisites

An address pool has been created by using the **dhcpv6 pool** command.

Example

Bind the network prefix fc00:1::/64 to the DHCPv6 server address pool pool1 and set the lifetime to infinite.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] address prefix fc00:1::/64 life-time infinite infinite
```

6.11.3 capwap-ac (IPv6 address pool view)

Function

The **capwap-ac** command configures the AC's IPv6 address in the IPv6 address pool view.

The **undo capwap-ac** command deletes the AC's IPv6 address configured in the IPv6 address pool view.

By default, the AC's IPv6 address is not configured in the IPv6 address pool view.

Format

capwap-ac *ipv6-address*

undo capwap-ac *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address for an AC.	The total length is 128 bit, which is divided into eight groups. The 16 bits of each group are represented by four hexadecimal characters. The format is X:X:X:X:X:X:X:X.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the AC+Fit AP scenario, the AC needs to establish connections with APs. The device functioning as a DHCPv6 server can specify the AC's IPv6 address for an AP. The AP then can connect to the specified AC. The device uses Option52 to carry the AC address.

If the AC and AP are located in the same network segment, the AP sends a broadcast packet to automatically discover the AC. In this case, the configuration of the **capwap-ac** command is optional. If the AC and AP are located in different network segments, you must configure the **capwap-ac** command.

Prerequisites

The IPv6 address pool is created using the **dhcpv6 pool** command.

Precautions

You can run the **capwap-ac** command multiple times to configure the IPv6 addresses of several ACs, and the AC's IPv6 address that is configured first takes precedence over the one configured later.

Example

Specify the AC's IPv6 address to fc00:1::1 in pool1 of the DHCPv6 server.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] capwap-ac fc00:1::1
```

6.11.4 conflict-address expire-time

Function

The **conflict-address expire-time** command sets the aging time for conflicted addresses in the IPv6 address pool.

The **undo conflict-address expire-time** command restores the default aging time of conflicted addresses in the IPv6 address pool.

By default, the aging time of conflicted addresses is 172800s (two days).

Format

conflict-address expire-time *expire-time*

undo conflict-address expire-time

Parameters

Parameter	Description	Value
expire-time	Specifies the aging time for the conflicted addresses in the address pool.	The value is an integer that ranges from 60 to 4294967295, in seconds.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **conflict-address expire-time** command is used on DHCPv6 servers. If the IPv6 address in the address pool is marked as a conflicted address, it cannot be allocated. To use these conflicted addresses, the administrator needs to mark these addresses as assignable. After the aging time configured using the **conflict-address expire-time** command expires, the conflicted addresses automatically become assignable.

Prerequisites

An address pool has been created by using the **dhcpv6 pool** command.

Example

Set the aging time of conflicted addresses in global address pool global1 to 36000s.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] conflict-address expire-time 36000
```

6.11.5 dhcpv6 client information-request

Function

The **dhcpv6 client information-request** command enables an interface to obtain configuration parameters (not including IPv6 addresses) using stateless DHCPv6 address autoconfiguration.

The **undo dhcpv6 client information-request** command disables an interface from obtaining configuration parameters (not including IPv6 addresses) using stateless DHCPv6 address autoconfiguration.

By default, the interface is disabled from obtaining configuration parameters (not including IPv6 addresses) using stateless DHCPv6 address autoconfiguration.

Format

dhcpv6 client information-request

undo dhcpv6 client information-request

Parameters

None

Views

VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcpv6 client information-request** command is used on the DHCPv6 client. After you run the **dhcpv6 client information-request** on the device that functions as a DHCPv6 client, IPv6 addresses are generated based on the Route Advertisement (RA) packets. The DHCPv6 server provides other configuration parameters such as IP addresses of the DNS, and SNTP servers except for IPv6 addresses and the interval for updating configuration parameters.

Prerequisites

1. IPv6 functions have been enabled globally using the **ipv6** command in the system view.
2. IPv6 functions have been enabled on interfaces using the **ipv6 enable** command in the interface view.
3. The IPv6 link-local address has been configured using the **ipv6 address auto link-local** or **ipv6 address** *ipv6-address* **link-local** command in the interface view.

Example

Configure the DHCPv6 client to obtain configuration parameters using stateless DHCPv6 address autoconfiguration on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address auto link-local
[HUAWEI-Vlanif100] dhcpv6 client information-request
```

Configure the DHCPv6 client to obtain configuration parameters using stateless DHCPv6 address autoconfiguration on the interface

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto link-local
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 client information-request
```

6.11.6 dhcpv6 client pd

Function

The **dhcpv6 client pd** command configures the DHCPv6 PD client function.

The **undo dhcpv6 client pd** command disables the DHCPv6 PD client function.

By default, the DHCPv6 PD client function is disabled.

Format

dhcpv6 client pd *prefix-name* [**hint** *ipv6-prefix/ipv6-prefix-length*] [**rapid-commit**] [**unicast-option**]

undo dhcpv6 client pd

Parameters

Parameter	Description	Value
prefix-name	Specifies the name of an IPv6 address prefix name.	The value is a string of 1 to 63 case-sensitive characters without spaces.
hint *ipv6-prefix/ipv6-prefix-length*	Specifies the required IPv6 address prefix and prefix length.	*ipv6-prefix*: The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X. *ipv6-prefix-length*: The value is an integer that ranges from 1 to 128.
rapid-commit	Indicates that the DHCPv6 PD client requests an IPv6 address prefix using the two-message exchange.	-
unicast-option	Indicates that the DHCPv6 PD client requests an IPv6 address prefix using the unicast mode.	-

Views

VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcpv6 client pd** command is used on the DHCPv6 PD client. After the **dhcpv6 client pd** is executed on the device that functions as a DHCPv6 PD client, the device requests an IPv6 address prefix in the DHCPv6 mode. The requested prefix is bound to the configured prefix name. You can specify the **hint** *ipv6-prefix/ipv6-prefix-length* parameter to set the required IPv6 address prefix and prefix length.

Prerequisites

1. IPv6 functions have been enabled globally using the **ipv6** command in the system view.
2. IPv6 functions have been enabled on interfaces using the **ipv6 enable** command in the interface view.
3. The IPv6 link-local address has been configured using the **ipv6 address auto link-local**, or **ipv6 address** *ipv6-address* **link-local** command in the interface view. Or the IPv6 global unicast IPv6 address has been configured using the **ipv6 address** { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } command in the interface view.

Configuration Precautions

When configuring the DHCPv6 PD client function, you cannot set *prefix-name* to **a**, **au**, **aut**, or **auto**. These prefix names cannot be applied to interfaces.

Example

Configure the DHCPv6 PD client to obtain IPv6 address prefix using stateless DHCPv6 address autoconfiguration on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address auto link-local
[HUAWEI-Vlanif100] dhcpv6 client pd example
```

Configure the DHCPv6 PD client to obtain IPv6 address prefix using stateless DHCPv6 address autoconfiguration on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto link-local
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 client pd example
```

6.11.7 dhcpv6 client renew

Function

The **dhcpv6 client renew** command updates the IPv6 address or prefix applied by a DHCPv6 client.

Format

dhcpv6 client renew

Parameters

None

Views

VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

The **dhcpv6 client renew** command applies to only the DHCP client and updates the IPv6 address or prefix applied by the DHCPv6 client.

Example

Manually update the applied IPv6 address.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 address auto dhcp
[HUAWEI-Vlanif100] dhcpv6 client renew
```

Manually update the applied IPv6 prefix.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] dhcpv6 client pd myprefix
[HUAWEI-Vlanif100] dhcpv6 client renew
```

6.11.8 dhcpv6 duid

Function

The **dhcpv6 duid** command configures a DUID for the DHCPv6 device.

By default, the device generates a DUID based on the link-layer (LL) address.

Format

dhcpv6 duid { **ll** | **llt** | *duid* }

Parameters

Parameter	Description	Value
ll	Configures the device to generate a DUID based on the link-layer address (MAC address).	-

Parameter	Description	Value
llt	Configures the device to generate a DUID based on the link-layer address (MAC address) plus time.	-
duid	Specifies the DUID of the device.	The value is a hexadecimal string with an even number (in the range of 8 to 28) of characters. The value contains only combinations of digits 0 to 9, uppercase letters A to F, and lowercase letters a to f.

Views

System view

Default Level

3: Management level

Usage Guidelines

A DUID identifies a DHCPv6 device. Each DHCPv6 server or client has a unique DUID. Servers use DUIDs to identify clients and clients use DUIDs to identify servers. When this command is run, a new DUID is stored in the :/dhcp/dhcp-duid.txt file of the storage device. You can run the **display dhcpv6 duid** command to check the DUID of the device.

Example

Configure the device to generate a DUID based on the link-layer address.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 duid ll
Warning: The DHCP unique identifier should be globally-unique and stable. Are you sure to change it? [Y/
N]y
```

6.11.9 dhcpv6 interface-id format

Function

The **dhcpv6 interface-id format** command configures the Interface-ID format in DHCPv6 packets.

The **undo dhcpv6 interface-id format** command restores the default Interface-ID format in DHCPv6 packets.

By default, the Interface-ID format in DHCPv6 packets is **default**.

Format

dhcpv6 interface-id format { **default** | **user-defined** *text* }

undo dhcpv6 interface-id format

Parameters

Parameter	Description	Value
default	Specifies the default Interface-ID format. The default Interface-ID format is %04svlan.%04cvlan.%mac:%portname. The values of the S-VLAN and C-VLAN are integers containing four characters. If the length is fewer than four characters, the value is prefixed with 0s. For example, if the outer VLAN value in the DHCPv6 packets received by the device is 11, the inner VLAN value is 22, the inbound interface is VLANIF100, and the device MAC address is 00e0-fc12-3456, the Interface-ID generated during the system parsing process is 0011.0022.00e0fc123456:vlanif100.	-
user-defined *text*	Specifies a user-defined format as the Interface-ID format. A user-defined format can be: ● Format defined by keywords: The Interface-ID is defined based on the keywords supported by the user-defined format. For example, if the name of the device to which the users are connected and the outer VLAN to which the users belong need to be recorded, the user-defined format can be %sysname %svlan. If the device name is HUAWEI and the S-VLAN is 100, the user location information recorded by the Interface-ID is HUAWEI 100. For description of the keywords supported by the user-defined format, see **Table 6-76**. ● Format defined by common character strings: The Interface-ID is directly defined as a character string. For example, if all users on an interface are located in the office building named N8, the Interface-ID can be directly defined as N8. ● Mixed format: The Interface-ID is defined by both the keywords and common character strings. For example, the Interface-ID can be defined as %sysname N8.	The value is a string of case-sensitive characters without spaces. The character string contains 1 to 251 characters, excluding the quotation marks.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Interface-ID records user access information such as the inbound interfaces of the DHCPv6 packets sent from the clients to the device. The device functions as a DHCPv6 relay or lightweight DHCPv6 relay agent (LDRA). When receiving the request packets sent from the DHCPv6 clients and forwarding the packets to the DHCPv6 server, the device can insert the Interface-ID to the packets to identify the DHCPv6 client location information. The location information can be used by the DHCPv6 server to assign IPv6 addresses and network parameters. You can run the **dhcpv6 interface-id format** command to configure the format of the Interface-ID inserted into DHCPv6 packets.

Table 6-76 Description of the keywords supported by the user-defined format

Keyword	Description
duid	Specifies the client ID, including information such as the client MAC address.
sysname	Specifies the device name of the client.
portname	Specifies the name of the inbound interface that receives the DHCPv6 packets sent from the client to the device.
porttype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is specified when the NAS interface is configured in certain scenarios.
iftype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is usually GE.
mac	Specifies the device MAC address.
slot	Specifies the slot number of the DHCPv6 packet sent from the client to the device.
subslot	Specifies the sub-slot number of the DHCPv6 packet sent from the client to the device.
port	Specifies the port number of the DHCPv6 packet sent from the client to the device.

Keyword	Description
svlan	Specifies the outer VLAN of the DHCPv6 packet sent by the client.
cvlan	Specifies the inner VLAN of the DHCPv6 packet sent by the client.
length	Specifies the total length of the keywords following the length keyword. The length of the length keyword is excluded.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Precautions

- The user-defined format content must be specified between the double quotation marks (""). For example, to configure the user-defined format content as **mac**, run the **dhcpv6 interface-id format user-defined "%mac"** command.
- Separators that cannot be digits must be added between the keywords in the user-defined format. Otherwise, the keywords cannot be parsed.
- The symbol % must be prefixed to the keywords in the user-defined format to differentiate them from common character strings. If a digit exists before the symbol % and keyword, the digit refers to the number of characters in the keyword.
- The self-defined content is encapsulated in ASCII format. In addition to the preceding precautions, note the following rules:
  - The symbol \ is an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents the character \.
  - An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
  - By default, the length of each keyword in an ASCII character string is the actual length of the keyword.

Example

Configure a user-defined format as the format of the Interface-ID in DHCPv6 packets and the device MAC address as the encapsulated content.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 interface-id format user-defined "%mac"
```

6.11.10 dhcpv6 interface-id insert enable

Function

The **dhcpv6 interface-id insert enable** command enables the function of adding the Interface-ID option in DHCPv6 packets.

The **undo dhcpv6 interface-id insert enable** command disables the function of adding the Interface-ID option in DHCPv6 packets.

By default, the function of adding the Interface-ID option in DHCPv6 packets is enabled.

NOTE

This command is supported only on the following models: S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S5720S-LI, S500, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731S-H, S5731-S, S5731S-S, S6735-S, S6720-EI, S6720S-EIS5732-H, S6730-H, S6730S-H, S6730-S, S6730S-S, S6720S-S.

Format

dhcpv6 interface-id insert enable

undo dhcpv6 interface-id insert enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Interface-ID option records user access information such as the inbound interface of the DHCPv6 Request packets sent from the clients to the device. The user access information can be used by the DHCPv6 server to assign IPv6 addresses and network parameters. When the device functions as a DHCPv6 relay agent or lightweight DHCPv6 relay agent (LDRA), and the device receives the Request packets sent from the DHCPv6 clients and forwards the packets to the DHCPv6 server, the device adds the Interface-ID option in the packets to identify location information of the DHCPv6 clients by default. If the DHCPv6 server interconnected to the device does not support the Interface-ID option, you can run the **undo dhcpv6 interface-id insert enable** command to configure the device not to add the Interface-ID option in DHCPv6 packets to flexibly control option information obtained by the DHCPv6 server.

Prerequisites

DHCP has been enabled globally using the **dhcp enable** command.

Example

Enable the function of adding the Interface-ID option in DHCPv6 packets on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 interface-id insert enable
```

6.11.11 dhcpv6 packet-rate

Function

The **dhcpv6 packet-rate** command enables rate limit of DHCPv6 messages and sets the rate threshold for DHCPv6 messages.

The **undo dhcpv6 packet-rate** command disables rate limit of DHCPv6 messages and deletes the rate threshold for DHCPv6 messages.

By default, rate limit of DHCPv6 messages is disabled.

Format

dhcpv6 packet-rate *packet-rate*

undo dhcpv6 packet-rate

Parameters

Parameter	Description	Value
packet-rate	Specifies the rate threshold for DHCPv6 messages.	The value is an integer that ranges from 0 to 400, in pps. If the value is 0, rate limit of DHCPv6 messages is disabled.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent clients from sending a large number of messages to attack the device, the device limits the rate of DHCPv6 messages. After the DHCPv6 packet rate limit is enabled and the rate threshold is configured using the **dhcpv6 packet-rate** command, the DHCPv6 packets are discarded when the packet rate exceeds the rate threshold.

Prerequisites

DHCP functions have been enabled globally using the **dhcp enable** command.

Precautions

When the value of *packet-rate* is greater than 200, you need to run the **car packet-type dhcpv6-reply cir** *cir-value* command to increase the maximum rate of DHCPv6 Reply messages.

Example

Enable rate limit of DHCPv6 messages and set the rate threshold for DHCPv6 messages to 200 pps.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 packet-rate 200
```

6.11.12 dhcpv6 packet-rate drop-alarm enable

Function

The **dhcpv6 packet-rate drop-alarm enable** command enables the alarm function for discarding DHCPv6 messages when the rate of DHCPv6 messages exceeds the limit.

The **undo dhcpv6 packet-rate drop-alarm enable** command disables the alarm function for discarding DHCPv6 messages when the rate of DHCPv6 messages exceeds the limit.

By default, the alarm function for discarding DHCPv6 messages is disabled when the rate of DHCPv6 messages exceeds the limit.

Format

dhcpv6 packet-rate drop-alarm enable

undo dhcpv6 packet-rate drop-alarm enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the alarm function of DHCPv6 messages discarded is enabled using the **dhcpv6 packet-rate drop-alarm enable** command, the device records alarm information when the number of DHCPv6 packets that are discarded exceeds the alarm threshold. The alarm threshold can be set using the **dhcpv6 packet-rate drop-alarm threshold** command.

Prerequisites

1. DHCP functions have been enabled globally using the **dhcp enable** command.
2. The DHCPv6 packet rate limit has been enabled using the **dhcpv6 packet-rate** command.

Example

Enable the alarm function for discarding DHCPv6 messages when the rate of DHCPv6 messages exceeds rate limit.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 packet-rate 200
[HUAWEI] dhcpv6 packet-rate drop-alarm enable
```

6.11.13 dhcpv6 packet-rate drop-alarm threshold

Function

The **dhcpv6 packet-rate drop-alarm threshold** command sets the alarm threshold for the number of DHCPv6 messages discarded when the rate of DHCPv6 messages exceeds the rate limit.

The **undo dhcpv6 packet-rate drop-alarm threshold** command restores the default alarm threshold of the number of DHCPv6 messages discarded.

By default, the alarm threshold is 100 packets when the alarm function of DHCPv6 messages discarded is enabled.

Format

dhcpv6 packet-rate drop-alarm threshold *threshold*

undo dhcpv6 packet-rate drop-alarm threshold

Parameters

Parameter	Description	Value
threshold	Specifies the alarm threshold for the number of DHCPv6 messages discarded when the rate of DHCPv6 messages exceeds the rate limit.	The value is an integer that ranges from 1 to 1000.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the alarm function of DHCPv6 messages discarded is enabled using the **dhcpv6 packet-rate drop-alarm enable** command, the device records alarm information when the number of DHCPv6 packets that are discarded exceeds the alarm threshold.

Prerequisites

1. The DHCP function has been enabled globally using the **dhcp enable** command.
2. The DHCPv6 packet rate limit has been enabled using the **dhcpv6 packet-rate** *packet-rate* command.
3. The alarm function for discarding DHCPv6 messages when the rate of DHCPv6 messages exceeds the limit has been enabled using the **dhcpv6 packet-rate drop-alarm enable** command.

Example

Configure the device to generate an alarm when the number of DHCPv6 messages discarded exceeds 150 packets.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 packet-rate 200
[HUAWEI] dhcpv6 packet-rate drop-alarm enable
[HUAWEI] dhcpv6 packet-rate drop-alarm threshold 150
```

6.11.14 dhcpv6 pool

Function

The **dhcpv6 pool** command creates an IPv6/IPv6 PD address pool or displays the IPv6/IPv6 PD address pool view.

The **undo dhcpv6 pool** command deletes the created IPv6/IPv6 PD address pool.

By default, no IPv6/IPv6 PD address pool is created.

Format

dhcpv6 pool *pool-name*

undo dhcpv6 pool *pool-name*

Parameters

Parameter	Description	Value
pool-name	Specifies the name of an IPv6/IPv6 PD address pool.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value contains digits, letters, underscores (_), and dots (.).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **dhcpv6 pool** command is used on DHCPv6/DHCPv6 PD servers. When configuring the DHCPv6/DHCPv6 PD server, run the **dhcpv6 pool** command to create an IPv6/IPv6 PD address pool for the DHCPv6/DHCPv6 PD server to assign IPv6 addresses or prefixes to DHCPv6/DHCPv6 PD clients.

Example

Create an IPv6 address pool **DHCPv6POOL**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool DHCPv6POOL
```

6.11.15 dhcpv6 relay advertise prefix-delegation route

Function

The **dhcpv6 relay advertise prefix-delegation route** command enables a DHCPv6 relay agent to forward routing information of DHCPv6 prefix delegation (DHCPv6 PD) terminals.

The **undo dhcpv6 relay advertise prefix-delegation route** command disables a DHCPv6 relay agent from forwarding routing information of DHCPv6 PD terminals.

By default, a DHCPv6 relay agent does not forward routing information of DHCPv6 PD terminals.

Format

dhcpv6 relay advertise prefix-delegation route

undo dhcpv6 relay advertise prefix-delegation route

Parameters

None

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcpv6 relay advertise prefix-delegation route** command is used on DHCPv6 relay agents. DHCPv6 PD terminals cannot advertise IPv6 routes. This command enables a DHCPv6 relay agent to add routes of DHCPv6 PD terminals to the routing table when DHCPv6 PD terminals apply for IP addresses from the DHCPv6 server through the DHCPv6 relay agent. The DHCPv6 relay agent then forwards the routing information to the DHCPv6 server.

Prerequisites

The DHCPv6 relay function has been enabled on the interface using the **dhcpv6 relay** { **destination** *ipv6-address* | **interface** *interface-type interface-number* } or **dhcpv6 relay server-select** *group-name* command.

Precautions

This command takes effect only for the first-hop DHCPv6 relay agent connected to DHCPv6 PD terminals.

Example

Enable VLANIF10 to forward routing information of DHCPv6 PD terminals.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] dhcpv6 relay destination FC00::1:3
[HUAWEI-Vlanif10] dhcpv6 relay advertise prefix-delegation route
```

6.11.16 dhcpv6 relay prefix-delegation route

Function

The **dhcpv6 relay prefix-delegation route** command saves routing information forwarded by a relay agent into a specified file.

The **undo dhcpv6 relay prefix-delegation route** command cancels the configuration.

By default, routing information forwarded by a relay agent into a specified file is not saved.

Format

dhcpv6 relay prefix-delegation route autosave *file-name*

undo dhcpv6 relay prefix-delegation route autosave

Parameters

Parameter	Description	Value
autosave	Backs up routing information learned from DHCPv6 PD terminals to the flash memory.	-

Parameter	Description	Value
file-name	Specifies the path and file name of the file where routing information of DHCPv6 PD terminals is to be saved, for example, flash:/*.pdr.	The value is a string of 1 to 51 case-insensitive characters and is a combination of digits, letters, and characters. It cannot contain spaces. **NOTE** The file name cannot contain any less than sign (<), greater than sign (>), question mark (?), asterisk (*), comma (,), back quote (`), slash (/), backslash (\), single quotation mark ('), colon (:), or double quotation mark ("), and the left square bracket ([) and right square bracket (]) cannot exist in pairs.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcpv6 relay prefix-delegation route** command is used on DHCPv6 relay agents. This command saves routing information forwarded by a relay agent into a specified file.

After this command is run, the system immediately saves routing information, and then saves routing information again every two hours. The interval at which the system saves routing information cannot be set.

Prerequisites

The DHCP function has been enabled using the **dhcp enable** command in the system view.

Example

Save routing information forwarded by a relay agent into a specified file.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 relay prefix-delegation route autosave flash:/dhcpv6-pd.pdr
Info: The operation may take a few seconds, Please wait for a moment.done.
```

6.11.17 dhcpv6 relay destination

Function

The **dhcpv6 relay destination** command enables the DHCPv6 relay function on interfaces and configures the IPv6 address of the DHCPv6 server or next-hop relay agent.

The **undo dhcpv6 relay destination** command disables the DHCPv6 relay function on an interface.

By default, the DHCPv6 relay function is disabled on an interface.

Format

dhcpv6 relay { **destination** *ipv6-address* | **interface** *interface-type interface-number* }

undo dhcpv6 relay { **destination** *ipv6-address* | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
ipv6-address	Specifies the destination address of relay messages, which can be the IPv6 address of the DHCPv6 server or next hop relay agent.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface *interface-type interface-number*	Specifies the type and number of the outbound interface of relay messages. The specified interface can only be a Layer 2 interface.	-

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a client applies to a DHCPv6 server on a different network segment for an IPv6 address, you need to deploy a relay agent between the client and the DHCPv6 server. In this manner, the relay agent transmits DHCPv6 messages exchanged between the client and the DHCPv6 server.

You can run the **dhcpv6 relay destination** *ipv6-address* command to enable the DHCPv6 relay function on an interface.

When the client and the server are in the same VLAN, you can run the **dhcpv6 relay interface** *interface-type interface-number* command to specify the outbound interface of relay messages.

Prerequisites

The DHCP function has been enabled using the **dhcp enable** command in the system view.

Precautions

- When you run the **dhcpv6 relay interface** *interface-type interface-number* command in the VLANIF interface view to specify the outbound interface of relay messages, the specified interface can only be a Layer 2 interface. If the specified outbound interface is not in the VLAN corresponding to the VLANIF interface, add the interface to the VLAN.
- When both the **dhcpv6 relay destination** *ipv6-address* and **dhcpv6 relay interface** *interface-type interface-number* commands are configured, relay messages are preferentially sent to the configured IPv6 address based on routes.

Example

Enable the DHCPv6 relay function on VLANIF100 and set the destination address of relay messages to fc00:1::1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] dhcpv6 relay destination fc00:1::1
```

Enable the DHCPv6 relay function on GE0/0/1 and set the destination address of relay messages to fc00:1::1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 relay destination fc00:1::1
```

6.11.18 dhcpv6 relay server-select

Function

The **dhcpv6 relay server-select** command configures a DHCPv6 server group for a DHCPv6 relay agent.

The **undo dhcpv6 relay server-select** command deletes a DHCPv6 server group for a DHCPv6 relay agent.

By default, no DHCPv6 server group is configured.

Format

dhcpv6 relay server-select *group-name*

undo dhcpv6 relay server-select

Parameters

Parameter	Description	Value
group-name	Specifies the name of a DHCPv6 server group.	The value is a string of 1 to 32 case-sensitive characters without spaces.

Views

VLANIF interface view, VBDIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The **dhcpv6 relay server-select** command is used on DHCPv6 relay agents. When a DHCPv6 client sends DHCPv6 Request packets to a DHCPv6 server through a DHCPv6 relay agent, you can run the **dhcp relay server-select** command to specify a DHCPv6 server group for the DHCPv6 relay agent and configure the IPv6 address of the DHCPv6 server.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.

2. A DHCPv6 server group has been created using the **dhcpv6 server group** command.
3. The IPv6 function has been enabled using the **ipv6 enable** command in the interface view.

Precautions

- Each DHCPv6 server group can be bound to multiple interfaces, but each interface can only be bound to one DHCPv6 server group.
- IP addresses of servers in a DHCPv6 server group cannot be on the same network segment with IP addresses of interfaces on the DHCPv6 relay agent.
- If you run the **dhcpv6 relay server-select** command multiple times in the same interface view, only the latest configuration takes effect.

Example

Configure the DHCPv6 server group named group 1 for the DHCPv6 relay agent on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 server group group1
[HUAWEI-dhcpv6-server-group-group1] dhcpv6-server fc00:1::1
[HUAWEI-dhcpv6-server-group-group1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] dhcpv6 relay server-select group1
```

Configure the DHCPv6 server group named group 1 for the DHCPv6 relay agent on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 server group group1
[HUAWEI-dhcpv6-server-group-group1] dhcpv6-server fc00:1::1
[HUAWEI-dhcpv6-server-group-group1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 relay server-select group1
```

6.11.19 dhcpv6 relay source-interface

Function

The **dhcpv6 relay source-interface** command configures the IPv6 address of an interface as the source IPv6 address of packets.

The **undo dhcpv6 relay source-interface** command restores the default setting.

By default, the IPv6 address of an interface is not configured as the source IPv6 address of packets.

Format

dhcpv6 relay source-interface *interface-type interface-number*

undo dhcpv6 relay source-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the interface type and number. - *interface-type*: specifies the interface type. Currently, only loopback interfaces are supported. - *interface-number*: specifies the interface number.	-

Views

System view, VBDIF interface view, VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, MultiGE sub-interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When forwarding packets from a DHCPv6 client, a DHCPv6 relay agent uses the IPv6 address of the packet inbound interface as the source IPv6 address of the packets. Therefore, you need to configure an IPv6 address for each interface on the DHCPv6 relay agent. As a result, the configuration is complex and IPv6 addresses may be wasted. You can run the **dhcpv6 relay source-interface** *interface-type interface-number* command on the DHCPv6 relay agent to specify the IPv6 address of the loopback interface as the source IPv6 address of the DHCPv6 relayed packets, simplifying the configuration and saving IPv6 addresses.

In addition, VBDIF interfaces functioning as gateways on distributed gateway devices use the same IPv6 address. If Layer 3 VXLAN gateways are distributed gateways and the IPv6 address is used to communicate with the server, the response packets from the server are forwarded to the incorrect distributed gateways (devices that do not send DHCPv6 request packets). To resolve this issue, you need to run the **dhcpv6 relay source-interface** *interface-type interface-number* command on each distributed gateway to specify the IPv6 address of the loopback interface as the source IPv6 address of the DHCPv6 relayed packets for ensuring that response packets from the server can be forwarded to the correct distributed gateways.

Prerequisites

Before you run this command in the system view, the first four conditions must be met. Before you run this command in the interface view, all the following conditions must be met.

- The device has been enabled to forward IPv6 unicast packets using the **ipv6** command.
- A loopback interface has been created using the **interface loopback** *loopback-number* command.
- An IPv6 address has been configured for the loopback interface using the **ipv6 address** command.
- DHCP has been enabled globally using the **dhcp enable** command.
- In the interface view:
  - The IPv6 function has been enabled on the interface using the **ipv6 enable** command.
  - The DHCPv6 relay function has been enabled on the interface using the **dhcpv6 relay** { **destination** *ipv6-address* | **interface** *interface-type interface-number* } or **dhcpv6 relay server-select** *group-name* command.

Precautions

If an IPv6 address is configured for the inbound interface that receives packets from DHCPv6 clients, the IPv6 address is used as the source IPv6 address of packets.

This command takes effect on all interfaces of the device if it is configured in the system view, and takes effect only on an interface if it is configured in the interface view. If this command is configured in both the interface view and system view, the configuration in the interface view takes effect.

If the DHCPv6 relay agent connects to the DHCPv6 server over a VPN network, you need to run the **ip binding vpn-instance** command to bind the loopback interface specified in the **dhcpv6 relay source-interface** command to the corresponding VPN instance.

Example

In the system view, configure the IPv6 address of a loopback interface as the source IPv6 address of packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface loopback 5
[HUAWEI-LoopBack5] ipv6 enable
[HUAWEI-LoopBack5] ipv6 address fc01:1::1/128
[HUAWEI-LoopBack5] quit
[HUAWEI] dhcp enable
[HUAWEI] dhcpv6 relay source-interface loopback 5
```

On VLANIF100, configure the IPv6 address of a loopback interface as the source IPv6 address of packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface loopback 5
[HUAWEI-LoopBack5] ipv6 enable
[HUAWEI-LoopBack5] ipv6 address fc01:1::1/128
[HUAWEI-LoopBack5] quit
[HUAWEI] dhcp enable
```

```
[HUAWEI] interface Vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] dhcpv6 relay destination fc00:1::1
[HUAWEI-Vlanif100] dhcpv6 relay source-interface loopback 5
```

On GE0/0/1, configure the IPv6 address of a loopback interface as the source IPv6 address of packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface loopback 5
[HUAWEI-LoopBack5] ipv6 enable
[HUAWEI-LoopBack5] ipv6 address fc01:1::1/128
[HUAWEI-LoopBack5] quit
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 relay destination fc00:1::1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 relay source-interface loopback 5
```

6.11.20 dhcpv6 relay option79 insert enable

Function

The **dhcpv6 relay option79 insert enable** command inserts the Option79 field into DHCPv6 messages.

The **undo dhcpv6 relay option79 insert enable** command restores the default setting.

By default, the Option79 field is not inserted into DHCPv6 messages.

Format

dhcpv6 relay option79 insert enable

undo dhcpv6 relay option79 insert enable

Parameters

None

Views

System view, VBDIF interface view, VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Application Scenario

The MAC address is used to identify the DHCPv4 client on the IPv4 network and the DUID is used to identify the DHCPv6 client on the IPv6 network. In an IPv4 and IPv6 dual-stack service deployment scenario, the administrator wants to establish connections between clients' MAC addresses and IPv4 or IPv6 addresses obtained by the clients and perform unified management over dual-stack clients based on the MAC address. However, the MAC address of the DHCPv6 client cannot be identified using the DUID currently.

As defined in RFC, a DHCPv6 relay agent can fill the link address and link type of a client into the Option79 field. When a device functions as a DHCPv6 relay agent, you can run the **dhcpv6 relay option79 insert enable** command to insert the Option79 field into DHCPv6 messages for enabling the DHCPv6 server to obtain the clients' MAC addresses. When this command is run and the DHCPv6 relay agent receives a Request message from a client, it inserts the Option79 field into the Request message and forwards the message to the DHCPv6 server. The DHCPv6 server then obtains the MAC address of the client by parsing the Option79 field.

Prerequisites

- Before the **dhcpv6 relay option79 insert enable** command is configured, DHCP has been globally enabled using the **dhcp enable** command in the system view and IPv6 has been globally enabled using the **ipv6** command.
- Before the **dhcpv6 relay option79 insert enable** command is configured in the interface view, the DHCPv6 relay function has been enabled in the interface view.

Precautions

- Only the first-hop DHCPv6 relay agent supports this function.
- This function takes effect for all interfaces if it is configured in the system view, and takes effect for a specified interface if it is configured in the view of the interface. If this command is configured in both the interface view and system view, the configuration in the interface view takes effect.

Example

Insert the Option79 option into DHCPv6 messages in the system view.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] dhcpv6 relay option79 insert enable
```

Insert the Option79 field into DHCPv6 messages in the interface view.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] dhcpv6 relay destination fc00:1::1
[HUAWEI-Vlanif100] dhcpv6 relay option79 insert enable
```

6.11.21 dhcpv6 remote-id format

Function

The **dhcpv6 remote-id format** command sets the format of the Remote-ID in DHCPv6 messages.

The **undo dhcpv6 remote-id format** command restores the default format of the Remote-ID in DHCPv6 messages.

By default, the default format of the Remote-ID in DHCPv6 messages is used.

Format

dhcpv6 remote-id format { **default** | **user-defined** *text* }

undo dhcpv6 remote-id format

Parameters

Parameter	Description	Value
default	Indicates to adopt the default format of the remote ID. The default format of the remote ID is %duid %portname:%04svlan.%04cvlan, where the values of the outer VLAN ID and inner VLAN ID are integers and composed of four characters. If the length is shorter than four characters, 0s are prefixed to the value. For example, if the outer VLAN value in the DHCPv6 packets received by the device is 11, the inner VLAN value is 22, the inbound interface is GE0/0/1, and the client DUID is 0003000180FB063545B3, the Remote-ID option generated during the system parsing process is 0003000180FB063545B3 GigabitEthernet 0/0/1:0011.0022.	-

Parameter	Description	Value
user-defined *text*	Specifies a user-defined format as the Remote-ID format. A user-defined format can be: - Format defined by keywords: The Remote-ID is defined based on the keywords supported by the user-defined format. For example, if the name of the device to which the users are connected and the outer VLAN to which the users belong need to be recorded, the user-defined format can be %sysname %svlan. If the device name is HUAWEI and the S-VLAN is 100, the user location information recorded by the Remote-ID is HUAWEI 100. For description of the keywords supported by the user-defined format, see **Table 6-77**. - Format defined by common character strings: The Remote-ID is directly defined as a character string. For example, if all users on an interface are located in the office building named N8, the Remote-ID can be directly defined as N8. - Mixed format: The Remote-ID is defined by both the keywords and common character strings. For	The value is a string of 3 to 247 case-sensitive characters with spaces.

Parameter	Description	Value
	example, the Remote-ID can be defined as %sysname N8.	

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The Remote-ID records user access information such as the DUID of the DHCPv6 packets sent from the clients to the device. The device functions as a DHCPv6 relay or lightweight DHCPv6 relay agent (LDRA). When receiving the request packets sent from the DHCPv6 clients and forwarding the packets to the DHCPv6 server, the device can insert the Remote-ID to the packets to identify the DHCPv6 client location information. The location information can be used by the DHCPv6 server to assign IPv6 addresses and network parameters. You can run the **dhcpv6 remote-id format** command to configure the format of the Remote-ID inserted into DHCPv6 packets.

Table 6-77 Description of the keywords supported by the user-defined format

Keyword	Description
duid	Specifies the client ID, including information such as the client MAC address.
sysname	Specifies the device name of the client.
portname	Specifies the name of the inbound interface that receives the DHCPv6 packets sent from the client to the device.
porttype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is specified when the NAS interface is configured in certain scenarios.
iftype	Specifies the type of the inbound interface that receives the DHCPv6 packets sent from the client to the device. The interface type is usually GE.

Keyword	Description
mac	Specifies the device MAC address.
slot	Specifies the slot number of the DHCPv6 packet sent from the client to the device.
subslot	Specifies the sub-slot number of the DHCPv6 packet sent from the client to the device.
port	Specifies the port number of the DHCPv6 packet sent from the client to the device.
svlan	Specifies the outer VLAN of the DHCPv6 packet sent by the client.
cvlan	Specifies the inner VLAN of the DHCPv6 packet sent by the client.
length	Specifies the total length of the keywords following the length keyword. The length of the length keyword is excluded.

Prerequisites

The DHCP function has been enabled using the **dhcp enable** command in the system view.

Follow-up Procedure

When the device functions as a DHCPv6 relay, you must run the **dhcpv6 remote-id insert enable** or **dhcpv6 remote-id rebuild enable** command to enable the function of inserting the Remote-ID into DHCPv6 relay packets after running the **dhcpv6 remote-id format** command to configure the Remote-ID format in DHCPv6 packets.

NOTE

When the device functions as an LDRA, the Remote-ID is inserted into DHCPv6 relay packets by default and the function does not need to be enabled.

Precautions

- The user-defined format content must be specified between the double quotation marks (""). For example, to configure the user-defined format content as **mac**, run the **dhcpv6 interface-id format user-defined "%mac"** command.
- Separators that cannot be digits must be added between the keywords in the user-defined format. Otherwise, the keywords cannot be parsed.
- The symbol % must be prefixed to the keywords in the user-defined format to differentiate them from common character strings. If a digit exists before the symbol % and keyword, the digit refers to the number of characters in the keyword.
- The self-defined content is encapsulated in ASCII format. In addition to the preceding precautions, note the following rules:

- The symbol \ is an escape character. The symbols %, \, and [] following the escape character indicate themselves. For example, \\ represents the character \.
- An ASCII character string can contain Arabic numerals, uppercase letters, lowercase letters, and the following symbols: ! @ # $ % ^ & * ( ) _ + | - = \ [ ] { } ; : ' " / . , < > `.
- By default, the length of each keyword in an ASCII character string is the actual length of the keyword.

Example

Set the customized format for the remote ID carried in DHCPv6 messages and encapsulate the MAC address of the device into the remote ID.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 remote-id format user-defined "%mac"
```

6.11.22 dhcpv6 remote-id insert enable

Function

Using the **dhcpv6 remote-id insert enable** command, you can enable the function of appending the remote ID to DHCPv6 relay messages.

Using the **undo dhcpv6 remote-id insert enable** command, you can disable the function of appending the remote ID to DHCPv6 relay messages.

By default, the function of appending the remote ID to DHCPv6 relay messages is disabled.

Format

dhcpv6 remote-id insert enable

undo dhcpv6 remote-id insert enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The remote ID carries information about a client and identifies a client. The DHCPv6 server can make decisions about address allocation, parameter setting, and prefix agent according to the remote ID. The remote ID is defined by the vendor. Usually, the remote ID carries the phone number of the caller in dialing, user name, IP address of the peer in a point-to-point connection, and access interface.

Prerequisite

DHCP has been enabled globally using the **dhcp enable** command.

Example

Enable the function of appending the remote ID to DHCPv6 relay messages on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 remote-id insert enable
```

6.11.23 dhcpv6 remote-id rebuild enable

Function

Using the **dhcpv6 remote-id rebuild enable** command, you can enable the function of appending the remote ID to DHCPv6 relay messages.

Using the **undo dhcpv6 remote-id rebuild enable** command, you can disable the function of appending the remote ID to DHCPv6 relay messages.

By default, the function of appending the remote ID to DHCPv6 relay messages is disabled.

Format

dhcpv6 remote-id rebuild enable

undo dhcpv6 remote-id rebuild enable

Parameters

None

Views

Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, MultiGE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

The remote ID carries information about a client and identifies a client. The DHCPv6 server can make decisions about address allocation, parameter setting, prefix agent according to the remote ID. The format of the remote ID is defined by the vendor. Usually, the remote ID carries the phone number and user name in a dial-up connection, or the peer IP address and access interface in a point-to-point connection.

Before running the **dhcpv6 remote-id rebuild enable** command, you must run the **dhcp enable** command to enable DHCP globally.

Example

Enable the function of appending the remote ID to DHCPv6 relay messages on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 remote-id rebuild enable
```

6.11.24 dhcpv6 server (system view)

Function

The **dhcpv6 server** command enables the DHCPv6 server or DHCPv6 PD server function in the system view.

The **undo dhcpv6 server** command disables the DHCPv6 server or DHCPv6 PD server function in the system view.

By default, the DHCPv6 server or DHCPv6 PD server function is disabled in the system view.

Format

dhcpv6 server { **allow-hint** | **preference** *preference-value* | **rapid-commit** | **unicast** } *

undo dhcpv6 server { **allow-hint** | **preference** | **rapid-commit** | **unicast** } *

Parameters

Parameter	Description	Value
allow-hint	Specifies the DHCPv6 server to allocate addresses, prefixes, and prefix lengths based on the DHCPv6 client requests. If the **allow-hint** parameter is specified, the server preferentially allocates addresses, prefixes, and prefix lengths based on the client requests. If the address, prefix, and prefix length requested by a client are not within the address pool or have been allocated to another client, the server ignores the client request and allocates another available address, prefix, and prefix length to the client.	-
preference *preference-value*	Specifies the server priority in the Advertise packet sent by the device. The DHCPv6 client selects the server with the highest priority based on the server priority in the Advertise packet to assign IPv6 addresses or prefixes.	The value is an integer that ranges from 0 to 255. By default, the value is 0. A larger value indicates a higher server priority.
rapid-commit	Indicates that the device supports fast address or prefix assignment, that is, two-message exchange.	-
unicast	Specifies unicast communication between the client and server during the address lease renewal process.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device functions as a DHCPv6 or DHCPv6 PD server, the DHCPv6 or DHCPv6 PD server function can be enabled in the system view or interface view. If the DHCPv6 or DHCPv6 PD server function is enabled in the interface view, the configuration information only takes effect on the interfaces and only one IPv6 address pool can be specified on an interface.

The DHCPv6 or DHCPv6 PD server and DHCPv6 clients are in different link scopes and a DHCPv6 relay exists. If the DHCPv6 or DHCPv6 PD server function is enabled in the interface view, configuration parameters such as IPv6 addresses or prefixes are assigned only to the clients in one network segment connected to the DHCPv6 relay, because only one IPv6 address pool can be specified on an interface. If configuration parameters such as IPv6 addresses or prefixes need to be assigned to the DHCPv6 clients in multiple network segments through the DHCPv6 relay, enable the DHCPv6 or DHCPv6 PD server function in the system view.

The configuration method of enabling the DHCPv6 or DHCPv6 PD server function in the interface view is affected by the physical interface status. If the interface status is Down, the DHCPv6 or DHCPv6 PD server cannot successfully assign network configuration parameters to clients through the DHCPv6 relay. When the DHCPv6 or DHCPv6 PD server function is enabled in the system view and there are multiple reachable routes between the DHCPv6 relay and DHCPv6 or DHCPv6 PD server, configuration parameters such as IPv6 addresses can be assigned to clients through the DHCPv6 relay as long as one route between the DHCPv6 relay and DHCPv6 or DHCPv6 PD server is reachable. This improves reliability of the configuration information obtained by the clients. In addition, no configuration is required on the interface, which reduces the administrator's maintenance workload.

When functioning as a DHCPv6 or DHCPv6 PD server, the device may be configured with multiple IPv6 address pools. After receiving the DHCPv6 request packets, the DHCPv6 or DHCPv6 PD server chooses the IPv6 address pool based on the following rules:

- When the device functions as the DHCPv6 server:
  - If a relay exists, the server chooses the address pool that belongs to the same link scope with the configured network prefix (using the **link-address** command or **address prefix**) based on the first link-address field that is not 0. The link-address field identifies the link scope of the DHCPv6 clients.
  - When the DHCPv6 server is enabled in the system view, the DHCPv6 server cannot assign network parameters (such as IPv6 addresses, DNS, NIS, and SNTP servers) to clients if no relay exists. To enable the DHCPv6

server to assign network parameters, enable the DHCPv6 server function in the interface view.

- When the device functions as the DHCPv6 PD server:
  - If a relay exists, choose the address pool in the same link scope with the configured network prefix (using the **link-address** command) based on the first link-address field that is not 0. The link-address field identifies the link scope of the DHCPv6 clients.
  - If no relay exists, the DHCPv6 PD server function cannot be enabled in the system view and can be enabled in the interface view, using the **dhcpv6 server** command.

Prerequisites

1. The DHCP function has been enabled globally using the **dhcp enable** command.
2. The IPv6 function has been enabled globally using the **ipv6** command.

Example

Enable the DHCPv6 server function in the system view, and configure the server priority to 255.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] dhcpv6 server preference 255
```

6.11.25 dhcpv6 server (interface view)

Function

The **dhcpv6 server** command enables the DHCPv6 server function on an interface.

The **undo dhcpv6 server** command disables the DHCPv6 server function on an interface.

By default, the DHCPv6 server function on an interface is disabled.

Format

dhcpv6 server *pool-name* [**allow-hint** | **preference** *preference-value* | **rapid-commit** | **unicast**] *

undo dhcpv6 server

Parameters

Parameter	Description	Value
pool-name	Specifies the name of the DHCPv6 address pool configured on an interface.	The value is a string of 1 to 31 case-sensitive characters without spaces. The value can contain digits, letters, underscores (_), and periods (.).
allow-hint	Specifies the DHCPv6 server to allocate addresses, prefixes, and prefix lengths based on the DHCPv6 client requests. If the **allow-hint** parameter is specified, the server preferentially allocates addresses, prefixes, and prefix lengths based on the client requests. If the address, prefix, and prefix length requested by a client are not within the address pool or have been allocated to another client, the server ignores the client request and allocates another available address, prefix, and prefix length to the client.	-
preference *preference-value*	Specifies the priority of the DHCPv6 server carried in the Advertise message sent by the DHCPv6 server. The DHCPv6 client chooses to obtain an IPv6 address or prefix from the DHCPv6 server with the highest priority based on the server priority carried in the Advertise message.	The value is an integer that ranges from 0 to 255. The default value is 0. A larger value indicates a higher priority of the DHCPv6 server.
rapid-commit	Configures the DHCPv6 server to support fast address prefix allocation.	-

Parameter	Description	Value
unicast	Specifies the unicast communication between the DHCPv6 client and DHCPv6 server during IPv6 address lease.	-

Views

VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dhcpv6 server** command is used on DHCP servers. If an IPv6 address pool is referenced by an interface, the interface assigns addresses or address prefixes in the address pool to clients after receiving the DHCPv6 Request messages.

Prerequisites

- DHCP functions have been enabled globally using the **dhcp enable** command.
- IPv6 functions have been enabled globally using the **ipv6** command.
- IPv6 functions have been enabled using the **ipv6 enable** command in the interface view.

Precautions

- The DHCPv6 client function, DHCPv6 relay function, and DHCPv6 server function cannot be enabled on the same interface simultaneously.
- Only one ipv6 address pool can be referenced by an interface.
- If the ipv6 address pool referenced by the interface does not exist, the DHCPv6 server function does not take effect.

Example

Associate DHCPv6 address pool Pool1 with VLANIF100 and set the priority of pool1 to 255.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
```

```
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] dhcpv6 server pool1 preference 255
```

Associate DHCPv6 address pool pool1 with GE0/0/1 and set the priority of Pool1 to 255.

```
<HUAWEI> system-view
[HUAWEI] dhcp enable
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] dhcpv6 server pool1 preference 255
```

6.11.26 dhcpv6-server (DHCPv6 server group view)

Function

The **dhcpv6-server** command adds a DHCPv6 server or a next-hop relay agent to a DHCPv6 server group.

The **undo dhcpv6-server** command deletes a DHCPv6 server or a next-hop relay agent that is configured in a DHCPv6 server group.

By default, no DHCPv6 server or next-hop relay agent is configured in a DHCPv6 server group.

Format

dhcpv6-server *ipv6-address* [**interface** *interface-type interface-number*]

undo dhcpv6-server *ipv6-address* [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of a DHCPv6 server or a next-hop relay agent.	The 128-bit IPv6 address is divided into eight groups. Each group contains four hexadecimal digits. The format is X:X:X:X:X:X:X:X.
interface *interface-type interface-number*	Specifies the type and number of an outbound interface for DHCPv6 packets. • *interface-type* specifies the type of an interface. • *interface-number* specifies the number of an interface.	-

Views

DHCPv6 server group view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The **dhcpv6-server** command is used on DHCPv6 relay agents. To ensure that the DHCPv6 relay agent can send DHCPv6 packets to multiple DHCPv6 servers, you can configure multiple DHCPv6 servers in a DHCPv6 server group. Multiple DHCPv6 servers can allocate IPv6 addresses and other network configuration information to DHCPv6 clients through the DHCPv6 relay agent.

A DHCPv6 client and a DHCPv6 server can have multiple DHCPv6 relay agents connected in between. A device functions as a DHCPv6 relay agent. If the device is connected to a DHCPv6 server, you need to specify the IPv6 address for the DHCPv6 server. If the device is connected to a next-hop relay agent, you need to specify the IPv6 address for the next-hop relay agent and specify the IPv6 address of the remote DHCPv6 server or the next-hop relay agent on the next-hop relay agent.

Prerequisites

1. The DHCP function has been enabled using the **dhcp enable** command in the system view.
2. A DHCPv6 server group has been created using the **dhcpv6 server group** command.

Precautions

If a DHCPv6 relay agent is connected to multiple DHCPv6 servers or next-hop relay agents, repeat this step. A maximum of 20 DHCPv6 servers or next-hop relay agents can be connected to the device.

Example

Add the DHCPv6 server at fc00:1::1 to the DHCPv6 server group named dhcp-srv1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 server group dhcp-srv1
[HUAWEI-dhcpv6-server-group-dhcp-srv1] dhcpv6-server fc00:1::1
```

6.11.27 dhcpv6 server database

Function

The **dhcpv6 server database** command enables the device to save DHCPv6 data to storage devices.

The **undo dhcpv6 server database** command disables the device from saving DHCPv6 data to storage devices.

By default, the device is disabled from saving DHCPv6 data to storage devices.

Format

dhcpv6 server database *url* [**write-delay** *interval*]

undo dhcpv6 server database *url*

Parameters

Parameter	Description	Value
url	Specifies the path and name of the file that data is saved to.	The value is a string of 1 to 63 case-insensitive characters without spaces.
write-delay *interval*	Specifies the interval at which DHCPv6 data is saved.	The value is an integer ranging from 300 to 86400, in seconds. The default value is 86400 seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device functions as a DHCPv6 or DHCPv6 PD server, run the **dhcpv6 server database** command to enable the device to save DHCPv6 data to storage devices. This avoids data loss caused by device faults. DHCPv6 data includes the last data recording time, address pool name, client DUID, IAID, address and prefix bound to the client DUID and IAID, conflicted address, and conflict detection time.

The device automatically saves current DHCPv6 data at the specified interval, and previous data files are overwritten. The interval can be set using the **write-delay** *interval* parameter.

Precautions

If the DHCPv6 client requests for lease renewal when the device (functioning as the DHCPv6 server) restarts, the device cannot receive the renewal request and the client fails to renew the lease.

Example

Configure the device to save DHCP data to the path flash:/dhcpv6.tbl and set the interval for saving data to 36000s.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 server database flash:/dhcpv6.tbl write-delay 36000
```

6.11.28 dhcpv6 server group

Function

The **dhcpv6 server group** command creates a DHCPv6 server group and enters the DHCPv6 server group view, or enters the view of a DHCPv6 server group that has been created.

The **undo dhcpv6 server group** command deletes a created DHCPv6 server group.

By default, no DHCPv6 server group is created.

Format

dhcpv6 server group *group-name*

undo dhcpv6 server group *group-name*

Parameters

Parameter	Description	Value
group-name	Specifies the name of a DHCPv6 server group.	The value is a string of 1 to 32 case-sensitive characters without spaces. It can contain digits, letters, and special characters such as underscores (_), hyphens (-), and periods (.). It cannot be set to **-** or **--**.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Use Scenario

The **dhcpv6 server group** command is used on DHCPv6 relay agents. Generally, a DHCPv6 relay agent serves multiple DHCPv6 servers. You can run the **dhcpv6**

server group command to create a DHCPv6 server group to manage all the DHCPv6 servers that share the DHCPv6 relay agent. The DHCPv6 server group allocates IPv6 addresses and other network configuration information to users connected to the DHCPv6 relay agent.

Follow-up Procedure

- After a DHCPv6 server group is configured, run the **dhcpv6-server** command to add DHCPv6 servers to the DHCPv6 server group.
- When configuring IP address for DHCPv6 servers, run the **dhcpv6 relay server-select** command on an interface to select the DHCPv6 server group of the DHCPv6 relay agent.

Precautions

A maximum of 32 DHCPv6 server groups can be configured on the device. A maximum of 20 DHCPv6 servers can be added to a DHCPv6 server group.

Example

Create a DHCPv6 server group named DHCPv6-srv1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 server group DHCPv6-srv1
[HUAWEI-dhcpv6-server-group-DHCPv6-srv1]
```

6.11.29 display dhcpv6 client

Function

The **display dhcpv6 client** command displays DHCPv6 client information.

Format

display dhcpv6 client [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about the DHCPv6 client with the specified interface type and number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display dhcpv6 client** command on the DHCPv6 client to check the address that is applied.

Example

Display the DHCPv6 client information.

```
<HUAWEI> display dhcpv6 client
Vlanif10 is in stateful DHCPv6 client mode.
Stateful DHCPv6 client is in BOUND state.
Preferred server DUID   : 000300060819A6CDA894
  Reachable via address : FE80::A19:A6FF:FECD:A897
IA NA IA ID 0x00000051 T1 43200 T2 69120
  Obtained     : 2018-04-18 15:08:49
  Renews       : 2018-04-18 15:09:19
  Rebinds      : 2018-04-18 15:09:37
  Address      : FC00:3::2
    Lifetime valid 120 seconds, preferred 60 seconds
    Expires at 2018-04-18 15:10:49(99 seconds left)
DNS server     : FC00:4::1
```

Table 6-78 Description of the display dhcpv6 client command output

Item	Description
Vlanif10 is in stateful DHCPv6 client mode.	The VLANIF10 interface is in stateful DHCPv6 client mode.
Stateful DHCPv6 client is in BOUND state.	The DHCPv6 client is in BOUND state.
Preferred server DUID	DUID of a DHCPv6 server.
Reachable via address	Source IPv6 address from which a DHCPv6 client receives packets.
Obtained	Time at which the DHCPv6 client obtains an IPv6 address.
Renews	Time (T1) at which the DHCPv6 client updates the lease extension time.
Rebinds	Time (T2) at which the DHCPv6 client rebinds the lease extension time.
Address	IPv6 address that the DHCPv6 client obtains.
Lifetime valid 120 seconds, preferred 60 seconds	The valid lifetime is 120 seconds and preferred lifetime is 60 seconds.
Expires at 2018-04-18 15:10:49(99 seconds left)	The address used by the DHCPv6 client will expire at 2018-04-18 15:10:49, and there are 99 seconds left.
DNS server	IPv6 address of the DNS server that the DHCPv6 client obtains.

6.11.30 display dhcpv6 client prefix

Function

The **display dhcpv6 client prefix** command displays the IPv6 address prefix obtained by the device.

Format

display dhcpv6 client prefix [**name** *prefix-name*]

Parameters

Parameter	Description	Value
name *prefix-name*	Specifies the IPv6 address prefix name.	The value must be an existing IPv6 address prefix name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display dhcpv6 client prefix** command to view IPv6 address prefixes on the device that functions as the DHCPv6 client.

Example

Display information about IPv6 prefix named **aaa** obtained by the device.

```
<HUAWEI> display dhcpv6 client prefix name aaa
Prefix name       : aaa
  Prefix          : FC00:3::/64
    Life time(sec): valid 172800 preferred 86400
```

Table 6-79 Description of the **display dhcpv6 client prefix** command output

Item	Description
Prefix name	IPv6 address prefix name.
Prefix	IPv6 address prefix.

Item	Description
Life time(sec)	- valid: Period during which an IPv6 address prefix is valid. - preferred: Period during which an IPv6 address prefix is valid since its lease is renewed.

6.11.31 display dhcpv6 client statistics

Function

The **display dhcpv6 client statistics** command displays DHCPv6 message statistics on the DHCPv6 client.

Format

display dhcpv6 client statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays DHCPv6 message statistics on a specified interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When the device functions as a DHCPv6 client, you can run this command to view DHCPv6 message statistics.

Example

Display DHCPv6 message statistics on the DHCPv6 client.

```
<HUAWEI> display dhcpv6 client statistics
 Message statistics of interface Vlanif10:
   Message                 Received
   Advertise               1
   Reply                   1
   Reconfigure             0
   Invalid                 0
```

```
Dropped untrusted reply  0

Message                 Sent
Solicit                1
Request                 1
Confirm                 0
Renew                   0
Rebind                 0
Release                0
Decline                0
Information-request      0
```

Table 6-80 Description of the **display dhcpv6 client statistics** command output

Item	Description
Message	Message type.
Received	Number of received messages.
Advertise	Number of Advertise messages received by the DHCPv6 client.
Reply	Number of Reply messages received by the DHCPv6 client.
Reconfigure	Number of Reconfigure messages received by the DHCPv6 client.
Invalid	Number of unknown-type messages received by the DHCPv6 client.
Dropped untrusted reply	When the **dhcp snooping check local-reply enable** command is configured on a device that functions as a DHCP client, the **dhcp snooping trusted** command must be configured on the interface connected to the DHCP server. Otherwise, the DHCP client discards response messages from the DHCP server.
Sent	Number of sent messages.
Solicit	Number of Solicit messages sent by the DHCPv6 client.
Request	Number of Request messages sent by the DHCPv6 client.
Confirm	Number of Confirm messages sent by the DHCPv6 client.
Renew	Number of Renew messages sent by the DHCPv6 client.
Rebind	Number of Rebind messages sent by the DHCPv6 client.

Item	Description
Release	Number of Release messages sent by the DHCPv6 client.
Decline	Number of Decline messages sent by the DHCPv6 client.
Information-request	Number of Information-request messages sent by the DHCPv6 client.

6.11.32 display dhcpv6 duid

Function

The **display dhcpv6 duid** command displays the DHCP unique identifier of a DHCPv6 device.

Format

display dhcpv6 duid

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A DUID identifies a DHCPv6 device. Each DHCPv6 server or client has a DUID. The **display dhcpv6 duid** command displays the DUID of a device.

Example

Display the DUID of a DHCPv6 device.

```
<HUAWEI> display dhcpv6 duid
The device's DHCPv6 unique identifier: 0001000117C667C280FB063545B3
```

6.11.33 display dhcpv6 relay configuration

Function

The **display dhcpv6 relay configuration** command displays configuration information about a DHCPv6 relay agent.

Format

display dhcpv6 relay configuration [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays configuration information about the DHCPv6 relay agent with the specified interface type and number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command on a DHCPv6 relay agent to check configuration information about a DHCPv6 relay agent including the source interface information and whether the Option79 field is inserted into DHCP messages.

Example

Display configuration information about a DHCPv6 relay agent.

```
<HUAWEI> display dhcpv6 relay configuration
DHCPv6 relay running information: global
Source interface:       -
Option79 insert:        enable
DHCPv6 relay running information: Vlanif10
Source interface:       -
Option79 insert:        enable
```

Table 6-81 Description of the **display dhcpv6 relay configuration** command output

Item	Description
DHCPv6 relay running information	Configuration information about a DHCPv6 relay agent, including configuration information in the global view and interface view.
Source interface	Specifies the interface IPv6 address as the source IPv6 address for sending messages. To configure this item, run the **dhcpv6 relay source-interface** command.
Option79 insert	Whether to insert the Option79 field into DHCPv6 messages. The value can be: ● enable: The Option79 field is inserted into DHCPv6 messages. ● disable: The Option79 field is not inserted into DHCPv6 messages. To configure this item, run the **dhcpv6 relay option79 insert enable** command.

6.11.34 display dhcpv6 relay prefix-delegation

Function

Using the **display dhcpv6 relay prefix-delegation** command, you can view DHCPv6 PD routing information forwarded by the DHCPv6 Relay.

Format

display dhcpv6 relay prefix-delegation { **client** [**interface** *interface-type interface-number*] | **route** [**interface** *interface-type interface-number*] }

Parameters

Parameter	Description	Value
client	Displays information about DHCPv6 PD clients.	-
interface *interface-type interface-number*	Specifies the type and the number of an interface.	-

Parameter	Description	Value
route	Displays routing information learned from DHCPv6 PD clients.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display dhcpv6 relay prefix-delegation** command is used on DHCPv6 relay agents. This command displays routing information that DHCPv6 relay agents learn from DHCPv6 PD terminals, including the destination IPv6 address, next hop address, outbound interface, and protocol type of each route. You can also use this command to view DHCPv6 PD routing information forwarded by the DHCPv6 Relay.

Example

Display DHCPv6 PD routing information forwarded by the DHCPv6 Relay.

```
<HUAWEI> display dhcpv6 relay prefix-delegation route
-------------------------------------------------------------------------------
 Destination   : FC00:1::/96
 Next-hop      : FC00:2::1
 Interface     : Vlanif62
 Protocol type : Unr
 Destination   : FC00:2::/96
 Next-hop      : FC00:2::2
 Interface     : Vlanif62
 Protocol type : Unr
-------------------------------------------------------------------------------
 Total count : 1  Print count : 1
```

Table 6-82 Description of the display dhcpv6 relay prefix-delegation route command output

Item	Description
Destination	Destination network segment of a route.
Next-hop	Next hop address of a route.
Interface	Outbound interface of a route.
Protocol type	Protocol type used by a route.
Total count	Number of routes displayed.

Item	Description
Print count	Number of routes printed. A maximum of 512 routes can be printed.

Display information about DHCPv6 PD terminals.

```
<HUAWEI> display dhcpv6 relay prefix-delegation client
-------------------------------------------------------------------------------
 DUID_EN       : 000612E978E600E04C774E5A
 Interface     : Vlanif62
 IPv6 address  : FC00:1::4E5A
     IA PD     : IA ID 1, T1 600, T2 900,
         IA Prefix: FC00:3::/96
            preferred lifetime 900 , valid lifetime 1200
            expired at 2010.02.21 15:01:54
         IA Prefix: FC00:4::/96
            preferred lifetime 900 , valid lifetime 1200
            expired at 2010.02.21 15:01:54
-------------------------------------------------------------------------------
 Total count : 1  Print count : 1
```

Table 6-83 Description of the display dhcpv6 relay prefix-delegation client command output

Item	Description
DUID_EN	DHCPv6 unique identifier (DUID) of a client, which is defined by the vendor.
Interface	Interface to which a client is connected.
IPv6 address	IPv6 address of a client.
IA PD	IPv6 prefix contained in the packet sent from a client.
Total count	Number of client records displayed.
Print count	Number of client records printed. A maximum of 512 records can be printed.

6.11.35 display dhcpv6 relay statistics

Function

Using the **display dhcpv6 relay statistics** command, you can view the statistics about DHCPv6 messages passing through the DHCPv6 relay agent.

Format

display dhcpv6 relay statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. If no interface is specified, the statistics about all the DHCPv6 messages are displayed. If the interface is specified, the statistics about DHCPv6 messages on the specified interface are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If a device is enabled with the DHCPv6 relay function, the system takes the statistics about DHCPv6 messages passing through the DHCP relay agent. After this command is run, you can view the statistics about DHCPv6 messages passing through the DHCP relay agent.

Example

Display the statistics about DHCPv6 messages on VLANIF 10.

```
<HUAWEI> display dhcpv6 relay statistics interface vlanif 10
 Interface Vlanif10 :
 MessageType           Receive        Send           Error
 Solicit               0              0              0
 Advertise             0              0              0
 Request               0              0              0
 Confirm               0              0              0
 Renew                 0              0              0
 Rebind                0              0              0
 Reply                 0              0              0
 Release               0              0              0
 Decline               0              0              0
 Reconfigure           0              0              0
 Information-request   0              0              0
 Relay-forward         0              0              0
 Relay-reply           0              0              0
 UnknownType           0              0              0
```

Table 6-84 Description of the display dhcpv6 relay statistics command output

Item	Description
Interface	Interface enabled with related DHCPv6 functions.
MessageType	Type of DHCPv6 messages.
Receive	Number of received DHCPv6 messages.
Send	Number of sent DHCPv6 messages.
Error	Number of DHCPv6 messages that fail to be parsed.

6.11.36 display dhcpv6 pool

Function

The **display dhcpv6 pool** command displays the IPv6 address pool configurations.

Format

display dhcpv6 pool [*pool-name* [**allocated** { **address** | **prefix** } | **binding** [*duid*] | **conflict address** | *ipv6-address* | *ipv6-prefix/prefix-length*]]

Parameters

Parameter	Description	Value
pool *pool-name*	Specifies the IPv6 address pool name.	The value is a string of 1 to 31 characters without spaces. The value contains digits, letters, underscores (_), and dots (.).
allocated { **address** | **prefix** }	Specifies IPv6 addresses or IPv6 address prefixes that have been assigned.	-
binding [*duid*]	Specifies addresses that are bound to DUIDs.	The value is a string of 2 to 256 characters in hexadecimal notation. The length of the string is an even.
conflict address	Specifies the conflicted IPv6 addresses in the IPv6 address pool.	-

Parameter	Description	Value
ipv6-address	Specifies IPv6 addresses in the IPv6 address pool.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-prefix/prefix-length	Specifies IPv6 prefixes in the IPv6 address pool.	The value is a 32-digit hexadecimal number, in the format X:X::X:X/M. The IPv6 address prefix length ranges from 1 to 128.

1: Monitoring level

Usage Guidelines

The **display dhcpv6 pool** command is used on DHCPv6 servers. The **display dhcpv6 pool** command displays information about IPv6 address pool configurations and dynamic address allocation.

Example

Display information about the IPv6 address pool **pool1**.

```
<HUAWEI> display dhcpv6 pool pool1
DHCPv6 pool: pool1
  Address prefix: FC00:1::/64
    Lifetime valid 4294967295 seconds, preferred 4294967295 seconds
    0 in use, 0 conflicts
  Prefix delegation: FC00:3::/60 64
    Lifetime valid 172800 seconds, preferred 86400 seconds
    0 in use
  Information refresh time: 10000
  DNS server address: FC00:4::1
  SIP server address: FC00:3::1
  NIS server address: FC00:1::2
  NISP server address: FC00:1::2
  SNTP server address: FC00:1::1
  Domain name: example.com
  SIP server domain name: sip.com
  NIS server domain name: nis.com
  NISP server domain name: nisp.com
  Vendor-specific option:
    Enterprise ID: 2011
      Suboption 10 address FC00:1::5
  conflict-address expire-time: 61
  renew-time-percent : 55
  rebind-time-percent : 85
  Active normal clients: 0
  Active pd clients: 0    Logging : Enable
```

Table 6-85 Description of the **display dhcpv6 pool** command output

Item	Description
DHCPv6 pool	Name of the IPv6 address pool.
Address prefix	Prefix bound to the IPv6 address pool. You can set the prefix using the **address prefix** command.
Prefix delegation	Agent prefix bound to the IPv6 address pool. You can set the agent prefix using the **prefix-delegation** command.
Information refresh time	Time for updating configuration parameters assigned to clients through stateless DHCPv6 address autoconfiguration. You can set the time using the **information-refresh** command.
DNS server address	DNS server address configured for the IPv6 address pool. You can configure the DNS server address using the **dns-server** command.
SIP server address	SIP server address configured for the IPv6 address pool. You can configure the SIP server address using the **sip-server** command.
NIS server address	NIS server address configured for the IPv6 address pool. You can configure the NIS server address using the **nis-server** command.
NISP server address	NISP server address configured for the IPv6 address pool. You can configure the NISP server address using the **nisp-server** command.
SNTP server address	SNTP server address configured for the IPv6 address pool. You can configure the SNTP server address using the **sntp-server** command.

Item	Description
Domain name	Domain name suffix allocated by the DHCPv6 server to the client. You can configure the domain name suffix using the **dns-domain-name** command.
SIP server domain name	SIP domain name suffix allocated by the DHCPv6 server to the client. You can configure the SIP domain name suffix using the **sip-domain-name** command.
NIS server domain name	NIS domain name suffix allocated by the DHCPv6 server to the client. You can configure the NIS domain name suffix using the **nis-domain-name** command.
NISP server domain name	NISP domain name suffix allocated by the DHCPv6 server to the client. You can configure the NISP domain name suffix using the **nisp-domain-name** command.
Vendor-specific option	Vendor-defined options. You can configure the vendor-defined options using the **vendor-specific** and **suboption** commands.
conflict-address expire-time	Aging time of conflicted addresses. You can set the aging time using the **conflict-address expire-time** command.
renew-time-percent	The percentage of the lease renewal time in the preferred lifetime. You can set the percentage of the lease renewal time in the preferred lifetime using the **renew-time-percent rebind-time-percent** command.
rebind-time-percent	The percentage of the lease rebinding time in the preferred lifetime. You can set the percentage of the lease rebinding time in the preferred lifetime using the **renew-time-percent rebind-time-percent** command.

Item	Description
Active normal clients	Number of DHCP clients.
Active pd clients	Number of DHCPv6 PD clients.
Logging	Whether the function of recording a log when the DHCPv6 or DHCPv6 PD server allocates an IPv6 address or prefix is enabled. The value can be: ● Enable: The function is enabled. ● Disable: The function is disabled. To configure this item, run the **logging** command.

6.11.37 display dhcpv6 relay

Function

The **display dhcpv6 relay** command displays the configuration of the interface enabled with the DHCPv6 relay function.

Format

display dhcpv6 relay [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the configuration of the specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no interface is specified, the configuration of all the interfaces enabled with the DHCPv6 relay function is displayed.

Example

Display the configurations of all interfaces enabled with the DHCPv6 relay function.

```
<HUAWEI> display dhcpv6 relay
Interface               Mode           Destination
-------------------------------------------------------------------------
GigabitEthernet0/0/1     Relay         FC00:4::3
Vlanif10                Relay         FC00:1::1:1
-------------------------------------------------------------------------------
 Print count : 2                  Total count : 2
```

Table 6-86 Description of the **display dhcpv6 relay** command output

Item	Description
Interface	Interface enabled with DHCPv6 relay functions.
Mode	DHCPv6 function mode.
Destination	Destination address of DHCPv6 relay messages. Address pointing to the DHCPv6 server, address of the next-hop DHCPv6 relay, or DHCPv6 server group. To configure the address, run the **dhcpv6 relay destination** or **dhcpv6 relay server-select** command.
Print count	The number of interfaces enabled with DHCPv6 relay functions that are displayed.
Total count	The total number of interfaces enabled with DHCPv6 relay functions.

6.11.38 display dhcpv6 server

Function

The **display dhcpv6 server** command displays information about the DHCPv6 server function.

Format

display dhcpv6 server [**database** | [**statistics**] [**interface** *interface-type interface-number*]]

Parameters

Parameter	Description	Value
database	Displays database configurations.	-
statistics	Displays message statistics on the DHCPv6 server.	-
interface *interface-type interface-number*	Displays information about the DHCP server with a specified interface type and number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display dhcpv6 server** command is used on DHCPv6 servers. The **display dhcpv6 server** command displays information about the DHCPv6 server function.

Example

Display information about the DHCPv6 server function.

```
<HUAWEI> display dhcpv6 server
 Interface                          DHCPv6 pool
 Vlanif10                           pool1
```

Table 6-87 Description of the **display dhcpv6 server** command output

Item	Description
Interface	Interface enabled with the DHCPv6 server function.
DHCPv6 pool	Name of the IPv6 pool that is configured on the interface. You can configure the IPv6 pool name using the **dhcpv6 server** command.

6.11.39 display dhcpv6 server group

Function

The **display dhcpv6 server group** command displays the configuration of a DHCPv6 server group.

Format

display dhcpv6 server group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Displays the configuration of a specified DHCPv6 server group. If this parameter is not specified, the configuration of all DHCPv6 server groups is displayed.	The value is a string of 1 to 32 case-sensitive characters without spaces.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Use Scenario

The **display dhcpv6 server group** command is used on DHCPv6 relay agents. You can run the **display dhcpv6 server group** command to view the configuration of DHCPv6 server groups created on a DHCPv6 relay agent.

Prerequisites

DHCPv6 server groups have been configured on the DHCPv6 relay agent using the **dhcpv6 server group** command.

Example

View the configuration of the DHCPv6 server group named group1 on the DHCPv6 relay agent.

```
<HUAWEI> display dhcpv6 server group group1
 DHCPv6 Group-name   : group1
   (0)   server-ip   : FC00:1::1
```

View the configuration of all the DHCPv6 server groups on the DHCPv6 relay agent.

```
<HUAWEI> display dhcpv6 server group
dhcpv6 server group
-------------------------------------------------------------------------------
 DHCPv6 Group-name   : g1
   (0)   server-ip   : FC00:2::1
   (1)   server-ip   : FC00:2::2
   (2)   server-ip   : FC00:2::3
   (3)   server-ip   : FC00:2::4
   (4)   server-ip   : FC00:2::5
   (5)   server-ip   : FC00:4::1
 DHCPv6 Group-name   : g2
   (0)   server-ip   : FC00:3::111
   (1)   server-ip   : FC00:3::122
   (2)   server-ip   : FC00:3::123
   (3)   server-ip   : FC00:3::124
   (4)   server-ip   : FC00:3::125
   (5)   server-ip   : FC00:3::126
   (6)   server-ip   : FC00:3::127
 DHCPv6 Group-name   : g3
   (0)   server-ip   : FC00:3::1
   (1)   server-ip   : FC00:3::2
   (2)   server-ip   : FC00:3::3
   (3)   server-ip   : FC00:3::4
   (4)   server-ip   : FC00:3::5
   (5)   server-ip   : FC00:3::6
   (6)   server-ip   : FC00:3::7
-------------------------------------------------------------------------------
 Total count : 3
```

Table 6-88 Description of the display dhcpv6 server group command output

Item	Description
DHCPv6 Group-name	Name of a DHCPv6 server group. To set this parameter, run the **dhcpv6 server group** command.
server-ip	IPv6 address of a DHCPv6 server in a DHCPv6 server group. To set this parameter, run the **dhcpv6-server (DHCPv6 server group view)** command.

6.11.40 display dhcpv6 statistics

Function

The **display dhcpv6 statistics** command displays DHCPv6 packet statistics.

Format

display dhcpv6 statistics [**verbose**]

Parameters

Parameter	Description	Value
verbose	Displays statistics about socket packet sending failures.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The device may become faulty when running the DHCPv6 service. Some fault location methods are required for administrators or device maintenance personnel to locate faults quickly. The most convenient and effective method is to provide statistics about packets and packet loss reasons. Run the **display dhcpv6 statistics** command to view DHCPv6 packet statistics.

Example

Display DHCPv6 packet statistics.

```
<HUAWEI> display dhcpv6 statistics
Input: total 10 packets, discarded 0 packets
  Solicit               :         10,  Advertise             :          0
  Request               :          0,  Confirm               :          0
  Renew                 :          0,  Rebind                :          0
  Reply                 :          0,  Release               :          0
  Decline               :          0,  Reconfigure           :          0
  Information-request   :          0,  Relay-forward         :          0
  Relay-reply           :          0,  Leasequery            :          0
  Leasequery-reply      :          0,

  Max-user limit        :        831,  Add bindtable failed  :        100
Output: total 0 packets, discarded 0 packets
```

Table 6-89 Description of the **display dhcpv6 statistics** command output

Item	Description
Input: total x packets, discarded y packets	Statistics about DHCPv6 packets received by the device. The number of received DHCPv6 packets is x and the number of discarded DHCPv6 packets is y.
Solicit	Number of SOLICIT packets received by the device.

Item	Description
Advertise	Number of ADVERTISE packets received by the device.
Request	Number of REQUEST packets received by the device.
Confirm	Number of CONFIRM packets received by the device.
Renew	Number of RENEW packets received by the device.
Rebind	Number of REBIND packets received by the device.
Reply	Number of REPLY packets received by the device.
Release	Number of RELEASE packets received by the device.
Decline	Number of DECLINE packets received by the device.
Reconfigure	Number of RECONFIGURE packets received by the device.
Information-request	Number of INFORMATION-REQUEST packets received by the device.
Relay-forward	Number of RELAY-FORW packets received by the device.
Relay-reply	Number of RELAY-REPL packets received by the device.
Leasequery	Number of LEASEQUERY packets received by the device.
Leasequery-reply	Number of LEASEQUERY-REPLY packets received by the device.

Item	Description
Max-user limit or Add bindtable failed	Information displayed if the DHCPv6 service is abnormal. The displayed information includes: ● Max-user limit: Total number of DHCPv6 messages discarded because the maximum number of users (configured by running the **dhcp snooping max-user-number** command) is exceeded. ● Add bindtable failed: Total number of DHCPv6 packets discarded because dynamic binding entries are added. New dynamic binding entries may be added if the user-side interface is Down, or IPSG is configured but ACL resources are insufficient. ● High cpu occupancy: Total number of DHCPv6 packets discarded because the CPU usage is excessively high. ● Port blocked: Total number of DHCPv6 packets discarded because the inbound interface is blocked. ● Rx buffers full: Total number of DHCPv6 packets discarded because the remaining queue length is shorter than the reserved threshold. ● L2fdb lookup failed: Total number of DHCPv6 Reply packets discarded because the DHCP snooping module fails to find user-side interfaces. ● Bad vlan id: Total number of DHCPv6 packets discarded because the interfaces receiving the DHCPv6 packets are not added to the VLANs corresponding to the VLAN tags carried in the packets or the DHCPv6 packets received on interfaces carry VLAN tags not in the range from 1 to 4094. ● Memory exhausted: Total number of DHCPv6 packets discarded because the memory is exhausted. ● L3if protocol down: Total number of DHCPv6 packets discarded because

Item	Description
	the Layer 3 protocol of the source interface goes Down. ● Rate limit: Total number of DHCPv6 packets discarded because rates of the messages exceed the limit, when the **dhcpv6 packet-rate** or **dhcp snooping check dhcpv6-rate enable** command is configured. ● Bad packet length: Total number of DHCPv6 packets discarded because the packet length is not in the range of 50 to 2048 bytes. ● Bad ip header checksum: Total number of DHCPv6 packets discarded because the checksum of the IP header is incorrect. ● Bad request: Total number of invalid DHCPv6 request packets that are discarded, when the **dhcp snooping check dhcp-request enable** or **dhcp snooping check dhcpv6-request mac** command is configured to check the validity of DHCPv6 request packets. ● Bad reply: Total number of DHCPv6 response packets discarded by untrusted interfaces configured with the **dhcp snooping enable** command. ● Client transferred: Total number of DHCPv6 packets discarded because the **undo dhcp snooping user-transfer enable** command is configured to disable interface flapping. ● Other error: Total number of DHCPv6 packets discarded due to other reasons.
Output: total x packets, discarded y packets	Statistics about DHCPv6 packets sent by the device. The number of sent DHCPv6 packets is x and the number of discarded DHCPv6 packets is y.

6.11.41 dns-domain-name

Function

The **dns-domain-name** command configures the DNS domain name suffix assigned by the DHCPv6 server to a DHCPv6 client.

The **undo dns-domain-name** command deletes the assigned domain name suffix.

By default, no DNS domain name suffix is configured for the DHCPv6 client.

Format

dns-domain-name *dns-domain-name*

undo dns-domain-name *dns-domain-name*

Parameters

Parameter	Description	Value
dns-domain-name	Specifies the DNS domain name suffix assigned to a DHCPv6 client.	The value is a string of 1 to 63 case-insensitive characters without spaces. It can be the combination of letters, digits, underscores (_), hyphens (-), or dots (.) and cannot be set to only hyphens (-) or hyphens (--).

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dns-domain-name** command is used on DHCPv6 servers. The DHCPv6 server specifies a domain name suffix when allocating IPv6 addresses for clients. You can use the **dns-domain-name** command on the DHCPv6 server to specify a domain name for each global address pool. When allocating IPv6 addresses to clients, the DHCPv6 server also sends the domain name suffix to the clients.

Precautions

A maximum of four different DNS domain names can be configured for an IPv6 address pool.

Example

Configure the domain name suffix assigned to the DHCPv6 client as **example.com** for the address pool **pool1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] dns-domain-name example.com
```

6.11.42 dns-server (IPv6 address pool view)

Function

The **dns-server** command configures a DNS server address for the DHCPv6 address pool.

The **undo dns-server** command deletes the configured DNS server address.

By default, no DNS server address is configured for the IPv6 address pool.

Format

dns-server *ipv6-address*

undo dns-server *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	DNS server IPv6 address configured for the DHCPv6 address pool.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dns-server** command is used on DHCPv6 servers. Before a host accesses the Internet, a DNS server needs to resolve the accessed domain name to an IP address. The DHCPv6 server needs to specify the IPv6 address of the DNS server for the global address pool so that the DHCPv6 client can be connected to the Internet. The DHCPv6 server specifies the IPv6 address of the DNS server when allocating IPv6 addresses to the clients.

Precautions

- To specify multiple DNS servers, run the **dns-server** command to configure multiple DNS server addresses.
- A maximum of two DNS server addresses can be configured for each IPv6 address pool. The first assigned DNS server address is used as a primary address. The priority of the first configured DNS server is higher than that of the other DNS server.

Example

Specify a DNS server with the IPv6 address fc00:1::1 for domain name resolution when IP addresses in the address pool **global1** are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] dns-server fc00:1::1
```

6.11.43 excluded-address

Function

The **excluded-address** command specifies the range of the IPv6 addresses that cannot be automatically assigned to clients from the IPv6 address pool.

The **undo excluded-address** command deletes the specified range of the IPv6 addresses that cannot be automatically assigned to clients from the address pool.

By default, all IPv6 addresses in the address pool can be automatically assigned to clients.

Format

excluded-address *start-ipv6-address* [**to** *end-ipv6-address*]

undo excluded-address *start-ipv6-address* [**to** *end-ipv6-address*]

Parameters

Parameter	Description	Value
start-ipv6-address	Specifies the start IPv6 address that cannot be automatically assigned.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
to *end-ipv6-address*	Specifies the end IPv6 address that cannot be automatically assigned.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X. *end-ipv6-address* and *start-ipv6-address* must be on the same network segment and *end-ipv6-address* must be greater than *start-ipv6-address*. If *end-ipv6-address* is not specified, only the *start-ipv6-address* cannot be automatically assigned.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **excluded-address** command is used on DHCPv6 servers. In an address pool, some IPv6 addresses need to be reserved for other services, and some IPv6 addresses are statically assigned to certain hosts (such as the DNS server and Web server) and cannot be automatically assigned to clients. You can run the **excluded-address** command to specify the range of the IPv6 addresses that cannot be automatically assigned to clients from the IPv6 address pool.

Prerequisites

1. An address pool has been created by using the **dhcpv6 pool** command.
2. Bind an IPv6 address prefix to an address pool by using the **address prefix**

Precautions

- The excluded IPv6 address or IPv6 address segment must be in the local address pool.
- The excluded IPv6 address or IPv6 address segment cannot be automatically assigned to clients from a local address pool.

- If you run the **excluded-address** command multiple times, you can specify multiple IPv6 addresses or IPv6 address segments that cannot be automatically assigned to clients.

Example

Specify IPv6 addresses fc00:1::1 to fc00:1::10 not to be automatically allocated from the address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] address prefix fc00:1::/64
[HUAWEI-dhcpv6-pool-global1] excluded-address fc00:1::1 to fc00:1::10
```

6.11.44 information-refresh

Function

The **information-refresh** command configures the time for updating configuration parameters assigned to clients through stateless DHCPv6 address autoconfiguration.

The **undo information-refresh** command restores the default time for updating IPv6 address pool configurations.

By default, the time for updating IPv6 address pool configurations is 86400s (24 hours).

Format

information-refresh *time*

undo information-refresh

Parameters

Parameter	Description	Value
time	Specifies the time for updating configuration parameters assigned to clients through stateless DHCPv6 address autoconfiguration.	The value is an integer that ranges from 600 to 4294967295, in seconds.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

The **information-refresh** command is used on DHCPv6 servers. When the DHCPv6 server assigns configuration parameters such as the DNS, NIS, and SNTP server addresses to the DHCPv6 clients through stateless autoconfiguration, you can use the **information-refresh** command to configure the time for updating these configuration parameters.

NOTE

If a Huawei device functions as a DHCPv6 client and the time configured using the **information-refresh** command on the DHCPv6 server is larger than three days (259200 seconds), the time for updating DHCPv6 client configuration information is three days. If the time configured using the **information-refresh** command on the DHCPv6 server is less than or equal to three days, the time for updating DHCPv6 client configuration information is the actually configured value.

Example

Set the time for updating configuration parameters assigned to clients to 10000s in the address pool pool1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] information-refresh 10000
```

6.11.45 ipv6 address auto dhcp

Function

The **ipv6 address auto dhcp** command enables an interface to obtain IPv6 addresses and other configuration parameters using stateful DHCPv6 address autoconfiguration.

The **undo ipv6 address auto dhcp** command disables an interface from obtaining IPv6 addresses and other configuration parameters using stateful DHCPv6 address autoconfiguration.

By default, the interface is disabled from obtaining IPv6 addresses and other configuration parameters using stateful DHCPv6 address autoconfiguration.

Format

ipv6 address auto dhcp [**hint** *ipv6-address*] [**rapid-commit**] [**unicast-option**]

undo ipv6 address auto dhcp

Parameters

Parameter	Description	Value
hint *ipv6-address*	Specifies the IPv6 address applied by a DHCPv6 client.	The total length is 128 bit, which is divided into eight groups. The 16 bits of each group are represented by four hexadecimal characters. The format is X:X:X:X:X:X:X:X.
rapid-commit	Specifies that a DHCPv6 client applies for an IPv6 address using two-message exchange.	-
unicast-option	Specifies that a DHCPv6 client applies for an IPv6 address using a unicast option.	-

Views

VLANIF interface view, Eth-Trunk interface view, GE interface view, XGE interface view, MultiGE interface view, MultiGE sub-interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk sub-interface view, GE sub-interface view, XGE sub-interface view, 25GE sub-interface view, 40GE sub-interface view, 100GE sub-interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **ipv6 address auto dhcp** [**rapid-commit**] command on the device that functions as a DHCPv6 client, the client uses stateful DHCPv6 address autoconfiguration to obtain IPv6 addresses and other configuration parameters, such as addresses of the DNS and SNTP servers, from the DHCPv6 server.

Prerequisites

1. IPv6 functions have been enabled globally using the **ipv6** command in the system view.
2. IPv6 functions have been enabled on interfaces using the **ipv6 enable** command in the interface view.
3. The IPv6 link-local address has been configured using the **ipv6 address auto link-local** or **ipv6 address** *ipv6-address* **link-local** command in the interface view.
4. The interface has been configured to automatically learn the IPv6 default route using the **ipv6 address auto global default** command in the interface view.

Precautions

The DHCPv6 server assigns an IPv6 address and other configuration parameters to a DHCPv6 client using two-message exchange only when two-message exchange is configured on both the server and client. If two-message exchange is not configured on the server or client, the server assigns an IPv6 address and other configuration parameters to the client using four-message exchange. Two-message exchange applies to the scenarios with one DHCPv6 server, while four-message exchange applies to the scenarios with multiple DHCPv6 servers.

Example

Configure the interface VLANIF100 to obtain IPv6 addresses and other configuration parameters from the DHCPv6 server using DHCPv6 stateful address autoconfiguration.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address auto link-local
[HUAWEI-Vlanif100] ipv6 address auto dhcp
```

Configure the interface GE0/0/1 to obtain IPv6 addresses and other configuration parameters from the DHCPv6 server using DHCPv6 stateful address autoconfiguration.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto link-local
[HUAWEI-GigabitEthernet0/0/1] ipv6 address auto dhcp
```

6.11.46 link-address

Function

The **link-address** command configures the network prefix in the IPv6 address pool view.

The **undo link-address** command deletes the network prefix configured in the IPv6 address pool view.

By default, no network prefix is configured in the IPv6 address pool view.

Format

link-address *ipv6-prefix/ipv6-prefix-length*

undo link-address *ipv6-prefix/ipv6-prefix-length*

Parameters

Parameter	Description	Value
ipv6-prefix/ipv6-prefix-length	Specifies the network prefix and prefix length.	*ipv6-prefix*: The 128-bit IPv6 address is divided into eight groups. Each group contains four hexadecimal digits. The format is X:X:X:X:X:X:X:X. *ipv6-prefix-length*: The value is an integer that ranges from 16 to 128.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DHCPv6 client needs to apply for network configuration information (for example, the IP address of the DNS server) except for the IPv6 address from the DHCPv6 server. If the **address prefix** is not configured in the IPv6 address pool, you can run the **link-address** command to configure the network prefix in the IPv6 address pool view.

When functioning as a DHCPv6 or DHCPv6 PD server, the device may be configured with multiple IPv6 address pools. After receiving the DHCPv6 request packets, the DHCPv6 or DHCPv6 PD server chooses the IPv6 address pool based on the following rules:

- When the device functions as the DHCPv6 server:
  - If a relay exists, the server chooses the address pool that belongs to the same link scope with the configured network prefix (using the **link-address** or **address prefix** command) based on the first link-address field that is not 0. The link-address field identifies the link scope of the DHCPv6 clients.
  - When the DHCPv6 server is enabled in the system view, the DHCPv6 server cannot assign network parameters (such as IPv6 addresses, DNS, NIS, and SNTP servers) to clients if no relay exists. To enable the DHCPv6 server to assign network parameters, enable the DHCPv6 server function in the interface view.
- When the device functions as the DHCPv6 PD server:
  - If a relay exists, choose the address pool in the same link scope with the configured network prefix (using the **link-address** command) based on

the first link-address field that is not 0. The link-address field identifies the link scope of the DHCPv6 clients.

- If no relay exists, the DHCPv6 PD server function cannot be enabled in the system view and can be enabled in the interface view, using the **dhcpv6 server** command.

Prerequisites

Idle addresses or prefixes are assigned to DHCPv6 clients from the IPv6 address pool. Reserved addresses, conflicted addresses, and used addresses cannot be assigned to DHCPv6 clients. Reserved addresses include unspecified addresses, multicast addresses, loopback addresses, link-local addresses, NSAP addresses, and anycast addresses (defined in RFC 2526).

Example

Bind the IPv6 address prefix fc00:1::/64 to the DHCPv6 server address pool named pool1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] link-address fc00:1::/64
```

6.11.47 lock (IPv6 address pool view)

Function

The **lock** command locks the IPv6 address pool.

The **undo lock** command unlocks the address pool.

By default, the IPv6 address pool is unlocked.

Format

lock

undo lock

Parameters

None

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **lock** command is used on DHCPv6 servers. When a DHCPv6 server needs to be migrated, you simply need to migrate address pools on the DHCPv6 server to another DHCPv6 server on the live network. To retain the addresses that have been assigned to clients from a global address pool, run the **lock** command to lock the global address pool. When new users get online, they apply for IPv6 addresses from a new address pool.

Precautions

After the **lock** command is executed, the IPv6 address pool is locked. The locked IPv6 address pool does not assign addresses or extend address lease but only release addresses.

Example

Lock the address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] lock
```

6.11.48 logging (IPv6 address pool view)

Function

The **logging** command enables the function of recording a log when the DHCPv6 or DHCPv6 PD server allocates an IPv6 address or prefix in the IPv6 address pool view.

The **undo logging** command disables the function of recording a log when the DHCPv6 or DHCPv6 PD server allocates an IPv6 address or prefix in the IPv6 address pool view.

By default, this function is disabled.

Format

logging [**allocation-address-success** | **allocation-prefix-success** | **detect-address-conflict** | **release-address-success** | **release-prefix-success** | **renew-address-success** | **renew-prefix-success**] *

undo logging [**allocation-address-success** | **allocation-prefix-success** | **detect-address-conflict** | **release-address-success** | **release-prefix-success** | **renew-address-success** | **renew-prefix-success**] *

Parameters

NOTE

If the following parameters are not specified, the function of recording related logs is enabled or disabled.

Parameter	Description	Value
allocation-address-success	Displays a log when an IPv6 address is successfully allocated.	-
allocation-prefix-success	Displays a log when an IPv6 prefix is successfully allocated.	-
detect-address-conflict	Displays a log when an IPv6 address conflict is detected.	-
release-address-success	Displays a log when an IPv6 address is released.	-
release-prefix-success	Displays a log when an IPv6 prefix is released.	-
renew-address-success	Displays a log when an IPv6 address is renewed.	-
renew-prefix-success	Displays a log when an IPv6 prefix is renewed.	-

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is applied to the DHCPv6 or DHCPv6 PD server. After the **logging** command is configured, the server records a log if an IPv6 address or prefix is allocated, renewed, or released, or an IPv6 address or prefix conflict is detected, facilitating routine maintenance and fault locating.

You can run the **display dhcpv6 pool** command to check the status of the log recording function on the server.

Prerequisites

An IPv6 address pool has been created using the **dhcpv6 pool** command.

Precautions

- After the log recording function is enabled, the server may frequently record logs if a large number of clients request for IPv6 addresses or prefixes, deteriorating device performance.
- IP address allocation logs are recorded in the AM module. To view log information, the information center must be enabled. In addition, default

settings for log output vary depending on various factors including the log level and output direction. For details, see Information Center Configuration in the *CLI-based Configuration - Device Management Configuration Guide*.

For example, the level of logs indicating that an IP address is successfully allocated, an IP address is successfully renewed, and an IP address is successfully released is informational, and these logs are not recorded in the log buffer by default. You can run the **info-center source AM channel 4 log level informational** command to change the level of the logs to be recorded in the log buffer. You can then run the **display logbuffer** command to check the preceding logs.

Example

Enable the function of recording a log when the server allocates an IPv6 address or prefix in the IPv6 address pool **pool1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] logging
```

6.11.49 nis-domain-name

Function

The **nis-domain-name** command configures the NIS domain name suffix assigned by the DHCPv6 server to a DHCPv6 client.

The **undo nis-domain-name** command deletes the NIS domain name suffix assigned to the DHCPv6 client.

By default, no NIS domain name suffix is configured for the DHCPv6 client.

Format

nis-domain-name *nis-domain-name*

undo nis-domain-name *nis-domain-name*

Parameters

Parameter	Description	Value
nis-domain-name	Specifies the NIS domain name suffix assigned to a DHCPv6 client.	The value is a string of 1 to 63 case-insensitive characters without spaces. It can be the combination of letters, digits, underscores (_), hyphens (-), or dots (.) and cannot be set to a single hyphen (-) or consecutive hyphens (--).

Usage Guidelines

Usage Scenario

The **nis-domain-name** command is used on DHCPv6 servers. The DHCPv6 server specifies an NIS domain name suffix when allocating IPv6 addresses for clients. You can use the **nis-domain-name** command on the DHCPv6 server to specify a NIS domain name suffix for each global address pool. When allocating IPv6 addresses to clients, the DHCPv6 server also sends the NIS domain name suffix to the clients.

Precautions

A maximum of four different NIS domain names can be configured for an IPv6 address pool.

Example

Configure the NIS domain name assigned to the DHCPv6 client as **nis.com** for the address pool pool1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] nis-domain-name nis.com
```

6.11.50 nisp-domain-name

Function

The **nisp-domain-name** command configures the NISP domain name suffix assigned by the DHCPv6 server to a DHCPv6 client.

The **undo nisp-domain-name** command deletes the assigned NISP domain name suffix.

By default, no NISP domain name suffix is configured for the DHCPv6 client.

Format

nisp-domain-name *nisp-domain-name*

undo nisp-domain-name *nisp-domain-name*

Parameters

Parameter	Description	Value
nisp-domain-name	Specifies the NISP domain name suffix assigned to a DHCPv6 client.	The value is a string of 1 to 63 case-insensitive characters without spaces. It can be the combination of letters, digits, underscores (_), hyphens (-), or dots (.) and cannot be set to only hyphens (-) or hyphens (--).

Usage Guidelines

Usage Scenario

The **nisp-domain-name** command is used on DHCPv6 servers. The DHCPv6 server specifies an NISP domain name suffix when allocating IPv6 addresses for clients. You can use the **nisp-domain-name** command on the DHCPv6 server to specify a NISP domain name for each global address pool. When allocating IPv6 addresses to clients, the DHCPv6 server also sends the domain name suffix to the clients.

Precautions

A maximum of four different NISP domain name suffixes can be configured for an IPv6 address pool.

Example

Configure the NISP domain name assigned to the DHCPv6 client as **nisp.com** for the address pool pool1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] nisp-domain-name nisp.com
```

6.11.51 nisp-server

Function

The **nisp-server** command configures the NISP server address assigned to the DHCPv6 client for the IPv6 address pool.

The **undo nisp-server** command deletes the configured NISP server address assigned to the DHCPv6 client from the IPv6 address pool.

By default, no NISP server address is configured for the IPv6 address pool.

Format

nisp-server *ipv6-address*

undo nisp-server *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	Indicates the NISP server IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

IPv6 address pool view

2: Configuration level

Usage Guidelines

Usage Scenario

The **nisp-server** command is used on DHCPv6 servers. The DHCPv6 server needs to specify the IPv6 address of the NISP server for the address pool so that the DHCPv6 client can be connected to the Internet. The DHCPv6 server specifies the IPv6 address of the NISP server when allocating IPv6 addresses to the clients.

Precautions

- A maximum of two NISP server addresses can be configured for each IPv6 address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- When multiple NISP servers are specified, you need to run the **nisp-server** repeatedly to configure multiple addresses.

Example

Specify fc00:1::2 as the IPv6 address of the NISP server when the IPv6 addresses in the address pool global1 are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] nisp-server fc00:1::2
```

6.11.52 nis-server

Function

The **nis-server** command configures the NIS server address assigned to the DHCPv6 client for the IPv6 address pool.

The **undo nis-server** command deletes the configured NIS server address assigned to the DHCPv6 client from the IPv6 address pool.

By default, no NIS server address is configured for the IPv6 address pool.

Format

nis-server *ipv6-address*

undo nis-server *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	Indicates the NIS server IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Precautions

- A maximum of two NIS server addresses can be configured for each IPv6 address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- When multiple NIS servers are specified, you need to run the **nis-server** repeatedly to configure multiple addresses.

Example

Specify fc00:1::2 as the IPv6 address of the NIS server when IPv6 addresses in the address pool **global1** are assigned to clients.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] nis-server fc00:1::2
```

6.11.53 prefix-delegation

Function

The **prefix-delegation** command configures an agent prefix in the address pool view.

The **undo prefix-delegation** command deletes the agent prefix in the address pool view.

By default, no IPv6 address agent prefix is configured in the address pool view.

Format

prefix-delegation *ipv6-prefix/ipv6-prefix-length assign-prefix-length* [**life-time** { *valid-lifetime* | **infinite** } { *preferred-lifetime* | **infinite** }]

prefix-delegation *ipv6-prefix/ipv6-prefix-length assign-prefix-length* [**life-time preferred-lifetime days** *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]] **valid-lifetime days** *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]]

prefix-delegation *ipv6-prefix/ipv6-prefix-length* **lock**

undo prefix-delegation *ipv6-prefix/ipv6-prefix-length* [**lock**]

Parameters

Parameter	Description	Value
ipv6-prefix/ipv6-prefix-length	Specifies the address prefix and the prefix length bound to an IPv6 address pool.	The value is a 32-digit hexadecimal number, in the format X:X::X:X/M. The IPv6 address prefix length ranges from 1 to 128.

Parameter	Description	Value
assign-prefix-length	Specifies the default prefix length. **NOTE** If the DHCPv6 server has been configured to allocate prefix lengths based on the DHCPv6 client requests, and the client-requested prefix length is within the range from *ipv6-prefix-length* to *assign-prefix-length*, the server allocates the prefix length based on the client request. If the client-requested prefix length is not within the preceding range or the server is not configured to allocate prefix lengths based on the DHCPv6 client requests, the server allocates the default prefix length. You can run the **dhcpv6 server allow-hint** or **dhcpv6 server** *pool-name* **allow-hint** command to configure the server to allocate prefix lengths based on the DHCPv6 client requests.	The value is an integer that ranges from 1 to 128. The *assign-prefix-length* must be greater than or equal to *ipv6-prefix-length*. The difference between the *assign-prefix-length* and *ipv6-prefix-length* must be less than or equal to 16.
life-time	Specifies the lifetime of the address prefix bound to an IPv6 address pool.	-
valid-lifetime	Specifies the valid lifetime.	The value ranges from 60 to 172799999, in seconds. The default value is 172800, that is two days.
preferred-lifetime	Specifies the preferred lifetime. The preferred lifetime cannot exceed the valid lifetime.	The value ranges from 60 to 172799999, in seconds. The default value is 86400, that is one day.
infinite	Sets the lifetime to infinite. When the preferred lifetime is set to infinite, the valid lifetime must be set to infinite.	-

Parameter	Description	Value
preferred-lifetime days *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]	Specifies the preferred lifetime of the IPv6 prefix. The time must be no less than 1 minute.	● *days*: indicates days. The value is an integer that ranges from 0 to 1999. ● *hours*: indicates hours. The value is an integer that ranges from 0 to 23. ● *minutes*: indicates minutes. The value is an integer that ranges from 0 to 59. ● *seconds*: indicates seconds. The value is an integer that ranges from 0 to 59.
valid-lifetime days *days* [**hours** *hours* [**minutes** *minutes* [**seconds** *seconds*]]]	Specifies the valid lifetime of the IPv6 prefix. The time must be no less than 1 minute and cannot be less than the preferred lifetime.	● *days*: indicates days. The value is an integer that ranges from 0 to 1999. ● *hours*: indicates hours. The value is an integer that ranges from 0 to 23. ● *minutes*: indicates minutes. The value is an integer that ranges from 0 to 59. ● *seconds*: indicates seconds. The value is an integer that ranges from 0 to 59.
lock	Locks the address prefix.	-

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the device functions as a DHCPv6 PD server, run the **prefix-delegation** command to configure an agent prefix in the address pool view. The DHCPv6 PD client divides the obtained prefix into prefixes of subnet segments and sends an RA message on the network segment that hosts directly connect to or exchange information with hosts using the DHCPv6 protocol. The RA message contains the prefixes of subnet segments. This enables hosts to automatically configure addresses.

Precautions

- Idle addresses or prefixes are assigned to DHCPv6 clients from the IPv6 address pool. Reserved addresses, conflicted addresses, and used addresses cannot be assigned to DHCPv6 clients. Reserved addresses include unspecified addresses, multicast addresses, loopback addresses, link-local addresses, NSAP addresses, and anycast addresses (defined in RFC 2526).
- The agent prefix cannot be overlapped.
- The agent prefix cannot be overlapped with the address prefix.
- The agent prefix cannot be overlapped with the prefix statically specified by a certain user.
- When the prefix pool is deleted, all prefix leases are deleted.
- Only one agent prefix can be configured for an address pool.

Example

Configure the agent prefix of the DHCPv6 server as fc00:1::/30 for the address pool pool1, set the prefix length to 42 and the lifetime to infinite.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] prefix-delegation fc00:1::/30 42 life-time infinite infinite
```

6.11.54 renew-time-percent rebind-time-percent

Function

The **renew-time-percent rebind-time-percent** command configures the percentage of the lease renewal time and the percentage of the rebinding time in the preferred lifetime of an IPv6 address pool.

The **undo renew-time-percent rebind-time-percent** command restores the default percentage of the lease renewal time and the default percentage of the rebinding time in the preferred lifetime of an IPv6 address pool.

By default, the percentage of the lease renewal time in the preferred lifetime of an IPv6 address pool is 50%, and the percentage of the rebinding time is 80%.

Format

renew-time-percent *renew-time-percent* **rebind-time-percent** *rebind-time-percent*

undo renew-time-percent rebind-time-percent

Parameters

Parameter	Description	Value
renew-time-percent	Specifies the percentage of the lease renewal time in the preferred lifetime of an IPv6 address pool.	The value is an integer that ranges from 10 to 89. The default value is 50.
rebind-time-percent	Specifies the percentage of the rebinding time in the preferred lifetime of an IPv6 address pool. The value of *rebind-time-percent* must be greater than that of *renew-time-percent*, and the difference between the values must be greater than or equal to 10.	The value is an integer that ranges from 20 to 99. The default value is 80.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to change the lease renewal time and rebinding time in an IPv6 address pool.

NOTE

When planning the lease renewal time and rebinding time, you can run the **address prefix** and **renew-time-percent rebind-time-percent** commands to configure the preferred lifetime and the percentage of the lease renewal time and the percentage of the rebinding time in the preferred lifetime respectively. If the lease renewal time and rebinding time are too short, the lease and renewal time (T1 and T2) of IPv6 addresses allocated to DHCPv6 clients by the DHCPv6 server are too short. As a result, DHCPv6 clients send lease renewal packets frequently. It is recommended that you set the lease renewal time and rebinding time based on the actual usage scenario.

Example

Configure the percentage of the lease renewal time and the percentage of the rebinding time in the preferred lifetime of the IPv6 address pool **test**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool test
[HUAWEI-dhcpv6-pool-test] renew-time-percent 55 rebind-time-percent 85
```

6.11.55 reset dhcpv6 client statistics

Function

The **reset dhcpv6 client statistics** command clears DHCPv6 message statistics on the DHCPv6 client.

Format

reset dhcpv6 client statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears DHCPv6 message statistics on a specified interface. If no interface is specified, all message statistics on the DHCPv6 client are cleared.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

This command applies to the DHCPv6 client. Collecting statistics about the DHCPv6 messages sent and received within a specified period helps you locate DHCPv6 faults. Before collecting new statistics, run the **reset dhcpv6 client statistics** [**interface** *interface-type interface-number*] command to clear the existing message statistics. After clearing existing statistics, run the **display dhcpv6 client statistics** [**interface** *interface-type interface-number*] command to view latest message statistics.

Example

Clear message statistics on the DHCPv6 client.

```
<HUAWEI> reset dhcpv6 client statistics
```

6.11.56 reset dhcpv6 pool

Function

The **reset dhcpv6 pool** command clears the IPv6 address pool configured on the device.

Format

reset dhcpv6 pool *pool-name* [**allocated** { **address** | **prefix** } | **binding** [*duid*] | **conflict address** | *ipv6-address* [**to** *ipv6-address*] | *ipv6-prefix/prefix-length*]

Parameters

Parameter	Description	Value
pool *pool-name*	Specifies the IPv6 address pool name.	The value is a string of 1 to 31 characters without spaces. The value contains digits, letters, underscores (_), and dots (.).
allocated { **address** | **prefix** }	Deletes IPv6 addresses or IPv6 address prefixes that have been assigned.	-
binding [*duid*]	Deletes addresses that are bound to DUIDs.	The value is a string of 2 to 256 characters in hexadecimal notation. The length of the string is an even.
conflict address	Resets the conflicted IPv6 addresses in the IPv6 address pool.	-
ipv6-address [**to** *ipv6-address*]	Resets IPv6 addresses in the IPv6 address pool. If only one IPv6 address is entered, only the entered IPv6 address is reset.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-prefix/prefix-length	Resets IPv6 prefixes in the IPv6 address pool.	The value is a 32-digit hexadecimal number, in the format X:X::X:X/M. The IPv6 address prefix length ranges from 16 to 128

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset dhcpv6 pool** command resets the address pool status. If an IPv6 address conflict occurs because two clients use the same IPv6 address, you need to set the IPv6 address pool to idle.

Precautions

If a user's IPv6 address is within the IPv6 address range specified when this command is run, the user cannot continue to use the IPv6 address after this command is run, and needs to send an IPv6 address application request again.

The address pool status cannot be restored after this command is run. Therefore, exercise caution when deciding to run this command.

Example

Set the status of all the conflicted IPv6 addresses in the IPv6 address pool mypool to idle.

```
<HUAWEI> reset dhcpv6 pool mypool conflict address
```

6.11.57 reset dhcpv6 relay prefix-delegation route

Function

The **reset dhcpv6 relay prefix-delegation route** command deletes routing information learned from DHCPv6 PD terminals on a DHCPv6 relay agent.

Format

reset dhcpv6 relay prefix-delegation route [**vpn6-instance** *vpn-instance-name*] *ipv6-address mask-length*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the destination IPv6 address of the routes to be deleted.	The 128-bit IPv6 address is divided into eight groups. Each group contains four hexadecimal digits. The format is X:X:X:X:X:X:X:X.

Parameter	Description	Value
mask-length	Specifies the mask length of the IPv6 address.	The value is an integer ranging from 0 to 128
vpn6-instance *vpn-instance-name*	Specifies the VPN instance name.	The value must be an existing VPN instance name.

Views

User view

Default Level

3: Management level

Usage Guidelines

The **reset dhcpv6 relay prefix-delegation route** command is used on DHCPv6 relay agents. Before collecting routing information about a specified IPv6 address, run the **reset dhcpv6 relay prefix-delegation route** command to delete the existing routing information.

Example

Delete routing information with destination IPv6 address fc00:1::1 learned from DHCPv6 PD terminals.

```
<HUAWEI> reset dhcpv6 relay prefix-delegation route fc00:1::1 64
```

6.11.58 reset dhcpv6 relay statistics

Function

The **reset dhcpv6 relay statistics** command clears DHCPv6 message statistics on the DHCPv6 relay agent.

Format

reset dhcpv6 relay statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. If no interface is specified, all the DHCPv6 message statistics are cleared. If an interface is specified, DHCPv6 message statistics on the specified interface are cleared.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

If a device is enabled with the DHCPv6 relay function, the system takes the statistics about DHCPv6 messages passing through the DHCP relay agent. You can use the **reset dhcpv6 relay statistics** command to clear current message statistics on the DHCPv6 relay agent.

Example

Clear the DHCPv6 message statistics on VLANIF 10.

```
<HUAWEI> reset dhcpv6 relay statistics interface vlanif 10
```

6.11.59 reset dhcpv6 server statistics

Function

The **reset dhcpv6 server statistics** command clears DHCPv6 message statistics on the DHCPv6 server.

Format

reset dhcpv6 server statistics [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Usage Guidelines

Collecting statistics about the DHCPv6 messages sent and received within a specified period helps you locate DHCPv6 faults. Before collecting new statistics, run the **reset dhcpv6 statistics** command to clear the existing message statistics. After clearing existing statistics, run the **display dhcpv6 statistics** command to view latest message statistics.

Example

Clear DHCPv6 packet statistics.

```
<HUAWEI> reset dhcpv6 statistics
```

6.11.61 sip-domain-name

Function

The **sip-domain-name** command configures the SIP domain name suffix assigned by the DHCPv6 server to a DHCPv6 client.

The **undo sip-domain-name** command deletes the assigned SIP domain name suffix.

By default, no SIP domain name suffix is configured for the DHCPv6 client.

Format

sip-domain-name *sip-domain-name*

undo sip-domain-name *sip-domain-name*

Parameters

Parameter	Description	Value
sip-domain-name	Specifies the SIP domain name suffix assigned to a DHCPv6 client.	The value is a string of 1 to 63 case-insensitive characters without spaces. It can be the combination of letters, digits, underscores (_), hyphens (-), or dots (.) and cannot be set to a single hyphen (-) or consecutive hyphens (--).

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **sip-domain-name** command is used on DHCPv6 servers. The DHCPv6 server specifies an SIP domain name when allocating IPv6 addresses for clients. You can use the **sip-domain-name** command on the DHCPv6 server to specify a SIP domain name for each global address pool. When allocating IPv6 addresses to clients, the DHCPv6 server also sends the domain name suffixes to the clients.

Precautions

A maximum of four SIP domain name suffixes can be configured for an IPv6 address pool.

Example

Configure the SIP domain name assigned to the DHCPv6 client as **sip.com** for the address pool **pool1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] sip-domain-name sip.com
```

6.11.62 sip-server (IPv6 address pool view)

Function

The **sip-server** command configures the SIP server address assigned to the DHCPv6 client for the IPv6 address pool.

The **undo sip-server** command deletes the configured SIP server address assigned to the DHCPv6 client from the IPv6 address pool.

By default, no SIP server address is configured for the IPv6 address pool.

Format

sip-server *ipv6-address*

undo sip-server *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	SIP server IPv6 address.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **sip-server** command is used on DHCPv6 servers. The DHCPv6 server needs to specify the IPv6 address of the SIP server for the address pool so that the DHCPv6 client can be connected to the Internet. The DHCPv6 server specifies the IPv6 address of the SIP server when allocating IPv6 addresses to the clients.

Precautions

- A maximum of two SIP server addresses can be configured for each address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- When multiple SIP servers are specified, you need to run the **sip-server** repeatedly to configure multiple addresses.

Example

Specify fc00:3::1 as the IPv6 address of the SIP server when the assigned IPv6 address belongs to the address pool **global1**.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] sip-server fc00:3::1
```

6.11.63 sntp-server

Function

The **sntp-server** command configures the SNTP server IPv6 address assigned to the DHCPv6 client for the IPv6 address pool.

The **undo sntp-server** command deletes the configured SNTP server IPv6 address assigned to the DHCPv6 client from the IPv6 address pool.

By default, no SNTP server IPv6 address is configured for the IPv6 address pool.

Format

sntp-server *ipv6-address*

undo sntp-server *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address of an SNTP server.	The value is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **sntp-server** command is used on DHCPv6 servers. The DHCPv6 server needs to specify the IPv6 address of the SNTP server for the IPv6 address pool so that the DHCPv6 client can be connected to the Internet. The DHCPv6 server specifies the IPv6 address of the SNTP server when allocating IPv6 addresses to the clients. After the clients receive the IPv6 address of the SNTP server, the clients synchronize the system time with the specified SNTP server.

Precautions

- A maximum of two SNTP server addresses can be configured for each IPv6 address pool. The first assigned address functions as the primary address, and the other address functions as a secondary address.
- When multiple SNTP servers are specified, you need to run the **sntp-server** command repeatedly to configure multiple addresses.

Example

Specify fc00:1::1 as the IPv6 address of the SNTP server when IPv6 addresses in the address pool **global1** are assigned.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool global1
[HUAWEI-dhcpv6-pool-global1] sntp-server fc00:1::1
```

6.11.64 static-bind address

Function

The **static-bind address** command statically binds an IPv6 address to the client DUID in the DHCPv6 address pool view.

The **undo static-bind address** command deletes the statically bound entries between the IPv6 address and the client DUID in the DHCPv6 address pool view.

By default, no IPv6 address is bound to the client DUID in the address pool view.

Format

static-bind address *ipv6-address* **duid** *client-duid* [**iaid** *iaid*] [**life-time** { *valid-lifetime* | **infinite** } { *preferred-lifetime* | **infinite** }]

undo static-bind address *ipv6-address*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address statically bound to an address pool.	The 128-bit IPv6 address is divided into eight groups. Each group contains four hexadecimal digits. The format is X:X:X:X:X:X:X:X.
duid *client-duid*	Configures the DUID of the DHCPv6 client that is statically bound to the IPv6 address.	The value is a string of 2 to 256 characters in hexadecimal notation. The length of the string is an even.
iaid *iaid*	Specifies IA identifier value.	The value is an integer that ranges from 1 to 4294967295.
life-time	Specifies the lifetime of the bound entries.	-
valid-lifetime	Specifies the valid lifetime of the bound entries.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 172800, that is two days.
preferred-lifetime	Specifies the preferred lifetime of the bound entries.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 86400, that is one day.

Parameter	Description	Value
infinite	Sets the lifetime of the bound entries to infinite.	-

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **static-bind address** command is used on DHCPv6 servers. If some special clients need to be statically assigned with fixed IPv6 addresses, bind the DUIDs of these clients to the IPv6 addresses. When receiving a request from a special client for requesting an IPv6 address, a DHCPv6 server assigns the fixed IPv6 address bound to the client DUID to this client.

Prerequisites

1. An address pool has been created by using the **dhcpv6 pool** command.
2. Bind an IPv6 address prefix to an address pool by using the **address prefix**

Example

Bind the IPv6 address fc00:1::2 with the client with DUID abcdef in address pool pool1 and set the lifetime to infinite.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] address prefix fc00:1::/64
[HUAWEI-dhcpv6-pool-pool1] static-bind address fc00:1::2 duid abcdef life-time infinite infinite
```

6.11.65 static-bind prefix

Function

The **static-bind prefix** command statically binds an IPv6 address prefix to the DHCPv6 PD client in the DHCPv6 address pool view.

The **undo static-bind prefix** command unbinds the IPv6 address prefixes from the DHCPv6 PD clients in the DHCPv6 address pool view.

By default, no IPv6 address prefix is bound to the DHCPv6 PD client in the address pool view.

Format

static-bind prefix *ipv6-prefix/ipv6-prefix-length* **duid** *client-duid* [**iaid** *iaid-value*] [**life-time** { *valid-lifetime* | **infinite** } { *preferred-lifetime* | **infinite** }]

undo static-bind prefix *ipv6-prefix/ipv6-prefix-length*

Parameters

Parameter	Description	Value
ipv6-prefix/ipv6-prefix-length	Specifies the IPv6 address prefix that is statically bound to an address pool.	The value is a 32-digit hexadecimal number, in the format X:X::X:X/M.
duid *client-duid*	Specifies the DUID of the DHCPv6 PD client that is statically bound to the IPv6 address prefix.	The value is a string of 2 to 256 characters in hexadecimal notation. The length of the string is an even.
iaid *iaid-value*	Specifies the IAID of the DHCPv6 PD client that is statically bound to the IPv6 address prefix.	The value is an integer that ranges from 1 to 4294967295.
life-time	Specifies the lifetime of the bound entries.	-
valid-lifetime	Specifies the valid lifetime.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 172800, that is two days.
preferred-lifetime	Specifies the preferred lifetime. The preferred lifetime cannot exceed the valid lifetime.	The value is an integer that ranges from 60 to 172799999, in seconds. The default value is 86400, that is one day.
infinite	Sets the lifetime to infinite. When the preferred lifetime is set to infinite, the valid lifetime must be set to infinite.	-

Views

IPv6 address pool view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **static-bind prefix** command is used on DHCPv6 PD servers. If some special DHCPv6 PD clients need to be statically assigned with fixed IPv6 address prefixes, bind the DUIDs and IAIDs of these clients to the IPv6 address prefixes. When receiving a request for applying for an IP address prefix from a special DHCPv6 PD client, a DHCPv6 PD server assigns the fixed IPv6 address prefix bound to the DUIDs and IAIDs to this client.

Prerequisites

An address pool has been created by using the **dhcpv6 pool** command.

Precautions

- When assigning addresses for DHCPv6 PD clients, bind the address prefix to the DUID of the client. The IAID of the client cannot be specified.
- The statically bound prefix cannot be overlapped with the prefix that is configured using the **prefix-delegation** command.

Example

Bind the IPv6 address prefix fc00:1::/64 to the DHCPv6 PD client with DUID abcdef and IAID 12 in address pool pool1 and set the lifetime of the binding entries to infinite.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] static-bind prefix fc00:1::/64 duid abcdef iaid 12 life-time infinite infinite
```

6.11.66 suboption

Function

The **suboption** command configures vendor-defined DHCPv6 sub-options.

The **undo suboption** command deletes vendor-defined DHCPv6 sub-options.

By default, no vendor-defined DHCPv6 sub-option is configured.

Format

suboption *suboption-code* { **address** *ipv6-address* &<1-4> | **ascii** *ascii-string* | **hex** *hex-string* }

undo suboption *suboption-code*

Parameters

Parameter	Description	Value
suboption-code	Specifies the code of the vendor-defined DHCPv6 sub-options.	The value is an integer that ranges from 1 to 65535.
address *ipv6-address*	Specifies the vendor-defined option code as the IPv6 address type.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
ascii *ascii-string*	Specifies the vendor-defined option code as an ASCII character string.	The value is a string of 1 to 255 characters.
hex *hex-string*	Specifies the vendor-defined option code as a hexadecimal string.	The value is a hexadecimal numeral string with an even number of characters (such as aa or aaaa). The even number ranges from 2 to 128.

Views

Vendor-defined mode view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **suboption** command is used on DHCPv6 servers. Run the **vendor-specific** command to enter the vendor-defined mode. In this mode, configure the vendor-defined DHCPv6 options. The DHCPv6 device can carry vendor-defined options such as the TFTP server name and address, and the configuration file of the device.

The **suboption** command configures vendor-defined DHCPv6 sub-options.

Precautions

A maximum of 16 vendor-defined sub-options can be configured in the vendor-defined mode view.

Example

Set Huawei-defined sub-option 10 to fc00:1::5 in the IPv6 address pool pool1 view.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] vendor-specific 2011
[HUAWEI-dhcpv6-pool-pool1-vs-2011] suboption 10 address fc00:1::5
```

6.11.67 vendor-specific

Function

The **vendor-specific** command configures vendor-defined options for the IPv6 address pool and enter the vendor-defined mode view.

The **undo vendor-specific** command deletes vendor-defined options configured for the IPv6 address pool.

By default, no vendor-defined option is configured.

Format

vendor-specific *vendor-id*

undo vendor-specific *vendor-id*

Parameters

Parameter	Description	Value
vendor-id	Indicates the ID of the vendor, which is assigned by the IANA. 2011 is the identifier for Huawei.	The value is an integer that ranges from 1 to 4294967295.

Views

IPv6 address pool view

Default Level

Usage Guidelines

Usage Scenario

The **vendor-specific** command is used on DHCP servers. You can use the **vendor-specific** command to enter the vendor-defined mode. In this mode, you can configure the vendor-defined DHCPv6 options. The DHCPv6 device can carry vendor-defined options such as the TFTP server name and address, and the configuration file of the device.

Precautions

A maximum of eight vendor-defined modes are configured for one IPv6 address pool.

Example

Configure Huawei-defined options for the IPv6 address pool pool1.

```
<HUAWEI> system-view
[HUAWEI] dhcpv6 pool pool1
[HUAWEI-dhcpv6-pool-pool1] vendor-specific 2011
```

6.12 IPv6 DNS Configuration Commands

6.12.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

6.12.2 display dns ipv6 dynamic-host

Function

The **display dns ipv6 dynamic-host** command displays IPv6 dynamic DNS entries.

Format

display dns ipv6 dynamic-host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays IPv6 dynamic DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.
all	Displays all IPv6 dynamic DNS entries, including both public and private DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public IPv6 dynamic DNS entries are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display dns ipv6 dynamic-host** command to view IPv6 dynamic DNS entries and check whether domain names match the mapping entries.

Example

Display IPv6 dynamic DNS entries.

```
<HUAWEI> display dns ipv6 dynamic-host
No  Domain-name       Ipv6Address     TTL
1   example           FC00:1::1       6
```

Display IPv6 dynamic DNS entries of the VPN instance vpn1.

```
<HUAWEI> display dns ipv6 dynamic-host vpn-instance vpn1
No      Domain-name                              Ipv6Address         TTL          VPN-Instance
1       example                                  2001:db8::2         6            vpn1
```

Table 6-90 Description of the **display dns ipv6 dynamic-host** command output

Item	Description
No	Sequence number of a dynamic IPv6 DNS entry.
Domain-name	Domain name.
Ipv6Address	IPv6 address mapping the domain name.
TTL	TTL value of the dynamic domain names in the cache (in seconds).
VPN-Instance	VPN instance name.

6.12.3 display ipv6 host

Function

The **display ipv6 host** command displays the IPv6 static DNS entries.

Format

display ipv6 host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays IPv6 static DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.
all	Displays all IPv6 static DNS entries, including both public and private static DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public IPv6 static DNS entries are displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After running the **ipv6 host** command to configure IPv6 static DNS entries, you can run this command to check whether mappings between host names and IPv6 addresses are correct.

Example

Display IPv6 static DNS entries.

```
<HUAWEI> display ipv6 host
Host                Age      Flags         IPv6Address(es)
www.example.com      0         static          FC00:1::8
www.sohu.com         0         static          FC00:1::9
```

Display IPv6 static DNS entries of the VPN instance vpn1.

```
<HUAWEI> display ipv6 host vpn-instance vpn1
Host          Age        Flags       IPv6Address(es)        VPN-Instance
RTB           0          static      2001:db8::1            vpn1
```

Table 6-91 Description of the **display ipv6 host** command output

Item	Description
Host	Host name. The value is set using the **ipv6 host** command.

Item	Description
Age	Aging time. The value 0 indicates that the entry is not aged out.
Flags	Identifiers. The value static indicates a static domain name.
IPv6Address(es)	IPv6 address mapping the domain name. The value is set using the **ipv6 host** command.
VPN-Instance	VPN instance name. The value is set using the **ipv6 host** command.

6.12.4 dns server ipv6

Function

The **dns server ipv6** command configures the IPv6 address of a DNS server.

The **undo dns server ipv6** command deletes the IPv6 address of a DNS server.

By default, no IPv6 addresses of DNS servers are configured.

Format

dns server ipv6 *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*]

undo dns server ipv6 *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address for a DNS server.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an outbound interface that communicates with the DNS server.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DNS client must work with the DNS server to implement dynamic domain name resolution. You can run the **dns server ipv6** command to specify the IPv6 address of the DNS server. The DNS client sends requests to the specified DNS server for domain name resolution.

During dynamic domain name resolution, the switch sends a domain name resolution request to the DNS servers according to the order in which they were configured. If the domain name resolution request on the first DNS server times out, the device sends the request to the next DNS server.

Precautions

The IPv6 address of the DNS server must be a global unicast address or link-local address.

- If a link-local address is configured as the IPv6 address of the DNS server, specify the outbound interface for communicating with the DNS server.
- If a global unicast address is configured as the IPv6 address of the DNS server, do not specify the outbound interface for communicating with the DNS server.

A maximum of six DNS server IP (IPv4 and IPv6) addresses can be configured on the switch.

If **vpn-instance** *vpn-instance-name* is specified, the system sends domain name resolution requests only to the DNS servers bound to the specified VPN instance.

Example

Configure the IPv6 address of the DNS server to fc00:1::1.

```
<HUAWEI> system-view
[HUAWEI] dns server ipv6 fc00:1::1
```

6.12.5 dns server ipv6 source-ip

Function

The **dns server ipv6 source-ip** command configures the source IPv6 address for the local end functioning as the DNS client to communicate with the DNS server.

The **undo dns server ipv6 source-ip** command deletes the source IPv6 address used for the local end functioning as the DNS client to communicate with the DNS server.

By default, no source IPv6 address is configured for the local end functioning as the DNS client to communicate with the DNS server.

Format

dns server ipv6 source-ip *ipv6-address* [**vpn-instance** *vpn-instance-name*]

undo dns server ipv6 source-ip [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
ipv6-address	Specifies the source IPv6 address for the local end functioning as the DNS client to communicate with the DNS server.	The value has 128 bits. It is represented as eight groups of four hexadecimal digits with the groups being separated by colons, in the format of X:X:X:X:X:X:X:X.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the source IPv6 address is specified, the DNS client uses the specified IPv6 address to communicate with the DNS server. This ensures communication security. If no source IPv6 address is specified, the DNS client needs to select a source IPv6 address according to the destination address each time it sends an IPv6 DNS request.

Precautions

If only one route from the DNS server to the client with an IPv6 address is reachable, you need to specify the source IPv6 address in the DNS query message when the DNS client sends a DNS query to the server.

If **vpn-instance** *vpn-instance-name* is specified, the specified source IPv6 address is used only when the device communicates with the DNS server bound to the specified VPN instance.

Example

Configure the source IPv6 address that the DNS client uses to communicate with the DNS server to fc00:1::1.

```
<HUAWEI> system-view
[HUAWEI] dns server ipv6 source-ip fc00:1::1
```

6.12.6 ipv6 host

Function

The **ipv6 host** command configures an IPv6 static DNS entry.

The **undo ipv6 host** command deletes an IPv6 static DNS entry.

By default, no IPv6 static DNS entry is configured.

Format

ipv6 host *host-name ipv6-address* [**vpn-instance** *vpn-instance-name*]

undo ipv6 host *host-name* [*ipv6-address* [**vpn-instance** *vpn-instance-name*]]

Parameters

Parameter	Description	Value
host-name	Specifies the host name.	The value is a string of 1 to 255 case-sensitive characters without any space. The value must contain at least one letter, and can consist of letters, digits, hyphens (-), dots (.), and underscores (_).

Parameter	Description	Value
ipv6-address	Specifies the IPv6 address mapping the host name.	The value consists of 128 octets, which are classified into 8 groups. Each group contains 4 hexadecimal numbers in the format X:X:X:X:X:X:X:X.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When requesting the IPv6 address mapping a domain name, the DNS client searches for the specified domain name in the static DNS table to obtain the corresponding IPv6 address. The **ipv6 host** command configures an IPv6 static DNS entry.

Precautions

Each domain name supports a maximum of eight IPv6 addresses.

Example

Configures an IPv6 static DNS entry mapping the host named **www.example.com**.

```
<HUAWEI> system-view
[HUAWEI] ipv6 host www.example.com fc00:1::8
```

6.12.7 reset dns ipv6 dynamic-host

Function

The **reset dns ipv6 dynamic-host** command clears IPv6 dynamic DNS entries.

Format

reset dns ipv6 dynamic-host [**vpn-instance** *vpn-instance-name* | **all**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears IPv6 dynamic DNS entries of a specified VPN instance.	The value must be an existing VPN instance name.
all	Clears all IPv6 dynamic DNS entries, including both public and private DNS entries. **NOTE** If neither **vpn-instance** *vpn-instance-name* nor **all** is specified, only public IPv6 dynamic DNS entries are cleared.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After confirming the action of deleting IPv6 dynamic DNS entries, you can run the **reset dns ipv6 dynamic-host** command to delete them.

Precautions

IPv6 dynamic DNS entries cannot be restored after being deleted. Confirm the action before you run the command.

Example

Clear all IPv6 dynamic DNS entries.

```
<HUAWEI> reset dns ipv6 dynamic-host all
```

6.13 IPv6 over IPv4 Tunnel Configuration Commands

6.13.1 Command Support

Only the following switch models support the IPv6 over IPv4 Tunnel:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.13.2 destination

Function

The **destination** command specifies the destination IP address of a tunnel interface.

The **undo destination** command deletes the destination IP address of a tunnel interface.

By default, no destination address is configured.

Format

destination [**vpn-instance** *vpn-instance-name*] *dest-ip-address*

undo destination

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance that the destination address of a tunnel belongs to. When the tunnel interface uses GRE, you can specify **vpn-instance** *vpn-instance-name*.	The value is the name of an existing VPN instance.
dest-ip-address	Specifies the destination IP address of a tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **destination** command to specify the destination IP address for the tunnel interface.

When using the **destination** command on a PE to specify the destination address of a GRE tunnel bound for a CE, you need to set **vpn-instance** *vpn-instance-name* in the command to specify the name of the VPN instance to which the destination address belongs.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the destination address of the local tunnel interface is the source address of the remote tunnel interface, and the source address of the local tunnel interface is the destination address of the remote tunnel interface.

Example

Establish a manual IPv6 over IPv4 tunnel between VLANIF 10 at 10.1.1.1 on switch HUAWEI1 and VLANIF 20 at 10.2.1.1 on switch HUAWEI2.

```
<HUAWEI1> system-view
[HUAWEI1] interface tunnel 1
[HUAWEI1-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI1-Tunnel1] source 10.1.1.1
[HUAWEI1-Tunnel1] destination 10.2.1.1
<HUAWEI2> system-view
[HUAWEI2] interface tunnel 1
[HUAWEI2-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI2-Tunnel1] source 10.2.1.1
[HUAWEI2-Tunnel1] destination 10.1.1.1
```

Set the destination address of the GRE tunnel Tunnel1 to 10.1.1.1 that belongs to vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] quit
[HUAWEI-vpn-instance-vpn1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] destination vpn-instance vpn1 10.1.1.1
```

6.13.3 interface tunnel

Function

The **interface tunnel** command creates a tunnel interface.

The **undo interface tunnel** command deletes the configured tunnel interface.

By default, no tunnel interface is configured.

Format

interface tunnel *interface-number*

undo interface tunnel *interface-number*

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface.	The value is an integer that ranges from 0 to 2047 .

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To forward data over a tunnel, ensure that the tunnel has been created. The system supports the following types of tunnels:

- LSP (Static LSP, BGP LSP, LDP LSP)
- MPLS TE
- GRE
- IPv6 over IPv4
- IPv4 over IPv6

You must use the **interface tunnel** command to create a tunnel interface when creating a tunnel except for LSP tunnels.

Precautions

Tunnel interface numbers are valid on the local device only. You can configure different numbers for the tunnel interfaces on the two ends.

Follow-up Procedure

After a tunnel interface is created, you need to configure an IP address and encapsulation type for the tunnel interface.

To save IP addresses, run the **ip address unnumbered** command to configure the tunnel interface to borrow an IP address of another interface.

The **tunnel-protocol** command configures an encapsulation protocol for the tunnel interface. Then basic configurations are performed based on the encapsulation protocol:

- On an MPLS TE tunnel, run the **destination**, **mpls te tunnel-id**, **mpls te signal-protocol**, and **mpls te commit** commands.
- On the GRE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, run the **source** and **destination** commands.

Example

Create a tunnel interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1]
```

6.13.4 source

Function

The **source** command configures the source address or source interface of the tunnel.

The **undo source** command deletes the configured source address or source interface.

The source address and source interface of a tunnel are not specified by default.

Format

source { *source-ip-address* | *interface-type interface-number* }

undo source

Parameters

Parameter	Description	Value
source-ip-address	Specifies the source address of a tunnel interface. If a tunnel interface works in IPv4-IPv6 mode, specify an IPv6 address as the source address of the tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface-type interface-number	Specifies the type and the number of the source interface of the tunnel. The following types of interfaces are often used: VLANIF and loopback.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **source** command to specify the source IP address for the tunnel interface.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the source address of the local tunnel interface is the destination address of the remote tunnel interface, and the destination address of the local tunnel interface is the source address of the remote tunnel interface.

Example

Set the tunnel type of Tunnel1 to IPv6 over IPv4 of manual mode and configure the source IP address of Tunnel1 as 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI-Tunnel1] source 10.1.1.1
```

Configure Tunnel1 of GRE and use Loopback1 address as the interface address.

```
<HUAWEI> system-view
[HUAWEI] interface Loopback 1
[HUAWEI-LoopBack1] ip address 10.2.1.1 32
[HUAWEI-LoopBack1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] source loopback 1
```

6.13.5 tunnel-protocol

Function

The **tunnel-protocol** command configures the tunnel protocol on a tunnel interface.

The **undo tunnel-protocol** command restores the tunnel protocol to the default configuration.

By default, no tunnel protocol is used on a tunnel interface.

Format

tunnel-protocol { **gre** | **ipv6-ipv4** [**6to4** | **isatap**] | **ipv4-ipv6** | **mpls te** | **none** }

undo tunnel-protocol

Parameters

Parameter	Description	Value
gre	Indicate that the GRE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameters.	-
ipv4-ipv6	Indicate that the IPv4 to IPv6 tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameter.	-
ipv6-ipv4 [**6to4** | **isatap**]	Configure the tunnel protocol of the tunnel interface as ipv6-ipv4: ● **ipv6-ipv4**: use a manual IPv6 over IPv4 tunnel ● **ipv6-ipv4 6to4** : using 6to4 tunnel ● **ipv6-ipv4 isatap** : using isatap tunnel **NOTE** Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support these parameter.	-

Parameter	Description	Value
mpls te	Indicate that the MPLS TE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730-S, S6730S-S, and S6730S-H support the parameter.	-
none	Indicate that no tunnel protocol is configured on a tunnel interface.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a tunnel interface using the **interface tunnel** command, run the **tunnel-protocol** command to configure the tunnel encapsulation mode for the tunnel interface.

The following tunnel encapsulation modes are available:

- GRE: encapsulates packets of some network layer protocols such as IP or IPX to enable these encapsulated packets to be transmitted on networks running other protocols such as IP.
- IPv4-IPv6: creates tunnels on the IPv6 networks to connect IPv4 isolated sites so that IPv4 isolated sites can access other IPv4 networks through the IPv6 public network.
- IPv6-IPv4: creates tunnels on the IPv4 networks to connect IPv6 isolated sites so that IPv6 packets can be transmitted on IPv4 networks.
- MPLS TE: integrates the MPLS technology with traffic engineering. It can reserve resources by setting up LSP tunnels for a specified path in an attempt to avoid network congestion and balance network traffic.

Precautions

- The **none** mode indicates the initial configuration, that is, no tunnel encapsulation mode is configured. In practice, you must select another tunnel encapsulation mode.
- You must configure the tunnel encapsulation mode before setting the source IP address or other parameters for a tunnel interface. Changing the encapsulation mode of a tunnel interface deletes other parameters of the tunnel interface.

Example

Set the tunnel encapsulation mode of Tunnel2 to GRE.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 2
[HUAWEI-Tunnel2] tunnel-protocol gre
```

6.14 IPv4 over IPv6 Tunnel Configuration Commands

6.14.1 Command Support

Only the following switch models support IPv4 over IPv6 Tunnel:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S

6.14.2 display interface tunnel

Function

The **display interface tunnel** command displays details of the tunnel interface.

Format

display interface tunnel [*interface-number* | **main**]

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface. If this parameter is not specified, the command displays information about all tunnel interfaces.	The value must be the number a tunnel interface that has been created.
main	Displays status and traffic statistics about main interface. The interface has no sub-interfaces. Status and traffic statistics about the interface are displayed whether you specify the main parameter or not.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check status of tunnels or diagnose the fault in these tunnels, run the **display interface tunnel** command. You can run this command to obtain tunnel interface information when configuring tunnels or when locating the fault on these tunnels.

Prerequisites

Before run **display interface tunnel**, please ensure that tunnel interface has been created using the **interface tunnel** command.

Example

Display the details of the tunnel interface.

```
<HUAWEI> display interface tunnel 1
Tunnel1 current state : UP
Line protocol current state : UP
Last line protocol up time : 2012-11-16 19:16:33 UTC+08:00
Description:
Route Port,The Maximum Transmit Unit is 1500
Internet Address is 10.3.1.2/24
Encapsulation is TUNNEL, loopback not set
Tunnel source 10.2.1.2 (Vlanif1234), destination 10.2.1.1
Tunnel protocol/transport GRE/IP, key disabled
keepalive enable period 5 retry-times 3
Checksumming of packets disabled
Current system time: 2012-11-16 19:17:39+08:00
Last 300 seconds input rate 16 bits/sec, 0 packets/sec
Last 300 seconds output rate 0 bits/sec, 0 packets/sec
Input:  5 packets, 650 bytes
Output:  0 packets, 0 bytes
    Input bandwidth utilization  :    0%
    Output bandwidth utilization :    0%
```

Table 6-92 Description of the display interface tunnel command output

Item	Description
Tunnel1 current state	Physical layer status of the tunnel interface: - UP: The interface is in normal state. - Administratively DOWN: The network administrator executes the **shutdown** command on the interface. After a tunnel interface is created, its physical layer status is Up.

Item	Description
Line protocol current state	Link protocol status: ● UP: The link layer protocol of the tunnel interface works normally. ● Down: The link layer protocol of the tunnel interface is abnormal.
Last line protocol up time	Last time the link layer protocol of the tunnel interface goes UP. **NOTE** This field is displayed only when the link layer protocol status of the tunnel interface is UP.
Description	Description of the tunnel interface.
Route Port	Indicates the Layer 3 interface.
The Maximum Transmit Unit is 1500	MTU of tunnel interfaces, which is 1500 bytes by default. Any packet larger than the MTU is fragmented before being sent. If non-fragmentation is configured, the packet is discarded.
Internet Address is 10.3.1.2/24	IP address of the tunnel interface is 10.3.1.2. The mask is 24 bits, that is, 255.255.255.0.
Encapsulation is TUNNEL,	Encapsulation type of packets on a tunnel interface. Packet encapsulation protects a whole IP packet.
loopback not set	The tunnel interface does not support a loopback test.
Tunnel source 10.2.1.2 (Vlanif1234)	The source address of the tunnel is 10.2.1.2. That is, the IP address of the VLANIF 1234 interface sending packets at the source side is 10.2.1.2.
destination 10.2.1.1	Destination address of the tunnel.
Tunnel protocol/ transport GRE/IP, key disabled	The tunnel encapsulation protocol is the GRE protocol, and the transport protocol is the IP protocol. Encapsulation protocol types of a tunnel are as follows: ● GRE: indicates Generic Routing Encapsulation. ● MPLS: encapsulates packets into MPLS packets. ● IPv6 over IPv4: encapsulates IPv6 packets into IPv4 packets. ● IPv4 over IPv6: encapsulates IPv4 packets into IPv6 packets. ● none: indicates no encapsulation. This is the default mode of the tunnel interface. key disabled: the key word recognition function of GRE is not enabled.

Item	Description
keepalive enable period 5 retry-times 3	The keepalive function of GRE.
Checksumming of packets disabled	The check sum function of GRE is not enabled.
Current system time	Current system time. If the time zone is configured and the daylight saving time is used, the time is in YYYY/MM/DD HH:MM:SS UTC±HH:MM DST format.
Last 300 seconds input rate	Incoming packet rate (bits per second and packets per second) within the last 300 seconds.
Last 300 seconds output rate	Outgoing packet rate (bits per second and packets per second) within the last 300 seconds.
Input	Total number of received packets.
Output	Total number of sent packets.
Input bandwidth utilization : --	Input bandwidth usage.
Output bandwidth utilization : --	Output bandwidth usage.

6.14.3 tunnel ipv4-ipv6 encapsulation-limit

Function

The **tunnel ipv4-ipv6 encapsulation-limit** command configures the maximum number of times that IPv6 encapsulation can be performed on embedded nodes of the IPv4 over IPv6 tunnel after an IPv4 packet is encapsulated the first time.

The **undo tunnel ipv4-ipv6 encapsulation-limit** command closes the function of IPv6 encapsulation on embedded nodes of the IPv4 over IPv6 tunnel.

By default, a maximum of four times of IPv6 encapsulation can be performed on embedded nodes of the IPv4 over IPv6 tunnel.

Format

tunnel ipv4-ipv6 encapsulation-limit *encapsulation-limit*

undo tunnel ipv4-ipv6 encapsulation-limit

Parameters

Parameter	Description	Value
encapsulation-limit	Specifies the maximum number of times for performing IPv6 encapsulation on embedded nodes of the IPv4 over IPv6 tunnel.	The value is an integer that ranges from 0 to 255.

Views

System view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maximum number of times that IPv6 encapsulation can be performed on embedded nodes of the IPv4 over IPv6 tunnel is the value of the tunnel encapsulation limit option carried in the destination option extension header in the IPv6 tunnel header.

- If this command is configured in the tunnel interface view, it takes effect only on the current tunnel interface.
- If this command is configured in the system view, it takes effect only on the mobile IPv6 network.

Prerequisites

Before running the **tunnel ipv4-ipv6 encapsulation-limit** command in the tunnel interface view, run the **tunnel-protocol ipv4-ipv6** command in the same view to set the tunnel mode to the IPv4 over IPv6 manual tunnel.

Precautions

The configuration in the system view and the configuration in the tunnel interface view are independent of each other.

When Huawei devices communicate with non-Huawei devices, you must run the **undo tunnel ipv4-ipv6 encapsulation-limit** command to restore the maximum number of times that IPv6 encapsulation on embedded nodes of the IPv4 over IPv6 tunnel can be performed after an IPv4 packet is encapsulated the first time to the default value.

Example

Set the maximum number of times of IPv6 encapsulation to be performed on the embedded nodes of the specified IPv4 over IPv6 tunnel to 3.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv4-ipv6
[HUAWEI-Tunnel1] tunnel ipv4-ipv6 encapsulation-limit 3
```

Set the maximum number of times of IPv6 encapsulation to be performed on the embedded nodes of all specified IPv4 over IPv6 tunnels to 3 on the local device.

```
<HUAWEI> system-view
[HUAWEI] tunnel ipv4-ipv6 encapsulation-limit 3
```

6.14.4 tunnel ipv4-ipv6 flow-label

Function

The **tunnel ipv4-ipv6 flow-label** command sets the flow label value.

The **undo tunnel ipv4-ipv6 flow-label** command restores the default flow label value.

The default flow label value is 0.

Format

tunnel ipv4-ipv6 flow-label *label-value*

undo tunnel ipv4-ipv6 flow-label

Parameters

Parameter	Description	Value
label-value	Specifies the flow label value.	The value is an integer that ranges from 0 to 1048575.

Views

Tunnel interface view, system view

Default Level

2: Configuration level

Usage Guidelines

The flow label value of the tunnel refers to the value specified in the flow label field in the IPv6 packet header on the inbound interface of the tunnel.

- If this command is configured in the tunnel interface view, it takes effect only on the current tunnel interface.
- If this command is configured in the system view, it takes effect only on the mobile IPv6 network.

Before running the **tunnel ipv4-ipv6 flow-label** command in the tunnel interface view, run the **tunnel-protocol ipv4-ipv6** command in the same view to set the tunnel mode to the IPv4 over IPv6 manual tunnel.

The configuration in the system view and the configuration in the tunnel interface view are independent of each other.

Example

Set the flow label value of a specified IPv4 over IPv6 tunnel to 10.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv4-ipv6
[HUAWEI-Tunnel1] tunnel ipv4-ipv6 flow-label 10
```

Set the flow label value of all the IPv4 over IPv6 tunnels on the local device to 10.

```
<HUAWEI> system-view
[HUAWEI] tunnel ipv4-ipv6 flow-label 10
```

6.14.5 tunnel ipv4-ipv6 hop-limit

Function

The **tunnel ipv4-ipv6 hop-limit** command sets the hop limit of the IPv6 tunnel packets.

The **undo tunnel ipv4-ipv6 hop-limit** command restores the hop limit of the IPv6 tunnel packets to the default value.

By default, the hop limit of the IPv6 tunnel packets is 64.

Format

tunnel ipv4-ipv6 hop-limit *hop-limit*

undo tunnel ipv4-ipv6 hop-limit

Parameters

Parameter	Description	Value
hop-limit	Specifies the hop limit of the IPv6 tunnel packets.	The value is an integer that ranges from 1 to 255.

Views

system view, Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Setting the hop limit of the IPv6 tunnel packets can terminate the packet transmission when routing loops occur on the IPv6 tunnel. To make IPv6 tunnel packets reach the egress of the tunnel, the tunnel hop limit cannot be set too small.

- If this command is configured in the tunnel interface view, it takes effect only on the current tunnel interface.

- If this command is configured in the system view, it takes effect only on the mobile IPv6 network.

Before running the **tunnel ipv4-ipv6 hop-limit** command in the tunnel interface view, run the **tunnel-protocol ipv4-ipv6** command in the same view to set the tunnel mode to the IPv4 over IPv6 manual tunnel.

The configuration in the system view and the configuration in the tunnel interface view are independent of each other.

Example

Set the hop limit of the specified tunnel interface to 100.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv4-ipv6
[HUAWEI-Tunnel1] tunnel ipv4-ipv6 hop-limit 100
```

6.14.6 tunnel ipv4-ipv6 traffic-class

Function

The **tunnel ipv4-ipv6 traffic-class** command sets the traffic level of the IPv4 over IPv6 tunnel.

The **undo tunnel ipv4-ipv6 traffic-class** command restores the traffic level to the default value.

By default, the traffic level of the IPv4 over IPv6 tunnel is 0.

Format

tunnel ipv4-ipv6 traffic-class { **original** | *class-value* }

undo tunnel ipv4-ipv6 traffic-class

Parameters

Parameter	Description	Value
original	Indicates that the value of the Traffic Class field in the IPv6 field of the IPv4 over IPv6 tunnel header uses the value in Traffic Class field of the original packet.	-
class-value	Specifies the traffic level of the IPv4 over IPv6 tunnel.	The value is an integer that ranges from 0 to 255.

Views

Tunnel interface view, system view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The traffic level of the IPv4 over IPv6 tunnel packets refers to the value of the traffic class field in the tunnel packet header of the ingress on the tunnel.

- If this command is configured in the tunnel interface view, it takes effect only on the current tunnel interface.
- If this command is configured in the system view, it takes effect only on the mobile IPv6 network.

Prerequisites

Before running the **tunnel ipv4-ipv6 traffic-class** command in the tunnel interface view, run the **tunnel-protocol ipv4-ipv6** command in the same view to set the tunnel mode to the IPv4 over IPv6 manual tunnel.

Precautions

The configuration in the system view and the configuration in the tunnel interface view are independent of each other.

Example

Set the traffic level of the specified IPv4 over IPv6 tunnel to 10.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv4-ipv6
[HUAWEI-Tunnel1] tunnel ipv4-ipv6 traffic-class 10
```

Set the traffic level of all the IPv4 over IPv6 tunnels on the local device to 10.

```
<HUAWEI> system-view
[HUAWEI] tunnel ipv4-ipv6 traffic-class 10
```

7 IP Unicast Routing Commands

7.1 Static Route Configuration Commands

7.1.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.1.2 ip route recursive-lookup bgp-vpnv4-route

Function

The **ip route recursive-lookup bgp-vpnv4-route enable** command enables a device to recurse static routes to cross routes on the remote VPN.

The **ip route recursive-lookup bgp-vpnv4-route disable** command disables a device from recursing static routes to cross routes on the remote VPN.

The **undo ip route recursive-lookup bgp-vpnv4-route disable** command enables a device to recurse static routes to cross routes on the remote VPN.

By default, a static route can recurse to a cross route on the remote VPN.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

ip route recursive-lookup bgp-vpnv4-route { **enable** | **disable** }

undo ip route recursive-lookup bgp-vpnv4-route disable

Parameters

Parameter	Description	Value
enable	Enables a device to recurse static routes to cross routes on the remote VPN.	-
disable	Disables a device from recursing static routes to cross routes on the remote VPN.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Recursion is required if next hops of static routes are not directly reachable. You can run the **ip route recursive-lookup bgp-vpnv4-route enable** command to enable the device to recurse a static route to a cross route on the remote VPN. The static route can then inherit the Label and Token information about the cross route. The device can forward data through the tunnel to which the static route recurses.

Precautions

The **ip route recursive-lookup bgp-vpnv4-route enable** command and the **undo ip route recursive-lookup bgp-vpnv4-route disable** command have the same function and do not generate configurations in the configuration file.

This command allows IPv4 static routes to recurse to cross routes on the remote VPN, not applicable to IPv6 static routes.

Example

Enable a device to recurse static routes to a cross route on the remote VPN.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup bgp-vpnv4-route enable
```

Disable a device from recursing static routes to a cross route on the remote VPN.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup bgp-vpnv4-route disable
```

Enable a device to recurse static routes to a cross route on the remote VPN.

```
<HUAWEI> system-view
[HUAWEI] undo ip route recursive-lookup bgp-vpnv4-route disable
```

7.1.3 ip route recursive-lookup blackhole protocol static

Function

The **ip route recursive-lookup blackhole protocol static disable** command disables a device from recursing static routes to blackhole routes.

The **ip route recursive-lookup blackhole protocol static enable** command allows a device to recurse static routes to blackhole routes.

The **undo ip route recursive-lookup blackhole protocol static disable** command allows a device to recurse static routes to blackhole routes.

By default, static routes can recurse to blackhole routes.

Format

ip route recursive-lookup blackhole protocol static { **disable** | **enable** }

undo ip route recursive-lookup blackhole protocol static disable

Parameters

Parameter	Description	Value
disable	Disables a device from recursing static routes to blackhole routes.	-
enable	Allows a device to recurse static routes to blackhole routes.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If IGP, static, and blackhole routes exist on a network and a link fault occurs, services may be interrupted because static routes may recurse to blackhole routes and remain active. To ensure uninterrupted services, run the **ip route recursive-lookup blackhole protocol static disable** command. This command will prevent static routes from recursing to blackhole routes so that static routes will become inactive and IGP routes will be selected.

Precautions

The **ip route recursive-lookup blackhole protocol static enable** and **undo ip route recursive-lookup blackhole protocol static disable** commands have the same function. You only need to run one of them.

Example

Disable a device from recursing static routes to blackhole routes.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup blackhole protocol static disable
```

Allow a device to recurse static routes to blackhole routes.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup blackhole protocol static enable
```

Allow a device to recurse static routes to blackhole routes.

```
<HUAWEI> system-view
[HUAWEI] undo ip route recursive-lookup blackhole protocol static disable
```

7.1.4 ip route recursive-lookup inherit-label-route enable

Function

The **ip route recursive-lookup inherit-label-route enable** command allows a device to recurse routes to cross routes on the remote VPN.

The **undo ip route recursive-lookup inherit-label-route enable** command disables a device from recursing routes to cross routes on the remote VPN.

By default, routes except static routes cannot recurse to cross routes on the remote VPN.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

ip route recursive-lookup inherit-label-route enable

undo ip route recursive-lookup inherit-label-route enable

Parameters

None

Views

System view

Default Level

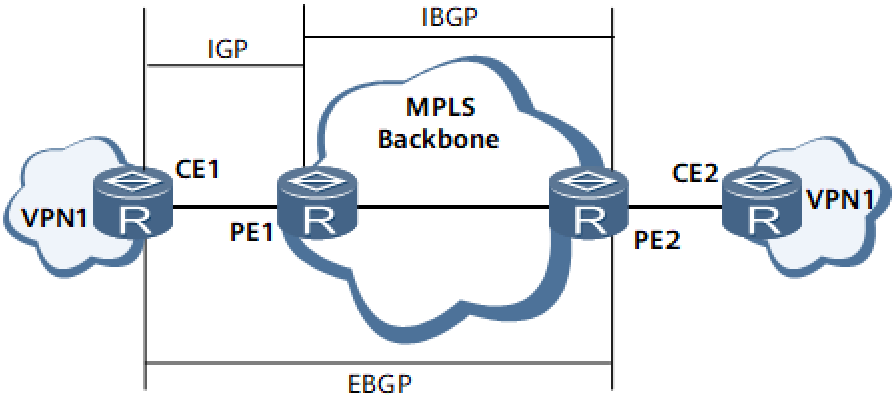
2: Configuration level

Usage Guidelines

Recursion is required if the next hop of a route is unreachable. To allow routes to recurse to cross routes on the remote VPN, run the **ip route recursive-lookup inherit-label-route enable** command. After the command is run, routes inherit the labels and tokens of the cross routes on the remote VPN, ensuring correct traffic forwarding. This command mainly applies to BGP/MPLS IP VPN scenarios.

In **Figure 7-1**, PE1 and PE2 are IBGP peers, and CE1 and PE1 are IGP neighbors. PE2 learns the IP address of CE1's loopback interface, and an EBGP peer relationship is established between CE1 and PE2 using loopback interface IP addresses. By default, the BGP routes that PE2 learns from CE1 through the EBGP peer connection cannot recurse to cross routes on the remote VPN. As a result, traffic fails to be forwarded. To address this problem, run the **ip route recursive-lookup inherit-label-route enable** command to allow the BGP routes to recurse to cross routes on the remote VPN. After the BGP routes inherit the labels and tokens of the cross routes, traffic can be correctly forwarded.

Figure 7-1 Basic BGP/MPLS IP VPN networking



Example

Allow a device to recurse routes to cross routes on the remote VPN.

```
<HUAWEI> system-view
[HUAWEI] ip route recursive-lookup inherit-label-route enable
```

7.1.5 ip route-static

Function

The **ip route-static** command configures a unicast static route.

The **undo ip route-static** command deletes a unicast static route.

By default, no unicast static route is configured.

Format

ip route-static *ip-address* { *mask* | *mask-length* } { *nexthop-address* | *interface-type interface-number* [*nexthop-address*] | **vpn-instance** *vpn-instance-name nexthop-address* } [**preference** *preference* | **tag** *tag*] * [**track** { **route-monitor-group** *route-monitor-group-name* | **bfd-session** *cfg-name* | **efm-state** *interface-type interface-number* | **nqa** *admin-name test-name* } | **permanent**] [**description** *text*]

ip route-static *ip-address* { *mask* | *mask-length* } **vpn-instance** *vpn-instance-name* [**preference** *preference* | **tag** *tag*] * [**description** *text*] (supported only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo ip route-static *ip-address* { *mask* | *mask-length* } [*nexthop-address* | *interface-type interface-number* [*nexthop-address*]] [**preference** *preference* | **tag** *tag*] * [**track** { **bfd-session** | **efm-state** } | **permanent**]

undo ip route-static [**track bfd-session**] **all**

undo ip route-static *ip-address* { *mask* | *mask-length* } **vpn-instance** *vpn-instance-name* (supported only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
ip-address	Specifies a destination IP address.	The value is in dotted decimal notation.
mask	Specifies a subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length. The 1s in each 32-bit mask must be consecutive. Therefore, a mask in dotted decimal notation can be presented by a mask length.	The value is an integer in the range from 0 to 32.

Parameter	Description	Value
nexthop-address	Specifies the next-hop address.	The value is in dotted decimal notation.
interface-type interface-number	Specifies the type and number of an interface that forwards packets.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance. If a VPN instance name is specified, the device searches the routing table of the VPN instance for a static route according to *nexthop-address*. If the *nexthop-address* parameter is not specified, the device searches a specified VPN instance forwarding table if the device fails to find a forwarding path in the public network forwarding table.	The value is a string of 1 to 31 case-sensitive characters with spaces. The string can contain spaces if it is enclosed with double quotation marks (").
preference *preference*	Specifies the preference of a static route. A smaller value indicates a higher preference.	The value is an integer that ranges from 1 to 255. The default value is 60.
tag *tag*	Specifies the tag value of a static route. By configuring different tag values, you can classify static routes to implement different routing policies. For example, routing protocols can import static routes with specified tag values through routing policies.	The value is an integer that ranges from 1 to 4294967295. The default value is 0.
track route-monitor-group *route-monitor-group-name*	Binds a static route to a route monitoring group for fast fault detection.	The value is a string of 1 to 31 case-sensitive characters.
track bfd-session *cfg-name*	Binds a static BFD session to a static route for fast fault detection.	*cfg-name* is a string of 1 to 15 characters without spaces. The string can contain spaces if it is enclosed with double quotation marks (").

Parameter	Description	Value
track efm-state *interface-type interface-number*	Detects the EFM OAM state of a specified interface.	-
track nqa *admin-name test-name*	Specifies the administrator name of an NQA test instance bound to a static route, and the name of the test instance.	The values of *admin-name* and *test-name* are both a string of 1 to 32 case-sensitive characters without spaces.
permanent	Configures permanent advertisement of static routes.	-
description *text*	Configures a description for a static route.	The value is a string of 1 to 80 characters that can contain spaces.
all	Deletes all IPv4 unicast static routes.	-

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **track bfd-session** *cfg-name* parameter.

2: Configuration level

Usage Guidelines

Usage Scenario

On a simple network, you can configure static routes to ensure network connectivity. If a switch cannot use dynamic routing protocols for network connectivity, static routes can be configured on the switch.

Precautions

When configuring unicast static routes, note the following:

- Only public routes support tunnel recursion.
- If no preference is set for a static route, the static route uses the default preference 60.

- When both the destination IP address and the mask are set to 0.0.0.0, a default route is configured. If the switch cannot find a route in the routing table to forward packets, the switch uses the default route to forward packets.
- By setting different preferences, you can implement different routing management policies. For example, if multiple routes to the same destination are configured with the same preference, load balancing can be implemented. If multiple routes to the same destination are configured with different preferences, route backup can be implemented.
- You can specify the **description** *text* parameter to add a description for a static route so that the administrator can easily check and maintain the static route. You can run the **display this** command in the system view or run the **display current-configuration** command to view the descriptions of static routes.
- When configuring static routes, you can specify outbound interfaces or next-hop addresses based on the outbound interface type. For example, you can specify only outbound interfaces for static routes on P2P interfaces and specify only next hops for static routes on NBMA interfaces, and you must specify next hops for static routes on broadcast interfaces.
- Static routes with the next hop associated with DHCP cannot work in load balancing mode with static routes with the same prefix and not associated with DHCP.
- In some cases, for example, the link layer protocol is PPP and the peer IP address is unknown, you can also specify outbound interfaces when configuring a switch. In this manner, you do not need to modify the switch configuration when the peer IP address changes.
- When a static route to be configured is a supernet route, you need to specify both the outbound interface and next-hop address for it. Otherwise, this route cannot be activated. A route that meets either of the following conditions is a supernet route:
  - When bitwise AND operations are performed on the destination address mask with the destination address and next hop address, the two obtained network addresses are the same, and the destination address mask is greater than or equal to the next hop address mask.
  - When bitwise AND operations are performed on the destination address mask with the destination address and next hop address, the two obtained network addresses are different. When bitwise AND operations are performed on the next hop address mask with the destination address and next hop address, however, the two obtained network addresses are the same.

Example

Set a static route with the destination address and mask are both 0.0.0.0 and the next-hop address 172.16.0.1.

```
<HUAWEI> system-view
[HUAWEI] ip route-static 0.0.0.0 0.0.0.0 172.16.0.1
```

7.1.6 ip route-static default-preference

Function

The **ip route-static default-preference** command sets a default preference for an IPv4 static route.

The **undo ip route-static default-preference** command restores the default preference of IPv4 static routes.

By default, the default preference of IPv4 static routes is 60.

Format

ip route-static default-preference *preference*

undo ip route-static default-preference

Parameters

Parameter	Description	Value
preference	Specifies a default preference for IPv4 static routes. A smaller value indicates a higher preference.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can change the status of a route by changing the preference of the route. You can use the **ip route-static default-preference** command to change the default preference of all the new IPv4 static routes.

Configuration Impact

After the **ip route-static default-preference** command is used, all the new IPv4 static routes that use the default preference are restored to a new default preference.

Precautions

After a default preference is specified, the new default preference is valid for subsequent rather than existing IPv4 static routes.

Example

Set the default preference of IPv4 static routes to 70.

```
<HUAWEI> system-view
[HUAWEI] ip route-static default-preference 70
```

7.1.7 ip route-static track bfd-session admindown invalid

Function

The **ip route-static track bfd-session admindown invalid** command disables a switch from selecting a static route if the BFD session associated with the route is in the AdminDown state.

The **undo ip route-static track bfd-session admindown invalid** command restores the default configuration.

By default, a static route can participate in route selection even if its bound BFD session is in the AdminDown state.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ip route-static track bfd-session session-name *bfd-name* **admindown invalid**

undo ip route-static track bfd-session session-name *bfd-name* **admindown invalid**

undo ip route-static track bfd-session admindown invalid

Parameters

Parameter	Description	Value
session-name *bfd-name*	Specifies a BFD session bound to a static route.	The value is a string of 1 to 15 case-insensitive characters without spaces. If the string is enclosed within double quotation marks ("), the string can contain spaces.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if a BFD session associated with a static route is in the AdminDown state, the route can participate in route selection on Huawei switches, but is not allowed for route selection on some non-Huawei devices. As a result, Huawei switches cannot communicate with such non-Huawei devices.

To address this problem, run the **ip route-static track bfd-session admindown invalid** command to configure the device not to select the static route if its bound BFD session is in the AdminDown state.

Prerequisites

The BFD session specified by *bfd-name* has been created.

Example

Disable a switch from selecting a static route if the BFD session associated with the route is in AdminDown state.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd bfda bind peer-ip 1.1.1.1
[HUAWEI-bfd-session-bfda] discriminator local 20
[HUAWEI-bfd-session-bfda] discriminator remote 10
[HUAWEI-bfd-session-bfda] commit
[HUAWEI-bfd-session-bfda] quit
[HUAWEI] ip route-static track bfd-session session-name bfda admindown invalid
```

7.1.8 ip route-static vpn-instance

Function

The **ip route-static vpn-instance** command configures a static route for a VPN instance.

The **undo ip route-static vpn-instance** command deletes static routes from a VPN instance.

By default, no static route is configured for a VPN instance.

Format

ip route-static vpn-instance *vpn-source-name destination-address* { *mask* | *mask-length* } { *nexthop-address* [**public**] | *interface-type interface-number* [*nexthop-address*] | **vpn-instance** *vpn-destination-name nexthop-address* } [**preference** *preference* | **tag** *tag*] * [**track** { **bfd-session** *cfg-name* | **efm-state** *interface-type interface-number* | **nqa** *admin-name test-name* } | **permanent**] [**description** *text*]

ip route-static vpn-instance *vpn-source-name destination-address* { *mask* | *mask-length* } { **public** | **vpn-instance** *vpn-destination-name* } [**preference** *preference* | **tag** *tag*] * [**description** *text*] (supported only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo ip route-static vpn-instance *vpn-source-name destination-address* { *mask* | *mask-length* } [*nexthop-address* | *interface-type interface-number* [*nexthop-address*]] [**preference** *preference* | **tag** *tag*] * [**track** { **bfd-session** | **efm-state** } | **permanent**]

undo ip route-static vpn-instance *vpn-source-name* **all**

undo ip route-static vpn-instance *vpn-source-name destination-address* { *mask* | *mask-length* } { **public** | **vpn-instance** *vpn-destination-name* } (supported only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
vpn-instance *vpn-source-name*	Specifies the name of the source VPN instance. Each VPN instance has its own routing table. The configured static routes are added to the routing table of the specified VPN instance.	The value must be an existing VPN instance name.
destination-address	Specifies the destination IP address of a static route.	The value is in dotted decimal notation.
mask	Specifies the subnet mask of the destination IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the destination IP address.	The value is an integer that ranges from 0 to 32.

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the outbound interface of a static route.	-
nexthop-address	Specifies the next-hop address of a static route. If the outbound interface of a static route is a broadcast interface, the next-hop address must be specified for the static route.	The value is in dotted decimal notation.
public	Specifies the next-hop address as a public network address but not an address in the source VPN instance. If the *nexthop-address* parameter is not specified, a device searches another outbound interface in the public IP routing table if the device fails to find a forwarding path in the current VPN instance forwarding table.	-
preference *preference*	Specifies the preference of a static route.	The value is an integer that ranges from 1 to 255. If this parameter is not specified, the default preference of a static route is 60.
tag *tag*	Specifies the tag value of a static route. By configuring different tag values, you can classify static routes to implement different routing policies. For example, routing protocols can import static routes with specified tag values through routing policies.	The value is an integer that ranges from 1 to 4294967295. The default value is 0.
track bfd-session *cfg-name*	Binds a static BFD session to a static route for fast fault detection.	*cfg-name* is a string of 1 to 15 characters without spaces.
track efm-state *interface-type interface-number*	Detects the EFM OAM state of a specified interface.	-

Parameter	Description	Value
track nqa *admin-name test-name*	Specifies the administrator name of an NQA test instance bound to a static route, and the name of the test instance.	The values of *admin-name* and *test-name* are both a string of 1 to 32 case-sensitive characters without spaces.
permanent	Configures permanent advertisement of static routes.	-
description *text*	Specifies the description of a static route. You can specify **description** to add a description for static routes, facilitating static route query and maintenance.	The value is a string of 1 to 80 characters that can contain spaces.
vpn-instance *vpn-destination-name*	Specifies the name of the destination VPN instance. The system searches the routing table of the VPN instance for the outbound interface of a static route according to the configured next-hop address. If the *nexthop-address* parameter is not specified, a device searches another specified VPN instance forwarding table if the device fails to find a forwarding path in the current VPN instance forwarding table. If **vpn-instance** *vpn-destination-name* is specified, devices can communicate with each other between VPNs.	The value is a string of 1 to 31 case-sensitive characters with spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
all	Deletes all static routes from a VPN instance.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You need to configure static routes for a VPN instance on a PE in the following scenarios:

- The PE connects to a CE.
- The specified VPN connects to the Internet.

Follow-up Procedure

After a static route is configured, import the static route to BGP running between PEs if the static route needs to be sent to the peer PE.

Precautions

- During the configuration of a static route for a VPN instance, the next-hop address can belong to the VPN instance or a public network. When the next-hop address of the static route is a public network address, specify **public** after *nexthop-address*.
- If the outbound interface of a static route is a broadcast interface, you must specify the next-hop address for the static route.
- You can specify **description** *text* to add a description for a static route so that the administrator can easily query and maintain the static route. To view the description of static routes, run the **display this** command in the system view or run the **display current-configuration** command.
- If two static routes with the same destination IP address are configured, one of the routes is specified with a next hop IP address or outbound interface, and the other static route is configured with a next-hop VPN instance, without an outbound interface or next hop IP address, the latest configuration overwrites the previous one.

Example

Configure a static route for VPN instance named **vpn1**, and set the destination address of the static route to 10.1.1.0/24 and next-hop address to 192.168.1.2 (IP address of VPN instance **vpn2**).

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] route-distinguisher 100:200
[HUAWEI-vpn-instance-vpn1-af-ipv4] quit
[HUAWEI-vpn-instance-vpn1] quit
[HUAWEI] ip vpn-instance vpn2
[HUAWEI-vpn-instance-vpn2] route-distinguisher 300:400
[HUAWEI-vpn-instance-vpn2-af-ipv4] quit
[HUAWEI-vpn-instance-vpn2] quit
[HUAWEI] ip route-static vpn-instance vpn1 10.1.1.0 24 vpn-instance vpn2 192.168.1.2
```

7.1.9 ipv6 route recursive-lookup inherit-label-route enable

Function

The **ipv6 route recursive-lookup inherit-label-route enable** command allows a device to recurse IPv6 routes to VPN remote cross routes.

The **undo ipv6 route recursive-lookup inherit-label-route enable** command disables a device from recursing IPv6 routes to VPN remote cross routes.

By default, IPv6 routes cannot recurse to VPN remote cross routes.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

ipv6 route recursive-lookup inherit-label-route enable

undo ipv6 route recursive-lookup inherit-label-route enable

Parameters

None

Views

System view

Default Level

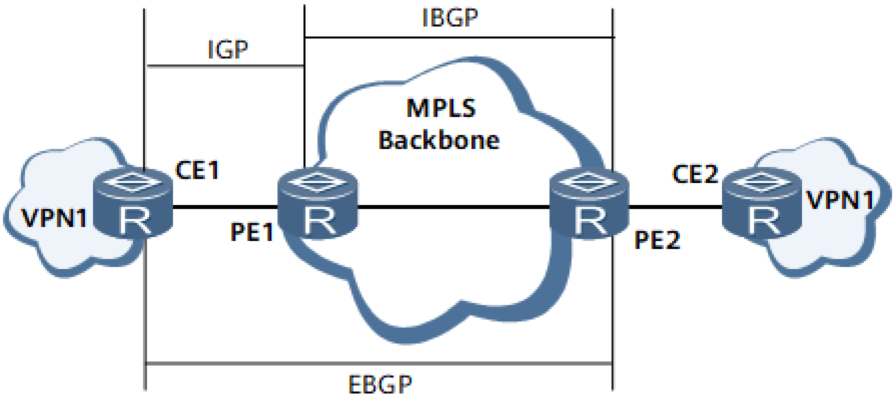
2: Configuration level

Usage Guidelines

Recursion is required if the next hop of a route is unreachable. To allow IPv6 routes to recurse to VPN remote cross routes, run the **ipv6 route recursive-lookup inherit-label-route enable** command. After the command is run, IPv6 routes inherit the labels and tokens of the VPN remote cross routes, ensuring correct traffic forwarding. This command mainly applies to BGP/MPLS IPv6 VPN scenarios.

In **Figure 7-2**, PE1 and PE2 are IBGP peers, and CE1 and PE1 are IGP neighbors. PE2 learns the IP address of CE1's loopback interface, and an EBGP peer relationship is established between CE1 and PE2 using loopback interface IP addresses. By default, the BGP routes that PE2 learns from CE1 through the EBGP peer connection cannot recurse to VPN remote cross routes. As a result, traffic fails to be forwarded. To address this problem, run the **ipv6 route recursive-lookup inherit-label-route enable** command to allow the BGP4+ routes to recurse to VPN remote cross routes. After the BGP4+ routes inherit the labels and tokens of the VPN remote cross routes, traffic can be correctly forwarded.

Figure 7-2 Basic BGP/MPLS IPv6 VPN networking



Example

Allow a device to recurse IPv6 routes to VPN remote cross routes.

```
<HUAWEI> system-view
[HUAWEI] ipv6 route recursive-lookup inherit-label-route enable
```

7.1.10 ipv6 route-static

Function

The **ipv6 route-static** command configures an IPv6 static route.

The **undo ipv6 route-static** command deletes configured IPv6 static routes.

By default, no IPv6 static route is configured.

Format

ipv6 route-static *dest-ipv6-address prefix-length* { *interface-type interface-number* [*nexthop-ipv6-address*] | *nexthop-ipv6-address* | **vpn-instance** *vpn-destination-name nexthop-ipv6-address* } [**preference** *preference* | **tag** *tag*] * [**track** { **bfd-session** *cfg-name* | **nqa** *admin-name test-name* }] [**description** *text*]

ipv6 route-static *dest-ipv6-address prefix-length* **vpn-instance** *vpn-destination-name* [**preference** *preference* | **tag** *tag*] * [**description** *text*] (support only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo ipv6 route-static *dest-ipv6-address prefix-length* [*interface-type interface-number* [*nexthop-ipv6-address*] | *nexthop-ipv6-address*] [**preference** *preference* | **tag** *tag*] * [**track bfd-session**]

undo ipv6 route-static [**track bfd-session**] **all**

undo ipv6 route-static *dest-ipv6-address prefix-length* **vpn-instance** *vpn-destination-name* [**preference** *preference* | **tag** *tag*] * (support only by the

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
dest-ipv6-address	Specifies a destination IPv6 address.	The value is a 32-bit hexadecimal number, in X:X:X:X:X:X:X:X format.
prefix-length	Specifies the length of an IPv6 prefix.	The value is an integer that ranges from 0 to 128.
interface-type interface-number	Specifies the type and number of an outbound interface.	-
vpn-instance *vpn-destination-name*	Specifies the name of a VPN instance. If the VPN instance name is specified, a switch searches the routing table of the VPN instance for the outbound interface of a static route according to the configured next-hop address. If the *nexthop-ipv6-address* parameter is not specified, a device searches a specified VPN instance forwarding table to find a forwarding path.	The value is a string of 1 to 31 case-sensitive characters with spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
nexthop-ipv6-address	Specifies the next-hop IPv6 address.	The value is a 32-bit hexadecimal number, in X:X:X:X:X:X:X:X format.
preference *preference*	Specifies the preference of an IPv6 static route.	The value is an integer that ranges from 1 to 255. The default value is 60.
tag *tag*	Specifies the tag value of a static route. By configuring different tag values, you can classify static routes to implement different routing policies. For example, routing protocols can import static routes with specified tag values through routing policies.	The value is an integer that ranges from 1 to 4294967295. The default value is 0.

Parameter	Description	Value
track bfd-session *cfg-name*	Binds a static BFD session to a static route for fast fault detection.	*cfg-name* is a string of 1 to 15 characters without spaces. The string can contain spaces if it is enclosed with double quotation marks (").
track nqa *admin-name test-name*	Specifies the administrator name of an NQA test instance bound to a static route, and the name of the test instance.	The values of *admin-name* and *test-name* are both a string of 1 to 32 case-sensitive characters without spaces.
description *text*	Specifies the description of a static route.	The value is a string of 1 to 80 characters that can contain spaces.
all	Deletes all IPv6 static routes.	-

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support **track bfd-session** *cfg-name* parameters.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a simple network, you can configure static routes to ensure network connectivity. If a device cannot use dynamic routing protocols for network connectivity, static routes can also be configured on the device.

You can specify **description** *text* to add a description for a static route so that the administrator can easily query and maintain the static route. To view the description of static routes, run the **display this** command in the system view or run the **display current-configuration** command.

Precautions

When configuring unicast static routes, note the following:

- If no preference is set for a static route, the static route uses the default preference 60.

- If the destination address and mask of a static route are all 0s, the static route is a default route.
- For an IPv6 static route, the next hop can be set to either an IP address/ outbound interface or a VPN instance. Only the most recent configuration takes effect.

Example

Configure an IPv6 static route on a public network.

```
<HUAWEI> system-view
[HUAWEI] ipv6 route-static fc00:0:0:2001::1 128 fc00:0:0:2002::2
```

7.1.11 ipv6 route-static default-preference

Function

The **ipv6 route-static default-preference** command sets a default preference for an IPv6 static route.

The **undo ipv6 route-static default-preference** command restores the default preference of IPv6 static routes.

By default, the default preference of IPv6 static routes is 60.

Format

ipv6 route-static default-preference *preference*

undo ipv6 route-static default-preference

Parameters

Parameter	Description	Value
preference	Specifies the default preference of IPv6 static routes. A smaller value indicates a higher preference.	The value is an integer that ranges from 1 to 255.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can change the activation status of routes by changing their preference. To change the default preference of a new IPv6 static route, run the **ipv6 route-static default-preference** command.

Configuration Impact

After the **ipv6 route-static default-preference** command is used, the default preference of all the new IPv6 static routes is changed.

The new default preference is valid only for new IPv6 static routes but not for existing IPv6 static routes.

Example

Set the default preference of IPv6 static routes to 70.

```
<HUAWEI> system-view
[HUAWEI] ipv6 route-static default-preference 70
```

7.1.12 ipv6 route-static track bfd-session admindown invalid

Function

The **ipv6 route-static track bfd-session admindown invalid** command disables a switch from selecting an IPv6 static route if the BFD session associated with the route is in the AdminDown state.

The **undo ipv6 route-static track bfd-session admindown invalid** command restores the default configuration.

By default, an IPv6 static route can participate in route selection even if the BFD session associated with it is in the AdminDown state.

Format

ipv6 route-static track bfd-session session-name *bfd-name* **admindown invalid**

undo ipv6 route-static track bfd-session [**session-name** *bfd-name*] **admindown invalid**

Parameters

Parameter	Description	Value
session-name *bfd-name*	Specifies a BFD session bound to an IPv6 static route.	The value is a string of 1 to 15 case-insensitive characters without spaces. The string can contain spaces if it is enclosed with double quotation marks (").

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if a BFD session associated with an IPv6 static route is in the AdminDown state, the route can participate in route selection on Huawei switches, but is not allowed for route selection on some non-Huawei devices. As a result, Huawei switches cannot communicate with such non-Huawei devices.

To address this problem, run the **ipv6 route-static track bfd-session admindown invalid** command to configure the switch not to select the IPv6 static route if the BFD session associated with it is in the AdminDown state.

Prerequisites

The BFD session specified by *bfd-name* has been created.

Precautions

The **undo ipv6 route-static track bfd-session admindown invalid** command enables all IPv6 static routes to participate in route selection even if the BFD sessions associated with them are in the AdminDown state.

Example

Disable a switch from selecting an IPv6 static route if the BFD session associated with the route is in the AdminDown state.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd bfda bind peer-ipv6 2001:db8:1::1
[HUAWEI-bfd-session-bfda] discriminator local 20
[HUAWEI-bfd-session-bfda] discriminator remote 10
[HUAWEI-bfd-session-bfda] commit
[HUAWEI-bfd-session-bfda] quit
[HUAWEI] ipv6 route-static track bfd-session session-name bfda admindown invalid
```

7.1.13 ipv6 route-static vpn-instance

Function

The **ipv6 route-static vpn-instance** command configures an IPv6 static route for a VPN instance.

The **undo ipv6 route-static vpn-instance** command deletes IPv6 static routes from a VPN instance.

By default, no IPv6 static routes are configured for VPN instances.

Format

ipv6 route-static vpn-instance *vpn-instance-name dest-ipv6-address prefix-length* { [*interface-type interface-number* [*nexthop-ipv6-address*]] | *nexthop-ipv6-address* [**public**] | **vpn-instance** *vpn-destination-name nexthop-ipv6-address* } [**preference** *preference* | **tag** *tag*] * [**track** { **bfd-session** *cfg-name* | **nqa** *admin-name test-name* }] [**description** *text*]

ipv6 route-static vpn-instance *vpn-instance-name dest-ipv6-address prefix-length* { **public** | **vpn-instance** *vpn-destination-name* } [**preference** *preference* | **tag** *tag*] * [**description** *text*] (support only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

undo ipv6 route-static vpn-instance *vpn-instance-name dest-ipv6-address prefix-length* [*interface-type interface-number*] [*nexthop-ipv6-address*] [**preference** *preference* | **tag** *tag*] *[**track bfd-session**]

undo ipv6 route-static vpn-instance *vpn-instance-name* [**track bfd-session**] **all**

undo ipv6 route-static vpn-instance *vpn-instance-name dest-ipv6-address prefix-length* { **public** | **vpn-instance** *vpn-destination-name* } [**preference** *preference* | **tag** *tag*] * (support only by the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S)

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance. Each VPN instance has its own unicast routing table. The configured static routes are added to the routing table of the specified VPN instance.	The value must be an existing VPN instance name.
dest-ipv6-address	Specifies a destination IPv6 address.	The value is a 32-bit hexadecimal number, in X:X:X:X:X:X:X:X format.

Parameter	Description	Value
prefix-length	Specifies the length of an IPv6 prefix. The length equals the number of consecutive 1s in the mask.	The value is an integer that ranges from 0 to 128.
interface-type	Specifies the type of an interface.	-
interface-number	Specifies the number of an interface.	-
nexthop-ipv6-address	Specifies the next-hop IPv6 address.	The value is a 32-bit hexadecimal number, in X:X:X:X:X:X:X:X format.
vpn-instance *vpn-destination-name*	Specifies the name of the destination VPN instance. If the name of the destination VPN instance is specified, a static route searches the destination VPN instance for an outbound interface according to the configured next-hop address. If the *nexthop-ipv6-address* parameter is not specified, a device searches the destination VPN instance forwarding table to find a forwarding path. If **vpn-instance** *vpn-destination-name* is specified, devices can communicate with each other between VPNs.	The value is a string of 1 to 31 case-sensitive characters with spaces. If the string is enclosed in double quotation marks (" "), the string can contain spaces.
public	Specifies a public network address as the next-hop address.	-
preference *preference*	Specifies the preference of a static route.	The value is an integer that ranges from 1 to 255.
tag *tag*	Specifies the tag value of a static route. By configuring different tag values, you can classify static routes to implement different routing policies. For example, routing protocols can import static routes with specified tag values through routing policies.	The value is an integer that ranges from 1 to 4294967295. The default value is 0.

Parameter	Description	Value
track bfd-session *cfg-name*	Binds a static BFD session to a static route for fast fault detection.	*cfg-name* is a string of 1 to 15 characters without spaces. The string can contain spaces if it is enclosed with double quotation marks (").
track nqa *admin-name test-name*	Specifies the administrator name of an NQA test instance bound to a static route, and the name of the test instance.	The values of *admin-name* and *test-name* are both a string of 1 to 32 case-sensitive characters without spaces.
description *text*	Specifies the description of a static route.	The value is a string of 1 to 80 characters that can contain spaces.
all	Deletes all the IPv6 static routes configured for the specified VPN instance.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a simple IPv6 VPN network, you can run the **ipv6 route-static vpn-instance** command to configure static routes for this VPN.

- To configure VPN users to access a public network, you can perform network address translation (NAT) or run the **ipv6 route-static vpn-instance** command with the keyword **public** specified to configure a public network address as the VPN route's next-hop address.
- You can specify **description** *text* to add a description for a static route so that the administrator can easily query and maintain the static route. To view the description of static routes, run the **display this** command in the system view or run the **display current-configuration** command.

Precautions

If a network fault occurs or the network topology changes, static routes cannot automatically change. Therefore, configure static routes with caution.

If the destination address and the prefix length are set to all 0s, a default route is configured.

Example

Configure a default route with next-hop address FC00:0:0:2001::1.

```
<HUAWEI> system-view
[HUAWEI] ipv6 route-static vpn-instance vpn1 :: 0 fc00:0:0:2001::1
```

7.2 RIP Configuration Commands

7.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.2.2 bfd all-interfaces enable(RIP)

Function

The **bfd all-interfaces enable** command enables BFD on all the interfaces in a RIP process.

The **undo bfd all-interfaces enable** command disables BFD on all the interfaces in a RIP process.

By default, BFD is disabled in a RIP process.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

bfd all-interfaces enable

undo bfd all-interfaces enable

Parameters

None

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

If BFD parameters are configured, but the **bfd all-interfaces enable** command is not configured, BFD sessions cannot be established.

NOTE

- The BFD priority on an interface is higher than the BFD priority on a RIP process.
- If the **rip bfd block** command is configured on an interface, the **bfd all-interfaces enable** command cannot be used to enable BFD on the interface.

Example

Enable BFD on all interfaces in a RIP process.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] rip
[HUAWEI-rip-1] bfd all-interfaces enable
```

7.2.3 bfd all-interfaces(RIP)

Function

The **bfd all-interfaces** command sets BFD session parameters.

The **undo bfd all-interfaces** command restores BFD session parameters to default values.

By default, the minimum intervals for receiving and sending BFD packets are 1000 ms and the detection time multiplier is 3.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

bfd all-interfaces { **min-rx-interval** *min-receive-value* | **min-tx-interval** *min-transmit-value* | **detect-multiplier** *detect-multiplier-value* } *

undo bfd all-interfaces { **min-rx-interval** [*min-receive-value*] | **min-tx-interval** [*min-transmit-value*] | **detect-multiplier** [*detect-multiplier-value*] } *

Parameters

Parameter	Description	Value
min-rx-interval *min-receive-value*	Specifies the minimum interval for receiving BFD packets from the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *min-transmit-value*	Specifies the minimum interval for sending BFD packets to the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *detect-multiplier-value*	Indicates the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The priority of BFD configured on an interface is higher than that configured for a RIP process. If BFD is enabled on an interface, BFD sessions are established using the BFD parameters set on the interface.

Actual interval at which BFD packets are transmitted on the local device = Max { transmit-value on the local device, receive-value on the peer}.

Actual interval at which BFD packets are received on the local device = Max { transmit-value on the peer, receive-value on the local device}.

Local BFD detection time = Actual interval at which BFD packets are received on the local device x detect-multiplier-value on the peer.

Prerequisites

BFD has been enabled on all the interfaces using the **bfd all-interfaces enable** command in the RIP view.

Example

Configure BFD for a RIP process and set the minimum interval for sending BFD packets to 500 ms.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] rip
[HUAWEI-rip-1] bfd all-interfaces enable
[HUAWEI-rip-1] bfd all-interfaces min-tx-interval 500
```

7.2.4 checkzero (RIP)

Function

The **checkzero** command enables the device to check the zero fields in RIP-1 packets.

The **undo checkzero** command disables the device from checking the zero fields in RIP-1 packets.

By default, the device checks the zero fields in RIP-1 packets.

Format

checkzero

undo checkzero

Parameters

None

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a RIP-1 packet, the values of some fields must be zero. These fields are zero fields. After zero field check is enabled, the device checks the zero fields in the RIP-1 packets and discards the packets in which the zero field values are not 0.

The **checkzero** command is valid only for RIP-1 packets.

Run the **undo checkzero** command to reduce CPU usage if there is no zero field to check (all neighbors are trusted).

Configuration Impact

By default, devices reject all RIP-1 packets in which the zero fields are not 0.

RIP-1 implementations vary with device manufacturers. If the third-party peer device allows zero fields in RIP-1 packets to carry non-zero values, run the **undo checkzero** command on the local device. The **undo checkzero** command causes potential security risks to network, so it is not recommended.

Example

Enable the device to check zero fields in RIP-1 packets.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] checkzero
```

7.2.5 default-cost (RIP)

Function

The **default-cost** command changes the default metric of imported routes.

The **undo default-cost** command restores the default metric of imported routes.

By default, the metric of imported routes is 0.

Format

default-cost *cost*

undo default-cost

Parameters

Parameter	Description	Value
cost	Specifies the default metric of imported routes.	The value is an integer that ranges from 0 to 15. The default value is 0.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

You can run one of the following commands to set the metric of imported routes. The following commands are listed in descending order of priorities.

- Run the **apply cost** command to set the metric of imported routes.
- Run the **import-route** (RIP) command to set the metric of imported routes.
- Run the **default-cost** (RIP) command to set the default metric of imported routes.

Example

Set the default metric for imported routes to 2.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] default-cost 2
```

7.2.6 default-route originate

Function

The **default-route originate** command configures RIP to originate a default route or advertise the default route in the routing table to neighbors.

The **undo default-route originate** command restores the default configuration.

By default, the device does not advertise the default route to neighbors.

Format

default-route originate [**cost** *cost* | { **match default** | **route-policy** *route-policy-name* } [**avoid-learning**]]*

undo default-route originate

Parameters

Parameter	Description	Value
cost *cost*	Specifies the metric of the default route.	The value is an integer that ranges from 0 to 15. The default value is 0.
match default	Indicates that the device advertises the default route imported from another routing protocol or RIP process in the routing table to neighbors.	-
avoid-learning	Disables RIP from importing default routes. If a default route in active state already exists in the routing table, the default route is set to inactive after this parameter is used.	-
route-policy *route-policy-name*	Specifies the name of the routing policy. RIP will originate the default route only if route permitted by the route policy is present as active in the routing table.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a routing table, the destination address and mask of a default route are all 0s. If the destination address of a packet does not match any entry in the routing table of the switch, the switch sends the packet along the default route.

If no default route exists and the destination address of the packet does not match any entry in the routing table, the switch discards the packet and sends an Internet Control Message Protocol (ICMP) packet, informing the originating host that the destination address or network is unreachable.

Default routes are originated unconditionally, or based on the configured routing policy or **match default**. When default routes are originated based on the configuration, default routes learned from RIP neighbors will be deleted.

- When the **default-route originate** command is configured without any parameter, the default route is originated unconditionally regardless of whether the default route exists in the IP routing table.
- When the **default-route originate** command is configured with **route-policy**, RIP will originate the default route only if the route that matches **route-policy** is active in the IP routing table.
- When the **default-route originate** command is configured with **match default**, RIP will originate the default route only if a default route learned by another routing protocol or RIP process is present in the IP routing table.
- When the **default-route originate** command is configured with **avoid-learning**, RIP will not learn the default route advertised by RIP peers.

Prerequisites

A RIP process has been created, and the RIP view is displayed using the **rip** command.

Example

Set the metric for the default route to 2.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] default-route originate cost 2
```

7.2.7 description (RIP)

Function

The **description** command configures a description for a RIP process.

The **undo description** command deletes the description of a RIP process.

By default, there is no description for a RIP process.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies a description for a RIP process.	It is a string of 1 to 80 case-sensitive characters. Spaces are supported.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By configuring descriptions for RIP processes, you can easily identify RIP processes.

Configuration Impact

If the **description** command is run multiple times, only the latest configuration takes effect.

Example

Configure a description for RIP process 100.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] description this process configure the poison reverse process
```

7.2.8 display default-parameter rip

Function

The **display default-parameter rip** command displays the default RIP configuration.

Format

display default-parameter rip

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the default RIP configuration is modified, running the **display default-parameter rip** command still displays the default configuration during RIP initialization.

Example

Display the default RIP configuration.

```
<HUAWEI> display default-parameter rip
```

```

Table 7-1 Description of the display default-parameter rip command output

Item	Description
Protocol Level Default Configurations	Default RIP protocol-level configuration.
RIP version	Default global RIP version.
Preference	Default RIP preference.
Checkzero	Whether zero fields in RIP-1 packets are checked by default.
Default-cost	Default metric of routes imported from other routing protocols.
Auto Summary	Whether RIP summarization is enabled by default.
Host-route	Whether host routes are added to routing tables by default.
Maximum Balanced Paths	Default maximum number of equal-cost routes for load balancing.
Update time	Default interval for sending Update packets.
Age time	Default aging time of RIP routes.

Item	Description
Garbage-collect time	Default Garbage-collect time of RIP routes.
Default-route	Whether the default route is used if no entries in the routing table match packets.
Verify-source	Whether source address check is enabled by default.
Graceful restart	Whether RIP GR is enabled by default.
Interface Level Default Configurations	Default RIP configuration on the interface.
Metricin	Default metric added to routes when RIP packets are received.
Metricout	Default metric added to routes when RIP packets are sent.
Input Packet Processing	Whether an interface is allowed to receive RIP packets by default.
Output Packet Processing	Whether an interface is allowed to send RIP packets by default.
Poison Reverse	Whether poison reverse is enabled by default.
Replay Protect	Whether replay-protect is enabled by default.
Split Horizon	Whether split horizon is enabled for the following interfaces: ● Broadcast and P2P interfaces ● NBMA interfaces
Packet Transmit Interval	Default interval for forwarding packets, in milliseconds.
Packet Transmit Number	Default number of forwarded packets.
RIP Protocol Version	Default RIP version on the interface.

7.2.9 display rip

Function

The **display rip** command displays the status and configuration of a RIP process.

Format

display rip [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
process-id	Displays the status and configuration of a specified RIP process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays the status and configuration of a RIP process with the specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display rip** command to check the status and configuration of a RIP process.

Example

Display the status and configuration of a RIP process. The command output shows that two VPN instances are running. One is a public instance and another one is a VPN instance named **VPN-Instance-1**.

```
<HUAWEI> display rip
Public VPN-instance
    RIP process : 1
       RIP version   : 1
       Preference    : 100
       Checkzero     : Enabled

      Number of routes sendable in a periodic update : 0
      Number of routes sent in last periodic update : 0
```

Table 7-2 Description of the display rip command output

Item	Description
RIP process	Running RIP process. To create a RIP process, run the **rip** command.
RIP version	Global RIP version. To set the RIP version, run the **version** command.
Preference	RIP preference. To set the RIP preference, run the **preference** command.
Checkzero	Whether zero fields in RIP-1 packets are checked. To check zero fields in RIP-1 packets, run the **checkzero** command.
Default-cost	Default metric for the routes imported from other routing protocols. To set the default metric, run the **default-cost** command.
Summary	Whether RIP summarization is enabled. To enable RIP summarization, run the **summary** command.
Host-route	Whether host routes are added to routing tables. To add host routes to routing tables, run the **host-route** command.

Item	Description
Maximum number of balanced paths	Maximum number of equal-cost routes for load balancing. To set the maximum number of equal-cost routes, run the **maximum load-balancing** command.
Update time	Interval for sending RIP Update packets. To set the interval for sending RIP Update packets, run the **timers rip** command.
Age time	Aging time of RIP routes. To set the RIP aging time, run the **timers rip** command.
Garbage-collect time	Garbage-collect time of RIP routes. To set the Garbage-collect time, run the **timers rip** command.
Graceful restart	Whether graceful restart is enabled for RIP routes.
BFD	Whether RIP is associated with BFD.
Silent-interfaces	Suppressed RIP interface, which only receives but does not send RIP packets. To specify the suppressed interface, run the **silent-interface** command.
Default-route	Whether RIP originates default routes. To configure RIP to originate default routes, run the **default-route originate** command.
Verify-source	Whether the source addresses of received RIP Update packets are checked. To check the source addresses of received RIP Update packets, run the **verify-source** command.
Networks	Network segment running RIP. To enable RIP for a network segment, run the **network** command.
Configured peers	RIP neighbors. To configure a RIP neighbor, run the **peer** command.
Number of routes in database	Number of routes in the RIP database.
Number of interfaces enabled	Number of interfaces running RIP.
Triggered updates sent	Number of RIP packets triggering update.
Number of route changes	Number of changed routes in the RIP database.
Number of replies to queries	Number of response packets to RIP requests.
Number of routes in ADV DB	Number of routes in each Update packet.

Item	Description
Number of routes sendable in a periodic update	Number of routes sent in each Update interval.
Number of routes sent in last periodic update	Number of routes sent in last Update interval.

7.2.10 display rip bfd session

Function

The **display rip bfd session** command displays information about BFD sessions.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

display rip *process-id* **bfd session** { **interface** *interface-type interface-number* | *neighbor-id* | **all** }

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
interface *interface-type interface-number*	Specifies the type and number of the interface on which the BFD session is configured.	-
neighbor-id	Specifies the RIP neighbor ID on which the BFD session is configured.	The value is in dotted decimal notation.

Parameter	Description	Value
all	Displays information about BFD sessions established on all BFD-enabled interfaces in the RIP process.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display rip bfd session** command can be used to view the following information in a RIP process:

- BFD sessions of a specified process
- BFD sessions on a specified interface
- BFD sessions on a specified neighbor

Example

Display information about BFD sessions in all RIP processes with IDs of 1.

```
<HUAWEI> display rip 1 bfd session all
 LocalIp      :10.1.0.1         RemoteIp :10.1.0.2        BFDState  :Up
 TX           :1000             RX       :1000            Multiplier:3
 BFD Local Dis:8192             Interface:Vlanif10
 Diagnostic Info: No diagnostic information
 LocalIp      :10.2.0.1         RemoteIp :10.2.0.2        BFDState  :Up
 TX           :1000             RX       :1000            Multiplier:3
 BFD Local Dis:8193             Interface:Vlanif20
 Diagnostic Info: No diagnostic information
```

Table 7-3 Description of the display rip bfd session all command output

Item	Description
LocalIp	Local IP address
RemoteIp	Remote IP address
BFDState	A BFD session status can be either Up or Down.
TX	Minimum interval at which BFD packets are sent
RX	Minimum interval at which BFD packets are received
Multiplier	Remote detection multiplier

Item	Description
BFD Local Dis	Local discriminator dynamically assigned by BFD
Interface	Local interfaces on which BFD sessions are configured
Diagnostic Info	Diagnostic information

7.2.11 display rip database

Function

The **display rip database** command displays all the active routes in the RIP database. These routes are sent in RIP Update packets.

Format

display rip *process-id* **database** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
verbose	Displays detailed information about the routes in the RIP database.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display rip database** command to check all the active routes in the RIP database. These routes are sent in RIP Update packets.

Example

Display the RIP database.

```
<HUAWEI> display rip 100 database
---------------------------------------------------
Advertisement State : [A] - Advertised
                      [I] - Not Advertised/Withdraw
---------------------------------------------------
```

```
10.0.0.0/8, cost 0, ClassfulSumm
   10.1.1.0/24, cost 0, [A], Imported
   10.10.10.0/24, cost 0, [A], Rip-interface
   10.137.220.0/23, cost 1, [A], nexthop 10.10.10.2
```

Table 7-4 Description of the display rip database command output

Item	Description
Advertisement State	Route status. ● [A]: Advertised ● [I]: Not Advertised/Withdraw
ClassfulSumm	Classful route summarization.
Imported	Routes imported from other routing protocols.
Rip-interface	Routes learned on the RIP interface.
nexthop	Next-hop address.

7.2.12 display rip graceful-restart

Function

The **display rip graceful-restart** command displays the GR status of RIP.

Format

display rip *process-id* **graceful-restart** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
verbose	Displays detailed information about GR status.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After receiving the GR abort notification from the helper or detecting a network topology change, the restarter stops the GR process.

Example

Display the GR status in RIP process 1.

```
<HUAWEI> display rip 1 graceful-restart
Restart mode     : Restarting
Restart status   : In Progress - Waiting for updates
Last complete reason : None
Update progress summary:
------------------------
Restart capable peers  : 0
 Completed: 0    Inprogress: 0
Restart incapable peers: 1
 Completed: 0    Inprogress: 1
Update period finishes in 293 seconds
```

Table 7-5 Description of the display rip graceful-restart command output

Item	Description
Restart mode	Role of a switch: ● Restarting: indicates the restarter. ● Helper: indicates the helper. ● None: indicates a common switch that does not participate in GR.
Restart status	GR status: ● In Progress - waiting for updates: indicates that the switch is waiting for Update packets. ● In Progress - calculating active routes: indicates that the switch is calculating RIP routes. ● Aborted - calculating active routes: indicates that the route exits from GR abnormally. ● GR completed: indicates that GR is complete.
Last complete reason	Reason that the switch exits from GR for the last time: ● Unknown: indicates an unknown reason. ● Abort: indicates that the switch exits from GR abnormally. ● Period Expired: indicates that GR period expires. ● Successful: indicates that the switch exits from GR normally. ● None: indicates that the switch does not perform GR.
Update progress summary	Title bar indicating the updated RIP progress summary

Item	Description
Restart capable peers	Number of neighbors that help the local switch to perform GR
Completed	Number of neighbors that have sent all Update packets
Inprogress	Number of neighbors that have not sent all Update packets
Restart incapable peers	Number of neighbors that cannot help the local switch to perform GR
Update period finishes in 293 seconds	Time to finish GR: 293 seconds

7.2.13 display rip interface

Function

The **display rip interface** command displays information about RIP interfaces.

Format

display rip *process-id* **interface** [*interface-type interface-number*] [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies the type and the number of an interface.	-
verbose	Displays detailed information about a RIP interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display rip interface** command output displays the configuration and operating status of RIP, which facilitate fault location and configuration verification.

Example

Display information about RIP on VLANIF100.

```
<HUAWEI> display rip 1 interface vlanif 100
 -------------------------------------------------------------------------
 Interface                IP Address      State    Protocol           MTU
 -------------------------------------------------------------------------
 Vlanif 100                10.1.1.2        UP       RIPv1 Compatible    500
```

Table 7-6 Description of the display rip interface command output

Item	Description
Interface	RIP-enabled interfaces
IP Address	IP address of the interface
State	Status of the interface: ● UP ● DOWN
Protocol	Version of RIP running on the interface: ● RIPv1 Compatible ● RIPv2 Multicast ● RIPv2 Broadcast To set the version of RIP, run the **rip version** command.
MTU	MTU value of the link

Display detailed information about RIP on VLANIF100.

```
<HUAWEI> display rip 1 interface vlanif 100 verbose
 Vlanif100 (10.1.1.1)
  State    :   UP            MTU : 500
  Metricin : 0
  Metricout : 1
  Input    : Enabled         Output : Enabled
  Protocol : RIPv1 Compatible (Non-Standard)
  Send version     : RIPv1 Packets
  Receive version  : RIPv1 Packets, RIPv2 Multicast and Broadcast Packets
  Poison-reverse                : Disabled
  Split-Horizon                 : Enabled
  Authentication type           : None
  Replay Protection   : Disabled
  BFD                 : Enabled (Static)
  Transmit-Interval   : 1000 ms
  Receive-Interval    : 1000 ms
  Detect-Multiplier   : 3
  Summary Address (es):  10.1.0.0/16
```

Table 7-7 Description of the display rip interface verbose command output

Item	Description
State	Status of the interface: - UP - DOWN
MTU	Maximum Transmission Unit
Metricin	Metric that is added to the route when the interface receives a RIP packet. To set the metric, run the **rip metricin** command.
Metricout	Metric that is added to the route when the interface sends a RIP packet. To set the metric, run the **rip metricout** command.
Input	Whether receiving packets is enabled. To enable the specified interface to receive RIP packets, run the **rip input** command.
Output	Whether sending packets is enabled. To enable the specified interface to send RIP packets, run the **rip output** command.
Protocol	Protocol running on the interface: - RIPv1 Compatible (Non-Standard) - RIPv1 - RIPv2 Multicast - RIPv2 Broadcast To set the version of RIP, run the **rip version** command.
Send version	Type of packets sent on the interface: - RIPv1 packets - RIPv2 Multicast Packets - RIPv2 Broadcast Packets
Receive version	Type of packets received on the interface: - RIPv1 packets - RIPv2 Multicast and Broadcast Packets
Poison-reverse	Whether poison reverse is enabled on the interface. To enable poison reverse, run the **rip poison-reverse** command.

Item	Description
Split-Horizon	Whether split horizon is enabled on the interface. To enable split horizon, run the **rip split-horizon** command.
Authentication type	Authentication type configured on the interface. To set the authentication mode and authentication parameters, run the **rip authentication-mode** command.
Replay Protection	Whether replay-protect is enabled on the interface. To enable the replay-protect function, run the **rip replay-protect** command.
BFD	Whether BFD is enabled on the interface: ● Enabled (Dynamic): indicates dynamic BFD is enabled on the interface. To enable BFD on the specified interface, run the **rip bfd enable** command. ● Blocked: indicates BFD is blocked on the interface. To block BFD on a specified interface, run the **rip bfd block** command.
Transmit-Interval	Interval for sending BFD packets to the peer on the interface. To set BFD session parameters on the specified interface, run the **rip bfd** command.
Receive-Interval	Interval for receiving BFD packets from the peer on the interface. To set BFD session parameters on the specified interface, run the **rip bfd** command.
Detect-Multiplier	BFD detect multiplier value configured on the interface. To set BFD session parameters on the specified interface, run the **rip bfd** command.
Summary Address (es)	Summary address

7.2.14 display rip neighbor

Function

The **display rip neighbor** command displays information about RIP neighbors.

Format

display rip *process-id* **neighbor** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
verbose	Displays detailed information about a RIP neighbor.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display rip neighbor** command to check information about RIP neighbors.

Example

Display information about the neighbor in RIP process 1.

```
<HUAWEI> display rip 1 neighbor
---------------------------------------------------------------
 IP Address      Interface        Type   Last-Heard-Time
---------------------------------------------------------------
 10.1.1.1        Vlanif100        RIP     0:0:7
 Number of RIP routes:1
```

Table 7-8 Description of the display rip neighbor command output

Item	Description
IP Address	IP address of the neighboring interface
Interface	Interface type
Type	Protocol used to establish adjacencies with neighbors
Last-Heard-Time	Time since the last time packets are received from neighbors
Number of RIP routes	Number of RIP routes

Display detailed information about the neighbor in RIP process 1.

```
<HUAWEI> display rip 1 neighbor verbose
---------------------------------------------------------------
 IP Address      Interface        Type   Last-Heard-Time
---------------------------------------------------------------
 10.1.1.1        Vlanif100    RIP    0:0:17
   Number of Active routes       : 1
   Number of routes in garbage   : 0
   Last Received Sequence Number : 0x0
```

Table 7-9 Description of the display rip neighbor verbose command output

Item	Description
Number of Active routes	Number of routes in the active state
Number of routes in garbage	Number of routes in the garbage state
Last Received Sequence Number	Sequence number of last received packet from neighbor

7.2.15 display rip neighbor last-nbr-down

Function

The **display rip neighbor last-nbr-down** command displays information about the last neighbor that goes Down in a RIP process.

Format

display rip *process-id* **neighbor last-nbr-down**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display rip neighbor last-nbr-down** command can be used to view information about the last 10 RIP neighbor that goes down and the reason why the neighbor goes down.

Example

View information about the last neighbor that goes Down in a RIP process.

```
<HUAWEI> display rip 1 neighbor last-nbr-down
 Neighbor IP Address            : 10.2.2.2
 Interface                      : Vlanif10
 Reason for Neighbor down       : Interface Down
 Time at which neighbor went down : 2011-06-02 11:53:50
```

Table 7-10 Description of the display rip neighbor last-nbr-down command output

Item	Description
Neighbor IP Address	IP address of a neighbor
Interface	Interface connected to a neighbor
Reason for Neighbor down	Reason that a neighbor goes Down: ● Unknown ● Interface Down ● Configuration Change ● Time Out (Normal) ● Time Out (Message Processing Failed) ● BFD Session Down ● Invalid Packet Received ● Received Worst Metric Routes ● Received NQA Down Notification
Time at which neighbor went down	Time when a neighbor goes Down

7.2.16 display rip route

Function

The **display rip route** command displays all the RIP routes that are learned from other switches and view the values of different timers related to each route.

Format

display rip *process-id* **route**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a RIP process is enabled on all devices that need to run RIP and the **network** command is run to enable RIP on the related network segment, the **display rip route** command can be used to view RIP routing information.

Example

Display all the RIP routes and the values of different timers related to each route.

```
<HUAWEI> display rip 1 route
 Route Flags: R - RIP
              A - Aging, G - Garbage-collect
 -------------------------------------------------------------------------
 Peer 192.168.5.1  on Vlanif100
      Destination/Mask        Nexthop     Cost   Tag     Flags   Sec
        172.16.0.0/16       192.168.5.1    1     0       RA      15
      192.168.14.0/24        192.168.5.1    2     0       RA      15
```

Table 7-11 Description of the display rip route command output

Item	Description
Route Flags	Route flags. First character indicating that the route is a RIP or TRIP route, Second character indicating the status of the route: ● RA: indicates that a RIP route is active. ● RG: indicates that a RIP route is inactive and that the Garbage-Collect timer has been started.
Destination/ Mask	Destination IP Address and its mask value
Nexthop	Next hop of the route
Cost	Metric value of the route

Item	Description
Tag	Tag that is used to differentiate internal RIP routes from external routes ● 0: indicates that a RIP route is internal route. ● 1: indicates that a RIP route is external route.
Sec	Time during which a route remains in a specific state

7.2.17 display rip statistics interface

Function

The **display rip statistics interface** command displays statistics on a RIP interface, including the number of packets sent and received on the interface.

Format

display rip *process-id* **statistics interface** { **all** | *interface-type interface-number* [**verbose** | **neighbor** *neighbor-ip-address*] }

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535.
all	Displays the statistics of all interfaces.	-
interface-type interface-number	Specifies the type and number of an interface.	-
verbose	Displays detail information about interface statistics.	-
neighbor *neighbor-ip-address*	Specifies the IP address of a neighbor.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display rip statistics interface** command to check packet statistics on a RIP interface, including the number of packets sent and received on the interface.

Example

Display statistics on VLANIF100 in RIP process 1.

```
<HUAWEI> display rip 1 statistics interface vlanif 100
Vlanif100(10.0.0.11)
Statistical information         Last min     Last 5 min    Total
----------------------------------------------------------------
Periodic updates sent           5            23            259
Triggered updates sent          5            30            408
Response packets sent           10           34            434
Response packets received       15           38            467
Response packets ignored        0            0             0
Request packets sent            1            3             8
Request packets received        4            20            40
Request packets ignored         0            0             0
Bad packets received            0            0             0
Routes received                 0            0             0
Routes sent                     0            0             0
Bad routes received             0            0             0
Packet authentication failed    0            0             0
Packet send failed              0            0             0
```

Table 7-12 Description of the display rip statistics interface command output

Item	Description
Statistical information	Packet type
Last min	Statistics within the last 1 minute
Last 5 min	Statistics within the last 5 minutes
Total	Total number of packets
Periodic updates sent	Number of periodic Update packets that are sent on the interface
Triggered updates sent	Number of triggered Update packets that are sent on the interface
Response packets sent	Number of RIP Response packets that are sent on the interface
Response packets received	Number of RIP Response packets that are received on the interface
Response packets ignored	Number of RIP Response packets that are ignored on the interface
Request packets sent	Number of RIP Request packets that are sent on the interface
Request packets received	Number of RIP Request packets that are received on the interface

Item	Description
Request packets ignored	Number of RIP Request packets that are ignored on the interface
Bad packets received	Number of received packets that cannot be parsed correctly
Routes received	Number of received routes
Routes sent	Number of sent routes
Bad routes received	Number of received routes that cannot be parsed correctly
Packet authentication failed	Number of packets that fail to pass authentication
Packet send failed	Number of RIP packets that fail to be sent

7.2.18 filter-policy export (RIP)

Function

The **filter-policy export** command configures egress filtering policy for RIP routes.

The **undo filter-policy export** command deletes the filtering policy.

By default, no filtering policy is configured.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } **export** [*protocol* [*process-id*] | *interface-type interface-number*]

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name*] **export** [*protocol* [*process-id*] | *interface-type interface-number*]

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the basic ACL that is used to filter the destination addresses of routes.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the ACL filtering route destination addresses.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list that is used to filter the destination addresses of routes.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol process-id	Specifies the name of the routing protocol that exports the routes and the protocol process ID. The imported route type can be **static**, **direct**, **rip**, **ospf**, **bgp**, **unr** and **isis**. The process ID must be specified when routes are imported from **isis**, **rip** or **ospf**.	The value is an integer that ranges from 1 to 65535.
interface-type interface-number	Specifies type and number of the interface based on which routes are filtered.	-

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Only filtered routes can be added to routing tables and advertised in Update packets.

When you remove an interface-based filtering policy, you must specify *interface-type interface-number* in the **undo filter-policy export** command. The policy on only one interface can be deleted each time.

This command runs in the RIP view. If the filtering policy is based on interfaces or protocols, each interface or protocol can be configured with only one filtering policy. If the interface or protocol is not specified, a global filtering rule is configured. Only one global filtering rule can be configured each time. If you run the command again when a global rule exists, the new policy overwrites the old one.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Filter the imported static routes based on the IP prefix list named abc. Then, only the routes that match the filtering policy are added into the RIP routing table and then sent through RIP Update packets.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] filter-policy ip-prefix abc export static
```

Filter the routes imported from IS-IS process 1 based on ACL 2002. Only the routes that match the filtering policy are added into the RIP routing table and then sent through RIP Update packets.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] filter-policy 2002 export isis 1
```

7.2.19 filter-policy import (RIP)

Function

The **filter-policy import** command filters the received RIP routes.

The **undo filter-policy import** command cancels route filtering.

By default, no filtering policy is configured.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* [**gateway** *ip-prefix-name*] } **import** [*interface-type interface-number*]

filter-policy gateway *ip-prefix-name* **import**

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* [**gateway** *ip-prefix-name*]] **import** [*interface-type interface-number*]

undo filter-policy [**gateway** *ip-prefix-name*] **import**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the basic ACL that is used to filter the destination addresses of routes.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the ACL filtering route destination addresses.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
interface-type interface-number	Indicates the type and the number of the interface based on which routes are filtered.	-
ip-prefix	Filters routes by using the IP prefix list.	-
ip-prefix-name	Specifies the address prefix list used to filter route destination addresses.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
gateway	Filters routes based on the gateway.	-

RIP view

Default Level

2: Configuration level

Usage Guidelines

The **filter-policy import** command filters received RIP routes, including:

- Filtering a specified route in the packet
- Not monitoring the Update packets from the device

To cancel route filtering, run the **undo filter-policy import** command. When you remove an interface-based filtering policy, you must specify *interface-type interface-number*. The policy on only one interface can be deleted each time.

This command runs in the RIP view. If the filtering policy is based on interfaces, each interface can be configured with only one filtering policy. If the interface is not specified, a global filtering policy is configured. Only one global filtering policy can be configured. If you run the command again when a global policy exists, the new policy overwrites the old one.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule takes effective only when the source address range is specified by the **source** parameter and the time period is specified by the **time-range** parameter.

Example

Filter the RIP Update packets that are received from all the interfaces according to the IP prefix list named **abc**.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] filter-policy ip-prefix abc import
```

7.2.20 graceful-restart (RIP)

Function

The **graceful-restart** command enables RIP GR on the restarter.

The **undo graceful-restart** command disables RIP GR on the restarter.

By default, RIP GR is disabled.

Format

graceful-restart [**period** *period* | **wait-time** *time* | **planned-only** *time*] *

undo graceful-restart

Parameters

Parameter	Description	Value
period *period*	Specifies the period of GR.	It is an integer ranging from 30 to 3600, in seconds. The default value is 180 seconds.
wait-time *time*	Specifies the period of GR performed between the restarter and the neighbors that do not support GR. The value of **wait-time** *time* cannot be greater than the value of **period** *period*.	It is an integer ranging from 1 to 3600, in seconds. The default value is 45 seconds.
planned-only *time*	Specifies the period of GR performed between the restarter and the neighbors that support GR.	It is an integer ranging from 5 to 3600, in seconds. The default value is 60 seconds.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Planned GR indicates the master/slave switchover triggered through the command. Unplanned GR indicates the master/slave switchover triggered because of a fault.

When most switches on a network do not support RIP GR, you are advised to set **wait-time** *time* to a larger value. This ensures that the restarter has enough time to learn correct routes.

If the restart switch completes GR before the period specified by **period** *period* expires, the restart switch automatically exits from GR. If the restart switch does not complete GR after the period specified by **period** *period* expires, the restart switch is forced to exit from GR.

If the period of GR performed between the restarter and the neighbors that do not support GR depends on **wait-time**, the restarter does not exit from GR regardless of whether GR is finished within **wait-time**. After **wait-time** expires, however, the restarter is forced to exit from GR.

Example

Enable RIP GR and set the GR period to 200s.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] graceful-restart period 200
```

7.2.21 host-route

Function

The **host-route** command adds host routes with 32 bits into the routing table.

The **undo host-route** command disables host routes with 32 bits from being added into the routing table.

By default, host routes can be added into the routing table.

Format

host-route

undo host-route

Parameters

None

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

This command applies to RIP-1. In RIP-2, host routes are added to the routing table, regardless of whether the command is run.

Example

Add host routes into the routing table.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] host-route
```

7.2.22 import-route (RIP)

Function

The **import-route** command configures RIP to import routes from other routing protocols.

The **undo import-route** command disables RIP from importing routes from other routing protocols.

By default, RIP does not import routes from other routing protocols.

Format

import-route bgp [**permit-ibgp**] [**cost** { *cost* | **transparent** } | **route-policy** *route-policy-name*] *

import-route { { **static** | **direct** | **unr** } | { { **rip** | **ospf** | **isis** } [*process-id*] } } [**cost** *cost* | **route-policy** *route-policy-name*] *

undo import-route { { **static** | **direct** | **bgp** | **unr** } | { { **rip** | **ospf** | **isis** } [*process-id*] } }

Parameters

Parameter	Description	Value
bgp | **static** | **direct** | **rip** | **ospf** | **isis** | **unr**	Specifies the routing protocol from which RIP imports routes.	-
permit-ibgp	Imports routes from IBGP to RIP.	-
process-id	Specifies a process ID. The process ID can be specified when you import routes from RIP, OSPF, or IS-IS to RIP.	The value is an integer that ranges from 1 to 65535.
cost *cost*	Specifies the metric for imported routes.	The value is an integer that ranges from 0 to 15.

Parameter	Description	Value
cost transparent	This parameter is valid only when RIP imports routes from BGP. The metric of the imported routes is the MED of the BGP routes.	-
route-policy *route-policy-name*	Specifies the routing policy for importing routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

After you run the **import-route** command to set a routing policy, RIP can import only the specified routes and sets the route attributes.

To import routes from RIP, or IS-IS, you can specify the process ID. If the process ID is specified, RIP imports routes only from the specified process. If no process ID is specified, RIP imports routes from all processes. When a static or direct route is imported, the process ID cannot be specified.

You can run one of the following commands to set the metric of the imported routes. The following commands are listed in the descending order of priorities.

- Run the **apply cost** command to set route metric.
- Run the **import-route** (RIP) command to set the metric for imported routes.
- Run the **default-cost (RIP)** command to set the default metric for routes.

NOTE

- RIP defines a 16-bit tag, while other routing protocols define 32-bit tags. If the routes of other protocols are imported to RIP and the tag is used in the routing policy, the tag value cannot exceed 65535. If the tag value exceeds 65535, the routing policy becomes invalid or the matching result is incorrect.
- After the **import-route direct** command is executed, routes to the network segment where the IP address of the management interface belongs are also imported in the RIP routing table. Therefore, use this command with caution.
- The **permit-ibgp** parameter cannot be set for the RIP VPN instance.
- Importing IBGP routes to RIP may cause routing loops.

Example

Import IBGP routes, which are filtered by policy abc, to RIP process 1 and set the metric to 5.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] import-route bgp permit-ibgp cost 5 route-policy abc
```

7.2.23 maximum load-balancing (RIP)

Function

The **maximum load-balancing** command configures the maximum number of equal-cost routes for load balancing.

The **undo maximum load-balancing** command restores the default setting.

By default, the maximum number of equal-cost routes on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S6720S-S, and S5736-S is 8, and the maximum number of equal-cost routes on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S is 16.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

maximum load-balancing *number*

undo maximum load-balancing

Parameters

Parameter	Description	Value
number	Specifies the number of equal-cost routes.	The value is an integer that ranges from 1 to 8 on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S and S6720S-S. The value ranges from 1 to 16 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

If a network has multiple redundant links, the maximum number of equal-cost routes can be configured to implement load balancing. With load balancing, network resources are fully utilized, situations where some links are overloaded while others are idle can be avoided, and delay in packet transmissions is shortened.

Example

Set the maximum number of equal-cost routes to 4.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] maximum load-balancing 4
```

7.2.24 network (RIP)

Function

The **network** command enables RIP for the interface on the specified network segment.

The **undo network** command disables RIP for the interface on the specified network segment.

By default, RIP is disabled for the interface on the specified network segment.

Format

network *network-address*

undo network *network-address*

Parameters

Parameter	Description	Value
network-address	Specifies the network address on which RIP is enabled. It must be the address of the natural network segment.	The value is in dotted decimal notation.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

An interface can be associated with only one RIP process.

Example

Enable RIP routes for the interface on the specified network segment.

```
<HUAWEI> system-view
[HUAWEI] rip
[HUAWEI-rip-1] network 10.0.0.0
```

7.2.25 peer (RIP)

Function

The **peer** command specifies the IP addresses of the RIP neighbors. After this command is configured, Update packets are sent to the peer in unicast instead of multicast or broadcast mode.

The **undo peer** command deletes the specified neighbor IP address.

By default, no RIP neighbor address is specified.

Format

peer *ip-address*

undo peer *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a neighbor.	The value is in dotted decimal notation.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Generally, you are advised to use the **peer** command because an interface may receive the same packets both in multicast (or broadcast) and unicast mode. You are advised to change the mode of the interface to the silent mode when configuring the **peer** command.

Example

Specify the IP address of the neighbor to 10.0.0.1.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] peer 10.0.0.1
```

7.2.26 preference (RIP)

Function

The **preference** command sets the preference for RIP routes.

The **undo preference** command restores the default preference of RIP routes.

The default preference for RIP routes is 100.

Format

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Parameters

Parameter	Description	Value
preference	Specifies the preference for routes.	The value is an integer ranging from 1 to 255. By default, it is 100.
route-policy *route-policy-name*	Specifies the routing policy that sets preference for the routes meeting conditions.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

A small value indicates a high preference. To enable RIP routes to have a higher preference than the routes learned by other IGP protocols, you need to configure a smaller preference value for the RIP routes. The preference determines the algorithm through which the optimal route is obtained among the routes in the IP routing table.

Example

Set the preference of RIP routes to 120.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] preference 120
```

Set the preference of RIP routes that match the routing policy named **rt-policy1** to 120.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] preference 120 route-policy rt-policy1
```

7.2.27 reset rip configuration

Function

The **reset rip configuration** command resets system parameters for a specified RIP process. When a RIP process starts, all the parameters of the process retain the default values.

Format

reset rip *process-id* **configuration**

Parameters

Parameter	Description	Value
process-id	Specifies a RIP process ID.	The value is an integer that ranges from 1 to 65535.

Views

User view

Default Level

3: Management level

Usage Guidelines

NOTICE

Restarting RIP processes may interrupt services. Exercise caution when you run this command.

After the command is executed, RIP neighbor relationships are set up again and learned routes are deleted.

Example

Reset the parameters of RIP process 100.

```
<HUAWEI> reset rip 100 configuration
```

7.2.28 reset rip statistics

Function

The **reset rip statistics** command resets the counter that is maintained by a particular RIP process. This command allows you to repeatedly record statistics during debugging.

Format

reset rip *process-id* **statistics** [**interface** { **all** | *interface-type interface-number* [**neighbor** *neighbor-ip-address*] }]

Parameters

Parameter	Description	Value
process-id	Specifies a RIP process ID.	The value is an integer ranging from 1 to 65535.
all	Clears statistics of all RIP processes.	-
interface all	Clears statistics on all the interfaces of a specified RIP process.	-
interface *interface-type interface-number*	Clears statistics on the interface with specified number and type.	-
neighbor *neighbor-ip-address*	Clears statistics on the RIP process between the local RIP interface and the specified neighbor.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

Statistics cannot be restored after being cleared. Exercise caution when you run this command.

Example

Clear statistics in RIP process 100.

```
<HUAWEI> reset rip 100 statistics
```

Clear statistics on all interfaces in RIP process 100.

```
<HUAWEI> reset rip 100 statistics interface all
```

7.2.29 rip

Function

The **rip** command starts the specified RIP in the system view.

The **undo rip** command stops the specified RIP process.

By default, no RIP process is started.

Format

rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo rip *process-id*

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer that ranges from 1 to 65535. The default value is 1.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If no VPN instance is specified, a RIP process is run globally or in the default VPN instance. Before configuring each global RIP parameter, you need to start RIP. This restriction is not applicable when you configure interface-related parameters.

Example

Start RIP process 1.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1]
```

Start RIP process 100 in the VPN instance named **abc**.

```
<HUAWEI> system-view
[HUAWEI] rip 100 vpn-instance abc
[HUAWEI-rip-100]
```

7.2.30 rip authentication-mode

Function

The **rip authentication-mode** command sets the RIP-2 authentication mode and authentication parameters. Only one authentication password is used for each authentication. If multiple authentication passwords are configured, the latest one takes effect.

The **undo rip authentication-mode** command cancels authentication.

By default, no authentication is configured.

Format

rip authentication-mode simple { **plain** *plain-text* | [**cipher**] *password-key* }

rip authentication-mode keychain *keychain-name*

rip authentication-mode md5 usual { **plain** *plain-text* | [**cipher**] *password-key* }

rip authentication-mode md5 nonstandard { **keychain** *keychain-name* | { **plain** *plain-text* | [**cipher**] *password-key* } *key-id* }

rip authentication-mode hmac-sha256 { **plain** *plain-text* | [**cipher**] *password-key* } *key-id*

undo rip authentication-mode

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Specifies simple authentication. **NOTE** Simple authentication mode carries potential risks. HMAC-SHA256 ciphertext authentication is recommended.	-
md5	Specifies MD5 authentication. **NOTE** MD5 ciphertext authentication carries potential risks. HMAC-SHA256 ciphertext authentication is recommended.	-
usual	Indicates that MD5 ciphertext authentication packets use the universal format (private standard).	-
nonstandard	Indicates that MD5 ciphertext authentication packets use non-standard packet format (IETF standard).	-
plain	Indicates that only plain text can be entered and only plain text is displayed when the configuration file is viewed. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. You are advised to select **cipher** to save the password in cipher text.	-

Parameter	Description	Value
plain-text	Specifies the authentication password that is displayed in plain text.	The value is a string of case-sensitive characters. It contains letters and digits without spaces. When the authentication mode is **simple** or **md5 usual**, the password consists of 1 to 16 characters. When the authentication mode is **md5 nonstandard** or **hmac-sha256**, the password consists of 1 to 255 characters.
cipher	Indicates that either plain text or cipher text can be entered and cipher text is displayed when the configuration file is viewed.	-
password-key	Specifies the authentication password that is displayed in cipher text.	The value is a string of case-sensitive characters. It contains letters and digits without spaces. ● When the authentication mode is **simple** or **md5 usual**, the password is in plain text (1 to 16 characters) or in cipher text (24 or 32 or 48 characters). If the source version supports a ciphertext password which is a string of 24 or 32 characters, the target version also supports this type of password. ● When the authentication mode is **md5 nonstandard** or **hmac-sha256**, the password is in plain text (1 to 255 characters) or in cipher text (20 to 392 characters).
keychain *keychain-name*	Specifies keychain authentication.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Parameter	Description	Value
key-id	Specifies the identifier of Cryptographic authentication.	The value is an integer that ranges from 1 to 255.
hmac-sha256	Indicates Keyed-Hash Message Authentication Code (HMAC) for Secure Hash Algorithm 256 (SHA256).	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Keychain authentication improves UDP connection security. Keychain authentication must be configured on both ends of a link. Encryption algorithms and passwords configured on both ends must be the same; otherwise, the UDP connection cannot be set up and RIP messages cannot be transmitted.

Example

Set HMAC-SHA256 authentication on VLANIF100, with the authentication password **YsHsjx_202206** and key-id **255**.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip authentication-mode hmac-sha256 cipher YsHsjx_202206 255
```

Set HMAC-SHA256 authentication on GE0/0/1, with the authentication password **YsHsjx_202206** and key-id **255**.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip authentication-mode hmac-sha256 cipher YsHsjx_202206 255
```

7.2.31 rip bfd

Function

The **rip bfd** command sets BFD session parameters on the specified interface.

The **undo rip bfd** command restores BFD session parameters set on the specified interface.

By default, the minimum intervals for receiving and sending BFD packets are 1000 ms and the detection time multiplier is 3.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

rip bfd { **min-rx-interval** *min-receive-value* | **min-tx-interval** *min-transmit-value* | **detect-multiplier** *detect-multiplier-value* } *

undo rip bfd { **min-rx-interval** [*min-receive-value*] | **min-tx-interval** [*min-transmit-value*] | **detect-multiplier** [*detect-multiplier-value*] } *

Parameters

Parameter	Description	Value
min-rx-interval *min-receive-value*	Specifies the minimum interval at which BFD packets are received from the remote device.	The value is an integer that ranges from 100 to 1000, in milliseconds. • After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. • After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *min-transmit-value*	Specifies the minimum interval at which BFD packets are sent to the remote device.	The value is an integer that ranges from 100 to 1000, in milliseconds. • After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. • After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Parameter	Description	Value
detect-multiplier *detect-multiplier-value*	Specifies the local detection multiplier.	The value is an integer ranging from 3 to 50.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The *min-receive-value* value is obtained after the local **min-rx-interval** value and a neighbor's **min-tx-interval** value are negotiated. For detailed negotiation policies, see **bfd all-interfaces**. If the switch does not receive BFD packets from the neighbor at the interval of *min-receive-value* x *detect-multiplier-value*, the neighbor will go Down.

Prerequisites

Enable BFD globally and run the **rip bfd enable** command before establishing a BFD session.

Precautions

BFD session parameters configured in a RIP process take effect only after BFD is enabled on the interface.

The BFD priority configured on an interface is higher than the BFD priority configured in a RIP process. If BFD session parameters are configured on an interface, establish a BFD session based on the configured parameters.

Example

Enable BFD on VLANIF100 and set the minimum sending interval to 600 ms and local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip bfd enable
[HUAWEI-Vlanif100] rip bfd min-tx-interval 600 detect-multiplier 4
```

Enable BFD on GE0/0/1 and set the minimum sending interval to 600 ms and local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
```

```
[HUAWEI-GigabitEthernet0/0/1] rip bfd enable
[HUAWEI-GigabitEthernet0/0/1] rip bfd min-tx-interval 600 detect-multiplier 4
```

7.2.32 rip bfd block

Function

The **rip bfd block** command blocks BFD on a specified interface.

The **undo rip bfd block** command disables the blocking function.

By default, the blocking function is disabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

rip bfd block

undo rip bfd block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command can be used to block the specified interface from enabling BFD on some links where no BFD session is needed.

Precautions

The **rip bfd block** and **rip bfd enable** commands are mutually exclusive. If both of them are configured, only the later configured one takes effect.

Example

Block BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip bfd block
```

Block BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip bfd block
```

7.2.33 rip bfd enable

Function

The **rip bfd enable** command enables BFD on the specified interface to establish a BFD session with default parameters.

The **undo rip bfd enable** command disables BFD on the specified interface.

By default, BFD is disabled on a RIP interface.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

rip bfd enable

undo rip bfd enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If BFD is not enabled globally, you can set BFD parameters on the specified interface but you cannot establish a BFD session on this interface.

The **rip bfd block** and **rip bfd enable** commands are mutually exclusive. If both of them are configured, only the later configured one takes effect.

Example

Enable BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip bfd enable
```

Disable BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo rip bfd enable
```

Enable BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip bfd enable
```

Disable BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] undo rip bfd enable
```

7.2.34 rip bfd static

Function

The **rip bfd static** command enables static BFD on a specified RIP interface.

The **undo rip bfd static** command disables static BFD on a specified RIP interface.

By default, static BFD is disabled on a RIP interface.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support

Format

rip bfd static

undo rip bfd static

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network deployed with high-speed data services, if a fault occurs on a link, a large amount of data is lost because it takes too long time for RIP to detect the fault. Deploying BFD for RIP to accelerate fault detection is necessary.

The **rip bfd static** command is used to enable BFD for RIP on a specified link to rapidly detect the fault on the link.

In addition, because many devices do not support BFD on the live network, this command can be also used to implement BFD between a BFD-capable device and a BFD-incapable device.

Prerequisites

BFD has been enabled globally using the **bfd** command.

Precautions

If **rip bfd static**, **rip bfd enable**, and **rip bfd block** are simultaneously configured, the latest configuration overrides the previous ones.

Example

Enable static BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] bfd
```

```
[HUAWEI-bfd] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip bfd static
```

Enable static BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip bfd static
```

7.2.35 rip input

Function

The **rip input** command enables the specified interface to receive RIP packets.

The **undo rip input** command disables the specified interface from receiving RIP packets.

By default, interfaces can receive RIP packets.

Format

rip input

undo rip input

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The priority of **silent-interface** is higher than the priority of **rip input** or **rip output** configured in the interface view. By default, an interface does not work in the silent state.

Example

Enable the specified interface VLANIF100 to receive RIP packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip input
```

Enable the specified interface GE0/0/1 to receive RIP packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip input
```

7.2.36 rip metricin

Function

The **rip metricin** command sets the metric that is added to the route when an interface receives a RIP packet.

The **undo rip metricin** command restores the additional metric to the default value.

By default, there is no metric added to the route when an interface receives a RIP packet.

Format

rip metricin { *value* | { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } *value1* }

undo rip metricin

Parameters

Parameter	Description	Value
value	Specifies the metric that is added to the received route.	The value is an integer ranging from 0 to 15. By default, it is 0.
acl-number	Specifies the basic ACL number.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the ACL name.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
value1	Specifies the metric that is added to the route that passes the filtering of the ACL or IP prefix list.	The value is an integer ranging from 1 to 15.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When an interface receives a route, RIP adds the additional metric of the interface to the route, and then installs the route into the routing table. Therefore, increasing the metric of an interface also increases the metric of the RIP route received by the interface.

Adjust RIP route selection by increasing the metrics of received routes.

Example

Set the additional metric to 12 when VLANIF100 receives RIP routes.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricin 12
```

Set the additional metric to 12 when GE0/0/1 receives RIP routes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip metricin 12
```

Set the additional metric to 12 using acl-name.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricin acl-name abcd 12
```

Set the additional metric to 12 using ip-prefix.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricin ip-prefix ip1 12
```

7.2.37 rip metricout

Function

The **rip metricout** command sets the metric that is added to the route when an interface sends a RIP packet.

The **undo rip metricout** command restores the additional metric to the default value.

By default, the metric that is added to the route when an interface sends a RIP packet is 1.

Format

rip metricout { *value* | { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* } *value1* }

undo rip metricout

Parameters

Parameter	Description	Value
value	Specifies the metric that is added to the sent route.	The value is an integer ranging from 1 to 15. By default, it is 1.
acl-number	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the name of an ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list. The name must be exclusive.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
value1	Specifies the metric that is added to the route that passes the filtering of the ACL or IP prefix list.	The value is an integer ranging from 2 to 15.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When a RIP route is advertised, the additional metric is added to the route. Therefore, increasing the metric of an interface also increases the metric of the RIP route sent on the interface. However, the metric of the route in the routing table remains unchanged.

You can specify the metric to be added to the RIP route that passes the filtering of the ACL or IP prefix list by specifying *value1*. If a RIP route does not pass the filtering, its metric is increased by 1.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Set the metric that is added when the interface sends RIP routes to 12.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricout 12
```

Set the metric that is added when the interface sends RIP routes to 12.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip metricout 12
```

Increase the metric of a RIP route that passes the filtering of ACL 2050 by 12.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricout 2050 12
```

Increase the metric of a RIP route that passes the filtering of ACL 2050 by 12.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip metricout 2050 12
```

Increase the metric of a RIP route that passes the filtering of the IP prefix list named **p1** by 12.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix p1 permit 10.10.10.1 24
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip metricout ip-prefix p1 12
```

Increase the metric of a RIP route that passes the filtering of the IP prefix list named **p1** by 12.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip metricout ip-prefix p1 12
```

7.2.38 rip mib-binding

Function

The **rip mib-binding** command sets the binding between the Management Information Base (MIB) and RIP process ID, and specifies the ID of the RIP process that receives SNMP requests.

The **undo rip mib-binding** command cancels the binding.

By default, there is no binding between the Management Information Base and RIP process ID.

Format

rip mib-binding *process-id*

undo rip mib-binding

Parameters

Parameter	Description	Value
process-id	Specifies the ID of a RIP process.	The value is an integer ranging from 1 to 65535. The default value is 1.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

All SNMP requests are sent to the bound RIP process.

Prerequisites

A RIP process has been created using the **rip** command.

Example

Configure RIP process 100 to receive SNMP requests.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] quit
[HUAWEI] rip mib-binding 100
```

7.2.39 rip output

Function

The **rip output** command enables an interface to send RIP packets.

The **undo rip output** command disables an interface from sending RIP packets.

By default, an interface can send RIP packets.

Format

rip output

undo rip output

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When a device running RIP is connected to a network running other routing protocols, you can run the **rip output** command on the interface that connects the device to the network to prevent the interface from sending useless packets to the network.

The priority of **silent-interface** is higher than the priority of **rip input** or **rip output** that is configured in the interface view. By default, an interface does not work in the silent state.

Example

Enable the interface VLANIF100 to send RIP packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip output
```

Enable the interface GE0/0/1 to send RIP packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip output
```

7.2.40 rip pkt-transmit

Function

The **rip pkt-transmit** command sets the interval for sending Update packets and the number of packets sent each time on the specified interface.

The **undo rip pkt-transmit** command restores the default values on an interface.

By default, the interval for sending RIP Update packets is 200 ms and 50 packets are sent each time.

Format

rip pkt-transmit { **interval** *interval* | **number** *pkt-count* } *

undo rip pkt-transmit

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for sending Update packets.	The value is an integer ranging from 50 to 500, in milliseconds. The default value is 200.
number *pkt-count*	Specifies the number of packets sent each time.	The value is an integer and ranges from 25 to 100. The default value is 50.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The **rip pkt-transmit** command can be used on an interface to control the interval for sending Update packets and the number of sent packets. This improves RIP performance.

Example

Set the interval for sending packets on VLANIF100 to 100 milliseconds and the number of the packets sent each time to 50.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip pkt-transmit interval 100 number 50
```

Set the interval for sending packets on GE0/0/1 to 100 milliseconds and the number of the packets sent each time to 50.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip pkt-transmit interval 100 number 50
```

7.2.41 rip poison-reverse

Function

The **rip poison-reverse** command enables poison reverse.

The **undo rip poison-reverse** command disables poison reverse.

By default, poison reverse is disabled.

Format

rip poison-reverse

undo rip poison-reverse

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

After poison reverse is enabled, RIP sets the cost of the routes learned from a specified interface to 16 (indicating unreachable), and then sends the routes to neighbors through the same interface.

When both split horizon and poison reverse are configured, only poison reverse takes effect.

Example

Enable poison reverse.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip poison-reverse
```

Enable poison reverse on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip poison-reverse
```

7.2.42 rip replay-protect

Function

The **rip replay-protect** command enables the replay-protect function.

The **undo rip replay-protect** command disables the replay-protect function.

By default, the replay-protect function is disabled.

Format

rip replay-protect [*window-range*]

undo rip replay-protect

Parameters

Parameter	Description	Value
window-range	Specifies the size of the connection-oriented transmission buffer.	It is an integer ranging from 50 to 50000. The default value is 50.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If the Identification field in the last RIP packet sent before a RIP interface goes Down is X, after the interface goes Up, the Identification field in the RIP packet sent by this interface becomes 0. If the remote end does not receive the RIP packet with the Identification field being 0, subsequent RIP packets will be discarded until the remote end receives the RIP packet with the Identification field being X+1. As a result, RIP routing information of both ends is inconsistent. To solve this problem, you need to configure the **rip replay-protect** command so that RIP can obtain the Identification field in the RIP packet sent before the RIP packet goes Down and increases the Identification field of the subsequently sent RIP packet by one.

Before configuring the **rip replay-protect** command, you need to configure the **rip authentication-mode** command in the RIP interface view to configure the authentication mode and authentication parameters of RIP-2.

NOTE

If you configure the **rip replay-protect** command in the same view for multiple times, only the last configuration takes effect.

Example

Enable the replay-protect function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip replay-protect
```

Enable the replay-protect function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip replay-protect
```

7.2.43 rip split-horizon

Function

The **rip split-horizon** command enables split horizon.

The **undo rip split-horizon** command disables split horizon.

By default, split horizon is enabled.

Format

rip split-horizon

undo rip split-horizon

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If a route is advertised through the interface from which the route is learned, the route is blocked by split horizon. Split horizon is used to avoid routing loops between neighboring devices.

Generally, it is not recommended that you disable split horizon.

If split horizon is enabled on the interface that is configured with secondary IP addresses, RIP Update packets may not be sent by each secondary address. An Update packet does not regard every network as the source unless split horizon is disabled.

If an interface is connected to a Non Broadcast Multiple Access (NBMA) network, split horizon on the interface is disabled by default.

If both poison reverse and split horizon are configured, simple split horizon (the route is suppressed by the interface through which the route is learned) is substituted by poison reverse. Here, simple split horizon means that the route is suppressed when it is advertised through the interface from which it is learned.

Example

Enable split horizon.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip split-horizon
```

Enable split horizon.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip split-horizon
```

7.2.44 rip summary-address

Function

The **rip summary-address** command configures a RIP switch to advertise a local summarized IP address.

The **undo rip summary-address** command disables a RIP switch from advertising a local summarized IP address.

By default, a RIP switch does not advertise local summarized IP addresses.

Format

rip summary-address *ip-address mask* [**avoid-feedback**]

undo rip summary-address *ip-address mask*

Parameters

Parameter	Description	Value
ip-address	Specifies the network IP address to be summarized.	The value is in dotted decimal notation.
mask	Specifies the network mask.	The value is in dotted decimal notation.
avoid-feedback	Specifies that learning the same summarized route from an interface is not allowed.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

After the keyword **avoid-feedback** is specified, an interface no longer learns the summarized route with the same IP address as the advertised summarized IP address. This avoids routing loops.

Example

Configure the switch to advertise a local summarized IP address.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip summary-address 10.0.0.0 255.0.0.0
```

Configure the switch to advertise a local summarized IP address.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip summary-address 10.0.0.0 255.0.0.0
```

7.2.45 rip valid-ttl-hops

Function

The **rip valid-ttl-hops** command enables the RIP GTSM functions and sets the TTL value to be detected.

The **undo rip valid-ttl-hops** command cancels the function.

By default, the RIP GTSM functions are disabled.

Format

rip valid-ttl-hops *valid-ttl-hops-value* [**vpn-instance** *vpn-instance-name*]

undo rip valid-ttl-hops [*valid-ttl-hops-value*] [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
valid-ttl-hops-value	Specifies the number of TTL hops to be detected. The valid TTL range of the detected packets is [255 -*valid-ttl-hops-value* + 1, 255].	The value is an integer ranging from 1 to 255.
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance. If this parameter is used, you need only to specify the TTL value to be detected by the VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a network demanding higher security, you can enable GTSM to improve the security of the RIP network. GTSM defends against attacks by checking the TTL value. If an attacker simulates RIP unicast packets and keeps sending them to a switch, a switch receives the packets and directly sends them to the main control board for RIP processing, without checking the validity of the packets. In this case, the switch is busy processing these packets, causing high usage of the CPU. GTSM protects the routers and enhances the system security by checking whether the TTL value in the IP packet header is in a pre-defined range.

The **rip valid-ttl-hops** command is used to enable RIP GTSM.

Precautions

GTSM configurations must be symmetrical. That is, GTSM must be enabled on devices at both ends.

If GTSM is enabled on a device, after the device receives a RIP packet, it checks whether the TTL value in the packet is in a pre-defined range. If the TTL value is beyond the pre-defined range, the device considers the packet as an attack packet and discards it.

Example

Enable the RIP GTSM functions, and configure the maximum number of TTL hops to 5 for the packets that a switch is allowed to receive.

```
<HUAWEI> system-view
[HUAWEI] rip valid-ttl-hops 5
```

7.2.46 rip version

Function

The **rip version** command sets the RIP version of an interface.

The **undo rip version** command restores the default setting.

By default, an interface sends only RIP-1 packets, but it can receive both RIP-1 and RIP-2 packets.

Format

rip version { **1** | **2** [**broadcast** | **multicast**] }

undo rip version

Parameters

Parameter	Description	Value
1	Indicates RIP-1 packets.	-
2	Indicates RIP-2 packets.	-

Parameter	Description	Value
broadcast	Indicates that RIP-2 packets are sent in broadcast mode.	-
multicast	Indicates that RIP-2 packets are sent in multicast mode. **NOTE** By default, RIP-2 packets are sent in multicast mode.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The versions of the request packets and response packets vary with the configured RIP version.

- If the version of RIP is not set, a device sends RIP-1 packets in broadcast mode and receives the RIP-1 and RIP-2 packets that are sent in broadcast mode.
- If the RIP version is set to RIP-1, a device sends only RIP-1 packets in broadcast mode and receives the RIP-1 packets that are sent in broadcast mode.
- If the RIP version is set to RIP-2, a device sends only RIP-2 packets in multicast mode and receives RIP-2 packets that are sent in multicast or broadcast mode.
- If the RIP version is set to multicast RIP-2, a device sends RIP-2 packets in multicast mode and receives RIP-2 packets that are sent in multicast mode.
- If the RIP version is set to broadcast RIP-2, a device sends RIP-2 packets in broadcast mode and receives RIP-1 and RIP-2 packets.

Precautions

You can also set a RIP version in a RIP process, but the RIP version that is set on an interface has a higher priority.

Example

Send RIP-2 packets in broadcast mode.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] rip version 2 broadcast
```

Send RIP-2 packets in broadcast mode.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] rip version 2 broadcast
```

7.2.47 silent-interface (RIP)

Function

The **silent-interface** command controls an interface only to receive packets to update its routing table and prevent it from sending RIP packets.

The **undo silent-interface** command enables an RIP interface to send Update packets.

The **silent-interface disable** command enables an RIP interface to send Update packets.

The **undo silent-interface disable** command controls an interface only to receive packets to update its routing table and prevent it from sending RIP packets.

By default, silent interface not enabled.

Format

silent-interface { **all** | *interface-type interface-number* }

undo silent-interface { **all** | *interface-type interface-number* }

silent-interface disable *interface-type interface-number*

undo silent-interface disable *interface-type interface-number*

Parameters

Parameter	Description	Value
all	Indicates that all interfaces are suppressed.	-
interface-type interface-number	Specifies the type and the number of the interface.	-
disable	Disables the suppression of the RIP interface so that the interface can send Update packets.	-

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a switch running RIP is connected to a network running other routing protocols, you can run the **silent-interface** command on the interface that connects the switch to the network to prevent the interface from sending useless packets to the network.

The **silent-interface** command is used together with the **peer (RIP)** command to advertise routes to the specified equipment.

Configuration Impact

If an interface is suppressed, the direct routes of the network segment where the interface resides can still be advertised to other interfaces.

Precautions

When the **silent-interface** command is used to suppress the specified interface, the priority of the **silent-interface** command is higher than the priority of the **rip input** and **rip output** command that is configured in the interface view.

NOTE

After you configure all interfaces as silent interfaces, you can run the **silent-interface disable** *interface-type interface-number* command to activate a specified silent interface.

Example

Configure all the interfaces as silent interfaces.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] silent-interface all
```

Configure the RIP interface VLANIF100 as a silent interface and enable it to send routes to the neighbor with the IP address of 10.1.1.1/24.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] silent-interface vlanif 100
[HUAWEI-rip-100] peer 10.1.1.1
```

Configure all interfaces as silent interfaces, and then activate the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] silent-interface disable vlanif 100
```

7.2.48 summary (RIP)

Function

The **summary** command enables RIP classful summarization. The summarized routes are advertised using natural masks.

The **undo summary** command disables classful summarization so that routing between subnets can be performed. The subnet information is then advertised. Route summarization reduces the routing table size.

By default, classful summarization is enabled for RIP-2.

Format

summary [**always**]

undo summary

Parameters

Parameter	Description	Value
always	Enables classful summarization no matter whether split horizon is configured.	-

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

RIP-1 does not support classful summarization. When using RIP-2, you can use the **undo summary** command to disable classful summarization.

RIP-2 route summarization improves scalability and efficiency on large networks. IP address summarization means that there is no sub-routing entry in the routing table. That is, there is no routing entry composed of single IP address. In addition to reducing the routing table size, route summarization enables the switch to handle more routes.

When classful summarization is enabled, the switch summarizes subnet addresses to the natural network segment border while advertising routes to the natural network segment border. When split horizon or poison reverse is enabled, route summarization will be invalid if the **always** parameter is not specified. When summarized routes are sent outside the natural network segment, split horizon or poison reverse must be disabled.

NOTE

- By default, classful summarization is enabled for RIP-2. If split horizon or poison reverse has been configured, classful summarization is invalid. When summarized routes are sent to the network border, split horizon and poison reverse must be disabled.
- The **summary always** command can enable classful summarization no matter whether split horizon or poison reverse is enabled.
- The summarization preference on interfaces is higher than the summarization preference in RIP processes. That is, the preference of **rip summary-address** is higher than the preference of **summary**. When summarization is configured on both interface and RIP process, the summarized route is advertised only when a few specific routes are beyond the summarization range configured on the interface.

Example

Enable RIP-2 classful summarization.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] version 2
[HUAWEI-rip-1] summary
```

Enable RIP-2 classful summarization when split horizon is enabled.

```
<HUAWEI> system-view
[HUAWEI] rip 1
[HUAWEI-rip-1] summary always
```

7.2.49 timers rip

Function

The **timers rip** command sets the values of RIP timers.

The **undo timers rip** command restores the values of RIP timers to the default value.

By default, the interval for sending Update packets is 30s, the time for aging routes is 180s, the time for deleting a route from the routing table is 120s.

Format

timers rip *update age garbage-collect*

undo timers rip

Parameters

Parameter	Description	Value
update	Specifies the interval for sending Update packets.	The value is an integer ranging from 1 to 86400, in seconds.
age	Specifies the time for aging routes.	The value is an integer ranging from 1 to 86400, in seconds.
garbage-collect	Specifies the time for deleting a route from the routing table, that is, the standard garbage collection time.	The value is an integer ranging from 1 to 86400, in seconds.

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

By adjusting the RIP timers, you can improve routing protocol performance to meet network requirements. If the values of the preceding three timers are set improperly, route flapping occurs.

The relationship of the values of the three timers is: *update* < *age* and *update* < *garbage-collect*. For example, if the update time is longer than the aging time, switches cannot inform neighbors on time if RIP routes change during the update time.

NOTE

Generally, the default values of the timers do not need to be changed, and thus the **timers rip** command must be used with caution.

Example

Set values for RIP timers.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] timers rip 35 170 240
```

7.2.50 verify-source (RIP)

Function

The **verify-source** command enables check on source IP addresses in RIP Update packets.

The **undo verify-source** command disables check on source IP addresses in RIP Update packets.

By default, the source IP addresses in RIP Update packets are checked.

Format

verify-source

undo verify-source

Parameters

None

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **verify-source** command is executed, RIP checks whether the IP addresses of interfaces that send and receive the Update packets are on the same network segment. If not, the device does not process the packets.

NOTE

It is not recommended that you disable source address check.

Example

Enable source address check in RIP 100.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] verify-source
```

7.2.51 version (RIP)

Function

The **version** command specifies a global RIP version.

The **undo version** command restores the default global RIP version.

By default, an interface sends only RIP-1 packets, and receives both RIP-1 and RIP-2 packets.

Format

version { **1** | **2** }

undo version

Parameters

Parameter	Description	Value
1	Sets the global RIP version to RIP-1.	-
2	Sets the global RIP version to RIP-2.	-

Views

RIP view

Default Level

2: Configuration level

Usage Guidelines

Two versions are available for RIP: RIP-1 and RIP-2. RIP-2 is an extension to RIP-1. You can run the **version** command to specify a global RIP version.

Example

Send and receive RIP-2 packets.

```
<HUAWEI> system-view
[HUAWEI] rip 100
[HUAWEI-rip-100] version 2
```

7.3 RIPng Configuration Commands

7.3.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.3.2 checkzero (RIPng)

Function

The **checkzero** command enables zero field check for RIPng packets.

The **undo checkzero** command disables zero field check for RIPng packets.

By default, zero field check is enabled for RIPng packets.

Format

checkzero

undo checkzero

Parameters

None

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

After zero field check is enabled, the switch refuses to process the RIPng packets in which zero fields are not 0. If all RIPng packets are reliable and no zero field needs to be checked, run the **undo checkzero** command to reduce CPU usage.

Example

Disable zero field check for RIPng packets.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] undo checkzero
```

7.3.3 default-cost (RIPng)

Function

The **default-cost** command sets the default cost for imported routes.

The **undo default-cost** command restores the default value 0.

By default, the default cost of RIPng routes is 0.

Format

default-cost *cost*

undo default-cost

Parameters

Parameter	Description	Value
cost	Sets the default cost of imported routes.	The value is an integer that ranges from 0 to 15.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

You can run one of the following commands to set the cost of imported routes. The following commands are listed in descending order of priorities.

- Run the **apply cost** command to set the cost of routes.
- Run the **import-route** command to set the cost of imported routes.
- Run the **default-cost** (RIPng) command to set the default cost of imported routes.

Example

Set the default cost of imported routes to 2.

```
<HUAWEI> system-view
[HUAWEI] ripng 100
[HUAWEI-ripng-100] default-cost 2
```

7.3.4 description (RIPng)

Function

The **description** command configures a description for a RIPng process.

The **undo description** command deletes the configured description of a RIPng process.

By default, there is no description for a RIPng process.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Configures a description for a RIPng process.	The description is a string of 1 to 80 case-sensitive characters that can contain spaces.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Configuring descriptions for RIPng processes helps identify and configure RIPng processes.

Precautions

If you run the **description** command multiple times, only the latest configuration takes effect.

Example

Configure a description for RIPng process 100.

```
<HUAWEI> system-view
[HUAWEI] ripng 100
[HUAWEI-ripng-100] description this process configure the poison reverse process
```

7.3.5 display default-parameter ripng

Function

The **display default-parameter ripng** command displays the default RIPng configuration.

Format

display default-parameter ripng

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After the default RIPng configuration is modified, you can use the **display default-parameter ripng** command to view the default RIPng configuration used when RIPng is initialized.

Example

Display the default RIPng configuration.

```
<HUAWEI> display default-parameter ripng
--------------------------------------------
 Protocol Level Default Configurations
--------------------------------------------
       Preference    : 100
       Checkzero     : Enabled
       Default-cost  : 0
       Maximum Balanced Paths : 8
       Update time   : 30 sec      Age time   : 180 sec
       Garbage-collect time            : 120 sec
--------------------------------------------
 Interface Level Default Configurations
--------------------------------------------
    Metricin                 : 0
    Metricout                : 1
    Input Packet Processing : Enabled
    Output Packet Processing: Enabled
    Poison Reverse           : Disabled
    Split Horizon
     For Broadcast and P2P Interfaces     :  Enabled
     For NBMA Interfaces and LoopBack     :  Disabled
    Default Route                          :  Disabled
    Packet Transmit Interval              :  200 msecs
    Packet Transmit Number                 :  30
```

Table 7-13 Description of the display default-parameter ripng command output

Item	Description
Protocol Level Default Configurations	Default RIPng process configuration.
Preference	RIPng route preference.

Item	Description
Checkzero	Whether zero field check is enabled for RIPng packets.
Default Cost	Default cost of routes imported by RIPng from other routing protocols.
Maximum Balanced Paths	Maximum number of equal-cost routes for load balancing.
Update time	Interval for sending Update packets.
Age time	Aging time of RIPng routes.
Garbage-Collect time	Time from when a route is marked invalid until the route is removed from the routing table.
Interface Level Default Configurations	Default RIPng configuration on an interface.
Metricin	Metric that is added to a route when a RIPng packet is received.
Metricout	Metric that is added to a route when a RIPng packet is sent.
Poison Reverse	Whether poison reverse is enabled.
Split Horizon	Whether split horizon is enabled: ● For Broadcast and P2P Interfaces: broadcast and P2P interfaces ● For NBMA Interfaces and LoopBack: NBMA and loopback interfaces
Default-route	Default route. This route is used when no matching entry can be found for a packet in the routing table.
Packet Transmit Interval	Interval for forwarding packets, in milliseconds.
Packet Transmit Number	Number of forwarded packets.
Input Packet Processing	Whether this interface is enabled to receive RIPng packets
Output Packet Processing	Whether this interface is enabled to send RIPng packets

7.3.6 display ripng

Function

The **display ripng** command displays the current operating status and configuration of RIPng processes.

Format

display ripng [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
process-id	Displays the current operating status and configuration of the specified RIPng process. If this parameter is not specified, the configurations of all RIPng processes are displayed.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays the status and configuration of a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ripng** command to check the current operating status and configuration of RIPng processes.

Example

Display information about a specified RIPng process.

```
<HUAWEI> display ripng 100
Public vpn-instance
    RIPng process : 100
       Preference : 100
       Checkzero : Enabled
       Default-cost : 0
       Maximum number of balanced paths : 8
       Update time   : 30 sec   Age time  : 180 sec
       Garbage-collect time : 120 sec
       Number of periodic updates sent : 0
       Number of trigger updates sent : 1
       Number of routes in database : 1
       Number of interfaces enabled : 1
       Total number of routes : 3
```

```
    Total number of routes in ADV DB is : 0
```

Table 7-14 Description of the display ripng command output

Item	Description
Public vpn-instance	Public VPN.
RIPng process	RIPng process ID.
Preference	RIPng process preference. To set the preference for RIPng routes, run the **preference (RIPng)** command.
Checkzero	Whether zero field check is enabled for RIPng packets.
Default-cost	Default cost of routes imported by RIPng from other routing protocols.
Maximum number of balanced paths	Maximum number of equal-cost routes for load balancing. To set the preference for RIPng routes, run the **maximum load-balancing (RIPng)** command.
Update time	Interval for sending Update packets.
Age time	Aging time of RIPng routes.
Garbage-collect time	Time from when a route is marked invalid until the route is removed from the routing table.
Number of periodic updates sent	Number of RIPng Update packets sent periodically.
Number of trigger updates sent	Number of triggered RIPng Update packets.
Number of routes in database	Number of routes in the RIPng database.
Number of interfaces enabled	Number of RIPng interfaces.
Total number of routes	Total number of routes of a RIPng process.
Total number of routes in ADV DB is	Total number of advertised routes in the database.

7.3.7 display ripng database

Function

The **display ripng database** command displays all the active routes in the RIPng database.

Format

display ripng *process-id* **database** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Displays all the active routes of the specified RIPng process.	The value is an integer that ranges from 1 to 65535.
verbose	Displays detailed information about the routes in the RIPng database.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ripng database** command to check all the active routes in the RIPng database.

Example

Display routes in the RIPng database.

```
<HUAWEI> display ripng 100 database
1::/64,
      via FE80::82FB:6FF:FE35:45B6, Vlanif200, cost 0, Imported
  2::/64,
      Vlanif100, cost 0, RIPng-interface
  3::/64,
      via FE80::82FB:6FF:FE35:45B6, Vlanif200, cost 16
  3::/64,
      Vlanif200, cost 0, RIPng-interface
  4::/64,
      via FE80::82FB:6FF:FE35:45B6, Vlanif200, cost 1
```

Table 7-15 Description of the display ripng database command output

Item	Description
1::/64	Destination IPv6 address of a route.
via	Next-hop link-local address.
cost	Cost of a route.
Imported	Route imported from other routing protocols.

Item	Description
RIPng-interface	Route generated by RIPng.

7.3.8 display ripng interface

Function

The **display ripng interface** command displays information about RIPng interfaces.

Format

display ripng *process-id* **interface** [*interface-type interface-number*] [**verbose**]

Parameters

Parameter	Description	Value
process-id	Displays interface information in the specified RIPng process.	The value is an integer that ranges from 1 to 65535.
interface-type interface-number	Displays information on the interface with the specified type and number.	-
verbose	Displays detailed information about RIPng interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays the configuration and operating status of RIPng. The information is helpful in fault location and configuration verification.

Example

Display information about VLANIF100 of the specified RIPng process.

```
<HUAWEI> display ripng 1 interface vlanif 100
 Vlanif100
    FE80::A0A:200:1
    State : UP, Protocol : RIPNG, MTU : 1440
```

Table 7-16 Description of the display ripng interface command output

Item	Description
FE80::A0A:200:1	Link-local address of the interface.
State	Status of the interface: ● UP ● DOWN
Protocol	Routing protocol running on the interface.
MTU	Link MTU.

Display detailed information about VLANIF100 of the specified RIPng process.

```
<HUAWEI> display ripng 1 interface vlanif100 verbose
 VLANIF100
    FE80::A0A:200:1
    State : UP, Protocol : RIPNG, MTU : 1440
    Metricin        : 0
    Metricout       : 1
    Input           : Enabled      Output : Enabled
    Default Route  : Disabled
    Poison Reverse : Disabled
    Split Horizon  : Enabled
```

Table 7-17 Description of the display ripng interface verbose command output

Item	Description
FE80::A0A:200:1	Link-local address of the interface.
State	Status of the interface: ● UP ● DOWN
Protocol	Routing protocol running on the interface.
MTU	Link MTU.
Metricin	Metric added to a received route. To set the metric, run the **ripng metricin** command.
Metricout	Metric added to a sent route. To set the metric, run the **ripng metricout** command.
Input	Indicates whether this interface is enabled to receive RIPng packets. To enable the specified interface to receive RIPng packets, run the **ripng input** command.
Output	Indicates whether this interface is enabled to send RIPng packets. To enable an interface to send RIPng packets, run the **ripng output** command.

Item	Description
Default Route	Whether the interface is enabled to advertise default routes. To generate a default route to the RIPng routing domain, run the **ripng default-route** command.
Poison Reverse	Whether poison reverse is enabled on the interface. To enable poison reverse for RIPng, run the **ripng poison-reverse** command.
Split Horizon	Whether split horizon is enabled on the interface. To enable split horizon for RIPng, run the **ripng split-horizon** command.

7.3.9 display ripng neighbor

Function

The **display ripng neighbor** command displays information about RIPng neighbors.

Format

display ripng *process-id* **neighbor** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Displays neighbor information in the specified RIPng process.	The value is an integer that ranges from 1 to 65535.
verbose	Displays detailed information about RIPng neighbors.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ripng neighbor** command to check information about RIPng neighbors.

Example

Display neighbor information in RIPng process 1.

```
<HUAWEI> display ripng 1 neighbor
 Neighbor : FE80::A0A:201:1 Vlanif100
    Protocol : RIPNG
```

Table 7-18 Description of the display ripng neighbor command output

Item	Description
Neighbor	IPv6 address and interface type of the neighbor interface.
Protocol	Routing protocol.

Display detailed neighbor information in RIPng process 1.

```
<HUAWEI> display ripng 1 neighbor verbose
 Neighbor : FE80::A0A:201:1 VLANIF100
    Protocol : RIPNG
    Number of Active routes      : 1
    Number of routes in garbage  : 0
```

Table 7-19 Description of the display ripng neighbor verbose command output

Item	Description
Number of Active routes	Number of active routes.
Number of routes in garbage	Number of garbage routes.

7.3.10 display ripng neighbor last-nbr-down

Function

The **display ripng neighbor last-nbr-down** command displays information about the last neighbor that goes Down in a RIPng process.

Format

display ripng *process-id* **neighbor last-nbr-down**

Parameters

Parameter	Description	Value
process-id	Displays information about the last neighbor that goes Down in the specified RIPng process.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ripng neighbor last-nbr-down** command can be used to view information about the last neighbor that goes Down in a RIPng process and the reason why the neighbor goes Down.

Example

Display information about the last neighbor that goes Down in a RIPng process.

```
<HUAWEI> display ripng 1 neighbor last-nbr-down
 Neighbor down index              : 1
 Neighbor Link local Address      : FE80::2E0:B7FF:FE5B:8242
 Interface                        : vlanif 100
 Reason for Neighbor down         : Interface Down
 Time at which neighbor went down : 2011-06-02 12:03:40+03:00 DST
```

Table 7-20 Description of the display ripng neighbor last-nbr-down command output

Item	Description
Neighbor down index	Index of the neighbor that goes Down.
Neighbor link local Address	IPv6 link-local address of the neighbor interface.
Interface	Interface connecting to the neighbor.
Reason for Neighbor down	Reason that a neighbor goes Down ● Interface Down ● Configuration Change ● Time Out (Normal) ● Time Out (Authentication Failed)
Time at which neighbor went down	Time the neighbor goes Down.

7.3.11 display ripng route

Function

The **display ripng route** command displays all the RIPng routes that the switch learns from other switches.

Format

display ripng *process-id* **route**

Parameters

Parameter	Description	Value
process-id	Displays the RIPng routes of the specified RIPng process that the switch learns from other switches.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ripng route** command is useful for debugging and testing protocols.

Example

Display all active and inactive RIPng routes and timers of each route.

```
<HUAWEI> display ripng 100 route
   Route Flags: R - RIPng
               A - Aging, G - Garbage-collect
 ----------------------------------------------------------------

 Peer 2000::1  on vlanif100
 Dest 2001:DB8:1::1/32,
     via 2000::1, cost  2, tag 0, RA, 6 Sec
 Dest 2001:DB8:1::2/64,
     via 2000::1, cost  2, tag 0, RA, 6 Sec
 Dest 2001:DB8:1::3/64,
     via 2000::1, cost  2, tag 0, RA, 6 Sec
 Dest 2001:DB8:1::4/64,
     via 2000::1, cost  2, tag 0, RA, 6 Sec
```

Table 7-21 Description of the display ripng route command output

Item	Description
Route Flags	Route tag. The first character indicates the type of the route, namely, a RIPng route; the second character indicates the status of the route: ● RA: The RIPng route is in aging state. ● RG: The RIPng route is in garbage collection state.
Peer	Neighbor connecting to the interface.
Dest	Destination IPv6 address.
via	Next-hop IPv6 address.
cost	Cost of a route.
tag	Route tag.
Sec	Time during which a route remains in the state indicated by the route tag.

7.3.12 display ripng statistics interface

Function

The **display ripng statistics interface** command displays statistics about packets received and sent by interfaces in a RIPng process.

Format

display ripng *process-id* **statistics interface** { **all** | *interface-type interface-number* [**verbose** | **neighbor** *neighbor-ipv6-address*] }

Parameters

Parameter	Description	Value
process-id	Displays statistics on the interface of the specified RIPng process.	The value is an integer that ranges from 1 to 65535.
all	Displays statistics on all interfaces.	-
interface-type interface-number	Displays statistics on the specified interface.	-
verbose	Displays detailed statistics.	-

Parameter	Description	Value
neighbor *neighbor-ipv6-address*	Displays statistics about the specified neighbor.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays the configuration and operating status of RIPng. The information is helpful in fault location and configuration verification.

Example

Display statistics about VLANIF100 of RIPng process 1.

```
<HUAWEI> display ripng 1 statistics interface vlanif 100
Vlanif100(FE80::2E0:B9FF:FE7F:1A01)
Statistical information         Last min     Last 5 min    Total
------------------------------------------------------------------
Periodic updates sent           5            23            259
Triggered updates sent          5            30            408
Response packets sent           10           34            434
Response packets received       15           38            467
Response packets ignored        0            0             0
Request packets sent            1            3             8
Request packets received        4            20            40
Request packets ignored         0            0             0
Bad packets received            0            0             0
Routes received                 2            10            0
Routes sent                     1            4             4
Bad routes received             0            0             0
Packets send failed             0            0             0
```

Table 7-22 Description of the display ripng statistics interface command output

Item	Description
Statistical information	Packet type.
Last min	Statistics within the last minute.
Last 5 min	Statistics within the last 5 minutes.
Total	Total statistics.
Periodic updates sent	Number of periodically sent Update packets.
Triggered updates sent	Number of triggered sent Update packets.
Response packets sent	Number of sent RIPng Response packets.

Item	Description
Response packets received	Number of received RIPng Response packets.
Response packets ignored	Number of ignored RIPng Response packets.
Request packets sent	Number of sent RIPng Request packets.
Request packets received	Number of received RIPng Request packets.
Request packets ignored	Number of ignored RIPng Request packets.
Bad packets received	Number of received packets that cannot be parsed.
Bad routes received	Number of received routes that cannot be parsed.
Routes received	Number of received routes.
Routes sent	Number of sent routes.
Packets send failed	Number of RIPng packets that fail to be sent.

7.3.13 filter-policy export (RIPng)

Function

The **filter-policy export** command specifies the filtering policy for sent routes.

The **undo filter-policy export** command cancels the configuration.

By default, no filtering policy is configured.

Format

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*]]

undo filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **export** [*protocol* [*process-id*]]

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic IPv6 ACL.	The value is an integer ranging from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of a named IPv6 ACL, which is case sensitive.	The name is a string of 1 to 64 case-sensitive characters without spaces.

Parameter	Description	Value
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of the routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol	Specifies the name of a routing protocol from which routes are imported.	The value can be **bgp**, **direct**, **isis**, **unr**, **ripng**, **static** or **ospfv3**.
process-id	Specifies the process ID of **IS-IS**, **RIPng** or **OSPFv3**.	The value is an integer that ranges from 1 to 65535.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

In some cases, you need to precisely control the advertisement of RIPng routes to meet complicated network requirements. RIPng can use an IPv6 prefix list, route policy and ACL to filter imported routes, allowing only the routes matching the IPv6 prefix list, route policy and ACL to be advertised to RIPng neighbors.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Use IPv6 prefix list **Filter2** to filter the RIPng Update packets that need to be advertised.

```
<HUAWEI> system-view
[HUAWEI] ripng 100
[HUAWEI-ripng-100] filter-policy ipv6-prefix Filter2 export
```

7.3.14 filter-policy import (RIPng)

Function

The **filter-policy import** command specifies the filtering policy for received routes. Only the routes that match the filtering policy can be received.

The **undo filter-policy import** command cancels the configuration.

By default, no filtering policy is configured.

Format

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **import**

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic IPv6 ACL.	The value is an integer ranging from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of a named IPv6 ACL, which is case sensitive.	The name is a string of 1 to 64 case-sensitive characters without spaces.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of the routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

In some cases, you need to precisely control the receiving of RIPng routes to meet complicated network requirements. RIPng can use an IPv6 prefix list, route policy and ACL to filter received RIPng routes, allowing only the routes matching the IPv6 prefix list, route policy and ACL to be added to RIPng routing tables.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Use IPv6 prefix list **Filter1** to filter received RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] filter-policy ipv6-prefix Filter1 import
```

7.3.15 import-route (RIPng)

Function

The **import-route** command imports routes.

The **undo import-route** command cancels importing routes.

By default, no route is imported.

Format

import-route { { **ripng** | **isis** | **ospfv3** } [*process-id*] | **bgp** [**permit-ibgp**] | **unr** | **direct** | **static** } [[**cost** *cost* | **inherit-cost**] | **route-policy** *route-policy-name*] *

undo import-route *protocol* [*process-id*]

Parameters

Parameter	Description	Value
protocol	Specifies the routing protocol from which routes are imported.	The value can be **direct**, **static**, **ripng**, **isis**, **unr**, **bgp**, or **ospfv3**.
ripng	Imports RIPng routes.	-
isis	Imports IS-IS routes.	-
ospfv3	Imports OSPFv3 routes.	-
process-id	Specifies the process ID of imported routes.	The value is an integer that ranges from 1 to 65535.
bgp	Imports BGP routes.	-

Parameter	Description	Value
permit-ibgp	Imports IBGP routes in a public network instance. **NOTE** - Import of IBGP routes in RIPng process can lead to routing loops. Administrators should take care of routing loops before configuring **permit-ibgp**.	-
unr	Imports UNR routes.	-
direct	Imports direct routes.	-
static	Imports static routes.	-
cost *cost*	Specifies the cost of imported routes. If no cost is specified, the default cost configured using the **default-cost (RIPng)** command is used.	The value is an integer that ranges from 0 to 15.
inherit-cost	Specifies to retain the original cost of the imported route.	-
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

You can configure a route-policy to allow RIPng to import only the routes that match the rout-policy and set attributes for imported routes.

You can run one of the following commands to set the cost of imported routes. The following commands are listed in descending order of priorities.

- Run the **apply cost** command to set the cost of routes.
- Run the **import-route** (RIPng view) command to set the cost of imported routes.
- Run the **default-cost (RIPng)** command to set the default cost of imported routes.

NOTE

After the **import-route direct** command is executed, routes to the network segment where the IPv6 address of the management interface belongs are also imported in the RIPng routing table. Therefore, use this command with caution.

Example

Import routes from IS-IS process 7 and set the cost of imported routes to 7.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] import-route isis 7 cost 7
```

Import the IBGP routes matching route-policy **abc** to RIPng process 1 and set the cost of imported routes to 5.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] import-route bgp permit-ibgp cost 5 route-policy abc
```

7.3.16 ipsec sa (RIPng)

Function

The **ipsec sa** command enables Internet Protocol Security (IPSec) authentication in a RIPng process.

The **undo ipsec sa** command disables IPSec authentication in a RIPng process.

By default, IPSec authentication is disabled in a RIPng process.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ipsec sa *sa-name*

undo ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of a Security Association (SA)	The value is an existing SA name.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ipsec sa** command enables IPSec authentication in a RIPng process. IPSec authenticates received and sent RIPng packets by using the specified SA (including the security algorithm and key). This improves the security of the RIPng network.

If the **ipsec sa** command is run for a RIPng process, all packets of the process will be authenticated by using the SA specified in the command. This means that the IPSec authentication configuration takes effect on all interfaces in the RIPng process.

If IPSec authentication needs to be enabled only on a certain RIPng interface, run the **ripng ipsec sa** command in the view of the interface.

Prerequisites

An IPSec SA has been configured.

Precaution

The **ripng ipsec sa** command takes precedence over the **ipsec sa** command. If both commands are run in respective views and different SA names are specified, only the configuration of the **ripng ipsec sa** command takes effect.

Example

Enable IPSec in a RIPng process and specify sa1 as the SA name.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] ipsec sa sa1
```

7.3.17 maximum load-balancing (RIPng)

Function

The **maximum load-balancing** command configures the maximum number of equal-cost routes for load balancing.

The **undo maximum load-balancing** command restores the default setting.

By default, the maximum number of equal-cost routes is 8.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

maximum load-balancing *number*

undo maximum load-balancing

Parameters

Parameter	Description	Value
number	Specifies the maximum number of equal-cost routes for load balancing.	The value is an integer that ranges from 1 to 8. The default value is 8.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

If there are multiple links on the network, you can set the maximum number of equal-cost routes for load balancing. This prevents some links from being heavily loaded and improves network resource efficiency.

Example

Set the maximum number of equal-cost routes to 4.

```
<HUAWEI> system-view
[HUAWEI] ripng 1
[HUAWEI-ripng-1] maximum load-balancing 4
```

7.3.18 preference (RIPng)

Function

The **preference** command specifies the preference for RIPng routes.

The **undo preference** command restores the default setting.

By default, the preference of RIPng routes is 100.

Format

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Parameters

Parameter	Description	Value
preference	Specifies the preference of RIPng routes.	The value is an integer that ranges from 1 to 255.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

A smaller value indicates a higher preference. To make RIPng routes take precedence over other IGP routes, set a smaller preference value for RIPng routes. The preference values also determine which routing protocol's routes are optimal routes in an IPv6 routing table.

Example

Set the preference of RIPng routes to 120.

```
<HUAWEI> system-view
[HUAWEI] ripng 100
[HUAWEI-ripng-100] preference 120
```

Set the preference of the RIPng routes matching route-policy **policy1** to 60.

```
<HUAWEI> system-view
```

```
[HUAWEI] ripng 100
[HUAWEI-ripng-100] preference route-policy policy1 60
```

7.3.19 reset ripng statistics

Function

The **reset ripng statistics** command clears statistics in a specified RIPng process.

Format

reset ripng *process-id* **statistics** [**interface** { **all** | *interface-type interface-number* [**neighbor** *neighbor-ipv6-address*] }]

Parameters

Parameter	Description	Value
process-id	Specifies a RIPng process ID.	The value is an integer that ranges from 1 to 65535.
interface all	Clears statistics on all interfaces.	-
interface *interface-type interface-number*	Clears statistics on the specified interface.	-
neighbor *neighbor-ipv6-address*	Clears statistics in the RIPng process with the specified neighbor.	The value is a 32-digit hexadecimal number, in the common format of X:X:X:X:X:X:X:X.

Views

User view

Default Level

3: Management level

Usage Guidelines

You can use the **reset ripng statistics** command in the user view to clear statistics in a specified RIPng process and re-collect statistics for debugging.

NOTICE

Statistics about a RIPng process cannot be restored after being cleared. So, exercise caution when using this command.

Example

Clear statistics on all the interfaces in RIPng process 100.

```
<HUAWEI> reset ripng 100 statistics interface all
Warning:The RIPNG statistics will be reset. Continue? [Y/N] y
```

7.3.20 ripng

Function

The **ripng** command creates a RIPng process.

The **undo ripng** command deletes a RIPng process.

By default, no RIPng process is created.

Format

ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo ripng *process-id*

Parameters

Parameter	Description	Value
process-id	Specifies a RIPng process ID.	The value is an integer that ranges from 1 to 65535. The default value is 1.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before configuring RIPng functions, run the **ripng** command to create a RIPng process.

When a RIPng process is deleted, the **ripng enable** command needs to be run again on interfaces.

Example

Create a specified RIPng process.

```
<HUAWEI> system-view
[HUAWEI] ripng 100
```

```
[HUAWEI-ripng-100]
```

7.3.21 ripng default-route

Function

The **ripng default-route** command generates a default route to the RIPng routing domain.

The **undo ripng default-route** command disables advertising RIPng default routes and forwarding IPv6 default routes.

By default, there is no default route in the RIPng routing domain.

Format

ripng default-route { **only** | **originate** } [**cost** *cost*]

undo ripng default-route

Parameters

Parameter	Description	Value
only	Advertises only IPv6 default routes (::/0) and suppresses the advertisement of other routes.	-
originate	Advertises IPv6 default routes (::/0) without affecting the advertisement of other routes.	-
cost *cost*	Specifies the cost of default routes.	The value is an integer that ranges from 0 to 15. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The generated default RIPng route is forcibly advertised in an Update packet through the specified interface, regardless of whether this route already exists in the IPv6 routing table.

This command can take effect only after IPv6 is enabled for the interface by the **ipv6 enable** command.

Example

Advertise only default routes in Update packets through an interface.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng default-route only
```

Advertise only default routes in Update packets through an interface.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng default-route only
```

Advertise default routes together with other routes in Update packets through an interface.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng default-route originate
```

Advertise default routes together with other routes in Update packets through an interface.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng default-route originate
```

7.3.22 ripng enable

Function

The **ripng enable** command enables RIPng on an interface.

The **undo ripng** command disables RIPng on an interface.

By default, RIPng process is disabled.

Format

ripng *process-id* **enable**

undo ripng

Parameters

Parameter	Description	Value
process-id	Specifies a RIPng process ID.	The value is an integer that ranges from 1 to 65535.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

This command can take effect only after IPv6 is enabled for the RIPng process and interfaces.

Example

Enable RIPng process 100 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ripng 100
[HUAWEI-ripng-100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address fc00:0:0:1::1/64
[HUAWEI-Vlanif100] ripng 100 enable
```

Enable RIPng process 100 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ripng 100
[HUAWEI-ripng-100] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00:0:0:1::1/64
[HUAWEI-GigabitEthernet0/0/1] ripng 100 enable
```

7.3.23 ripng input

Function

The **ripng input** command enables the specified interface to receive RIPng packets.

The **undo ripng input** command disables the specified interface from receiving RIPng packets.

By default, interfaces can receive RIPng packets.

Format

ripng input

undo ripng input

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When a device running RIPng is connected to a network running other routing protocols, you can run the **undo ripng input** command on the interface that connects the device to the network to prevent the interface from receiving RIPng packets from the network.

Example

Disable VLANIF100 interface to receive RIPng packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo ripng input
```

7.3.24 ripng ipsec sa

Function

The **ripng ipsec sa** command enables Internet Protocol Security (IPSec) authentication on a RIPng interface.

The **undo ripng ipsec sa** command disables IPSec authentication on a RIPng interface.

By default, IPSec authentication is disabled on a RIPng interface.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ripng ipsec sa *sa-name*

undo ripng ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of a Security Association (SA).	The value is an existing SA name.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ripng ipsec sa** command enables IPSec on a RIPng interface. IPSec authenticates received and sent RIPng packets by using the specified SA (including the security algorithm and key). This improves the security of the RIPng network.

The command can take effect only after IPv6 is enabled for the interface by the **ipv6 enable** command.

If the **ripng ipsec sa** command is run on an interface, all RIPng packets received and sent by the interface will be authenticated by using the SA specified in the command.

Prerequisites

An IPSec SA has been configured.

Precaution

The **ripng ipsec sa** command takes precedence over the **ipsec sa** command. If both commands are run in respective views and different SA names are specified, only the configuration of the **ripng ipsec sa** command takes effect.

Example

Enable IPSec authentication on a RIPng interface and specify sa3 as the SA name.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ripng ipsec sa sa3
```

7.3.25 ripng metricin

Function

The **ripng metricin** command sets the metric that is added to the RIPng route received by an interface.

The **undo ripng metricin** command restores the default metric added to a received RIPng route.

By default, an interface does not add the metric to a received RIPng route.

Format

ripng metricin *value*

undo ripng metricin

Parameters

Parameter	Description	Value
value	Specifies the value of the metric to be added to a received RIPng route.	The value is an integer that ranges from 0 to 15. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When an interface receives a valid RIPng route, the interface adds a metric to the route before adding the route to the routing table. The metric of this route is changed in the routing table. That is, increasing the metric of an interface also increases the metric of the RIPng route received by the interface.

Before running the **ripng metricin** command on an interface, run the **ipv6 enable** command to enable IPv6 on the interface.

Example

Set the metric that is added to a received RIPng route to 12.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng metricin 12
```

Set the metric that is added to a received RIPng route to 12.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng metricin 12
```

7.3.26 ripng metricout

Function

The **ripng metricout** command sets the metric that is added to the RIPng route sent by an interface.

The **undo ripng metricout** command restores the default setting.

By default, the metric that is added to the RIPng route sent by an interface is 1.

Format

ripng metricout { *value* | { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } *value1* }

undo ripng metricout

Parameters

Parameter	Description	Value
value	Specifies the metric added to a sent route.	The value is an integer that ranges from 1 to 15. The default value is 1.
acl6-number	Specifies the number of a basic IPv6 ACL.	The value is an integer ranging from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of a named IPv6 ACL.	The name is a string of 1 to 64 case-sensitive characters without spaces.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
value1	Specifies the metric added to the route matching the IPv6 prefix list.	The value is an integer that ranges from 2 to 15.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

An interface adds a metric to a route before advertising the route. Therefore, increasing the metric of an interface also increases the metric of the RIPng routes sent by the interface. The metric of the route in the routing table, however, remains unchanged.

Before running the **ripng metricout** command on an interface, run the **ipv6 enable** command to enable IPv6 on the interface.

Example

Set the metric that is added to a route sent on an interface to 12.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng metricout 12
```

Set the metric that is added to a route sent on an interface to 12.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng metricout 12
```

Set the metric that is added to the RIPng route matching IPv6 prefix list **p1** to 12.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ip ipv6-prefix p1 permit fc00:0:0:1::1 128
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng metricout ipv6-prefix p1 12
```

7.3.27 ripng output

Function

The **ripng output** command enables an interface to send RIPng packets.

The **undo ripng output** command disables an interface from sending RIPng packets.

By default, an interface can send RIPng packets.

Format

ripng output

undo ripng output

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

When a device running RIPng is connected to a network running other routing protocols, you can run the **undo ripng output** command on the interface that connects the device to the network to prevent the interface from sending RIPng packets to the network.

Example

Disable VLANIF100 interface to send RIPng packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] undo ripng output
```

7.3.28 ripng pkt-transmit

Function

The **ripng pkt-transmit** command sets the interval for sending Update packets and the number of packets sent each time on a specified interface.

The **undo ripng pkt-transmit** command restores the default value.

By default, the interval for sending Update packets is 200 ms and the number of packets sent each time is 30 on the RIPng interface.

Format

ripng pkt-transmit { **interval** *interval* | **number** *pkt-count* } *

undo ripng pkt-transmit

Parameters

Parameter	Description	Value
interval *interval*	Specifies the interval for sending Update packets.	The value is an integer that ranges from 50 to 500, in milliseconds. The default value is 200.
number *pkt-count*	Specifies the number of packets sent each time.	The value is an integer that ranges from 25 to 100. The default value is 30.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Running the **ripng pkt-transmit** command in the interface view as required can accurately control the interval for sending packets and the number of sent packets. RIPng performance is then improved.

Before running the **ripng pkt-transmit** command on an interface, run the **ipv6 enable** command to enable IPv6 on the interface.

Example

Set the interval for sending Update packets on VLANIF100 to 100 ms and the number of packets sent each time to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng pkt-transmit interval 100 number 50
```

Set the interval for sending Update packets on GE0/0/1 to 100 ms and the number of packets sent each time to 50.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng pkt-transmit interval 100 number 50
```

7.3.29 ripng poison-reverse

Function

The **ripng poison-reverse** command enables poison reverse for RIPng.

The **undo ripng poison-reverse** command disables poison reverse for RIPng.

By default, poison reverse is disabled for RIPng.

Format

ripng poison-reverse

undo ripng poison-reverse

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

After poison reverse is configured, the route learned from an interface is also sent to the neighboring device through the same interface. The metric of this route is set to 16, indicating that the route is unreachable.

When split horizon and poison reverse are configured on the same interface, only poison reverse takes effect.

Before running the **ripng poison-reverse** command on an interface, run the **ipv6 enable** command to enable IPv6 on the interface.

Example

Enable poison reverse for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng poison-reverse
```

Enable poison reverse for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng poison-reverse
```

Disable poison reverse for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ripng poison-reverse
```

7.3.30 ripng split-horizon

Function

The **ripng split-horizon** command enables split horizon for RIPng.

The **undo ripng split-horizon** command disables split horizon for RIPng.

By default, split horizon is enabled except on the NBMA network.

Format

ripng split-horizon

undo ripng split-horizon

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

After split horizon is enabled, a route is blocked if the route is advertised through the interface that learns the route. The split horizon mechanism avoids routing loops between adjacent neighbors.

When poison reverse and split horizon are configured on the same interface, only poison reverse takes effect.

Before running the **ripng split-horizon** command on an interface, run the **ipv6 enable** command to enable IPv6 on the interface.

Example

Enable split horizon for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ripng split-horizon
```

Enable split horizon for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ripng split-horizon
```

Disable split horizon for RIPng Update packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] undo ripng split-horizon
```

7.3.31 ripng summary-address

Function

The **ripng summary-address** command configures a RIPng device to advertise summarized IPv6 addresses on an interface.

The **undo ripng summary-address** command deletes this configuration.

By default, a RIPng switch does not advertise summarized IPv6 addresses.

Format

ripng summary-address *ipv6-address prefix-length* [**avoid-feedback**]

undo ripng summary-address *ipv6-address prefix-length*

Parameters

Parameter	Description	Value
ipv6-address	Specifies a summarized IPv6 address.	The value is a 32-digit hexadecimal number, in the X:X:X:X:X:X:X:X format.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 0 to 128.
avoid-feedback	Disables an interface from learning the same summarized route.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

If the prefix and prefix length of a route match the defined IPv6 prefix, the defined IPv6 prefix is advertised instead of the route. As a result, multiple routes are replaced by a single route that has a lower metric.

After the keyword **avoid-feedback** is specified, an interface no longer learns the summarized route with the same IP address as the advertised summarized IP address. This avoids routing loops.

This command can take effect only after IPv6 is enabled for the RIPng process and interfaces.

Example

Configure IPv6 address FC00:200::3EFF:FE11:6770 for VLANIF100, set the prefix length to 64 bits, and summarize the configured IPv6 address as an IPv6 address with prefix FC00:200::/35 in RIPng process 100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ripng 100
[HUAWEI-ripng-100] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ipv6 address fc00:200::3EFF:FE11:6770/64
```

```
[HUAWEI-Vlanif100] ripng 100 enable
[HUAWEI-Vlanif100] ripng summary-address fc00:200:: 35
```

Configure IPv6 address FC00:200::3EFF:FE11:6770 for GE0/0/1, set the prefix length to 64 bits, and summarize the configured IPv6 address as an IPv6 address with prefix FC00:200::/35 in RIPng process 100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ripng 100
[HUAWEI-ripng-100] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ipv6 address fc00:200::3EFF:FE11:6770/64
[HUAWEI-GigabitEthernet0/0/1] ripng 100 enable
[HUAWEI-GigabitEthernet0/0/1] ripng summary-address fc00:200:: 35
```

7.3.32 timers ripng

Function

The **timers ripng** command configures RIPng timers.

The **undo timers ripng** command restores the default values of timers.

By default, the interval for sending RIPng Update packets is 30s, the aging time of routes is 180s, and the time for deleting routes from an IPv6 routing table is 120s.

Format

timers ripng *update age garbage-collect*

undo timers ripng

Parameters

Parameter	Description	Value
update	Specifies the interval for sending Update packets. This parameter is the basic timing parameter of routing protocols.	The value is an integer that ranges from 1 to 86400, in seconds. The default value is 30 seconds.
age	Specifies the aging time of routes. The value of *age* must be at least three times the value of *update*. If no Update packet of a route is received within the aging time, the route becomes invalid (unreachable).	The value is an integer that ranges from 1 to 86400, in seconds. The default value is 180 seconds.
garbage-collect	Specifies the time from when a route is found invalid until it is deleted from the routing table.	The value is an integer that ranges from 1 to 86400, in seconds. The default value is 120 seconds.

Views

RIPng view

Default Level

2: Configuration level

Usage Guidelines

The basic timing parameters of RIPng can be adjusted because RIPng adopts a distributed asynchronous routing algorithm. On the network, these parameters on switches need to be consistent with those on access servers.

The command can take effect only after the global IPv6 is enabled.

If the values of the preceding four timers are set improperly, route flapping occurs. The relationship of the values of the four timers is: *update* < *age* and *update* < *garbage-collect*. For example, if the update time is longer than the aging time, switches cannot inform neighbors on time if RIPng routes change during the update time.

Example

Set values for RIPng timers.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ripng 100
[HUAWEI-ripng-100] timers ripng 5 15 30
```

7.4 OSPF Configuration Commands

7.4.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.4.2 abr-summary (OSPF area)

Function

The **abr-summary** command configures route summarization on an area border router (ABR).

The **undo abr-summary** command disables route summarization on an ABR.

By default, route summarization is not configured on ABRs.

Format

abr-summary *ip-address mask* [**cost** { *cost* | **inherit-minimum** } | [**advertise** [**generate-null0-route**] | **not-advertise** | **generate-null0-route** [**advertise**]]] *

undo abr-summary *ip-address mask*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a summarized route.	The value is in dotted decimal notation.
mask	Specifies the mask of the IP address of the summarized route.	The value is in dotted decimal notation.
advertise | **not-advertise**	Indicates whether to advertise the summarized route. By default, the summarized route is advertised.	-
cost *cost*	Specifies the cost of the summarized route. By default, the highest cost of specific routes is used as the cost of the summarized route.	The value is an integer that ranges from 0 to 16777214.
inherit-minimum	Indicates that the smallest cost of specific routes is used as the cost of the summarized route.	-
generate-null0-route	Generates a blackhole route to prevent routing loops.	-

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale OSPF network, route search speed may decrease due to a large routing table size. Route summarization can be configured to reduce the size of the routing table and simplify management.

Route summarization aggregates multiple routes with the same IP prefix into one. If a link connected to a device within a summarized IP address range alternates between Up and Down states, the link status change is not advertised to the devices outside that IP address range. This prevents route flapping and improves network stability.

When the ABR sends routing information to other areas, it originates Type 3 LSAs for each network segment. If any contiguous segments exist in this area, run the **abr-summary** command to summarize these segments into one. The ABR then sends just one summarized LSA, and no LSAs that belong to the summarized network segment specified by the command. Therefore, the routing table size is reduced, and switch performance is improved.

Prerequisites

The **network** command has been run to specify the segments that need to be summarized before configuring route summarization.

Precautions

- This command applies only to ABRs for intra-area route summarization. The **asbr-summary** command configures AS Boundary Routers (ASBRs) to summarize the routes imported by OSPF.
- Route summarization cannot be configured on ABRs in different areas of the same process.

Example

In OSPF 100 area 1, summarize routes in two network segments, 10.42.10.0 and 10.42.110.0, into one route 10.42.0.0, and advertise the summarized route to other areas.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] network 10.42.10.0 0.0.0.255
[HUAWEI-ospf-100-area-0.0.0.1] network 10.42.110.0 0.0.0.255
[HUAWEI-ospf-100-area-0.0.0.1] abr-summary 10.42.0.0 255.255.0.0
```

7.4.3 advertise mpls-lsr-id

Function

The **advertise mpls-lsr-id** command configures OSPF to advertise MPLS LSR IDs to multiple areas as intra-area routes.

The **undo advertise mpls-lsr-id** command cancels the configuration.

By default, OSPF does not advertise MPLS LSR IDs to multiple areas as intra-area routes.

NOTE

Only the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H support this command.

Format

advertise mpls-lsr-id [**cost** *cost*]

undo advertise mpls-lsr-id

Parameters

Parameter	Description	Value
cost *cost*	Specifies the cost of the advertised route.	The value is an integer that ranges from 0 to 65535. By default, it is 0.

Views

OSPF view

Usage Guidelines

Usage Scenario

The prerequisite of a valid tunnel is that an intra-area route to the egress is reachable. When an ABR serves as the egress of tunnels in two areas, OSPF considers that only one tunnel is valid, because there is only one intra-area route to the egress, namely the IP address of the ABR's loopback interface (used as an MPLS LSR ID for tunnel establishment). To the other areas, this route is an inter-area route. To allow the tunnels in both areas to take effect, run the **advertise mpls-lsr-id** command to configure OSPF to advertise the intra-area route to the MPLS LSR ID to all areas connected to this device.

Prerequisites

Before running this command, the **mpls te** command has been run to enable MPLS TE globally.

Configuration Impact

Running this command may have the following impacts:

- If the OSPF area where the local switch resides does not have the interface whose IP address is the MPLS LSR ID, the type of the OSPF routes (with the destination address being the MPLS LSR ID) on the other devices in this OSPF area will be changed from inter-area to intra-area, and the cost will also be changed.
- If an OSPF NSSA has the interface whose IP address is the MPLS LSR ID and the forwarding address of the NSSA LSAs advertised in this area is the MPLS LSR ID, the forwarding address of these NSSA LSAs will be changed and the NSSA LSAs will be re-advertised, thus causing route calculation.

Example

Configure OSPF to advertise MPLS LSR IDs to multiple areas as intra-area routes.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] advertise mpls-lsr-id
```

7.4.4 area (OSPF)

Function

The **area** command creates an OSPF area and displays the OSPF area view.

The **undo area** command deletes a specified area.

By default, the system does not creates any OSPF area.

Format

area *area-id*

undo area *area-id*

Parameters

Parameter	Description	Value
area-id	Specifies an area ID. The area with the *area-id* of 0 is the backbone area.	The value can be a decimal integer or in dotted decimal notation. When the value is an integer, the value ranges from 0 to 4294967295.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The number of devices increases with the expansion of a network. This leads to a large LSDB on every OSPF-enabled device on a large-scale network. Route flapping frequently occurs and as such, a large number of OSPF packets are transmitted on the network. This wastes bandwidth resources.

OSPF resolves this problem by partitioning an AS into different areas. An area is regarded as a logical group, and each group is identified by a unique area ID.

Configuration Impact

After OSPF partitions the AS into different areas, the functions of multiple devices in the same area, such as the timer, filter, and summarization, can be planned and configured uniformly in the area. Therefore, the size of the LSDB is reduced, and network performance is improved.

Prerequisites

An OSPF process has been started using the **ospf** command.

Precautions

- At the border of an area resides a switch instead of a link.
- A network segment or a link belongs to only one area. Specify the area to which each OSPF interface belongs.
- The backbone area is responsible for forwarding inter-area routing information. The routing information between the non-backbone areas must be forwarded through the backbone area.
- All non-backbone areas must maintain connectivity with the backbone area. The backbone area must also maintain connectivity within itself.

Example

Enter the view of an OSPF area.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 0
[HUAWEI-ospf-100-area-0.0.0.0]
```

7.4.5 asbr-summary (OSPF)

Function

The **asbr-summary** command configures an AS Boundary Router (ASBR) to summarize the routes imported by OSPF.

The **undo asbr-summary** command disables an ASBR from summarizing the routes imported by OSPF.

By default, ASBRs do not summarize the routes imported by OSPF.

Format

asbr-summary *ip-address mask* [[**not-advertise** | **generate-null0-route**] | **tag** *tag* | **cost** *cost* | **distribute-delay** *interval*] *

asbr-summary type nssa-trans-type-reference [**cost nssa-trans-cost-reference**]

undo asbr-summary type

undo asbr-summary *ip-address mask*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a summarized route.	The value is in dotted decimal notation.

Parameter	Description	Value
mask	Specifies the mask of the IP address of the summarized route.	The value is in dotted decimal notation.
not-advertise	Indicates that the summarized route is not advertised. If this parameter is not specified, the summarized route is advertised.	-
generate-null0-route	Generates a blackhole route to prevent routing loops.	-
tag *tag*	Specifies the tag of the summarized route.	The value is an integer that ranges from 0 to 4294967295. The default value is 1.
cost *cost*	Specifies the cost of the summarized route. By default, for Type 1 external routes, the cost of the summarized route is the highest cost of specific routes; for Type 2 external routes, the cost of the summarized route equals the highest cost of specific routes plus 1.	The value is an integer that ranges from 0 to 16777214.
distribute-delay *interval*	Specifies the delay in advertising the summarized route.	The value is an integer that ranges from 1 to 65535, in seconds.
type nssa-trans-type-reference	Enables OSPF to consider Type 5 LSAs that have been translated from Type 7 LSAs when it sets types for summary routes on ASBRs. By default, when OSPF sets types for summary routes on ASBRs, OSPF does not consider Type 5 LSAs that have been translated from Type 7 LSAs.	-

Parameter	Description	Value
cost nssa-trans-cost-reference	Enables OSPF to consider Type 5 LSAs that have been translated from Type 7 LSAs when it sets costs for summary routes on ASBRs. If the **asbr-summary type nssa-trans-type-reference cost nssa-trans-cost-reference** command is not run, OSPF does not consider Type 5 LSAs that have been translated from Type 7 LSAs when setting types and costs for summary routes on ASBRs.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale OSPF network, route search speed may decrease due to a large routing table size. Configure route summarization to reduce the routing table size and simplify management.

Route summarization aggregates multiple routes with the same IP prefix into one. If a link connected to a device within a summarized IP address range alternates between Up and Down states, the link status change is not advertised to the devices outside the IP address range. This prevents route flapping and improves network stability.

Imported routes with the same prefix can be summarized into one and advertised as one route using the **asbr-summary** command. Route summarization reduces routing information and routing table size, improving device performance.

After route summarization is implemented, if the local device:

- If a local router is an ASBR in an NSSA, the local router summarizes all imported Type 5 LSAs within the summary address range.
- If the local router is an ASBR in an NSSA, the local router summarizes all imported Type 7 LSAs within the summary address range.
- If the local router functions as both an ASBR and an ABR in an NSSA, the local router summarizes all imported Type 7 LSAs within the address range. It also summarizes the Type 5 LSAs that are translated from Type 7 LSAs.

Precautions

When a large number of routes are summarized, specify the **distribute-delay** parameter to set a delay in advertising the summarized routes. This ensures that the advertised summarized routes contain more valid routes and avoids network flapping and incorrect routing information.

Example

Configure route summarization for the imported routes.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] asbr-summary 10.2.0.0 255.255.0.0 not-advertise tag 2 cost 100
```

Cancel route summarization for the imported routes.

```
[HUAWEI-ospf-100] undo asbr-summary 10.2.0.0 255.255.0.0
```

7.4.6 authentication-mode (OSPF area)

Function

The **authentication-mode** command sets an authentication mode and a password for an OSPF area.

The **undo authentication-mode** command cancels the authentication mode configured for an OSPF area.

By default, no authentication mode is configured.

Format

authentication-mode simple [**plain** *plain-text* | [**cipher**] *cipher-text*]

authentication-mode { **md5** | **hmac-md5** | **hmac-sha256** } [*key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* }]

authentication-mode keychain *keychain-name*

undo authentication-mode

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Sets simple authentication. In simple authentication, the password type is **cipher** by default. **NOTICE** Simple authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
plain	Sets a plaintext password. If this parameter is specified, you can only enter a plaintext password, which is then displayed in plain text when the configuration file is viewed. **NOTICE** If **plain** is specified, the password is saved in the configuration file in plain text. This carries security risks. You are advised to specify **cipher** to save the password in cipher text.	-
plain-text	Sets a plaintext password.	The value is a string of case-sensitive characters that can be letters or digits without spaces. In **simple** authentication, the value is a string of 1 to 8 characters. In **md5**, **hmac-md5** or **hmac-sha256** authentication, the value is a string of 1 to 255 characters.
cipher	Sets a ciphertext password. Either a plaintext or ciphertext password can be entered, and cipher text is displayed when the configuration file is viewed.	When **cipher** is configured, the password can only be entered in cipher text. Then, the password is displayed in cipher text in configuration files. MD5 authentication, HMAC-SHA256 authentication or HMAC-MD5 authentication defaults to use the password in cipher text.

Parameter	Description	Value
cipher-text	Specifies the ciphertext password.	The value is a string of case-sensitive characters that can be letters or digits without spaces. In **simple** authentication, the value is a string of 1 to 8 characters in plain text, or a string of 24 or 32 or 48 characters in cipher text. In **md5**, **hmac-sha256** or **hmac-md5** authentication, the value is a string of 1 to 255 characters in plain text, or a string of 20 to 392 characters in cipher text.
md5	Indicates MD5 authentication using the ciphertext password. **NOTICE** MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-md5	Indicates HMAC MD5 authentication using the ciphertext password. **NOTICE** HMAC-MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-sha256	Indicates HMAC-SHA256 authentication.	-
key-id	Specifies authentication key ID of the interface's cipher authentication. The key ID must be consistent with that of the peer.	The value is an integer that ranges from 1 to 255.

Parameter	Description	Value
keychain	Indicates keychain authentication. **NOTE** Before configuring this parameter, run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, OSPF authentication will fail. Currently, only the **HMAC-MD5**, **SM3**, and **HMAC-SHA256** algorithms can be used in OSPF.	-
keychain-name	Specifies the keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPF authentication can be configured to improve network security to meet high security demands. When area authentication is used, interfaces on all devices in an area must have the same area authentication mode and the password.

Precautions

The priority of area authentication is lower than the priority of interface identification. The **ospf authentication-mode** command can be used to change the priority of interface authentication.

Example

Configure HMAC-SHA256 authentication for OSPF area 0.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
```

```
[HUAWEI-ospf-100] area 0
[HUAWEI-ospf-100-area-0.0.0.0] authentication-mode hmac-sha256
```

7.4.7 bandwidth-config enable

Function

The **bandwidth-config enable** command enables a device to calculate the cost of an OSPF interface based on the configured interface bandwidth.

The **undo bandwidth-config enable** command disables a device from calculating the cost of an OSPF interface based on the configured interface bandwidth.

By default, a device is not enabled to calculate the cost of an OSPF interface based on the configured interface bandwidth.

Format

bandwidth-config enable

undo bandwidth-config enable

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

External factors may affect the physical bandwidth of a link and change the physical bandwidth of an interface, thereby deteriorating network performance. To enable a device to adjust and optimize the route selection rules, run the **bandwidth** *bandwidth* command in the OSPF interface to adjust the interface bandwidth and run the **bandwidth-config enable** command to enable the device to calculate the cost of an OSPF interface based on the configured interface bandwidth. The calculation formula is as follows: Cost of the interface = Bandwidth reference value/Interface bandwidth.

Precautions

- If the **bandwidth** command is not configured, the OSPF interface cost is calculated based on the physical bandwidth of the interface.
- If the **bandwidth-config enable** command is not configured, the OSPF interface cost is calculated based on the physical bandwidth of the interface.

Example

Enable a device to calculate the cost of an OSPF interface based on the configured interface bandwidth.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] bandwidth-config enable
```

7.4.8 bandwidth-reference (OSPF)

Function

The **bandwidth-reference** command sets a bandwidth reference value that is used to calculate interface costs.

The **undo bandwidth-reference** command restores the default bandwidth reference value.

The default bandwidth reference value is 100 Mbit/s.

Format

bandwidth-reference *value*

undo bandwidth-reference

Parameters

Parameter	Description	Value
value	Specifies a bandwidth reference value for link cost calculation.	The value is an integer ranging from 1 to 2147483648, in Mbit/s. The default value is 100 Mbit/s.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The calculation formula is as follows: Interface cost = Bandwidth reference value/ Interface bandwidth. The integer of the calculated result is the interface cost. If the calculated result is smaller than 1, the interface cost value is 1. If the **bandwidth-reference** command is executed to configure a new bandwidth reference value, the interface cost will be changed. As a result, OSPF will re-select routes.

The default bandwidth reference value is 100 Mbit/s. The interface cost value is 100000000 divided by the interface bandwidth value.

Precautions

- After the **bandwidth-reference** command is configured in a process view, bandwidth reference values of all interfaces in the process are changed to the specified value.
- If the **bandwidth-reference** command is run on an Eth-Trunk interface, the bandwidth of the Eth-Trunk interface is equal to the total bandwidth of all its member interfaces.

Example

Set the bandwidth reference value to 1000 Mbit/s.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] bandwidth-reference 1000
```

7.4.9 bfd all-interfaces (OSPF)

Function

The **bfd all-interfaces** command enables bidirectional forwarding detection (BFD) in an OSPF process and sets the parameter values of a BFD session.

The **undo bfd all-interfaces** command disables BFD in an OSPF process and restores the default parameter values of a BFD session.

By default, BFD is disabled in an OSPF process.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

bfd all-interfaces enable

undo bfd all-interfaces enable

bfd all-interfaces { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* | **frr-binding** } *

undo bfd all-interfaces { **min-rx-interval** | **min-tx-interval** | **detect-multiplier**| **frr-binding** } *

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **frr-binding** parameter.

Parameters

Parameter	Description	Value
min-rx-interval *receive-interval*	Indicates the minimum interval at which BFD packets are received from the remote end.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *transmit-interval*	Indicates the minimum interval at which BFD packets are sent to the remote end.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Indicates the local detection multiplier.	The value is an integer ranging from 3 to 50. By default, it is 3.
frr-binding	Binds the BFD status to the link status of an interface.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device communicates with its neighbors, BFD can fast detect faults to minimize the fault impact on services.

You can bind a BFD session to an interface or an OSPF process. If a BFD session is bound to both an interface and an OSPF process, the BFD session bound to an interface takes precedence over that bound to an OSPF process.

Precautions

- *receive-interval* is negotiated based on the **min-rx-interval** value on the local end and the **min-tx-interval** value on the remote end. The local end uses the larger one between the **min-rx-interval** value on the local end and the **min-tx-interval** value on the remote end as the remote **min-tx-interval**. If the local end does not receive any BFD packets within the interval of *receive-interval* × *multiplier-value* (local detection multiplier), it declares that the remote end is unreachable.
- An OSPF device sets up BFD sessions with only the neighbors in Exstart state. Two ends can set up a BFD session only when the **bfd** command is run on both ends to configure BFD globally and the **bfd all-interfaces enable** command is run.
- The **bfd all-interfaces** command and the **ospf bfd block** command are mutually exclusive.

Example

Configure BFD in an OSPF process and set the minimum interval for sending BFD packets to 400 ms.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] bfd all-interfaces enable
[HUAWEI-ospf-1] bfd all-interfaces min-tx-interval 400
```

7.4.10 default (OSPF)

Function

The **default** command configures default parameters for OSPF-imported external routes. The parameters include the cost, type (Type 1 or Type 2), tag, and number of imported routes.

The **undo default** command restores the default setting.

By default, the default cost of the imported external routes is 1; the upper limit of the imported external routes is 2147483647; the type of the imported external routes is Type 2; the default tag value is 1.

Format

default { **cost** { *cost-value* | **inherit-metric** } | **limit** *limit* | **tag** *tag* | **type** *type* } *

undo default { **cost** | **limit** | **tag** | **type** } *

Parameters

Parameter	Description	Value
cost *cost-value*	Specifies the default cost of the external routes imported by OSPF.	The value is an integer ranging from 0 to 16777214. By default, it is 1.
inherit-metric	Indicates that the cost of the imported route is the cost that the route itself carries. If no cost is specified, the default cost set using the **default** command is used.	-
limit *limit*	Specifies the default upper limit of the external routes to be imported within a given period.	The value is an integer ranging from 1 to 2147483647.
tag *tag*	Specifies the tag of the external routes.	The value is an integer ranging from 0 to 4294967295. By default, it is 1.
type *type*	Specifies the type of the external routes.	The value is an integer ranging from 1 to 2. By default, it is 2. ● 1: Type 1 external route ● 2: Type 2 external route

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The imported external routes carry various parameters that can change the priorities and next hops of those routes in the OSPF routing table.

By setting default parameters for OSPF-imported external routes, you can change OSPF routing policies.

The route tag is used to identify protocol-related information. For example, it can be used to differentiate AS numbers when OSPF receives BGP routes. It also allows you to apply OSPF routing policies to tagged routes.

Follow-up Procedure

The priority of the **default (OSPF)** command is the lowest. Thus, ensure that no other commands are configured when configuring this command. Otherwise, this command cannot take effect.

Precautions

You can run any of the following commands to set a cost for an imported route. The following commands are listed in the descending order of priority.

- **apply cost**
- **import-route (OSPF)**
- **default (OSPF)**

Example

Set the default values for the cost, type, and tag of imported routes.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] default cost 10 tag 100 type 2
```

7.4.11 default-cost (OSPF Area)

Function

The **default-cost** command sets a cost for the Type3 default route that is transmitted to a stub or NSSA by OSPF.

The **undo default-cost** command restores the default setting.

By default, the cost of the Type3 default route transmitted to a stub or NSSA is 1.

Format

default-cost *cost*

undo default-cost

Parameters

Parameter	Description	Value
cost	Specifies the cost of the Type3 default route transmitted to a stub or NSSA by OSPF.	The value is an integer ranging from 0 to 16777214.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Configuring a cost for a default route can change OSPF route selection, improving networking flexibility.

This command is applicable to area border routers (ABRs) connected to stubs or NSSAs.

Prerequisites

A default route exists in the local routing table.

Example

Set Area 1 as a stub area, and set the cost of the Type 3 default route transmitted to this stub area to 20.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] stub
[HUAWEI-ospf-100-area-0.0.0.1] default-cost 20
```

7.4.12 default-route-advertise (OSPF)

Function

The **default-route-advertise** command advertises default routes to a common OSPF area.

The **undo default-route-advertise** command disables advertisement of default routes to a common OSPF area.

By default, OSPF devices in a common OSPF area do not generate default routes.

Format

default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost* | **type** *type* | **route-policy** *route-policy-name* [**match-any**]] *

default-route-advertise summary cost *cost*

undo default-route-advertise

Parameters

Parameter	Description	Value
always	Generates and advertises an LSA that describes the default route, regardless of whether there are active default routes of other OSPF processes in the routing table of the host. - If **always** is configured, the switch does not calculate the default routes from other switches. - If **always** is not configured, an LSA for advertising a default route can be generated only when there are active default routes of other OSPF processes in the routing table of the local device.	-
permit-calculate-other	Generates and advertises an ASE LSA that describes the default route only when there are active default routes of other OSPF processes in the routing table of the local device. The device still calculates the default routes from other devices. **NOTE** If neither **always** nor **permit-calculate-other** is configured, - When there are active default routes of other OSPF processes in the routing table of the local device, the device does not calculate the default routes from other devices. - When there are no active default routes of other OSPF processes in the routing table of the local device, the device still calculates the default routes from other devices.	-
cost *cost*	Specifies the cost of the ASE LSA.	The value is an integer that ranges from 0 to 16777214. The default value is 1.

Parameter	Description	Value
type *type*	Specifies the type of the external routes.	The value is 1 or 2. The default value is 2. ● 1: Type 1 external route ● 2: Type 2 external route
route-policy *route-policy-name*	Specifies the name of a routing policy. The device advertises default routes according to the parameters of the configured routing policy when there are matched default routes of other OSPF processes in the routing table of the device.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
summary	Advertises the Type 3 summary LSA of the specified default route. Before specifying this parameter, ensure that a VPN is enabled. Otherwise, routes cannot be advertised.	-
match-any	Indicates that a device matches the routing entry in the routing table against a routing policy and then advertises the default route according to the parameters set through the routing policy.	-

2: Configuration level

Usage Guidelines

Usage Scenario

The **import-route (OSPF)** command cannot be used to import a default route from another AS. Running the **default-route-advertise** command on an ASBR can advertise a non-OSPF default route in a common OSPF area.

If the ASBR has a default route, the **default-route-advertise** command enables the ASBR to advertise the default route 0.0.0.0 to the OSPF area.

If the ASBR has no default route, the **default-route-advertise always** command or the **default-route-advertise** command can be used:

- With **always** configured: The ASBR can advertise the default route 0.0.0.0 even if there is no default route. This allows the default route to remain in the routing table and prevents the ASBR from using a default route sent by another device.
- Without **always** configured: The ASBR generates an LSA. It describes a default route only when the local routing table contains an activated non-OSPF default route (except BGP route).

  If the local routing table contains an activated default BGP route, the default route can be injected to the OSPF routing table based on the following situations:
  - Whether the **ospf** *process-id* **vpn-instance** *vpn-instance-name* command is run together with the **vpn-instance-capability simple** command:
    - If the two commands are executed together, to inject an activated default EBGP route into the OSPF routing table, run the **default-route-advertise** command. To inject an activated default IBGP route to the OSPF routing table, run the **import-route bgp permit-ibgp** command before you run the **default-route-advertise** command.
    - If only the **ospf** *process-id* **vpn-instance** *vpn-instance-name* command is run, to inject an activated default EBGP or IBGP route into the OSPF routing table, run the **default-route-advertise** command.
  - If the **ospf** *process-id* **vpn-instance** *vpn-instance-name* command is not run, to inject an activated default EBGP route into the OSPF routing table, run the **default-route-advertise** command. To inject an activated default IBGP route to the OSPF routing table, run the **import-route bgp permit-ibgp** command before you run the **default-route-advertise** command.

NOTICE

Injecting an IBGP route into the OSPF routing table may cause a routing loop. Exercise caution when you perform this step.

If a routing policy is configured with **match-any**, and multiple routes match the policy, a default LSA will be generated based on the optimal route. The principles for optimal route selection are as follows:

1. A route configured with **type** takes precedence over that not configured with **type**. A route configured with a smaller **type** value takes precedence over that configured with a larger **type** value.
2. A route configured with **cost** takes precedence over that not configured with **cost**. A route configured with a smaller **cost** value takes precedence over that configured with a larger **cost** value.
3. A route configured with **tag** takes precedence over that not configured with **tag**. A route configured with a smaller **tag** value takes precedence over that configured with a larger **tag** value.

Prerequisites

Before advertising a default route, OSPF compares the priorities of default routes in an OSPF area and then advertises a default route with the highest priority. If a static default route is configured on an OSPF device, check the priority of the static default route. The priority must be lower than that of the default route to be advertised by OSPF. This ensures that the default route advertised by OSPF will be added to the routing table of the OSPF device.

Configuration Impact

After the **default-route-advertise** command is configured on the ASBR, the ASBR will generate a Type 5 ASE LSA with a link state ID of 0.0.0.0 and mask of 0.0.0.0. In addition, it will advertise the ASE LSA in an entire OSPF area.

If a routing policy is configured, default routes are advertised based on the following principles:

- If a default route matches the routing policy, a default route is generated on an OSPF device based on the parameters configured in the routing policy. Parameters such as **cost**, **tag**, and **type** can be configured in the routing policy.
- If the default route does not match the routing policy, and **always** is configured, the default route is still advertised.
  - If **always** is not configured, the OSPF device will not advertise the default route.
  - If **always** is configured, OSPF devices will advertise the default route. In addition, only **always** configured in the **default-route-advertise** command takes effect on advertisement of default routes.

Precautions

In different OSPF areas, OSPF advertises default routes using different modes. This **default-route-advertise** command can be used to advertise default routes to a common OSPF area. In a stub, totally stub, or totally NSSA area, default routes are advertised automatically. In an NSSA, the **nssa default-route-advertise** command is used to advertise default routes.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the device advertises the default route as long as a default route that is not generated by the current OSPF process exists in the local routing table.

If the **default-route-advertise command** is used in multiple OSPF processes to generate default routes, routing loops tend to occur. To prevent this issue, you are advised to configure route-policies to filter routes so that default routes will not be learned from these OSPF processes.

Example

Configure an ASBR to advertise the ASE LSA of the default route to common OSPF areas when it has no default route.

```
<HUAWEI> system-view
```

```
[HUAWEI] ospf 1
[HUAWEI-ospf-1] default-route-advertise always
```

7.4.13 description (OSPF)

Function

The **description** command configures a description for an OSPF process.

The **undo description** command deletes the description.

By default, there is no description for any OSPF process.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of an OSPF process.	The value is a string of 1 to 80 case-sensitive characters, spaces supported.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An OSPF process description helps identify special processes, facilitating network maintenance.

Configuration Impact

If the **description** command is run multiple times, the latest configuration overrides the previous one.

Example

Configure a description for an OSPF process.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] description this process contains 3 areas
```

7.4.14 description (OSPF Area)

Function

The **description** command configures a description for an OSPF area.

The **undo description** command deletes the description.

By default, there is no description for any OSPF area.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of an OSPF area.	The value is a string of 1 to 80 case-sensitive characters, spaces supported.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

An OSPF area description helps identify special areas, facilitating network maintenance.

Example

Configure a description for OSPF area 1.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] description this is a stub area
```

7.4.15 display default-parameter ospf

Function

The **display default-parameter ospf** command displays the default OSPF configuration.

Format

display default-parameter ospf

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display default-parameter ospf** command to check the default OSPF configuration during OSPF initialization. After the OSPF configuration is modified, this command still displays the default OSPF configuration during OSPF initialization.

Example

Display the default OSPF configuration.

```
<HUAWEI> display default-parameter ospf
 Process View:

Table 7-23 Description of the **display default-parameter ospf** command output

Item	Description
Process View	Process view.
Default Metric	Default metric of the imported external route.
Default Tag	Default tag value of the imported external route.
Default Type	Default type of the imported external route.
SPF Intelligent-timer Max-interval(msec)	Default maximum interval of SPF calculation.
SPF Intelligent-timer Start-interval(msec)	Default start interval of SPF calculation.
SPF Intelligent-timer Hold-interval(msec)	Default hold interval of SPF calculation.
Lsa Maxage(sec)	Default maximum age of the LSA.
Lsa Refresh Time(sec)	Default maximum interval for generating an LSA. If the LS age of the LSAs generated by the device reaches the LSA Refresh Time, a new instance must be generated for the LSAs.
Lsa Maxagediff Interval(sec)	Default value difference in the MaxAge fields of LSAs. If the value difference in the MaxAge fields of two LSAs is greater than MaxAgeDiff Interval, the two LSAs are considered to belong to different instances of the same LSA.
Minimum Lsa Arrival Interval(sec)	Default minimum interval for receiving the same LSA.
Minimum Lsa Originate Interval(sec)	Default minimum interval for sending the same LSA.
Sham Link Cost	Default cost of the sham link.
VPN Domain ID	Default domain ID of the VPN.
VPN Router Tag	Default router tag of the VPN.
Route Preference for Internal Routes	Default preference of the internal route.
Route Preference for External Routes	Default preference of the external route.
Area View	Area view.
Default Stub Cost	Default cost of a route in the stub area.

Item	Description
Interface View	Interface view.
P2P&Broadcast Hello Interval(sec)	Default interval for sending Hello packets on a P2P or broadcast network.
P2MP&NBMA Hello Interval(sec)	Default interval for sending Hello packets on a P2MP or NBMA network.
P2P&Broadcast Dead Interval(sec)	Default interval for declaring a neighbor to be Down after no Hello packets are received on a P2P or broadcast network.
P2MP&NBMA Dead Interval(sec)	Default interval for declaring a neighbor to be Down after no Hello packets are received on a P2MP or NBMA network.
Poll Interval(sec)	Default interval for the local device to send Hello packets to a neighbor in the Down state on the NBMA network. The value of Poll Interval is greater than the value of Hello Interval.
Router DR Priority	Default priority of the DR.
Retransmit Interval(sec)	Default interval for retransmitting packets.
Transmit Delay(sec)	Default estimated time for transmitting an LSU packet over this interface. LSAs in the LSU packet must have their age incremented by this amount before transmission.

7.4.16 display gtsm statistics

Function

The **display gtsm statistics** command displays GTSM statistics on a device.

Format

display gtsm statistics all

Parameters

Parameter	Description	Value
all	Displays GTSM statistics on a device.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display gtsm statistics** command to view GTSM statistics, including the total number of BGP, BGPv6, OSPF, LDP, OSPFv3, and RIP packets, the number of packets that have passed, and the number of discarded packets on a device.

Example

Display GTSM statistics on the device.

```
<HUAWEI> display gtsm statistics all
GTSM Statistics Table
----------------------------------------------------------------
SlotId  Protocol  Total Counters  Drop Counters  Pass Counters
----------------------------------------------------------------
 0      BGP       0               0              0
 0      BGPv6     0               0              0
 0      OSPF      0               0              0
 0      LDP       0               0              0
 0      OSPFv3    0               0              0
 0      RIP       0               0              0
----------------------------------------------------------------
```

Table 7-24 Description of the **display gtsm statistics** command output

Item	Description
SlotId	Slot ID.
Protocol	Protocol type: ● Software-based forwarding: protocol differentiated, displaying BGP, BGPv6, OSPF, LDP, OSPFv3, or RIP ● Hardware-based forwarding: protocol undifferentiated, displaying -----
Total Counters	Total number of packets.
Drop Counters	Total number of dropped packets.
Pass Counters	Total number of packets that have passed.

7.4.17 display ospf abr-asbr

Function

The **display ospf abr-asbr** command displays information about the ABRs and ASBRs of OSPF.

Format

display ospf [*process-id*] **abr-asbr** [*router-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
router-id	Specifies the router ID of an ABR or ASBR.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

An area border router (ABR) can belong to two or more areas. One of the areas must be a backbone area. An ABR is used to connect the backbone area and non-backbone areas. The connection with the backbone area can be physically or logically.

An AS boundary router (ASBR) exchanges routing information with other ASs. An ASBR may not reside at the boundary of an AS. It can be an internal device or an ABR. If an OSPF device imports external routes, the device is an ASBR.

This command can view information about the ABRs and ASBRs of OSPF.

Example

Display information about the ABRs and ASBRs of OSPF.

```
<HUAWEI> display ospf abr-asbr

        OSPF Process 1 with Router ID 1.1.1.1
               Routing Table to ABR and ASBR

 RtType      Destination       Area       Cost  Nexthop         Type
 Intra-area  10.10.10.11       0.0.0.0    1     10.2.0.3        ABR
```

Table 7-25 Description of the **display ospf abr-asbr** command output

Item	Description
RtType	Intra-area or inter-area router.
Destination	Router ID of the ABR or ASBR.
Area	Area ID.

Item	Description
Cost	Cost of the route from the local device to the ABR or ASBR.
NextHop	Next hop address through which packets are transmitted to the ABR or ASBR.
Type	ABR or ASBR.

7.4.18 display ospf asbr-summary

Function

The **display ospf asbr-summary** command displays information about OSPF route summarization.

Format

display ospf [*process-id*] **asbr-summary** [*ip-address mask*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
ip-address	Specifies the summary IP address.	The value is in dotted decimal notation.
mask	Specifies the mask of the summary IP address. If no IP address or mask is specified, summarization information of all the imported routes is displayed.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After an AS is divided into areas, configuring route aggregation can reduce routing information transmitted between areas. This reduces the size of the routing table and improves route performance. After the **asbr-summary (OSPF)** command is run to configure OSPF route summarization on an ASBR, you can run the **display ospf asbr-summary** command to view information about OSPF route summarization on the ASBR.

Example

Display summarization information about all the imported OSPF routes.

```
<HUAWEI> display ospf asbr-summary
         OSPF Process 1 with Router ID 192.168.1.2
                 Summary Addresses
 Total summary address count: 1
                 Summary Address
 net         : 10.0.0.0
 mask         : 255.0.0.0
 tag         : 10
 status      : Advertise
 Cost        : 0 (Not Configured)
 delay       : 30 (Configured)
 The Count of Route is : 2
 Destination     Net Mask       Proto      Process   Type     Metric
 10.1.0.0        255.255.0.0     Static     1         2        10
 10.2.0.0        255.255.0.0     Static     1         2        10
```

Table 7-26 Description of the **display ospf asbr-summary** command output

Item	Description
Total summary address count	Number of routes that are being summarized through the **asbr-summary** command.
net	Network address of the summary route.
mask	Network mask of the summary route.
tag	Tag of the summary route.
status	Advertisement status of the summary route: ● Advertise: indicates that the summary route is advertised. ● DoNotAdvertise: indicates that the summary route is not advertised.
Cost	Cost of the summarized route.
delay	Delay for advertising the summary route.
The Count of Route is	Number of routes that are being summarized.
Destination	Destination address of the routes that are being summarized.
Net Mask	Mask of the routes that are being summarized.
Proto	Protocol of the routes that are being summarized.
Process	Process ID.

Item	Description
Type	Type of the imported AS external route, which can be Type 1 or Type 2.
Metric	Metric of the routes that are being summarized.

7.4.19 display ospf bfd session

Function

The **display ospf bfd session** command displays information about the BFD-enabled neighbor.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

display ospf [*process-id*] **bfd session** *interface-type interface-number* [*router-id*]

display ospf [*process-id*] **bfd session** { *router-id* | **all** }

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies the type and number of an interface.	-

Parameter	Description	Value
router-id	Specifies the router ID of the neighbor.	The value is in dotted decimal notation.
all	Indicates all the OSPF-enabled interfaces in the OSPF process.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

A BFD session can be associated with OSPF to fast detect a link fault and notifies OSPF of the fault. This speeds up OSPF's response to the change of the network topology.

The **display ospf bfd session** command displays information about the BFD-enabled neighbor.

Example

Display information about the BFD-enabled neighbor.

```
<HUAWEI> display ospf bfd session all
          OSPF Process 1 with Router ID 10.3.3.3
  Area 0.0.0.0 interface 192.168.1.1(Vlanif100)'s BFD Sessions
 NeighborId:10.2.2.2          AreaId:0.0.0.0           Interface:Vlanif100
 BFDState:up                  rx    :1000              tx       :1000
 Multiplier:3                 BFD Local Dis:8198       LocalIpAdd:10.1.1.1
 RemoteIpAdd:10.1.1.2         Diagnostic Info:No diagnostic information
```

Table 7-27 Description of the **display ospf bfd session all** command output

Item	Description
NeighborId	Router ID of the neighbor.
AreaId	Area ID.
Interface	Interface through which the local device establishes a BFD session with the neighbor.
BFDState	BFD status: - up - down - unknown

Item	Description
rx	Negotiated minimum interval for receiving BFD packets.
tx	Negotiated minimum interval for sending BFD packets.
Multiplier	Remote detection multiplier.
BFD Local Dis	Local discriminator dynamically assigned by BFD.
LocalIpAdd	Local IP address.
RemoteIpAdd	Remote IP address.
Diagnostic Info	Diagnostic information: ● Init: indicates that the BFD session is in the Initiate state. ● Admin down: indicates that the **shutdown** command is run on the local BFD session. ● BFD global disable: indicates that BFD is not enabled globally. ● BFD session number exceed: indicates that the number of BFD sessions exceeds the limit. ● Detect down: indicates that the local link becomes Down. ● Receive admin down: indicates that the remote link becomes Down. ● BFD is in rearranging: indicates that the board of the BFD session changes, and the data of the BFD session is transferred to another board. ● No diagnostic information: indicates that no diagnostic information exists. ● No BFD packets were received: indicates that detection expires because no BFD packets are received within a specified period. ● administrator down event received: indicates that the device receives an event that the BFD session is set Down by the network administrator.

7.4.20 display ospf brief

Function

The **display ospf brief** command displays OSPF brief information.

Format

display ospf [*process-id*] **brief**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no OSPF process ID is specified, brief information about all the OSPF processes is displayed.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In addition to OSPF brief information, running this command also displays the following information:

- Configured Router ID
- Configured VPN domain ID

When locating OSPF faults, you can run the **display ospf brief** command to obtain OSPF brief information. You can then analyze OSPF faults according to the brief information.

Example

Display OSPF brief information.

```
<HUAWEI> display ospf brief
          OSPF Process 1 with Router ID 10.5.5.5
                  OSPF Protocol Information

 RouterID: 10.5.5.5         Border Router:  AREA
 Multi-VPN-Instance is not enabled
 Opaque Capable
 Global DS-TE Mode: Non-Standard IETF Mode
 Graceful-restart capability: disabled
 Helper support capability  : enabled
        filter capability   : disabled
```

```
       policy capability   : strict lsa check, planned and un-planned

Interface: 10.100.100.100 (LoopBack100)
Cost: 0       State: P-2-P     Type: P2P       MTU: 1500
Timers: Hello 10 , Dead 40 , Poll  120 , Retransmit 5 , Transmit Delay 1
```

Table 7-28 Description of the **display ospf brief** command output

Item	Description
RouterID	Current router ID.
Border Router	Border router: ● AS: autonomous system border router (ASBR). ● AREA: area border router (ABR). ● NSSA: ABR of an NSSA.
Multi-VPN-Instance is not enabled	The current process does not support multi-VPN-instance.

Item	Description
Opaque Capable	Opaque-LSA capability is enabled. To enable the Opaque-LSA capability, run the **opaque-capability enable** command.
Global DS-TE Mode	Globally configured DS-TE mode: ● Non-Standard IETF Mode: The IETF mode is not supported. ● Standard IETF Mode: The IETF mode is supported.
Graceful-restart capability	Whether graceful restart is enabled: ● disabled: Graceful restart is disabled. ● planned only: Planned-GR is supported. ● un-planned: Unplanned-GR is supported. ● totally: Totally GR is supported. ● planned and un-planned: Planned-GR and unplanned-GR are supported. To enable the GR function, run the **graceful-restart (OSPF)** command.
Helper support capability	Whether the Helper mode is enabled: ● enabled: The Helper mode is enabled. ● not configured: The Helper mode is disabled. To configure a device as a GR helper, run the **graceful-restart helper-role (OSPF)** command.
filter capability	Whether the filtering rule of the Helper mode is enabled: ● ip-prefix: The IP prefix filtering rule of the Helper mode is enabled. ● acl-number: The basic ACL filtering rule of the Helper mode is enabled. ● acl-name: The named ACL filtering rule of the Helper mode is enabled. ● disabled: The filtering rule of the Helper mode is disabled.

Item	Description
policy capability	Whether a policy is configured for the Helper mode: ● strict lsa check: The Helper checks all LSAs. To prevent the Helper from checking AS external LSAs, run the **graceful-restart helper-role ignore-external-lsa** command. ● ignore external lsa check: The Helper does not check AS external LSAs. ● planned and un-planned: The Helper supports planned-GR and unplanned-GR. To configure the Helper to support only planned-GR, run the **graceful-restart helper-role planned-only** command. ● planned: The Helper supports only planned-GR.
Applications Supported: MPLS Traffic-Engineering	OSPF supports Traffic Engineering (TE).
Spf-schedule-interval	Interval for performing SPF calculation. To set the interval for OSPF to calculate routes, run the **spf-schedule-interval** command.
Route Preference	Preference of the default route.
ASE Route Preference	Priority of the external route.
Default ASE parameters	Default parameters of the external LSA. ● Metric: default metric of the external LSA. ● Tag: default tag of the external LSA. ● Type: default type of the external LSA.
SPF Computation Count	Number of times that SPF calculation is performed.
RFC 1583 Compatible	Whether RFC 1583 compatibility is enabled. To convert rules defined in RFC 2328 into rules defined in RFC 1583, run the **rfc1583 compatible** command.
Retransmission limitation is disabled	Retransmission limit is disabled. To enable retransmission limit and set the maximum number of retransmissions, run the **retransmission-limit** command.

Item	Description
Import routes limitation is enabled, the maximal limitation value	Maximum number of imported routes is restricted and that the maximum value is displayed.
Area Count	Number of areas in the current process.
Nssa Area Count	Number of NSSAs in the current process.
Process total up interface count	Number of interfaces that are up.
Process valid up interface count	Number of interfaces that are valid.
Flush protect mode	Whether master/slave board switching triggered by abnormal OSPF LSA aging is enabled: ● false: Master/Slave board switching triggered by abnormal OSPF LSA aging is disabled. ● true: Master/Slave board switching triggered by abnormal OSPF LSA aging is enabled.
ExChange/Loading Neighbors	Number of neighbors in the ExChange/Loading state.
Area	Information about each area in the current process, including ID of the current area in dotted decimal notation.
Authtype	Area authentication type, including none-authentication, simple authentication, MD5 authentication, HMAC-SHA256 authentication, and HMAC-MD5 authentication.
Area flag	Flag used to describe the area attributes, including Transit/Vlink/Stub/Nssa/Normal.
SPF scheduled Count	Number of times that SPF calculation is performed.
Interface	Interface information in the area.
Cost	Cost of an OSPF interface. To set the cost for an OSPF on an interface, run the **ospf cost** command.

Item	Description
State	Interface status: ● Down ● Waiting ● Loopback ● P-2-P ● DR ● BDR ● DROTHER DR and BDR DROTHER exist in only broadcast and NBMA networks, and P-2-P exists in only P2P and P2MP Vlinks.
Type	Interface type, including P2P, broadcast, NBMA, and P2MP.
MTU	MTU value of the interface.
Priority	Interface priority.
Designated Router	(Optional) the current interface is not the DR.
Backup Designated Router	(Optional) the current interface is not the BDR.
Timers	Interval of the timer.
Hello	Interval of the Hello timer. To set the interval for sending Hello packets on an interface, run the **ospf timer hello** command.
Dead	Interval of the Dead timer. To set the dead interval after which an interface considers its OSPF neighbor invalid, run the **ospf timer dead** command.
Poll	Interval of the Poll timer. To set the poll interval for sending Hello packets on NBMA networks, run the **ospf timer poll** command.
Retransmit	Interval of the Retransmit timer. To set the interval for retransmitting LSA on an interface, run the **ospf timer retransmit** command.

Item	Description
Transmit Delay	(Optional) delay for transmitting LSAs on the interface. To add the transmission delay to LSAs before they are sent by an interface, run the **ospf trans-delay** command.
Router ID conflict state	Status of the automatic recovery function. The value can be one of the following: ● Normal: The automatic recovery function is properly detecting router ID conflict. ● Wait select: The automatic recovery function delays defining a new router ID if the device starts after an unexpected delay (two hours by default). ● Selecting: The automatic recovery function restarts the OSPF process with the router ID and waits for the restarted OSPF process to take effect. ● RtrId Changed: The automatic recovery function determines whether router ID conflict occurs after the new router ID takes effect and returns to the Normal state if no new router ID conflict is detected. ● Suspend: If the maximum number of conflict times is reached, automatic recovery function does not define a new router ID any longer. The maximum number of conflict times is three by default.
Area interface up count	The number of interfaces up in the area.

7.4.21 display ospf cumulative

Function

The **display ospf cumulative** command displays OSPF statistics.

Format

display ospf [*process-id*] **cumulative**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no OSPF process ID is specified, statistics of all the OSPF processes are displayed.	The value is an integer ranging from 1 to 65535.

Views

All views

Retransmit Count: 0
```

Table 7-29 Description of the **display ospf cumulative** command output

Item	Description
IO Statistics	Statistics of the transmitted packets and LSAs.
Type	OSPF packet type.
Input	Number of received packets.
Output	Number of sent packets.
Hello	OSPF Hello packet.
DB Description	OSPF Database Description packet.
Link-State Req	OSPF Link State Request packet.
Link-State Update	OSPF Link State Update packet.
Link-State Ack	OSPF Link State Acknowledgement packet.
Checksum Sum	Checksum of the AS external LSA.
ASE	Number of ASE routes (If there are no ASE routes, **Disabled** is displayed.).
LSAs originated by this router	Detailed statistics of the transmitted LSAs.
Router	Router LSA.
Network	Network LSA.
Sum-Net	Type 3 summary LSA.
Sum-Asbr	Type 4 summary LSA.
External	AS external LSA.
NSSA	NSSA.
Opq-Link	Number of Type 9 Opaque LSAs.
Opq-Area	Number of Type 10 Opaque LSAs.
Opq-As	Number of Type 11 Opaque LSAs
LSAs Originated	Generated LSAs.
LSAs Received	Received LSAs.

Item	Description
Routing Table	Routing table.
Intra Area	Number of intra-area routes.
Inter Area	Number of inter-area routes.
Up Interface Cumulate	Statistics of up state interface.
Neighbor Cumulate	Statistics of neighbors.
Neighbor cumulative data	Detailed statistics of neighbors: ● Down ● Init ● Attempt ● 2-Way ● Exstart ● Exchange ● Loading ● Full
Retransmit Count	Total number of nodes in the retransmission list.

7.4.22 display ospf error

Function

The **display ospf error** command displays OSPF error information.

Format

display ospf [*process-id*] **error** [**lsa** | **interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no OSPF process ID is specified, error information of all OSPF processes is displayed.	The value is an integer ranging from 1 to 65535.
lsa	Displays the OSPF LSA errors.	-

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

Usage Guidelines

When locating OSPF faults, you can run the **display ospf error** command to obtain OSPF error information. You can then analyze OSPF faults according to the OSPF error information.

Example

Display OSPF error information.

```
<HUAWEI> display ospf error
          OSPF Process 1 with Router ID 10.1.1.1
                  OSPF error statistics

General packet errors:
 0     : IP: received my own packet     0     : Bad packet
 0     : Bad version                    0     : Bad checksum
 0     : Bad area id                    0     : Drop on unnumbered interface
 1     : Bad virtual link               0     : Bad authentication type
 0     : Bad authentication key         0     : Packet too small
 0     : Packet size > ip length        0     : Transmit error
 0     : Interface down                 0     : Unknown neighbor
 0     : Bad net segment                0     : Extern option mismatch
 0     : Router id confusion            0     : Bad authentication sequence number

HELLO packet errors:
 0     : Netmask mismatch               0     : Hello timer mismatch
 0     : Dead timer mismatch            0     : Virtual neighbor unknown
 0     : NBMA neighbor unknown          0     : Invalid Source Address

DD packet errors:
 0     : Neighbor state low             0     : Unknown LSA type
 0     : MTU option mismatch

LS ACK packet errors:
 0     : Neighbor state low             0     : Unknown LSA type

LS REQ packet errors:
 0     : Neighbor state low             0     : Empty request
 0     : Bad request

LS UPD packet errors:
 0     : Neighbor state low             0     : Newer self-generate LSA
 0     : LSA checksum bad               0     : Received less recent LSA
 0     : Unknown LSA type

Opaque errors:
```

```
 0     : 9-out of flooding scope        0     : 10-out of flooding scope
 0     : 11-out of flooding scope       0     : Unknown TLV type

Retransmission for packet over Limitation errors:
 0     : Number for DD Packet           0     : Number for Update Packet
 0     : Number for Request Packet

Receive Grace LSA errors:
 0     : Number of invalid LSAs         0     : Number of policy failed LSAs
 0     : Number of wrong period LSAs

Configuration errors:
0     : Tunnel cost mistake
```

Table 7-30 Description of the **display ospf error** command output

Item	Description
General packet errors	Indicates general packet errors.
IP: received my own packet	Indicates that the packet sent by its own interface is received and therefore the packet is not processed.
Bad packet	Indicates that the parsed packet is incorrect, including the checksum of the length field.
Bad version	Indicates that the OSPF version is incorrect, that is, it is not version 2.
Bad checksum	Indicates that the OSPF checksum is incorrect.
Bad area id	Indicates that the area ID in the received packet does not match the local area ID. (Vlink can receive packets from only Area 0 and its own area.)
Drop on unnumbered interface	Indicates that the unnumbered rather than P2P interface receives packets (the interface must be of the P2P type).
Bad virtual link	Indicates that the Vlink receives invalid packets.
Bad authentication type	Indicates that packet authentication is incorrect. If the value of this field keeps increasing, the OSPF authentication types of the two devices that establish the neighbor relationship are inconsistent. In this case, run the **area-authentication-mode** command to configure the same authentication type for the two devices.
Bad authentication key	Packet authentication key is incorrect.
Packet too small	Indicates that the length of the received packet does not equal the sum of the IP header length and the packet length.
Packet size > ip length	Indicates that the length of the OSPF packet is greater than the permitted length of the IP packet.

Item	Description
Transmit error	Indicates that sending packets to the socket fails.
Interface down	Indicates the number of times that the OSPF interface goes Down.
Unknown neighbor	Indicates that OSPF packets are received from non-OSPF neighbors on NBMA networks, virtual links, and sham links.
HELLO packet errors	Indicates Hello packet errors.
Netmask mismatch	Indicates that the address mask does not match the local address mask.
Hello timer mismatch	Indicates that the Hello intervals on the two ends are inconsistent. If the value of this field keeps increasing, the value of the Hello timers on the two devices that establish the neighbor relationship are inconsistent. In this case, check the interface configurations of the two devices and run the **ospf timer hello** command to set the same value for the Hello timers.
Dead timer mismatch	Indicates that the Dead intervals on the two ends are inconsistent. If the value of this field keeps increasing, the values of the dead timers on the two devices that establish the neighbor relationship are inconsistent. In this case, check the interface configurations of the two devices and run the **ospf timer dead** command to set the same value for the dead timers.
Extern option mismatch	Indicates that the extension attributes of the Hello packets on the two ends are inconsistent. If the value of this field keeps increasing, the area types of the two devices that establish the neighbor relationship are inconsistent (the area type of one device is common area, and the area type of the other device is stub area or NSSA). In this case, configure the same area type for the two devices (in the OSPF area view, the **stub** command indicates the area type is stub and the **stub** command indicates the area type is nssa).
Bad net segment	The source address of received packets is not on the same network segment as the IP address of the interface that receives packets.
Router id confusion	Indicates that the router IDs on the two ends are the same.

Item	Description
Bad authentication sequence number	Indicates bad authentication sequence number errors.
Virtual neighbor unknown	Indicates that the router ID of the packet is inconsistent with that of the neighbor that is configured by the virtual link.
NBMA neighbor unknown	Indicates that the status of the NBMA neighbor is not active.
Invalid Source Address	Indicates that the source address of LSA is invalid.
DD packet errors	Indicates DD packet errors.
Neighbor state low	Indicates the following situations: ● A DD packet is received but its neighbor status is lower than 2-way. ● An LSR packet is received but its neighbor status is lower than Exchange. ● An LSU packet is received but its neighbor status is lower than Exchange. ● An LSAck packet is received but its neighbor status is lower than Exchange.
Unknown LSA type	Indicates the unknown LSA type.
MTU option mismatch	Indicates that the MTU check of the OSPF interface is enabled and the MTU of the DD packet received by the interface is greater than the MTU of the interface.
LS ACK packet errors	Indicates LSAck packet errors.
Bad ack	Indicates the number of times that incorrect LSAck packets are received.
Duplicate ack	Indicates the number of times that duplicate LSAck packets are received.
LS REQ packet errors	Indicates LSR packet errors.
Empty request	Indicates empty LSR packets.
Bad request	Indicates the BadRequest event in the protocol.
LS UPD packet errors	Indicates LSU packet errors.
Newer self-generate LSA	Indicates the number of new self-generated LSAs. This field is reserved for future use.
LSA checksum bad	Indicates that the LSA checksum is incorrect.
Received less recent LSA	Indicates that the LSA older than the local LSA is received.

Item	Description
Opaque errors	Indicates opaque errors.
9-out of flooding scope	Indicates the number of Type 9 LSAs that exceed the flooding scope.
10-out of flooding scope	Indicates the number of Type 10 LSAs that exceed the flooding scope.
11-out of flooding scope	Indicates the number of Type 11 LSAs that exceed the flooding scope.
Unknown TLV type	Indicates the unknown TLV type.
Retransmission for packet over Limitation errors	Indicates the number of times that retransmitting packets expires.
Number for DD Packet	Indicates the number of times that retransmitting DD packets expires.
Number for Update Packet	Indicates the number of times that retransmitting LSU packets expires.
Number for Request Packet	Indicates the number of times that retransmitting LSR packets expires.
Receive Grace LSA errors	Indicates the number of received incorrect Grace LSAs.
Number of invalid LSAs	Indicates the total number of invalid LSAs.
Number of policy failed LSAs	Indicates the total number of policy failed LSAs.
Number of wrong period LSAs	Indicates the total number of wrong period LSAs.
Configuration errors	Indicates configuration errors.
Tunnel cost mistake	Indicates the number of times that the cost of the OSPF tunnel interface is smaller than 1. This count increases by one each time the cost of the OSPF tunnel interface is smaller than one. If the cost is smaller than one, the cost is calculated as one.

Display the OSPF LSA errors.

```
<HUAWEI> display ospf error lsa
 OSPF Process  1  with Router ID 10.1.1.14

 Last Received Bad LSA Header
    LS Age             : 36
    Link State Type    : 0x0008
    Link State ID      : 0.0.1.66
    Advertising Router : 10.10.10.22
    LS Sequence Number : 0x80000002
    LS Checksum        : 0x00bd2e
    Length             : 96
```

```
  Interface          : Vlanif100
  Recv Time            : 2011-05-27 14:37:17
```

Table 7-31 Description of the display ospf error lsa command output

Item	Description
Last Received Bad LSA Header	Bad LSA information received last time.
LS Age	Aging time of the LSA.
Link State Type	LSA type.
Link State ID	LSA state ID.
Advertising Router	Router that advertises or generates LSAs.
LS Sequence Number	Sequence number in the LSA header.
LS Checksum	LSA checksum.
Length	Size of the LSA.
Interface	LSA receiving interface.
Recv Time	LSA receiving time.

7.4.23 display ospf global-statistics

Function

The **display ospf global-statistics** command displays global OSPF statistics. If no OSPF process ID is specified, brief information about all the OSPF processes is displayed.

Format

display ospf global-statistics { **process** *process-id* | **vpn-instance** *vpn-instance-name* | **public-instance** | **timewheel** | **brief** }

Parameters

Parameter	Description	Value
process *process-id*	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
public-instance	Displays the statistics of all the public network instances.	-
timewheel	Displays the number of updated or aged LSAs in different periods.	-
brief	Displays brief information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospf global-statistics** command to check global OSPF statistics for fault location.

Example

Display global OSPF statistics, including statistics of neighbors, processes, and instances.

```
<HUAWEI> display ospf global-statistics brief
  Neighbor cumulative data (OSPF total statistics):
  ---------------------------------------------------------
  Down:              0        Init:                 0      Attempt:     0    2-Way:     0
  Exstart:           0        Exchange:             0      Loading:     0    Full:   2400
  Instance Numer:     1        Process Number:        2
  HighSocketExpire:   27       HighSocketEmpty:  526275
  Total Neighbor Number:                   0
  Total Press:   LOW
```

Table 7-32 Description of the **display ospf global-statistics brief** command output

Item	Description
Neighbor cumulative data (OSPF total statistics)	Neighbor statistics.
Instance Number	Number of instances, including public network instances and VPN instances.
Process Number	Number of OSPF processes running on the device.
HighSocketExpire	Number of unprocessed messages in high-priority queues.
HighSocketEmpty	Number of processed messages in high-priority queues.

Item	Description
Total Neighbor Number	Total number of OSPF neighbors.
Total Press	Total pressure of the current service. In most cases, the Total Press field is **LOW**. If the number of retransmission timers or the number of LSAs being flooded in the OSPF processes exceeds a certain value (default 300), or the number of OSPF neighbors exceeds 300, the Total Press field is **HIGH**. If the number of retransmission timers and the number of LSAs being flooded in the OSPF processes fall below a certain value (default 300), or the number of OSPF neighbors falls below 300, the Total Press field is **LOW**.

Display global statistics of OSPF process 1.

```
<HUAWEI> display ospf global-statistics process 1
  OSPF 1 statistics data:
  -----------------------------------------
  LSA NUM of Flood cache:          0
  Packet NUM of FloodUpdt Hash:          0
  Packet NUM of Flood Queue:          0
```

Table 7-33 Description of the **display ospf global-statistics process 1** command output

Item	Description
LSA NUM of Flood cache	Number of LSAs being flooded in the OSPF process.
Packet NUM of FloodUpdt Hash	Number of Update packets waiting to be flooded in the OSPF process, and the total size of the Update packets does not reach the MTU.
Packet NUM of Flood Queue	Number of Update packets waiting to be flooded in the OSPF process, and the total size of the Update packets reaches the MTU.

Display OSPF time wheel information.

```
<HUAWEI> display ospf global-statistics timewheel
 ================== TimeWheel Info Begin ===================
 TimeWheel current index is 2845, datanode count is 8
 Bucket Number: 3596, Expiry time: 1306(s), Datanode Count: 0
 High expiry time: 0, Low expiry time 527742(s)
```

```
Bucket Number: 3597, Expiry time: 1307(s), Datanode Count: 0
High expiry time: 0, Low expiry time 527743(s)
Bucket Number: 3598, Expiry time: 1308(s), Datanode Count: 0
```

Table 7-34 Description of the **display ospf global-statistics timewheel** command output

Item	Description
TimeWheel current index	Current index of the time wheel.
datanode count	Total number of nodes in the time wheel.
Bucket Number	Total number of indexes of the time wheel.
Expiry time	Expiry time of the index.
High expiry time	High expiry time corresponding to the index in the time wheel after the system starts.
Low expiry time	Low expiry time corresponding to the index in the time wheel after the system starts.

7.4.24 display ospf graceful-restart

Function

The **display ospf graceful-restart** command displays the status of OSPF GR.

Format

display ospf [*process-id*] **graceful-restart** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
verbose	Displays detailed information about OSPF GR.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospf graceful-restart** command to view details and statistics of the GR.

Example

Display OSPF GR information.

```
<HUAWEI> display ospf graceful-restart

         OSPF Process 1 with Router ID 10.1.1.1
 Graceful-restart capability     : enabled
 Graceful-restart support        : planned and un-planned, totally
 Helper-policy support           : planned and un-planned, strict lsa check
 Current GR state                : normal
 Graceful-restart period         : 120 seconds

 Number of neighbors under helper:
  Normal neighbors    : 0
  Virtual neighbors   : 0
  Sham-link neighbors : 0
  Total neighbors     : 0

 Number of restarting neighbors : 0

 Last exit reason:
  On graceful restart : successful exit
  On Helper           : none
```

Display detailed information about OSPF GR.

```
<HUAWEI> display ospf graceful-restart verbose

         OSPF Process 1 with Router ID 10.1.1.1
 Graceful-restart capability     : enabled
 Graceful-restart support        : planned and un-planned, totally
 Helper-policy support           : planned and un-planned, strict lsa check
 Current GR state                : normal
 Graceful-restart period         : 120 seconds

 Number of neighbors under helper:
  Normal neighbors    : 0
  Virtual neighbors   : 0
  Sham-link neighbors : 0
  Total neighbors     : 0
 Number of restarting neighbors : 0

 Last exit reason:
  On graceful restart : successful exit
  On Helper           : none

 All area count      : 1

                Area ID    : 0.0.0.0

 Authtype       : None     Area flag : Normal

 Normal interface count: 1

 Interface: 10.1.1.1 (Vlanif100)
 GR state : normal                  State: P-2-P          Type: P2P
 Last Helper Exit reason: none
 Neighbor count of this interface : 1

 Neighbor          IP address        GR state    Last Helper Exit reason
 10.2.2.2          10.1.1.2          Normal      none
```

Table 7-35 Description of the **display ospf graceful-restart** command output

Item	Description
Graceful-restart capability	Whether IETF GR is enabled: ● enabled ● disabled
Graceful-restart support	IETF GR mode that is supported currently: ● planned: indicates that only planned-GR is supported. ● planned and un-planned: indicates that both planned GR and unplanned GR are supported. ● totally: indicates that totally GR is supported. ● partial: indicates that partial GR is supported.
Helper-policy support	Policy that supports the Helper: ● planned: indicates that the Helper supports only planned GR. ● planned and un-planned: indicates the Helper supports both planned GR and unplanned GR. ● strict lsa check: indicates that the Helper supports strict external LSA check. ● ignore external lsa check: indicates that the Helper does not check external LSAs. ● never: indicates that the device does not support the Helper mode.
Current GR state	Current GR status: ● Normal: indicates that GR is in the Normal state. ● Under GR: indicates that the device enters the Restarter mode. ● Under Helper: indicates that the device enters the Helper mode.
Graceful-restart period	GR period.

Item	Description
Number of neighbors under helper	Number of neighbors in the Helper state: ● Normal neighbors: indicates the number of normal neighbors. ● Virtual neighbors: indicates the number of virtual neighbors. ● Sham-link neighbors: indicates the number of sham link neighbors. ● Total neighbors: indicates the total number of neighbors.
Number of restarting neighbors	Number of restarted devices displayed on the Helper.
Last exit reason	Reason why a device exits from GR last time: ● On graceful restart: indicates the reason that the Restarter exits from GR. ● On Helper: indicates the reason that the Helper exits from GR.
On graceful restart	Reason why the Restarter exits from GR: ● 1-way hello received: indicates that 1-way Hello packets are received. ● back-link check failed: indicates that the back link check fails. ● DR election fail: indicates that DR election fails. ● grace period expired: indicates that the GR period expires. ● interface state change: indicates that the interface state machine changes. ● none: indicates that the device never performs GR since startup. ● successful exit: indicates that the Restarter successfully exits from GR. ● two Grace-LSAs received: indicates that two Grace LSAs are received.

Item	Description
On Helper	Reason why the Helper exits from GR: ● flooding change LSA: indicates that the changed LSAs are received. ● grace period expired: indicates that the GR period expires. ● graceful restart unconfigured at process level: indicates that the GR function of the OSPF process is disabled. ● interface state change: indicates that the interface state machine changes. ● policy check failed for received grace LSA: indicates the policy that mismatches the Helper. ● received 1-way hello packet: indicates that 1-way Hello packets are received. ● received flushed grace LSA: indicates that flushed Grace LSAs are received. ● received multiple grace LSA: indicates that multiple Grace LSAs are received. ● neighbor reset: indicates that GR is disabled when neighbors are in the Helper mode. ● none: indicates that the device never enters the Helper mode since startup. ● successful exit: indicates that the Helper successfully exits from GR.
All area count	Number of areas in the process.
Area ID	Area ID.
Authtype	Authentication type.
Area flag	Area attributes: ● Normal ● NSSA ● Stub
Normal interface count	Number of interfaces in the area.
Interface	IP address of the interface.

Item	Description
GR state	GR status of the interface: - Normal: indicates that the device is in the Normal state. - Restarter: indicates that the device enters the Restarter mode. - Helper: indicates that the device enters the Helper mode.
State	Interface status: - P-2-P - DR - BDR - DROther - Waiting - Down
Type	Interface type: - P2P - P2MP - NBMA - Broadcast

Item	Description
Last Helper Exit reason	Reason why the neighbor exits from the Helper mode the last time: ● none: indicates that the device never enters the Helper mode since startup. ● successful exit: indicates that the neighbor successfully exits from the Helper mode. ● grace period expired: indicates that the GR period expires. ● received flushed grace LSA: indicates that flushed Grace LSAs are received. ● flooding change LSA: indicates that the changed LSAs are received. ● received multiple grace LSA: indicates that multiple Grace LSAs are received. ● received 1-way hello packet: indicates that 1-way Hello packets are received. ● policy check failed for received grace LSA: indicates the policy that mismatches the Helper. ● neighbor reset: indicates that the network topology changes after the **reset** command is run on the neighbor of the Helper. ● interface state change: indicates that the interface state machine changes. ● graceful restart unconfigured at process level: indicates that the neighbor is not configured with the GR function.
Neighbor count of this interface	Total number of neighbors of this interface.
Neighbor	Router ID of the neighbor.
IP address	IP address of the neighboring interface.
GR state	GR status of the neighbor: ● Normal: indicates that the neighbor is in the Normal state. ● Restarter: indicates that the neighbor enters the Restarter mode. ● Helper: indicates that the neighbor enters the Helper mode.

7.4.25 display ospf interface

Function

The **display ospf interface** command displays information about OSPF interfaces.

Format

display ospf [*process-id*] **interface** [**all** | *interface-type interface-number*] [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
all	Displays information about all OSPF interfaces.	-
interface-type interface-number	Specifies the interface type and the interface number.	-
verbose	Displays verbose configuration information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ospf interface** command output displays the configuration and operating status of OSPF, which facilitate fault location and configuration verification.

Example

Display OSPF interface information.

```
<HUAWEI> display ospf interface

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0         (MPLS TE not enabled)
 IP Address      Type         State    Cost  Pri    DR              BDR
 192.168.1.2     Broadcast    DR        1     1     192.168.1.2     192.168.1.3

 Area: 0.0.0.1         (MPLS TE not enabled)
```

```
IP Address      Type         State     Cost  Pri   DR             BDR
172.16.0.1      Broadcast    DR        1     1     172.16.0.1     172.16.0.2
```

Table 7-36 Description of the **display ospf interface** command output

Item	Description
Area	ID of the area to which the interface belongs.
IP Address	IP address of the interface (regardless of whether TE is enabled on the interface).
Type	Interface type: P2P, PTMP, broadcast, or NBMA.
State	Status of the interface, which is determined by the OSPF interface state machines: ● Down: The status of the interface is Down. If an interface is Down, the interface is unavailable and cannot be used to transmit traffic. ● Loopback: The interface connecting to the network on the device is in the Loopback state. The loopback interface cannot be used to transmit data but can collect interface information by performing the ICMP ping operation or bit error detection. ● Waiting: The device is determining the DR and BDR on the network. The DR or BDR election mechanism should not be implemented until the waiting period ends. This prevents unnecessary changes in the DR and BDR roles. ● P-2-P: The interface is connected to a P2P network or a virtual link. ● DROther: The device itself is not elected as the DR or BDR. Instead, another device connecting to the broadcast network or NBMA network is elected as the DR. The device starts to set up adjacency with the DR and BDR (if existing). ● BDR: The device functions as the BDR on the network, and will turn into a DR when the current DR fails. The device sets up adjacency with other devices that access the network. ● DR: The device functions as the DR on the network. The device sets up adjacency with other devices that access the network.
Cost	Cost of the interface.

Item	Description
Pri	Priority of the device interface during the DR and BDR election The greater the value, the higher the priority.
DR	DR of the network where the interface resides.
BDR	BDR of the network where the interface resides.
Timer Hello	Interval for sending Hello packets.

Display detailed information about an OSPF interface.

```
<HUAWEI> display ospf interface Vlanif 501 verbose

         OSPF Process 1 with Router ID 192.168.2.1
                 Interfaces

 Interface: 192.168.100.2 (Vlanif501)
 Cost: 1       State: BDR       Type: Broadcast    MTU: 1500
 Priority: 1
 Designated Router: 192.168.100.1

Link-State Update            4          3
   Link-State Ack            2          3
 ALLSPF GROUP
 ALLDR GROUP
 OpaqueId: 0   PrevState: Waiting
 Effective cost: 1, enabled by OSPF Protocol
 Suppress flapping peer: enable(flapping-count: 0, threshold: 10)
```

Table 7-37 Description of the **display ospf interface verbose** command output

Item	Description
IO Statistics	Statistics about received and sent OSPF packets.
Type	OSPF packet type.
Input	Number of OSPF packets that the interface receives.
Output	Number of OSPF packets sent by the interface.
DB Description	Statistics about received and sent OSPF DD packets.

Item	Description
Link-State Req	Statistics about received and sent OSPF LSR packets.
Link-State Update	Statistics about received and sent OSPF LSU packets.
Link-State Ack	Statistics about received and sent OSPF LSAck packets.
ALLSPF GROUP	ALLSPF GROUP that the interface joins.
ALLDR GROUP	ALLDR GROUP that the interface joins.
OpaqueId	Opaque ID of the interface.
PrevState	Previous state of the interface.
Effective cost	Effective cost of the interface: ● enabled by OSPF Protocol: default value or the one configured using the **ospf cost** command. ● enabled by RUI: RUI route cost. ● enabled by IGP_LDP: interface cost configured in LDP. ● enabled by BGP_IGP: interface cost configured in BGP. ● enabled by Tunnel: cost generated after a TE Tunnel is configured.

Item	Description

Suppress flapping peer	Status of OSPF neighbor relationship flapping suppression:
	● enable: OSPF neighbor relationship flapping suppression is enabled.
	– flapping-count: number of valid flapping_events
	If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping_event is recorded, and the flapping_count is incremented by 1. To change *detecting-interval*, run the **ospf suppress-flapping peer detecting-interval** *detecting-interval* command.
	– threshold: flapping suppression threshold
	When the flapping_count reaches or exceeds **threshold**, flapping suppression takes effect. To configure the threshold, run the **ospf suppress-flapping peer threshold** *threshold* command.
	● disable: OSPF neighbor relationship flapping suppression is disabled. In this case, the following information is displayed, without flapping-count or threshold:
	`Suppress flapping peer: disable`
	● hold-down: OSPF neighbor relationship flapping suppression works in Hold-down mode. In this case, an example of the displayed information is as follows:
	`Suppress flapping peer: hold-down(start: 2016-01-02 09:58:41, remain-interval: 476 sec)`
	– start: time when the flapping suppression started
	– remain-interval: remaining time of the flapping suppression
	● hold-max-cost: OSPF neighbor relationship flapping suppression works in Hold-max-cost mode. In this case, an example of the displayed information is as follows:
	`Suppress flapping peer: hold-max-cost(start: 2016-01-02 09:58:41, remain-interval: 476 sec)`

7.4.26 display ospf lsdb

Function

The **display ospf lsdb** command displays an OSPF Link State Database (LSDB).

Format

display ospf [*process-id*] **lsdb** [**brief**]

display ospf [*process-id*] **lsdb** [{ **router** | **network** | **summary** | **asbr** | **ase** | **nssa** | **opaque-link** | **opaque-area** | **opaque-as** } [*link-state-id*]] [**originate-router** [*advertising-router-id*] | **self-originate**] [**age** { **min-value** *min-age-value* | **max-value** *max-age-value* } *]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
brief	Displays brief information about the LSDB.	-
router	Displays information about the router LSA.	-
network	Displays information about the network LSA.	-
summary	Displays information about the network summary LSA.	-
asbr	Displays information about the ASBR summary LSA.	-
ase	Displays information about the AS external LSA.	-
nssa	Displays information about the status of external links in the NSSA.	-
opaque-link	Displays information about the opaque link LSA.	-
opaque-area	Displays information about the opaque area LSA.	-

Parameter	Description	Value
opaque-as	Displays information about the opaque AS LSA.	-
originate-router	Displays the LSA of the advertising router.	-
link-state-id	Specifies the ID of an LSA.	The value is an IP address in dotted decimal notation.
advertising-router-id	Specifies the router ID of the device that advertises the LSA.	The value is an IP address in dotted decimal notation.
self-originate	Displays information about the self-originated LSA.	-
age	Displays the LSAs that meet the age filtering rule.	-
min-value *min-age-value*	Displays information about only LSAs with the **age** value greater than or equal to the *min-age-value* value.	The value is an integer ranging from 0 to 3600.
max-value *max-age-value*	Displays information only about LSAs with the **age** value less than or equal to the *max-age-value* value.	The value is an integer ranging from 0 to 3600.

1: Monitoring level

Usage Guidelines

To check information about the LSDB, run the **display ospf lsdb** command. You can choose to view:

- Brief information about the LSDB
- LSAs of a specified type
- LSAs of the originating device
- Locally originated LSAs

The command output helps you troubleshoot OSPF faults.

Example

Display information about the OSPF LSDB.

```
<HUAWEI> display ospf lsdb
         OSPF Process 1 with Router ID 10.1.1.1
                 Link State Database

                         Area: 0.0.0.0
 Type      LinkState ID    AdvRouter          Age  Len   Sequence   Metric
 Router    10.1.1.1        10.1.1.1          1348  48    800007C9    10000
 Router    10.1.1.2        10.1.1.2          1078  60    80000654       0
 Network   192.168.10.1    192.168.10.1      1349  32    80000060       0

                 AS External Database
 Type      LinkState ID    AdvRouter          Age  Len   Sequence   Metric
 External  0.0.0.0         10.1.1.2          1743  36    800005FE       1
```

Table 7-38 Description of the **display ospf lsdb** command output

Item	Description
Area	Area whose LSDB information needs to be displayed.
Type	LSA type: Router, Network, Sum-Net, Sum-Asbr, NSSA, External, Opq-Link, Opq-Area, and Opq-As.
LinkState ID	Link State ID in the LSA header.
AdvRouter	Device that advertises or generates LSAs.
Age	Aging time of the LSA.
Len	Size of the LSA.
Sequence	Sequence number in the LSA header.
Metric	Metric.
AS External Database	LSDB that contains external LSAs.

Display brief information about the OSPF LSDB.

```
<HUAWEI> display ospf lsdb brief
        OSPF Process 1 with Router ID 10.1.1.1
                LS Database Statistics

 Area ID         Stub   Router   Network  S-Net   S-ASBR   Type-7   | Subtotal
 0.0.0.0         0      3        2        0       0        0        | 5

                                                                 | Total
                                                                 | 5
```

Table 7-39 Description of the **display ospf lsdb brief** command output

Item	Description
Area ID	Area to which the device belongs.
Stub	Number of stub networks.
Router	Number of Router LSAs.
Network	Number of network LSAs.
S-Net	Number of Sum-Net LSAs.
S-ASBR	Number of Sum-Asbr LSAs.
Type-7	Number of Type 7 LSAs.
Opq-9	Number of Opq-Link LSAs.
Opq-10	Number of Opq-Area LSAs.
ASE	Number of ASE routes.
Opq-11	Number of Opq-As LSAs.
Subtotal	Total number of sub-items.
Total	Total quantity.

Display information about router LSAs in the LSDB.

```
<HUAWEI> display ospf lsdb router
          OSPF Process 1 with Router ID 10.1.1.1
                          Area: 0.0.0.0
                  Link State Database

  Type      : Router
  Ls id     : 10.2.2.2
  Adv rtr   : 10.2.2.2
  Ls age    : 52
  Len       : 48
  Options   :  E
  seq#      : 80000006
  chksum    : 0xbf5a
  Link count: 2
     Link ID: 10.2.1.2
     Data   : 10.2.1.2
     Link Type: TransNet
     Metric : 1
     Link ID: 10.2.2.2

     Link Type: StubNet
     Metric : 0
     Priority : Medium
```

Table 7-40 Description of the **display ospf lsdb router** command output

Item	Description
Ls id	Link State ID in the LSA header.

Item	Description
Adv rtr	Device that advertises or generates LSAs.
Ls age	Aging time of the LSA.
Len	Size of the LSA.
Options	Options field: - E: allows Flood AS-external-LSAs. - MC: forwards IP multicast packets. - N/P: processes Type-7 LSAs. - DC: processes the required links.
seq#	Sequence number, which is used to check the order of LSAs.
chksum	LSA checksum.
Link count	Number of links.
Link ID	Link ID of the router LSA, which is classified according to the link type. - If the type of link is **Point-to-Point**, **Link ID** indicates the router ID of a neighbor. - If the type of link is **TransNet**, **Link ID** indicates IP address of DR. - If the type of link is **Stub**, **Link ID** indicates IP address. - If the type of link is **Virtual Link**, **Link ID** indicates the router ID of a neighbor.
Data	Link data of the router LSA. - If the type of link is Point-to-Point, TransNet, or Virtual Link, **Data** indicates IP address. - If the type of link is Stub, **Data** indicates mask of IP address.
Link Type	Link type of the router LSA: P-2-P, TransNet, StubNet, or Virtual.
Metric	Link metric of the router LSA.

Item	Description
Priority	OSPF convergence priorities: - Critical: indicates that the convergence priority of OSPF routes is critical. - High: indicates that the convergence priority of OSPF routes is high. - Medium: indicates that the convergence priority of OSPF routes is medium. - Low: indicates that the convergence priority of OSPF routes is low.

Display information about network LSAs in the LSDB.

```
<HUAWEI> display ospf 1 lsdb network 10.1.1.1
         OSPF Process 1 with Router ID 10.1.1.1
                         Area: 0.0.0.0

7.4.27 display ospf mesh-group

Function

The **display ospf mesh-group** command displays brief information about OSPF mesh groups.

Format

display ospf [*process-id*] **mesh-group** [**brief**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no process ID is specified, brief information about mesh groups in all OSPF processes is displayed.	The value is an integer ranging from 1 to 65535.
brief	Displays brief information about mesh groups in each OSPF area.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When concurrent links exist between a switch and its neighbor, run the **mesh-group enable** command to enable the mesh group function and identify the mesh group using the router ID of the switch. When receiving LSAs, the switch will select a primary link to flood LSAs. The link interface does not flood in reverse. This avoids repeated flooding, reducing link load and saving resources.

Running the **display ospf mesh-group** command allows you to check brief information about mesh groups in a specified process in an OSPF area.

Example

Display brief information about OSPF mesh groups.

```
<HUAWEI> display ospf mesh-group

    OSPF Process 1 with Router ID 10.1.1.1
                  Mesh-Groups

Area 0.0.0.0
       Mesh-Group ID:10.2.2.2

    Interface              IP Address/Mask      Nbr State
    Vlanif100               10.11.10.202/24      Exchange
    Vlanif200               10.22.20.202/24      Loading
    Vlanif300               10.33.30.202/24      Full
    Count of Interface in this Mesh-Group: 1
    Count of Mesh-Group in this Area: 1
```

Table 7-45 Description of the **display ospf mesh-group** command output

Item	Description
Area	OSPF area.
Mesh-Group ID	Key ID of a mesh group, namely, the router ID of a neighbor.
Interface	Interface enabled with the mesh-group feature.
IP Address/Mask	IP address and mask of the interface enabled with the mesh-group feature.
Nbr State	Neighbor status on the interface.
Count of Interface in this Mesh-Group	Number of interfaces in the mesh group.
Count of Mesh-Group in this Area	Number of mesh groups in the area.

7.4.28 display ospf migp-routing

Function

The **display ospf migp-routing** command displays OSPF Multicast IGP (MIGP) routing information.

Format

display ospf [*process-id*] **migp-routing** [*ip-address* [*mask* | *mask-length*]] [**interface** *interface-type interface-number*] [**nexthop** *nexthop-address*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
ip-address	Specifies an IP address.	The value is in dotted decimal notation.
mask	Specifies a subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer ranging from 0 to 32.
interface-type interface-number	Specifies the type and number of an interface.	-
nexthop *nexthop-address*	Displays the route with a specified next hop IP address.	The value is in dotted decimal notation.

Usage Guidelines

Usage Scenario

When both multicast and MPLS TE tunnels are configured on a network and the TE tunnels are configured with IGP Shortcut, the outbound interface that an IGP calculates for a route may be not a physical interface but a TE tunnel interface. Based on a unicast route to a multicast source address, a switch can send a Join message through a TE tunnel interface. In this case, devices spanned by the TE tunnel cannot detect the Join message so that they do not create any multicast forwarding entry.

To solve this problem, you can run the **local-mt enable** command to configure local multicast topology (MT). MT allows multicast routing entries to be created correctly.

If local MT is enabled and the outbound interface of the calculated route is a TE tunnel interface of IGP Shortcut type, the route management (RM) module creates a separate Multicast IGP (MIGP) routing table for the multicast protocol, calculates the physical outbound interface of the route, and adds the IP address of the physical outbound interface to the MIGP routing table.

Running the **display ospf migp-routing** command allows you to view the physical outbound interface of the route with the outbound interface of the TE tunnel interface. The physical outbound interface is OSPF routing information in the MIGP routing table.

Precautions

- Local MT supports only OSPF processes of public network instances.
- Local MT does not support forwarding adjacency (FA).

Example

Display OSPF MIGP routing information.

```
<HUAWEI> display ospf migp-routing
          OSPF Process 1 with Router ID 10.2.2.2
                   MIGP Routing Tables

 Routing for Network
 Destination        Cost  Type       NextHop         AdvRouter       Area
 192.168.3.0/24     4     Stub       10.0.1.1        10.5.5.5        0.0.0.0

 Total Nets: 4
 Intra Area: 4  Inter Area: 0  ASE: 0  NSSA: 0
```

Table 7-46 Description of the **display ospf migp-routing** command output

Item	Description
Destination	Destination IP address.
Cost	Cost of the route to the destination address.
Type	Router types are as follows: - Inter-area: Indicates routes between areas. - Stub: indicates routes within an area, including routes advertised based on router LSAs, and direct routes to non-broadcast and non-NBMA networks. - Transit: indicates routes within an area, including routes advertised based on network LSAs.
NextHop	Next hop address to the destination address.
AdvRouter	Advertising router.
Area	Area ID.
Total Nets	Total number of networks in an area, between areas, in ASE areas, and in NSSAs.
Intra Area	Total number of intra-area routes (that is, stub routes and transit routes).
Inter Area	Total number of inter-area routes.
ASE	Total number of routes in the ASE area.

Item	Description
NSSA	Total number of routes in the NSSA.

Display OSPF MIGP routing information with the specified next hop address.

```
<HUAWEI> display ospf migp-routing nexthop 10.0.1.1
         OSPF Process 1 with Router ID 10.2.2.2

 Destination : 192.168.3.0/24

 NextHop     : 10.0.1.1                  Interface : Vlanif20
 Priority    : Medium
```

Table 7-47 Description of the **display ospf migp-routing nexthop** command output

Item	Description
Priority	OSPF convergence priorities: ● Critical: indicates that the convergence priority of OSPF routes is critical. ● High: indicates that the convergence priority of OSPF routes is high. ● Medium: indicates that the convergence priority of OSPF routes is medium. ● Low: indicates that the convergence priority of OSPF routes is low.

7.4.29 display ospf nexthop

Function

The **display ospf nexthop** command displays OSPF next hop information.

Format

display ospf [*process-id*] **nexthop**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output can display information about all the OSPF next hops, which helps you troubleshoot OSPF faults.

Example

Display OSPF next hop information.

```
<HUAWEI> display ospf nexthop
          OSPF Process 100 with Router ID 10.0.0.1
              Routing Nexthop information
Next hops:
Address         Type      Refcount  IntfAddr       Intf Name
----------------------------------------------------------------------
10.0.0.1        Local     3         10.0.0.1       Vlanif100
10.0.0.2        Local     5         10.0.0.1       Vlanif100
```

Table 7-48 Description of the **display ospf nexthop** command output

Item	Description
Next hops	Detailed information about the next hop.
Address	Address of the next hop.
Type	Type of the route passing through the next hop. Local indicates that the route is destined for the local network segment.
Refcount	Number of OSPF routes that use the next hop.
IntfAddr	IP address of the interface.
Intf Name	Name of the interface.

7.4.30 display ospf peer

Function

The **display ospf peer** command displays information about neighbors in each OSPF area.

Format

display ospf [*process-id*] **peer** [[*interface-type interface-number*] [*neighbor-id*] | **brief** | **last-nbr-down**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies the interface type and the interface number.	-
neighbor-id	Specifies the neighbor's router ID.	It is in dotted decimal notation.
brief	Displays brief information about neighbors in each OSPF area.	-
last-nbr-down	Displays brief information about the last neighbor that went Down in the OSPF area.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output can display information about OSPF neighbors, and help you troubleshoot OSPF faults, verify the configurations of OSPF neighbors, and check whether the neighbor performs Graceful Restart (GR).

Example

Display information about the OSPF neighbor.

```
<HUAWEI> display ospf peer
         OSPF Process 1 with Router ID 10.1.1.2
                 Neighbors

 Area 0.0.0.0 interface 10.1.1.2(Vlanif100)'s neighbors
 Router ID: 10.1.1.1          Address: 10.1.1.1           GR State: Normal
   State: Full  Mode:Nbr is Slave  Priority: 1
   DR: 10.1.1.2  BDR: 10.1.1.1    MTU: 0
   Dead timer due in 35  sec
   Retrans timer interval: 5
   Neighbor is up for 00:00:05
   Authentication Sequence: [ 0 ]
```

Table 7-49 Description of the **display ospf peer** command output

Item	Description
Area	Area to which the neighbor belongs.
interface	Interface that connects to the neighbor.
Router ID	Router ID of the neighbor.
Address	Address of the neighboring interface.
GR State	GR status after OSPF GR is enabled: ● Normal: indicates that a switch is in the Normal state and does not perform GR. ● Doing GR: indicates that a switch is performing GR. ● Complete GR: indicates that a switch finishes GR. ● Helper: indicates that the neighbor is the Helper when a switch is performing GR.

Item	Description
State	Neighbor status: - Down: It is the initial status of the neighbor, indicating that the neighbor does not receive any information. On an NBMA network, when the neighbor is in the Down state, Hello packets can still be transmitted at the poll interval, which is longer than the Hello interval. - Attempt: It exists only on an NBMA network, indicating that two ends are attempting to establish the neighbor relationship. The interval for sending Hello packets is the Hello interval, which is shorter than the poll interval. - Init: It indicates that the Hello packet has been received from the neighbor. - 2-Way: It indicates that the Hello packet has been received from the neighbor, and the neighbor list of the Hello packet contains the local Router ID. That is, the two ends can interwork. - ExStart: It is the first step of establishing adjacencies. In this step, the master and slave relationship and DD sequence number are negotiated. - Exchange: It indicates that the LSDBs start to be synchronized. In this process, DD packets, LSR packets, and LSU packets are exchanged. - Loading: It indicates that the LSDBs are being synchronized. In this process, LSR packets and LSU packets are exchanged. - Full: It indicates that the LSDB of the neighbor is already synchronized, and the Full adjacency is established between both ends.
Mode	Master or slave in the process of exchanging DD packets: - Nbr is Master: indicates that the neighbor is the master and actively sends DD packets. - Nbr is Slave: indicates that the neighbor is the slave and cooperates with the master to send DD packets.
Priority	Priority of the neighboring device.
DR	Designated router.
BDR	Backup designated router.
MTU	MTU value of the neighboring interface.

Item	Description
Dead timer due in 35 sec	The dead timer due in 35 seconds.
Retrans timer interval	Interval for retransmitting LSAs, in seconds.
Neighbor is up for	Time during which the neighbor remains Up.
Authentication Sequence	Authentication sequence number.

Display brief information about OSPF neighbors.

```
<HUAWEI> display ospf 1 peer brief
        OSPF Process 1 with Router ID 10.10.10.1
                 Peer Statistic Information
 ----------------------------------------------------------------------------
 Area Id         Interface                  Neighbor id      State
 0.0.0.0         Vlanif10                   10.10.10.3       Full
 ----------------------------------------------------------------------------
 Total Peer(s):     1
```

Table 7-50 Description of the **display ospf peer brief** command output

Item	Description
Area Id	Area to which the neighbor belongs.
Interface	Interface that connects to the neighbor.
Neighbor id	Router ID of the neighbor.
Total Peer(s)	Number of neighbors.

Display information about the OSPF neighbor that went Down for the last time.

```
<HUAWEI> display ospf 1 peer last-nbr-down
         OSPF Process 1 with Router ID 10.1.1.1

                      Last Down OSPF Peer

        Neighbor Ip Address : 10.2.1.2
        Neighbor Area   Id  : 0.0.0.0
        Neighbor Router Id  : 2.2.2.2
        Interface           : Vlanif100
        Immediate Reason    : Neighbor Down Due to Kill Neighbor
        Primary Reason      : Logical Interface State Change
        Down Time           : 2012-09-14 17:17:7
```

Table 7-51 Description of the **display ospf peer last-nbr-down** command output

Item	Description
Neighbor Ip Address	Address of the neighboring interface.

Item	Description
Neighbor Area Id	Area to which the neighbor belongs.
Neighbor Router Id	Router ID of the neighbor.
Interface	Interface that connects to the neighbor.
Immediate Reason	Immediate reason that the neighbor went Down: ● Neighbor Down Due to Inactivity: indicates that the inactivity timer times out. ● Neighbor Down Due to LL Down: indicates that the link is Down. For example, the interface went Down from Up or the IP address of the link is deleted. ● Neighbor Down Due to Kill Neighbor: indicates that the kill neighbor event is generated on the neighbor state machine. ● Neighbor Down Due to 1-Wayhello: indicates that the neighbor went Down because it receives a 1-way packet. ● Received: indicates that the AdjOK? event is generated on this interface. ● Neighbor Down Due to SequenceNum Mismatch: indicates that the SequenceNum Mismatch event is generated on the neighbor state machine. ● Neighbor Down Due to BadLSreq: indicates that the BadLSreq event is generated on the neighbor state machine.

Item	Description
Primary Reason	Primary reason that the neighbor went Down: ● Hello Not Seen: indicates that no Hello packet is received. ● Interface Parameter Mismatch: indicates that the parameters set on both ends of the link do not match. ● Logical Interface State Change: indicates that the status of the logical interface changes. ● Physical Interface State Change: indicates that the status of the physical interface changes. ● OSPF Process Reset: indicates that the OSPF process restarts. ● Area reset: indicates that the area restarts because the area type changes. ● Area Option Mis-match: indicates that the area options of the interfaces on both ends of the link do not match. ● Vlink Peer Not Reachable: indicates that the neighbor on the virtual link is not reachable. ● Sham-Link Unreachable: indicates that the neighbor on the sham link is not reachable. ● Undo Network Command: indicates that the **network** command is deleted. ● Undo NBMA Peer: indicates that the neighbor configuration on the NBMA interface is deleted. ● Passive Interface Down: indicates that the neighbor relationship went Down because the **silent-interface** command is configured on the local interface. ● Opaque Capability Enabled: indicates that Opaque capability is enabled. ● Opaque Capability Disabled: indicates that Opaque capability is disabled. ● Virtual Interface State Change: indicates that the status of a virtual link interface changes. ● BFD Session Down: indicates that the BFD session went Down. ● Down Retransmission Limit Exceed: indicates that the number of retransmission times reaches the limit. ● 1-Wayhello Received: indicates that the device receives 1-way hello packets. ● Router State Change from DR or BDR to DROTHER: indicates that the interface state machine changes to DROTHER from DR or BDR.

Item	Description
	- Neighbor State Change from DR or BDR to DROTHER: indicates that the neighbor state machine changes to DROTHER from DR or BDR. - NSSA Area Configure Change: indicates that the configuration of the NSSA area changes. - Stub Area Configure Change: indicates that the configuration of the Stub area changes. - Received Invalid DD Packet: indicates that invalid DD packets are received. - Not Received DD during RouterDeadInterval: indicates that no DD packet is received during the time when the Dead timer starts. - M,I,MS bit or SequenceNum Incorrect: indicates that the M, I, and MS bits do not comply with specifications in the protocol. - Unable Opaque Capability,Find 9,10,11 Type Lsa: indicates that Type9, Type10, and Type11 LSAs are received and Opaque capability is disabled. - Not NSSA,Find 7 Type Lsa in Summary List: indicates that this area is not an NSSA area and Type7 LSAs are found in the summary table. - LSrequest Packet,Unknown Reason: indicates that LSR packets are received with the reason unknown. - NSSA or STUB Area,Find 5 ,11 Type Lsa: indicates that this area is an NSSA or Stub area and Type5 and Type11 LSAs are found. - LSrequest Packet,Request Lsa is Not in the Lsdb: indicates that the neighbor sends an LSR to this process or area to request an LSA and this LSA does not exist in the LSDB of this process. - LSrequest Packet, exist same lsa in the Lsdb: indicates that this process receives an LSA that is same as that in the LSDB and the LSA is found in the request list of the neighbor. - LSrequest Packet, exist newer lsa in the Lsdb: indicates that this process receives a new LSA that exists in the local LSDB and the LSA is found in the request list of the neighbor. - Neighbor state was not full when LSDB overflow: indicates that the LSDB overflows and the neighbor state machine is not Full. - Filter LSA configuration change: indicates that the configuration of LSA filter changes. - ACL changed for Filter LSA: indicates that the ACL configuration of LSA filter changes.

Item	Description
	- Reset Ospf Peer: indicates that the OSPF neighbor is restarted.
Down Time	Time when the neighbor went Down.

7.4.31 display ospf request-queue

Function

The **display ospf request-queue** command displays the OSPF request list.

Format

display ospf [*process-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies the interface type and number.	-
neighbor-id	Specifies the neighbor's router ID.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output helps you troubleshoot OSPF faults.

Example

Display the OSPF request list.

```
<HUAWEI> display ospf request-queue
 OSPF Process 1 with Router ID 10.1.1.1
 OSPF Request List
  The Router's Neighbor is Router ID 10.4.4.4         Address 172.16.4.2
  Interface 172.16.4.1        Area 0.0.0.2
  Request list:
```

```
     Type       LinkState ID      AdvRouter         Sequence   Age
     Router     10.1.1.1          10.1.1.1         8000001b    677
```

Table 7-52 Description of the **display ospf request-queue** command output

Item	Description
The Router's Neighbor is Router ID	Router ID of the neighbor.
Address	IP address of the neighboring interface.
Interface	IP address of the interface.
Area	Area to which the local device belongs.
Request list	Request list.
Type	LSA type: Router LSA, network LSA, network summary LSA, ASBR summary LSA, AS external LSA, NSSA LSA, and opaque LSA
LinkState ID	Link state ID in the LSA header.
AdvRouter	Advertising router in the LSA header.
Sequence	Sequence number in the LSA header.
Age	Aging time in the LSA header.

7.4.32 display ospf retrans-queue

Function

The **display ospf retrans-queue** command displays the OSPF retransmission list.

Format

display ospf [*process-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*] [**low-level-of-retrans-times-range** *min-time*] [**high-level-of-retrans-times-range** *max-time*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies the interface type and number.	-
neighbor-id	Specifies the neighbor's router ID.	It is in dotted decimal notation.

Parameter	Description	Value
low-level-of-retrans-times-range *min-time*	Specifies the minimum number of allowed LSA retransmission.	The value is an integer ranging from 0 to 65535.
high-level-of-retrans-times-range *max-time*	Specifies the maximum number of allowed LSA retransmission.	The value is an integer ranging from 1 to 65535.

Usage Guidelines

The command output helps you troubleshoot OSPF faults.

Example

Display the OSPF retransmission list.

```
<HUAWEI> display ospf retrans-queue

        OSPF Process 1 with Router ID 10.1.1.1
                OSPF Retransmit List

  The Router's Neighbor is Router ID 10.2.2.2  Address 192.168.0.2
  Interface 192.168.0.1      Area 0.0.0.0
  Retransmit list:
       Type       LinkState ID      AdvRouter         Sequence   Age
       Router     10.1.1.1          10.1.1.1          80000002   533
```

Table 7-53 Description of the **display ospf retrans-queue** command output

Item	Description
The Router's Neighbor	Basic information about the neighboring switch.
Router ID	Router ID of the neighbor.
Address	IP address of the neighboring interface.
Interface	IP address of the interface.
Area	Area ID.
Retransmit List	Retransmission list.

Item	Description
Type	LSA type: Router LSA, network LSA, network summary LSA, ASBR summary LSA, AS external LSA, NSSA LSA, and opaque LSA
LinkState ID	Link state ID in the LSA header.
AdvRouter	Advertising router in the LSA header.
Sequence	Sequence number in the LSA header.
Age	Aging time in the LSA header.

7.4.33 display ospf routing

Function

The **display ospf routing** command displays an OSPF routing table.

Format

display ospf [*process-id*] **routing router-id** [*router-id*]

display ospf [*process-id*] **routing** [*ip-address* [*mask* | *mask-length*]] [**interface** *interface-type interface-number*] [**nexthop** *nexthop-address*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
router-id *router-id*	Specifies the router ID of a destination router.	The value is in dotted decimal notation.
ip-address	Specifies an IP address.	The value is in dotted decimal notation.
mask	Specifies a subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length.	The value is an integer ranging from 0 to 32.

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface.	-
nexthop *nexthop-address*	Displays the route with a specified next hop IP address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

By using this command with different parameters, you can view the routes of a specified interface or next hop.

The command output helps you troubleshoot OSPF faults.

Example

Display the OSPF routing table.

```
<HUAWEI> display ospf routing
         OSPF Process 1 with Router ID 10.2.2.9
                  Routing Tables

 Routing for Network
 Destination        Cost  Type       NextHop         AdvRouter       Area
 10.12.12.0/24      1     Transit    10.12.12.10     10.2.2.9        0.0.0.1
 10.13.13.0/24      1     Stub       10.13.13.1      10.2.2.9        0.0.0.0
 10.11.11.0/24      2     Transit    10.12.12.11     10.0.0.1        0.0.0.1

 Routing for ASEs
 Destination        Cost      Type       Tag      NextHop         AdvRouter
 10.0.0.0/8         1         Type2      1        10.12.12.11     10.0.0.1

 Total Nets: 4
 Intra Area: 3  Inter Area: 0  ASE: 1  NSSA: 0
```

Table 7-54 Description of the **display ospf routing** command output

Item	Description
Destination	Destination network.
Cost	Cost of the route to the destination address.

Item	Description

Type	- Type 1 external route:
	When the cost of external routes equals that of AS internal routes, and can be compared with the cost of OSPF routes, these external routes have a high reliability and can be configured as Type 1 external routes.
	- Type 2 external route:
	When the cost of the routes from an ASBR to the destination outside an AS is much greater than the cost of the internal routes to the ASBR, these external routes have a low reliability and can be configured as Type 2 external routes.
	Type of the destination network:
	- Inter-area: indicates inter-area routes.
	- Intra-area: indicates intra-area routes.
	  – Stub: indicates the routes advertised by router LSAs, which correspond to the direct routes of non-broadcast and non-NBMA networks.
	  – Transit: indicates the routes advertised by network LSAs.

NextHop	Next hop address to the destination address.
AdvRouter	Device that advertises LSAs.
Area	Area ID.
Tag	Tag of the external route.
Total Nets	Total number of networks in an area, between areas, in ASE areas, and in NSSAs.
Intra Area	Total number of intra-area networks (that is, stub networks and transit networks).
Inter Area	Total number of inter-area networks.
ASE	Total number of networks in the ASE area.
NSSA	Total number of networks in the NSSA.

7.4.34 display ospf sham-link

Function

The **display ospf sham-link** command displays the sham links of an OSPF area.

If no OSPF process ID or area ID is specified, all sham links are displayed.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

display ospf [*process-id*] **sham-link** [**area** *area-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the ID of an OSPF area.	The value is an integer ranging from 0 to 4294967295 or in the IPv4 address format.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospf sham-link** command to check information about the sham links of an OSPF area. The information helps determine the establishment of sham links.

Example

Display all OSPF sham links.

```
<HUAWEI> display ospf sham-link
          OSPF Process 100 with Router ID 10.1.1.2
 Sham Link:
 Area       NeighborId     Source-IP      Destination-IP   State   Cost
 0.0.0.1    10.1.1.2       10.3.3.3       10.5.5.5         P-2-P   10
```

Display the OSPF sham link of Area 1.

```
<HUAWEI> display ospf sham-link area 1
         OSPF Process 100 with Router ID 10.1.1.2
  Sham-Link: 10.3.3.3 --> 10.5.5.5
  Neighbor ID: 10.1.1.2,    State: Full
  Area: 0.0.0.1
  Cost: 10  State: P-2-P, Type: Sham
  Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
```

Table 7-55 Description of the **display ospf sham-link** command output

Item	Description
Area	OSPF area that the sham link belongs to.
NeighborId	Neighbor ID of the switch.
Source-IP	Source IP address of the sham link.
Destination-IP	Destination IP address of the sham link.
State	Interface status of the sham link. P-2-P indicates the point-to-point link.
Cost	Cost of the sham link.
Type	Connection type.
Timers	Information about the following items: the interval for sending Hello messages, Dead time, retransmission interval, and transmission delay on the interface.

7.4.35 display ospf spf-statistics

Function

The **display ospf spf-statistics** command displays route calculation statistics in OSPF processes.

Format

display ospf [*process-id*] **spf-statistics** [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no OSPF process ID is specified, brief information about route calculation statistics in all processes is displayed.	The value is an integer ranging from 1 to 65535.

Parameter	Description	Value
verbose	Displays detailed information about route calculation statistics.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display ospf spf-statistics** command displays route calculation statistics in OSPF processes, including the time when route calculation occurs, cause of route calculation, and number of changed routes.

When identifying the cause of OSPF route flapping, you can run this command to obtain OSPF route calculation statistics, and then identify the cause according to the command output.

Example

Display brief information about route calculation statistics in OSPF process 1.

```
<HUAWEI> display ospf 1 spf-statistics

          OSPF Process 1 with Router ID 10.2.2.2
Routing table change statistics:
Date          Time           Intra       Inter    External    Reason
2008-08-14    10:17:16        17          17       17          LSA
2008-08-14    09:16:47        77          62       127          Other
2008-08-14    08:16:37        0          0        0          LSA
2008-08-14    07:04:40        24          230      108          LSA
2008-08-14    06:03:15        204          230      18          Other
2008-08-14    05:02:55        34          236      128          LSA
2008-08-14    04:01:49        54          130      158          LSA
2008-08-14    03:01:48        44          220      138          LSA
2008-08-14    02:01:43        22          233      158          LSA
2008-08-14    01:00:53        977          897      907          LSA
```

Table 7-56 Description of the **display ospf spf-statistics** command output

Item	Description
Date	Date when route calculation occurs.
Time	Time when route calculation occurs.
Intra	Number of intra-area routes in the routing table, which are changed because of route calculation.
Inter	Number of inter-area routes in the routing table, which are changed because of route calculation.

Item	Description
External	Number of external routes in the routing table, which are changed because of route calculation.
Reason	Cause of route calculation: - LSA: indicates that route calculation is caused by LSAs. - Other: indicates that route calculation is caused by other causes. For example, the configuration changes; or the interface goes Down.

Display detailed information about route calculation statistics in OSPF process 1.

```
<HUAWEI> display ospf 1 spf-statistics verbose

          OSPF Process 1 with Router ID 10.10.10.2
Routing table change statistics:

```

Table 7-57 Description of the **display ospf spf-statistics verbose** command output

Item	Description
Time	Date and time when route calculation occurs.
Intra	Number of intra-area routes in the routing table, which are added and deleted because of route calculation.
Inter	Number of inter-area routes in the routing table, which are added and deleted because of route calculation.
External	Number of external routes in the routing table, which are added and deleted because of route calculation.

Item	Description
The reason of calculation is	Cause of route calculation: ● LSA: indicates that route calculation is caused by LSAs. ● Other: indicates that route calculation is caused by other causes. For example, the configuration changes; or the interface goes Down.
No.	Sequence number of the LSA that causes route calculation, which ranges from 1 to 10.
Type	Type of the LSA that causes route calculation, including Router, Network, Sum-Net, External, and NSSA.
LS ID	Link state ID of the LSA that causes route calculation.
Adv Router	Router ID of the switch that generates the LSA that causes route calculation.

7.4.36 display ospf statistics updated-lsa

Function

The **display ospf statistics updated-lsa** command displays the frequent updates of the LSAs that the LSDB receives.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

display ospf [*process-id*] **statistics updated-lsa** [**originate-router** *advertising-router-id* | **history**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If no OSPF process ID is specified, this command displays brief information about the route calculation statistics in all processes.	The value is an integer ranging from 1 to 65535.
originate-router	Specifies the link status of the advertising switch.	-
advertising-router-id	Specifies the ID of the advertising switch.	The value is in dotted decimal notation
history	Specifies the change history of LSAs that the LSDB receives.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

The **display ospf statistics updated-lsa** command displays the frequent updates of LSAs, facilitating the location of the cause for a routing flapping.

- If the **history** parameter is not configured, the **display ospf statistics updated-lsa** command only displays the updates of LSAs within the latest hour.
- If the **history** parameter is configured, the **display ospf statistics updated-lsa** command displays the change history of LSAs within the last 24 hours.

Precautions

- If you run the **reset ospf** command to restart the OSPF process, the real-time and historical statistics on the process will be cleared.
- The **display ospf statistics updated-lsa** command is used only to display the frequent updates of LSAs. The updated LSAs are compared with the LSAs in the local LSDB, and those with the **age** greater than 900 will not be displayed except those with the **age** of 3600.

Example

Display the LSA updates within the last one hour.

```
<HUAWEI> display ospf statistics updated-lsa
          OSPF Process 1 with Router ID 10.1.1.1
               Statistics of Received LSAs

 Begin time: 2011-04-25 11:37:32

7.4.37 display ospf vlink

Function

The **display ospf vlink** command displays OSPF virtual links.

Format

display ospf [*process-id*] **vlink**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output helps you troubleshoot OSPF faults.

Example

Display OSPF virtual links.

```
<HUAWEI> display ospf vlink
          OSPF Process 1 with Router ID 10.1.1.1
                  Virtual Links
 Virtual-link Neighbor-id  -> 10.2.2.2, Neighbor-State: Full
 Interface: 10.1.1.1 (Vlanif10)
 Cost: 1  State: P-2-P  Type: Virtual
 Transit Area: 0.0.0.1
 Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
 GR State: Normal
```

Table 7-61 Description of the **display ospf vlink** command output

Item	Description
Virtual-link Neighbor-id	ID of the neighboring switch that is connected through the virtual link.
Neighbor-State	Neighbor status, such as Down, Init, 2-Way, ExStart, Exchange, Loading, and Full.
Interface	Information about interfaces in the area, that is, IP address and name of the primary interface (If the interface is a serial interface, **Unknown** is displayed.)
Cost	Cost.
State	Interface status.
Type	Interface type.
Transit Area	Transit area ID if the current interface is a virtual link.
Timers	Information about the following items: the interval for sending Hello messages, Dead time, retransmission interval, and transmission delay on the interface.
GR State	GR status: ● Normal: indicates that a switch is in the Normal state and does not perform GR. ● Doing GR: indicates that a switch is performing GR. ● Complete GR: indicates that a switch finishes GR. ● Helper: indicates that the neighbor is the Helper when a switch is performing GR.

7.4.38 dn-bit-set

Function

The **dn-bit-set disable** command disables OSPF from setting the DN bit in LSAs.

The **undo dn-bit-set disable** command enables OSPF to set the DN bit in LSAs.

By default, OSPF is enabled to set the DN bit in LSAs.

Format

dn-bit-set disable { **summary** | **ase** | **nssa** }

undo dn-bit-set disable { **summary** | **ase** | **nssa** }

Parameters

Parameter	Description	Value
summary	Specifies that the DN bit is not set in summary LSAs.	-
ase	Specifies that the DN bit is not set in ASE LSAs.	-
nssa	Specifies that the DN bit is not set in NSSA LSAs.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **dn-bit-set disable** command can be used in the following scenarios:

- In the VPN option A scenario, the local PE imports BGP routes to generate LSAs and advertise the generated LSAs to the peer PE. According to RFC 4577, setting of the DN bit is restricted. The peer PE may fail to calculate a route. In this situation, the **dn-bit-set disable** command can be used to set the DN bit on or remove the setting of the DN bit from the local PE.
- When a PE is connected to an MCE, the MCE needs to calculate routes advertised by the PE. By default, the MCE does not check the DN bit. In this situation, the **dn-bit-set disable** command can be used to set the DN bit on or remove the setting of the DN bit from the local PE.

NOTE

To prevent routing loops, the OSPF multi-instance process uses a bit as a flag. The bit is called DN bit.

Configuration Impact

When the **dn-bit-set disable** command is used to disable OSPF from setting the DN bit in LSAs, routing loops may occur. If the parameter **ase** or **nssa** is specified, the DN bit in ASE LSAs or NSSA LSAs is not set. You can use the **route-tag** command to set the same tag value to prevent routing loops. Therefore, it is recommended that the **dn-bit-set disable** command be used in only the scenarios specified in **Usage Scenario**.

If the **dn-bit-set disable ase** command is configured, the DN bit is not set in type 5 LSAs that are converted from type 7 LSAs even if the DN bit is set in type 7 LSAs.

Precautions

The **dn-bit-set disable** command can be configured for only private OSPF processes. The configuration of this command takes effect only on the PEs.

The **dn-bit-check disable** command can be used to control whether OSPF running on the peer PE checks the DN bit when calculating routes.

Example

Disable OSPF from setting the DN bit in ASE LSAs.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv4] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospf 100 vpn-instance test
[HUAWEI-ospf-100] dn-bit-set disable ase
```

7.4.39 dn-bit-check

Function

The **dn-bit-check disable** command disables OSPF from checking the DN bit in LSAs.

The **undo dn-bit-check disable** command enables OSPF to check the DN bit in LSAs.

By default, OSPF is enabled to check the DN bit in LSAs.

Format

dn-bit-check disable { **summary** [**router-id** *router-id*] | **ase** | **nssa** }

undo dn-bit-check disable { **summary** [**router-id** *router-id*] | **ase** | **nssa** }

Parameters

Parameter	Description	Value
summary	Specifies that the DN bit in summary LSAs is not checked.	-
router-id *router-id*	Specifies the ID of a device on which the DN bit in summary LSAs is checked.	-
ase	Specifies that the DN bit in ASE LSAs is not checked.	-
nssa	Specifies that the DN bit in NSSA LSAs is not checked.	-

Views

OSPF view

Usage Guidelines

Usage Scenario

In the VPN option A scenario, the local PE imports BGP routes to generate LSAs and advertise the generated LSAs to the peer PE. According to RFC 4577, setting of the DN bit is restricted. The peer PE may fail to calculate a route. In this situation, you need to use the **dn-bit-check disable** command to disable OSPF from checking the DN bit in LSAs.

NOTE

To prevent routing loops, the OSPF multi-instance process uses a bit as a flag. The bit is called DN bit.

Configuration Impact

When the **dn-bit-check disable** command is run, routing loops may occur. If the parameter **ase** or **nssa** is specified, the DN bit in ASE LSAs or NSSA LSAs is not checked. You can use the **route-tag** command to set the same tag value to prevent routing loops. Therefore, run the **dn-bit-check disable** command only in the scenario specified in **Usage Scenario**.

Precautions

When a PE is connected to an MCE, the MCE does not check the DN bit by default.

The **dn-bit-check disable** command can be configured only for private OSPF processes. The configuration of this command takes effect only on the PEs.

In this scenario, you can run the **dn-bit-set disable** command to set the DN bit on or remove the setting of the DN bit from the local PE.

Example

Disable OSPF from checking the DN bit in summary LSAs.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv4] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospf 100 vpn-instance test
[HUAWEI-ospf-100] dn-bit-check disable summary router-id 10.1.1.1
```

7.4.40 domain-id (OSPF)

Function

The **domain-id** command sets an ID for an OSPF domain.

The **undo domain-id** command restores the default setting.

By default, the domain ID is null.

Format

domain-id { **null** | *domain-id* [**type** *type* **value** *value* | **secondary**] * }

undo domain-id [*domain-id* [**type** *type* **value** *value*]]

Parameters

Parameter	Description	Value
domain-id	Specifies the ID of an OSPF domain.	The value can be an integer or in dotted decimal notation. ● If it is an integer, the value ranges from 0 to 4294967295, and it is converted to dotted decimal notation when the ID is displayed. ● If it is in dotted decimal notation, it is displayed as entered.
null	Indicates that the OSPF domain ID is null.	-
type *type*	Specifies the type of the OSPF domain ID.	It can be 0005, 0105, 0205, or 8005. By default, it is 0005.
value *value*	Specifies the value of the type of the OSPF domain ID.	The value is a hexadecimal number that ranges from 0x0 to 0xffff, and the default value is 0x0.
secondary	Indicates the ID of a secondary domain.	The maximum number of **domain-id secondary** in each OSPF process is 1000.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Domain IDs are used to identify domains.

If the local OSPF area and an OSPF area of a remote VPN attempts to exchange Type 3 LSAs, the two areas must be in the same OSPF domain. You can run the **domain-id** command to configure the same domain ID for the two OSPF areas.

The routes that are imported from a PE switch are advertised using External-LSAs. The routes destined for different nodes in the same OSPF domain are advertised based on Type 3 LSAs. This requires that the nodes in the same OSPF domain be configured with the same domain ID.

If the **undo domain-id** command without any parameter is executed, the primary domain ID will be deleted.

NOTE

OSPF direct routes to the PE do not carry the domain ID, while BGP direct routes to the PE carry the domain ID.

Configuration Impact

Before sending routes to a remote CE switch, a PE switch sends Type 3 LSAs or Type 5 LSAs to the CE based on domain ID. If local domain IDs are the same as or compatible with remote domain IDs in BGP routes, the PE advertises Type 3 routes. If local domain IDs are different from or incompatible with remote domain IDs in BGP routes, the PE advertises Type 5 routes.

Precautions

- Each OSPF domain has one or multiple domain IDs. One of them is a primary ID and the others are secondary IDs.
- If an OSPF instance does not have a specific domain ID, its ID is considered as null.
- If the value of the domain ID is 0, **secondary** cannot be configured.
- The maximum number of **domain-id secondary** items configured in an OSPF process is 1000.
- The **domain-id** command is forbidden in public networks.

Example

Set an OSPF domain ID.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] domain-id 234
```

7.4.41 eca-route-type compatible

Function

The **eca-route-type compatible** command sets the route type of the extended community attribute of OSPF VPN to 0x8000.

The **undo eca-route-type compatible** command restores the route type of the extended community attribute of OSPF VPN to 0x0306.

By default, the route type of the extended community attribute of OSPF VPN is 0x0306.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

eca-route-type compatible

undo eca-route-type compatible

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **eca-route-type compatible** command is used in OSPF VPN scenarios.

- For the switch supporting RFC 4577, you can set the route type of the extended community attribute of OSPF VPN to 0x0306 and configure the switch to identify both 0x0306 and 0x8000 route types.
- For the switch that does not support RFC 4577, you can set the route type of the extended community attribute of OSPF VPN to 0x8000 and configure the switch to identify only the 0x8000 route type.

The **eca-route-type compatible** command enables different switches to communicate with each other and avoid the failure in parsing the route type because the route type of the extended community attribute of OSPF VPN is unrecognized.

Precautions

The **eca-route-type compatible** command is forbidden in public network.

Example

Set the route type of the extended community attribute of OSPF VPN to 0x8000.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv4] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospf 1 vpn-instance test
[HUAWEI-ospf-1] eca-route-type compatible
```

7.4.42 enable log

Function

The **enable log** command enables the logging function.

The **undo enable log** command disables the logging function.

By default, the logging function is disabled.

Format

enable log [**config** | **error** | **state** | **snmp-trap**]

undo enable log [**config** | **error** | **state** | **snmp-trap**]

Parameters

Parameter	Description	Value
config	Enables the configuration log.	-
state	Enables the state log.	-
error	Enables the error log.	-
snmp-trap	Enables the SNMP trap log.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Running the **enable log** command can enable the logging function. You can view running status of devices based on logs, facilitating device maintenance.

If the **undo enable log** command is executed, the logging function will be disabled. Then, running status of devices will be not displayed. This is inconvenient for network maintenance.

Precautions

Configuring different parameters in the **enable log** command can display different log information. If no parameter is not specified, the command output displays all log information.

Example

Enable the OSPF logging function.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] enable log
```

7.4.43 filter export (OSPF Area)

Function

The **filter export** command filters the outgoing Type3 LSAs of the local area.

The **undo filter export** command restores the default setting.

By default, the outgoing Type3 LSAs of the local area are not filtered.

Format

filter { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } **export**

undo filter [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name*] **export**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The command can be used to filter out invalid LSAs sent to neighbors to reduce the size of the LSDB and speed up network convergence.

Configuration Impact

After filtering conditions are set for the outgoing summary LSAs to be advertised using the **filter export** command, only the outgoing Type3 LSAs that pass the filtering can be advertised.

Precautions

- The command can be configured only on an ABR.
- For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule takes effective only when the source address range is specified by the **source** parameter and the time period is specified by the **time-range** parameter.
- Run the **filter import** command to set filtering conditions for the incoming Type3 LSAs to be advertised.
- Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, OSPF advertises all Type 3 LSAs.
- Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, OSPF advertises all Type 3 LSAs.

Example

Configure OSPF to filter outgoing Type 3 LSAs.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] area 1
[HUAWEI-ospf-1-area-0.0.0.1] filter 2000 export
```

7.4.44 filter import (OSPF Area)

Function

The **filter import** command filters the incoming Type3 LSAs of the local area.

The **undo filter import** command restores the default setting.

By default, the incoming Type3 LSAs are not filtered.

Format

filter { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } **import**

undo filter [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name*] **import**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the name of an ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPF area view

2: Configuration level

Usage Guidelines

Usage Scenario

After filtering conditions are set for the incoming summary LSAs to be advertised using the **filter import** command, only the incoming Type3 LSAs that pass the filtering can be received.

Configuration Impact

The command can be used to filter out invalid LSAs sent to neighbors to reduce the size of the LSDB and speed up network convergence.

Precautions

- The command can be configured only on an ABR.
- For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule takes effect only when the source address range is specified by the **source** parameter and the time period is specified by the **time-range** parameter.
- Run the **filter export** command to set filtering conditions for the outgoing Type3 LSAs to be advertised.
- Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, OSPF receives all Type 3 LSAs.
- Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, OSPF receives all Type 3 LSAs.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all the routes learned by the specified protocol are imported to the OSPF routing table.

Example

Configure an ABR to filter incoming Type 3 LSAs of the area where the ABR resides.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] filter ip-prefix my-prefix-list import
```

7.4.45 filter-lsa-out peer

Function

The **filter-lsa-out peer** command configures a switch to filter the LSAs that are sent by specified neighbors on a P2MP network.

The **undo filter-lsa-out peer** command cancels the configuration.

By default, the LSAs that are sent by specified neighbors on a P2MP network are not filtered.

Format

filter-lsa-out peer *ip-address* { **all** | { **summary** [**acl** { *acl-number* | *acl-name* }] | **ase** [**acl** { *acl-number* | *acl-name* }] | **nssa** [**acl** { *acl-number* | *acl-name* }] } * }

undo filter-lsa-out peer *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a P2MP neighbor. This parameter is configured by the neighbor using the **ip address** command.	The value is in dotted decimal notation.
all	Filters all the outgoing LSAs except Grace LSAs.	-
summary	Filters the outgoing network summary LSAs (Type 3).	-
acl *acl-number*	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ase	Filters the outgoing AS external LSAs (Type 5).	-
nssa	Filters the outgoing NSSA LSAs (Type 7).	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a P2MP network, when multiple P2MP links exist between two devices, you can configure the local device to filter the outgoing LSAs on the specified link. This reduces unnecessary LSA retransmission attempts and saves bandwidth resources.

For an ACL, when the **rule** command is used to configure filtering rules, only the source address range that is specified by the **source** parameter and the period of time that is specified by the **time-range** parameter take effect.

Prerequisites

OSPF does not regard a network as a P2MP network by default regardless of any link layer protocol. A P2MP network is forcibly changed from the network of another type using the **ospf network-type p2mp** command.

Configuration Impact

This command is valid for all the interfaces of the OSPF process.

Follow-up Procedure

Configure a device to filter the outgoing LSAs on the specified OSPF interface by using the **ospf filter-lsa-out** command.

Example

On a P2MP network, configure a switch to filter all the LSAs (except Grace LSAs) sent to neighbor 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] filter-lsa-out peer 10.1.1.1 all
```

7.4.46 filter-policy export (OSPF)

Function

The **filter-policy export** command filters the imported routes when these routes are advertised based on a filtering policy.

The **undo filter-policy export** command restores the default setting.

By default, the imported routes to be advertised are not filtered.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*]]

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name*] **export** [*protocol* [*process-id*]]

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol process-id	Filters imported routes of a specified protocol. The value can be **direct**, **rip**, **isis**, **bgp**, **ospf**, **unr**, or **static**. When the routing protocol is RIP, IS-IS, or OSPF, you can specify a process ID.	The value is an integer that ranges from 1 to 65535. The default value is 1.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After OSPF imports external routes using the **import-route** command, you can use the **filter-policy export** command to filter the imported routes to be advertised. Only the external routes that pass the filtering can be converted into AS-external LSAs and advertised.

The *protocol* or *process-id* parameter can be specified to determine a specified protocol or process. If the *protocol* or *process-id* parameter is not specified, OSPF filters all imported routes.

Precautions

- This command can be configured only on ASBRs because AS-external-LSAs are generated by ASBRs.
- For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule takes effective only when the source address range is specified

by the **source** parameter and the time period is specified by the **time-range** parameter.

- Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all external routes imported to OSPF are converted to Type 5 LSAs (AS-external-LSAs) or Type 7 LSAs (NSSA-external-LSAs) and then are advertised to neighbors.
- Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all external routes imported to OSPF are converted to Type 5 LSAs (AS-external-LSAs) or Type 7 LSAs (NSSA-external-LSAs) and then are advertised to neighbors.

Example

Filter the routes that are imported from RIP and advertised by OSPF based on a filtering policy.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] import-route rip
[HUAWEI-ospf-100] filter-policy 2000 export
```

7.4.47 filter-policy import (OSPF)

Function

The **filter-policy import** command configures a filtering policy to filter routes received by OSPF.

The **undo filter-policy import** command restores the default setting.

By default, OSPF does not filter received routes.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* [**secondary**] } **import**

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* [**secondary**]] **import**

Parameters

Parameter	Description	Value
acl-number	Specifies the basic ACL number.	The value is an integer ranging from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of an address prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of the route policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
secondary	Selects a secondary route.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **filter-policy import** command is used to set a filtering policy for received routes. Only the routes that pass the filtering can be added to the routing table. The routes that fail to pass the filtering cannot be added to the routing table but can be advertised.

The OSPF routing information is recorded in the LSDB. Instead of filtering the received or sent LSAs, the device filters routes calculated by OSPF using the **filter-policy import** command.

Precautions

For an ACL configured using the **acl** command, when the **rule** command is used to configure a filtering rule, the filtering rule takes effect only when the source address range is specified by the **source** parameter and the time period is specified by the **time-range** parameter.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes received by OSPF are delivered to the IP routing table.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all routes received by OSPF are delivered to the IP routing table.

Example

Configure OSPF to filter received routes.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] filter-policy 2000 import
```

7.4.48 flooding-control

Function

The **flooding-control** command restricts the flooding of updated LSAs.

The **undo flooding-control** command cancels the restriction on the flooding of updated LSAs.

By default, this function is enabled when the number of neighbors exceeds 256.

Format

flooding-control [**number** *transmit-number* | **timer-interval** *transmit-interval*] *

undo flooding-control [**number** | **timer-interval**] *

Parameters

Parameter	Description	Value
number *transmit-number*	Sets the number of updated LSAs to be flooded each time.	The value is an integer ranging from 1 to 1000. By default, the value is 50.
timer-interval *transmit-interval*	Sets the interval for flooding updated LSAs.	The value is an integer that ranges from 30 to 100000, in milliseconds. By default, the value is 30.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple neighbors are configured or a large number of updated LSAs are flooded, a switch may receive a large number of updated LSAs in a short period. If the switch is busy processing these update packets and discards the Hello packets that maintain neighbor relationships, neighbor relationships may be interrupted. During the reestablishment of neighbor relationships, more packets need to be exchanged, which deteriorates the processing of packets.

To avoid the preceding problem, you can run the **flooding-control** command to restrict the flooding of updated LSAs to keep stable neighbor relationships.

Configuration Impact

After the **flooding-control** command is run, the flooding of updated LSAs is immediately restricted.

Precautions

By default, a switch spends 50 ms in flooding updated LSAs each time. If not all the updated LSAs are flooded within 50 ms, the switch floods the remaining LSAs after the time specified by *transmit-interval*.

Example

Set the number of updated LSAs to be flooded each time to 100.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] flooding-control number 100
```

7.4.49 frr (OSPF)

Function

The **frr** command creates and then displays the OSPF FRR view.

The **undo frr** command deletes the OSPF FRR view.

By default, the OSPF FRR view does not exist.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Format

frr

undo frr

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPF IP FRR allows devices to fast switch traffic from faulty links to back up links without interrupting traffic. This function protects traffic and greatly improves the reliability of OSPF networks. OSPF IP FRR must be configured in the OSPF FRR view. The **frr** command run in the OSPF view creates and displays the OSPF FRR view.

Follow-up Procedure

The **frr** command run in the OSPF view creates and displays the OSPF FRR view only, but cannot enable the OSPF IP FRR function. Run the **loop-free-alternate** command in the OSPF view to enable OSPF IP FRR to create the loop-free backup route.

Example

Create and display the OSPF FRR view.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] frr
[HUAWEI-ospf-1-frr]
```

7.4.50 frr-policy route (OSPF)

Function

The **frr-policy route** command configures a filtering policy for the OSPF IP FRR backup routes. The filtering policy determines what kind of OSPF backup route can be added to the routing table.

The **undo frr-policy route** command cancels the filtering function.

By default, the filtering function is disabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

frr-policy route route-policy *route-policy-name*

undo frr-policy route

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of the policy used to filter OSPF backup routes.	The value must be an existing route-policy.

Views

OSPF FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPF IP FRR allows devices to fast switch traffic on fault links to back up links without interrupting traffic. This protects traffic and greatly improves the reliability of OSPF networks.

After the filtering policy is configured using the **frr-policy route** command, only the OSPF backup route that satisfies filtering rules can be delivered to the forwarding table.

Configuration Impact

To protect the traffic over a specific OSPF route, you can configure a filtering policy *route-policy-name* that the OSPF route matches to ensure that the backup route can be added to the forwarding table. When this route fails, OSPF can fast switch the traffic to a backup route.

Precautions

The **frr-policy route** command is cyclic in nature, and only the latest configuration takes effect.

If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, OSPF adds all backup routes to the IP routing table.

Example

Configure OSPF to add the OSPF backup routes that match the named ACL **abc** to the IP routing table.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] frr
[HUAWEI-ospf-1-frr] loop-free-alternate
[HUAWEI-ospf-1-frr] frr-policy route route-policy abc
```

7.4.51 frr-priority static low

Function

The **frr-priority static low** command enables dynamic backup links to take preference over static backup links so that the LFA algorithm is used to calculate the nexthop and outbound interface.

The **undo frr-priority static** command disables this function.

By default, this function is disabled, static backup links take preference over dynamic backup links during route selection.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

frr-priority static low

undo frr-priority static

Parameters

None

Views

OSPF FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The nexthop and outbound interface of an OSPF loop-free backup link can be obtained using either of the following methods:

- For a static backup link, after IP FRR is enabled using the **ip frr** command in the system view or VPN instance view, configure a nexthop and an outbound interface for the static backup link.
- For a dynamic backup link, after OSPF IP FRR is enabled using the **loop-free-alternate** command, enable the device to use the LFA algorithm to calculate the nexthop and outbound interface for the dynamic backup link.

By default, static backup links take preference over dynamic backup links during route selection. However, static backup links are less flexible than dynamic backup links. If a link failure occurs, static backup links cannot update automatically, but dynamic backup links can. Therefore, to ensure automatic link updates, run the **frr-priority static low** command to enable dynamic backup links to take preference over static backup links so that the LFA algorithm is used to calculate the nexthop and outbound interface.

Prerequisites

The OSPF IP FRR view has been displayed using the **frr** command.

Example

Enable the device to use the LFA algorithm to calculate the backup nexthop and outbound interface.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] frr
[HUAWEI-ospf-1-frr] frr-priority static low
```

7.4.52 graceful-restart (OSPF)

Function

The **graceful-restart** command enables the GR function.

The **undo graceful-restart** command disables the GR function.

By default, OSPF GR is disabled.

Format

graceful-restart [**period** *period* | **planned-only** | **partial**] *

undo graceful-restart [**period** | **planned-only** | **partial**] *

Parameters

Parameter	Description	Value
period *period*	Specifies the duration of GR.	It is an integer ranging from 1s to 1800s. The default value is 120s.
planned-only	Indicates that the switch supports only the planned GR. By default, the switch supports both the planned GR and unplanned GR.	-
partial	Indicates that the switch partially supports the GR. By default, the switch totally supports the GR.	-

NOTE

Planned GR: indicates that a device manually restarts or performs a master/slave device switchover by using the command. Before the device restarts or performs a master/slave device switchover, Restarter will send a grace LSA.

Unplanned GR: indicates that a device restarts or performs a master/slave device switchover because of faults. A device directly performs a master/slave device switchover without sending a grace LSA, and then enters GR after the slave device goes Up. It is different from the planned GR.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent traffic interruption caused by route flapping after an active/standby switchover, you can run the **graceful-restart** command to enable OSPF GR. After the **graceful-restart** command is run to enable GR for a switch, the Helper function is also enabled.

Prerequisites

Opaque LSAs provide a generic mechanism for OSPF extension:

- OSPF supports GR using Type 9 LSAs.
- OSPF supports TE using Type 10 LSAs.

Before configuring OSPF GR, you must enable opaque LSA capability running the **opaque-capability enable** command.

Configuration Impact

After an OSPF process is restarted using GR, the Restarter switch and the Helper switch reestablish the neighbor relationship, exchange routing information, synchronize the LSDB, and update the routing table and forwarding table. This implements OSPF fast convergence, prevents traffic interruption, and stabilizes the network topology.

Precautions

If there are special requirements on the GR Helper, run the **graceful-restart helper-role** command to configure the requirements.

You are advised not to enable OSPF GR if BFD is enabled for a stack of fixed switches. This is because the time taken for smooth data switching during a master/standby switchover in the stack may be longer than the BFD timeout interval, in which situation BFD sessions go Down and OSPF GR fails.

Example

Enable OSPF GR and set the GR period to 200s.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] opaque-capability enable
[HUAWEI-ospf-1] graceful-restart period 200
```

7.4.53 graceful-restart helper-role (OSPF)

Function

The **graceful-restart helper-role** command configures a device as a GR helper.

The **undo graceful-restart helper-role** command cancels the configuration.

By default, the device does not function as a GR helper.

Format

graceful-restart [**period** *period* | **partial** | **planned-only**] * **helper-role** { [{ **ip-prefix** *ip-prefix-name* | **acl-number** *acl-number* | **acl-name** *acl-name* } | **ignore-external-lsa** | **planned-only**] * | **never** }

undo graceful-restart [**period** | **partial** | **planned-only**] * **helper-role** [[{ **ip-prefix** | **acl-number** | **acl-name** } | **ignore-external-lsa** | **planned-only**] * | **never**]

Parameters

Parameter	Description	Value
period *period*	Specifies the duration of GR.	The value is an integer that ranges from 1 to 1800, in seconds. The default value is 120.
planned-only	Configures the device to support only planned GR. By default, the device supports both the planned GR and unplanned GR.	-
partial	Configures the device to support partial GR. By default, the device supports totally GR.	-
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list. The name is a string.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
acl-number *acl-number*	Specifies the basic ACL number.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ignore-external-lsa	Indicates that the device does not check Type 5 and Type 7 LSAs.	-
planned-only	Indicates that the device supports only planned GR.	By default, the device supports both planned GR and unplanned GR.
never	Indicates that the device does not support the Helper mode.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an OSPF neighbor supports GR and can be a restarter, the current device needs to be set to helper mode, and the neighbor is assisted to complete the GR process.

After the **graceful-restart** command is run to enable GR for a switch, the Helper function is also enabled.

Prerequisites

OSPF supports GR using Type 9 LSAs. So before configuring GR, run the **opaque-capability enable** command to enable opaque LSA capability.

Example

Configure a device as an OSPF GR helper and configure the helper to support only planned GR.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] graceful-restart helper-role planned-only
```

7.4.54 gtsm default-action

Function

The **gtsm default-action** command sets the default action that is performed on the packets that do not match the GTSM policies.

The **undo gtsm default-action drop** command restores the default setting.

By default, the packets that do not match the GTSM policies can pass the filtering.

Format

gtsm default-action { **drop** | **pass** }

undo gtsm default-action drop

Parameters

Parameter	Description	Value
drop	Indicates that the packets that do not match the GTSM policies cannot pass the filtering. The packets are dropped.	-
pass	Indicates that the packets that do not match the GTSM policies can pass the filtering.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For a network demanding high security, you can configure Generalized TTL Security Mechanism (GTSM) to improve the security of the OSPF network. GTSM defends against attacks by checking the Time-to-Live (TTL) value. If an attacker simulates real OSPF packets and keeps sending them to a switch, a switch receives the packets and directly sends them to the main control board for OSPF processing, without checking the validity of the packets. In this case, the switch is busy in processing these packets, causing high usage of the CPU. GTSM function protects the switch by checking whether the TTL value in the IP packet header is in a pre-defined range to improve the system security.

GTSM only checks the TTL values of the packets that match the GTSM policy. The packets that do not match the GTSM policy can pass the filtering using the **undo gtsm default-action drop** command or using the **gtsm default-action** command to set the **pass** parameter, or be dropped after the **gtsm default-action** command is run to set the **drop** parameter.

Configuration Impact

If the default action to be taken on GTSM packets is drop, the connection cannot be established by the switch. Therefore, GTSM improves security but reduces the ease of use.

Precautions

You can enable the log function by using the **gtsm log drop-packet** command to record the information about dropped packets for further fault location.

If you configure the default action by using the **gtsm default-action** command but not configure GTSM policy (the **drop** or **pass** parameter), GTSM does not take effect.

Example

Set the default action performed on the packets that do not match the GTSM policies to **drop**.

```
<HUAWEI> system-view
[HUAWEI] gtsm default-action drop
```

Set the default action performed on the packets that do not match the GTSM policy to pass the filtering.

```
<HUAWEI> system-view
[HUAWEI] undo gtsm default-action drop
```

7.4.55 gtsm log drop-packet all

Function

The **gtsm log drop-packet** command configures a GTSM-capable switch to record logs when it drops packets.

The **undo gtsm log drop-packet** command configures a GTSM-capable switch not to record logs when it drops packets.

By default, a GTSM-capable switch does not record logs when dropping packets.

Format

gtsm log drop-packet all

undo gtsm log drop-packet all

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For a network demanding higher security, you can configure Generalized TTL Security Mechanism (GTSM) to improve the security of the OSPF network. GTSM defends against attacks by checking the Time-to-Live (TTL) value. If an attacker simulates real OSPF packets and keeps sending them to a device, an interface board on the device receives the packets and directly sends them to the main control board for OSPF processing, without checking the validity of the packets. In this case, the device is busy in processing these packets, causing high usage of the CPU. GTSM function protects the device by checking whether the TTL value in the IP packet header is in a pre-defined range to improve the system security.

GTSM only checks the TTL values of the packets that match the GTSM policy. The packets that do not match the GTSM policy can be allowed or dropped by using the **gtsm default-action** command.

You can also enable the logging function by using the **gtsm log drop-packet** command to record the information about dropped packets for further fault location.

Prerequisites

The **gtsm default-action drop** command has been run.

Example

Enable all GTSM-capable boards to record logs when they drop packets.

```
<HUAWEI> system-view
[HUAWEI] gtsm default-action drop
[HUAWEI] gtsm log drop-packet all
```

7.4.56 import-route (OSPF)

Function

The **import-route** command imports routes learned by other protocols.

The **undo import-route** command cancels the configuration.

By default, routes learned by other protocols are not imported.

Format

import-route { **limit** *limit-number* | { **bgp** [**permit-ibgp**] | **direct** | **unr** | **rip** [*process-id-rip*] | **static** | **isis** [*process-id-isis*] | **ospf** [*process-id-ospf*] } [**cost** *cost* | **type** *type* | **tag** *tag* | **route-policy** *route-policy-name*] * }

undo import-route { **limit** | **bgp** | **direct** | **unr** | **rip** [*process-id-rip*] | **static** | **isis** [*process-id-isis*] | **ospf** [*process-id-ospf*] }

NOTE

Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **bgp** [**permit-ibgp**] and **isis** [*process-id-isis*] parameter.

Parameters

Parameter	Description	Value
bgp	Specifies the BGP protocol whose routes are imported. **NOTE** If this parameter is specified, only EBGP routes can be imported; IBGP routes cannot be imported.	-
permit-ibgp	IBGP routes that are permitted to be imported. **NOTE** The import of IBGP routes may cause route loops. Therefore, this command must not be configured unless it is necessary.	-

Parameter	Description	Value
direct	Specifies the direct protocol whose routes are imported.	-
unr	Specifies the imported source routing protocol as **unr**. User Network Route (UNR) is allocated if dynamic routing protocols cannot be used when users are getting online.	-
rip	Specifies the RIP protocol whose routes are imported.	-
process-id-rip	Specifies the process ID of the protocol whose routes are imported.	The value is an integer ranging from 1 to 65535. The default value is 1.
static	Specifies the static protocol whose routes are imported.	-
isis	Specifies the IS-IS protocol whose routes are imported.	-
process-id-isis	Specifies the process ID of the protocol whose routes are imported.	The value is an integer ranging from 1 to 65535. The default value is 1.
ospf	Specifies the OSPF protocol whose routes are imported.	-
process-id-ospf	Specifies the process ID of the protocol whose routes are imported.	The value is an integer ranging from 1 to 65535. The default value is 1.
limit *limit-number*	The maximum number of external routes that can be imported into an OSPF process.	The value is an integer that ranges from 1 to 4294967295.
cost *cost*	Indicates the route cost.	The value is an integer ranging from 0 to 16777214. For details about the default value, see **default (OSPF)**.

Parameter	Description	Value
route-policy *route-policy-name*	Imports only the route that meets the requirements of the specified route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
tag *tag*	Specifies the tag of the external LSA.	The value is an integer ranging from 0 to 4294967295. For details about the default value, see **default (OSPF)**.
type *type*	Specifies the type of the external routes.	The value is an integer ranging from 1 to 2. For details about the default value, see **default (OSPF)**. ● 1: Type 1 external route ● 2: Type 2 external route

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Importing routes discovered by other routing protocols can enrich OSPF routing information.

OSPF routes are classified into the following types in the descending order of priorities:

- Intra-area routes: refer to the routes in an area within an autonomous system.
- Inter-area routes: refer to the routes between different areas of the same AS. Intra-area routes and area external routes are internal routes of an AS.
- Type 1 external routes: When the cost of external routes equals that of AS internal routes, and can be compared with the cost of OSPF routes, these external routes have a high reliability and can be configured as Type 1 external routes.
- Type 2 external routes: When the cost of the routes from an ASBR to the destination outside an AS is much greater than the cost of the internal routes

to the ASBR, these external routes have a low reliability and can be configured as Type 2 external routes.

On a non-PE device, only EBGP routes are imported after the **import-route bgp** command is configured. IBGP routes are also imported after the **import-route bgp permit-ibgp** command is configured. If IBGP routes are imported, routing loops may occur. To prevent loops, run the **preference (OSPF)** and **preference (BGP)** commands to specify preferences for OSPF and BGP routes. If IBGP routes need to be imported, run the **import-route bgp permit-ibgp** command, and run the **preference (OSPF)** and **preference (BGP)** commands to set the preference of OSPF ASE routes lower than that of IBGP routes (preference value of OSPF ASE routes larger than that of IBGP routes).

On a PE, configuring the **import-route bgp** command imports both EBGP routes and IBGP routes, regardless of whether the **import-route bgp permit-ibgp** command is configured or not. If the **import-route bgp permit-ibgp** command and the **default-route-advertise (OSPF)** command are both configured, the active IBGP default routes can be imported into OSPF.

Prerequisites

To import certain external routes using a route-policy, a route-policy must have been created using the **route-policy** command before running the **import-route** command.

Configuration Impact

After a route-policy is configured, the OSPF process imports only routes that satisfy certain conditions. This prevents devices from receiving unrequired routes.

Precautions

You can use the **default (OSPF)** command to configure default parameters for external routes imported by OSPF, including the cost, type (Type 1 or Type 2), tag, and number of routes.

NOTE

The **import-route (OSPF)** command cannot import the default route of an external protocol. To enable a device to advertise the default route of an external protocol it learns when updating the OSPF routing table to other devices within the area, run the **default-route-advertise (OSPF)** command.

After the **import-route direct** command is executed, routes to the network segment where the IP address of the management interface belongs are also imported in the OSPF routing table. Therefore, use this command with caution.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all the routes learned by the specified protocol are imported to the OSPF routing table.

Example

Import Type 2 RIP routes, with the process 40, the tag being 33 and cost being 50.

```
<HUAWEI> system-view
```

```
[HUAWEI] ospf 100
[HUAWEI-ospf-100] import-route rip 40 type 2 tag 33 cost 50
```

7.4.57 local-mt enable (OSPF)

Function

The **local-mt enable** command enables OSPF Local Multicast-Topology (MT).

The **undo local-mt enable** command disables OSPF local MT.

By default, OSPF local MT is disabled.

NOTE

Only the S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-Hsupport this command.

Format

local-mt enable

undo local-mt enable

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast and an MPLS TE tunnel are configured on a network and the TE tunnel is configured with IGP Shortcut, the outbound interface of the route calculated by an IGP is not an actual physical interface but a TE tunnel interface. The device uses a unicast route to the multicast source address to send multicast Join messages from the TE tunnel interface. The device spanned by the TE tunnel, however, cannot sense the multicast Join messages. As a result, multicast forwarding entries will not be created on these devices.

To avoid the preceding problem, you can run the **local-mt enable** command to enable OSPF local Multicast-Topology (MT). MT allows the multicast routing entries to be correct created to guide the forwarding of multicast traffic.

After OSPF local MT is enabled, if the outbound interface of the calculated route is a TE tunnel interface of the IGP Shortcut type, the route management (RM) module creates a separate MIGP routing table for the multicast protocol, calculates the actual physical outbound interface for the route, and adds the physical interface to the MIGP routing table for multicast forwarding.

Prerequisites

IGP Shortcut feature has been enabled using the **enable traffic-adjustment** command.

Precautions

- To control the number of entries in the MIGP routing table and speed up the MIGP routing table search, you can run the **local-mt filter-policy** command to configure a policy for filtering multicast source address. Then only the multicast source address that matches the policy to be added to the MIGP routing table. Configure the routing policy before enabling local MT. This can prevent excessive routes to non-multicast source address from being added to the MIGP routing table and keeps the number of routes in the MIGP routing table within the upper limit.
- Local MT is applicable only to the OSPF process of a public network instance.
- OSPF local MT does not support forwarding adjacency (FA).

Example

Enable local MT on OSPF process 1.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] local-mt enable
```

7.4.58 local-mt filter-policy (OSPF)

Function

The **local-mt filter-policy** command configures the filtering policy of OSPF Local Multicast-Topology (MT).

The **undo local-mt filter-policy** command deletes the filtering policy of OSPF local MT.

By default, the filtering policy of OSPF local MT is not configured.

Format

local-mt filter-policy { **acl** { *acl-number* | *acl-name* } | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* }

undo local-mt filter-policy

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of the basic access control list (ACL).	The value is an integer ranging from 2000 to 2999.

Parameter	Description	Value
acl *acl-name*	Specifies the name of a Named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of the route policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast and an MPLS TE tunnel are configured on a network and the TE tunnel is configured with IGP Shortcut, the outbound interface of the route calculated by an IGP is not an actual physical interface but a TE tunnel interface. The device uses a unicast route to the multicast source address to send multicast Join messages from the TE tunnel interface. The device through which the TE tunnel passes, however, cannot sense the multicast Join messages. As a result, multicast forwarding entries will not be created.

To avoid the preceding problem, you can create a proper multicast routing table to guide the forwarding of multicast packets by configuring local MT. After OSPF local MT is enabled, if the outbound interface of the calculated route is a TE tunnel interface of the IGP Shortcut type, the route management (RM) module creates a separate MIGP routing table for the multicast protocol, calculates the actual physical outbound interface for the route, and adds the physical interface to the MIGP routing table for multicast forwarding.

To control the number of entries in the MIGP routing table and speed up the MIGP routing table search, you can configure filtering conditions by using the **local-mt filter-policy** command to allow only the matching routes to the multicast source address to be added to the MIGP routing table.

Prerequisites

OSPF local MT has been enabled using the **local-mt enable** command.

Precautions

You are recommended to configure the routing policy before enabling local MT. This can prevent the excessive routes to the not-multicast source address from being added to the MIGP routing table and keeps the number of routes in the MIGP routing table within the upper limit.

When the rule command is used to configure filtering rules for an ACL configured using the **acl** command, only the source address range that is specified by the **source** parameter and the period of time that is specified by the **time-range** parameter take effect.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all OSPF routes are added to the MIGP routing table.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all OSPF routes are added to the MIGP routing table.

Example

Configure the filtering policy of OSPF local MT.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] local-mt enable
[HUAWEI-ospf-1] local-mt filter-policy acl 2000
```

7.4.59 loop-free-alternate (OSPF)

Function

The **loop-free-alternate** command enables OSPF IP FRR to enable the device to use the LFA algorithm to calculate the nexthop and outbound interface for the dynamic backup link.

The **undo loop-free-alternate** command disables OSPF IP FRR.

By default, this function is disabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

loop-free-alternate

undo loop-free-alternate

Parameters

OSPF FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **frr** command run in the OSPF view creates and displays the OSPF FRR view only, but cannot enable the OSPF IP FRR function. You must run the **loop-free-alternate** command in the OSPF view to enable OSPF IP FRR use the LFA algorithm to calculate the nexthop and outbound interface for the dynamic backup link to create the loop-free backup route.

Follow-up Procedure

Run the **frr-policy route** command in the OSPF view to configure a filtering policy for OSPF IP FRR. Only the OSPF backup route that satisfies specific rules can be delivered to the forwarding table.

Example

Enable OSPF IP FRR to create the loop-free backup route.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] frr
[HUAWEI-ospf-1-frr] loop-free-alternate
```

7.4.60 lsa-arrival-interval

Function

The **lsa-arrival-interval** command sets an interval for receiving LSAs.

The **undo lsa-arrival-interval** command restores the default interval for receiving LSAs.

By default, the interval for receiving LSA packets is one second.

Format

lsa-arrival-interval { *interval* | **intelligent-timer** *max-interval start-interval hold-interval* }

undo lsa-arrival-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for receiving LSAs.	The value is an integer ranging from 0 to 10000, in ms.
intelligent-timer	Enables an intelligent timer to receive LSAs.	-
max-interval	Specifies the maximum interval for receiving LSAs.	The value is an integer ranging from 1 to 120000, in ms. The default value is 1000.
start-interval	Specifies the initial interval for receiving LSAs.	The value is an integer ranging from 0 to 60000, in ms. The default value is 500.
hold-interval	Specifies the Holdtime interval for receiving LSAs.	The value is an integer ranging from 1 to 60000, in ms. The default value is 500.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent frequent LSA updates caused by network connection or frequent route flapping, you can set the interval for receiving LSAs using this command. A router receives LSAs only when it meets the set interval.

In a stable network where routes need to be fast converged, you can set the interval for receiving LSAs at millisecond level to receive and update LSAs in time. The change of the topology or the route, therefore, can be immediately detected, and LSDB synchronization speed is improved.

If there is no special requirement for the network, using the default value is recommended.

Configuration Impact

After this command is configured, the interval for receiving LSAs is as follows:

1. The initial interval for receiving LSAs is specified by the parameter *start-interval*.
2. The interval for receiving LSAs for the nth (n≥2) time is equal to *hold-interval* × $2^{(n-2)}$.
3. When the interval specified by *hold-interval* x $2^{(n-2)}$ reaches the maximum interval specified by *max-interval*, OSPF performs SPF calculation at the maximum interval until *max-interval* expires without flapping or the OSPF process is restarted.

Precautions

You are advised to set the receiving interval specified by **lsa-arrival-interval** to be a value smaller than or equal to the Holdtime interval specified by**lsa-originate-interval**.

Example

Set the interval for receiving LSAs to 0 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] lsa-arrival-interval 0
```

7.4.61 lsa-originate-interval

Function

The **lsa-originate-interval** command sets an interval for updating LSAs.

The **undo lsa-originate-interval** command restores the default interval for updating LSAs.

By default, the interval for updating LSA packets is 5 seconds.

Format

lsa-originate-interval { **0** | { **intelligent-timer** *max-interval start-interval hold-interval* | **other-type** *interval* } * }

undo lsa-originate-interval

Parameters

Parameter	Description	Value
0	Sets an interval for updating LSAs to 0 ms, that is, deletes the initial interval (5000 ms) for updating LSAs.	-

Parameter	Description	Value
intelligent-timer	Enables an intelligent timer to update OSPF router LSAs and network LSAs.	-
max-interval	Specifies the maximum interval for updating OSPF LSAs.	The value is an integer ranging from 1 to 120000, in ms. The default value is 5000.
start-interval	Specifies the initial interval for updating OSPF LSAs.	The value is an integer that ranges from 0 to 60000, in ms. The default value is 500.
hold-interval	Specifies the Holdtime interval for updating OSPF LSAs.	The value is an integer ranging from 1 to 60000, in ms. The default value is 1000.
other-type	Sets the interval for updating the LSAs other than the OSPF router LSAs and network LSAs.	-
interval	Specifies the interval for updating LSAs.	The value is an integer ranging from 0 to 10, in seconds. The default value is 5.

Views

OSPF view

Usage Guidelines

Usage Scenario

To prevent frequent LSA updates caused by network connection or frequent route flapping, you can set the interval for receiving LSAs using this command. A router receives LSAs only when it meets the set interval.

In a stable network where routes need to be fast converged, you can set the interval for receiving LSAs at millisecond level to update LSAs in time. The change of the topology or the route, therefore, can be immediately detected, and LSDB synchronization speed is improved.

If there is no special requirement for the network, using the default value is recommended.

Configuration Impact

After this command is configured, the interval for updating LSAs is as follows:

1. The initial interval for updating LSAs is specified by the parameter *start-interval*.
2. The interval for updating LSAs for the nth ($n \geq 2$) time is equal to *hold-interval* × $2^{(n-2)}$.
3. When the interval specified by *hold-interval* x $2^{(n-2)}$ reaches the maximum interval specified by *max-interval*, OSPF performs SPF calculation at the maximum interval until *max-interval* expires without flapping or the OSPF process is restarted.

Precautions

You are advised to set the updating interval specified by **lsa-originate-interval** to be a value longer than or equal to the Holdtime interval specified by **lsa-arrival-interval**.

Example

Set the interval for updating LSAs to 0 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] lsa-originate-interval 0
```

7.4.62 lsdb-overflow-limit

Function

The **lsdb-overflow-limit** command sets the maximum number of external LSAs in an OSPF LSDB.

The **undo lsdb-overflow-limit** command restores the default configuration.

By default, the maximum number of external LSAs is not set.

Format

lsdb-overflow-limit *number*

undo lsdb-overflow-limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of external LSAs in an LSDB.	The value is an integer ranging from 1 to 1000000.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the number of external LSAs (Type 5 and Type 7 LSAs) imported by OSPF exceeds the limit, the excessive external LSAs cannot be processed properly and are discarded.

To avoid the preceding problem, you can set the maximum number of external LSAs in the LSDB to adjust and optimize OSPF networks.

Prerequisites

If **OSPF is in LSDB overflow status** is displayed in the **display ospf lsdb brief** command output, you must run the **lsdb-overflow-limit** command to set the maximum number of external LSAs imported by OSPF.

Precautions

The configuration of this command must be consistent in the entire AS.

Example

Set a maximum number of 400000 external LSAs allowed in an LSDB.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] lsdb-overflow-limit 400000
```

7.4.63 maximum load-balancing (OSPF)

Function

The **maximum load-balancing** command sets the maximum number of equal-cost routes for load balancing.

The **undo maximum load-balancing** command restores the default setting.

By default, the maximum number of equal-cost routes on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S6720S-S, and S5736-S is 8, and the maximum number of equal-cost routes on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S is 16.

Product	Support

Format

maximum load-balancing *number*

undo maximum load-balancing

Parameters

Parameter	Description	Value
number	Specifies the maximum number of equal-cost routes.	The value is an integer that ranges from 1 to 8 on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S and S6720S-S. The value ranges from 1 to 16 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

2: Configuration level

Usage Guidelines

Usage Scenario

If a routing protocol discovers multiple routes with the same cost to a single destination, traffic can be balanced among these routes. The **maximum load-balancing** command sets the maximum number of equal-cost routes that can carry out load balancing. This optimizes the routing policy and ensures traffic forwarding on a complex network.

Configuration Impact

Packets will be balanced among multiple equal-cost routes to a single destination.

Follow-up Procedure

If more existing equal-cost OSPFv3 routes than the value set using the **maximum load-balancing** command are available, valid routes are selected for load balancing based on the following criteria:

- Route preference: Routes with lower preferences are selected for load balancing.
- Interface index: If routes have the same priorities, routes with higher interface index values are selected for load balancing.
- Next hop IP address: If routes have the same priorities and interface index values, routes with larger IP address are selected for load balancing.

The **nexthop** command allows routes with a specified weight to carry out load balancing.

Precautions

To disable load balancing, set the value of *number* to 1.

Example

Set the maximum number of the equal-cost routes.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] maximum load-balancing 2
```

Restore the default maximum number of equal-cost routes for carrying out load balancing.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] undo maximum load-balancing
```

7.4.64 maximum-routes

Function

The **maximum-routes** command sets the maximum number of routes of different types that OSPF supports.

The **undo maximum-routes** command restores the default maximum number of routes of different types that OSPF supports.

Format

maximum-routes { **external** | **inter** | **intra** } *number*

undo maximum-routes { **external** | **inter** | **intra** }

Parameters

Parameter	Description	Value
external	Indicates the maximum number of AS external routes that OSPF supports.	-
inter	Indicates the maximum number of inter-area routes that OSPF supports.	-
intra	Indicates the maximum number of intra-area routes that OSPF supports.	-
number	Specifies the maximum number of routes of different types.	The value is an integer. ● When the **external** parameter is specified, the value of *number* is an integer ranging from 100 to 5000000. ● When the **inter** parameter is specified, the value of *number* is an integer ranging from 100 to 1000000. ● When the **intra** parameter is specified, the value of *number* is an integer ranging from 100 to 100000.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Based on the real world situation of a network, such as the convergence speed, you can run the **maximum-routes** command to configure the maximum number of routes of different types. This ensures full use of network resources and improves network performance.

Precautions

The maximum number of routes supported by OSPF cannot exceed the maximum number of all routes supported by the switch.

The **maximum-routes** command configuration limits the maximum number of routes that can be locally calculated. Therefore, the command configuration affects the maximum number of routes that can be sent, but does not affect the maximum number of LSAs that can be received.

Example

Set the maximum number of routes that OSPF supports.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] maximum-routes intra 500
```

7.4.65 mesh-group enable

Function

The **mesh-group enable** command enables the mesh-group function.

The **undo mesh-group enable** command disables the mesh-group function.

By default, the mesh-group function is disabled.

Format

mesh-group enable

undo mesh-group enable

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When concurrent links exist between the device and its neighbor, the **mesh-group enable** command enables the mesh-group function. The router ID of a neighboring device uniquely identifies a mesh group. After LSAs are received, the device selects a primary link to flood the received LSAs, without performing reverse flooding. This prevents repeated flooding, reduces the load on the links, and saves system resources.

Device interfaces that meet the following conditions can form a mesh group:

- The interfaces belong to the same area and OSPF process.
- The neighbor status is Exchange or Full.
- Each interface is connected only to one neighbor.

Precautions

After the device is enabled with the mesh-group function, if the router IDs of the directly connected neighbor are the same, the LSDBs of the entire network cannot be synchronized and routes cannot be calculated correctly. In this case, you need to reconfigure the router ID of the neighbors, and then restart the neighbors to validate the configured router ID.

Example

Enable the mesh-group function on the switch.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] mesh-group enable
```

7.4.66 network (OSPF area)

Function

The **network** command specifies the interface that runs OSPF and the area to which the interface belongs.

The **undo network** command deletes the interface that runs OSPF.

By default, an interface does not belong to any area.

Format

network *network-address wildcard-mask* [**description** *text*]

undo network *network-address wildcard-mask*

Parameters

Parameter	Description	Value
network-address	Specifies the address of the network segment where the interface resides.	The value is in dotted decimal notation.
wildcard-mask	Specifies the wildcard mask of an IP address, which is the reverse form of the mask of the IP address. For example, 0.0.0.255 indicates that the mask length is 24 bits. **NOTE** When configuring a short mask, ensure that the area does not contain many interface addresses and secondary addresses. Otherwise, the neighbor relationship may fail to be established due to excessively long router-LSAs.	The value is in dotted decimal notation.

Parameter	Description	Value
description *text*	Specifies the description of the specified OSPF network segment.	The value is a string of 1 to 80 case-sensitive characters with spaces supported.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating an OSPF process, you can run the **network** command to configure the network segments in an area and specify *network-address* and *wildcard-mask* to configure one or multiple interfaces in an area. To run OSPF on an interface, ensure that the primary IP address of this interface is in the network segment range specified in the **network** (OSPF) command. If the secondary IP address of the main interface is in the network segment range specified in this command, the main interface cannot run OSPF.

OSPF can run on an interface only when the following two conditions are met:

- The mask length of the interface's IP address is not less than that specified in the **network** command. OSPF uses a reverse mask. For example, 0.0.0.255 indicates that the mask length is 24 bits.

  NOTE

  When the *wildcard-mask* parameter in the **network** command is set to all 0s, OSPF runs on the interface if its IP address is the IP address specified in the **network** *network-address* command.

- The primary address of the interface must be within the network segment range specified in the **network** command.

Precautions

- OSPF neighbor relationships cannot be established using the secondary IP addresses of interfaces.
- After the **network** 0.0.0.0 0.0.0.0 command is configured, the device automatically changes the command to **network** 0.0.0.0 255.255.255.255. That is, all interfaces (including the management interface) will run OSPF. Therefore, exercise caution when configuring this command.
- For the same **network** *address wildcard-mask*, the last description configured by **description** takes effect.

- On a loopback interface, by default, OSPF advertises its IP address in the form of a 32-bit host route, independent of the mask length of the IP address on the interface.
- To advertise the network segment route of a loopback interface, you need to run the **ospf network-type** command to set the network type to broadcast or NBMA.
- When an OSPF sham link is configured, the local address cannot be advertised through the OSPF process of a private network.
- Two areas that overlap cannot be configured between different processes in the same instance, or between different areas in the same process.
- The **ospf enable** command configuration takes precedence over the **network** command configuration.

Example

Configure the primary IP address of the interface that runs OSPF to be in the network segment of 192.168.1.0/24, set the ID of the OSPF area where the interface resides to 2, and configure the description for the network segment.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 2
[HUAWEI-ospf-100-area-0.0.0.2] network 192.168.1.0 0.0.0.255 description this network is connected to
Beijing
```

7.4.67 nexthop (OSPF)

Function

The **nexthop** command sets a preference for equal-cost routes. After OSPF calculates the equal-cost routes, the next hop is chosen from these equal-cost routes based on the value of weights. A smaller value indicates a higher preference.

The **undo nexthop** command cancels the preference of these equal-cost routes.

By default, the value of weight is 255. Equal-cost routes have no preference, and they forward packets at the same time. Load balancing is performed among them.

Format

nexthop *ip-address* **weight** *value*

undo nexthop *ip-address*

Parameters

Parameter	Description	Value
ip-address	Indicates the IP address of the next hop.	The value is in dotted decimal notation.

Parameter	Description	Value
weight *value*	Indicates the weight of the next hop. A smaller value indicates a higher preference.	It is an integer that ranges from 1 to 254.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

You can run the **nexthop** command to set a high preference for specified valid routes if both of the following conditions are met:

- The number of equal-cost routes on a network is larger than the value configured using the **maximum load-balancing** command.
- Valid routes must be specified for load balancing.

Example

Set a preference for equal-cost routes in OSPF.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] nexthop 10.0.0.3 weight 1
```

7.4.68 nssa (OSPF Area)

Function

The **nssa** command configures an NSSA.

The **undo nssa** command cancels the configuration of an NSSA.

By default, no OSPF area is configured as an NSSA.

Format

nssa [{ **default-route-advertise** [**backbone-peer-ignore**] | **suppress-default-route** } | **flush-waiting-timer** *interval-value* | **no-import-route** | **no-summary** | **set-n-bit** | **suppress-forwarding-address** | **translator-always** | **translator-interval** *interval-value* | **zero-address-forwarding** | **translator-strict**] *

undo nssa [**flush-waiting-timer** *interval-value*]

Parameters

Parameter	Description	Value
default-route-advertise	Generates default Type7 LSAs on the ASBR and then advertises them to the NSSA. **NOTE** If the backbone-peer-ignore parameter is not configured, the ABR automatically generates a default NSSA LSA (Type7 LSA) and advertises it in the NSSA when an interface in the backbone area is in Up state and an OSPF neighbor relationship in Full state exists on the ABR. Type 7 LSAs carrying the default route will be generated only when the default route 0.0.0.0/0 exists in the routing table on the ASBR.	-
backbone-peer-ignore	Prevents the ABR from checking the neighbor status when the ABR generates default Type 7 LSAs and advertises them to the NSSA. Specifically, the ABR generates default Type 7 LSAs and advertises them to the NSSA as long as an interface that is Up exists in the backbone area.	-
suppress-default-route	Generates default Type-7 LSAs on the ASBR or ABR and then not advertises them to the NSSA.	-
flush-waiting-timer *interval-value*	Indicates the interval for an ASBR to send aged Type 5 LSAs. The parameter takes effect only when it is set.	The value is an integer that ranges from 1 to 40, in seconds.
no-import-route	Indicates that no external route is imported to an NSSA.	-
no-summary	Indicates that an ABR is prohibited from sending summary LSAs to the NSSA.	-
set-n-bit	Sets the N-bit in DD packets.	-
suppress-forwarding-address	Sets the FA of the Type 5 LSAs translated from Type 7 LSAs by the NSSA ABR to 0.0.0.0.	-
translator-always	Specifies an ABR in an NSSA as an all-the-time translator. Multiple ABRs in an NSSA can be configured as translators.	-

Parameter	Description	Value
translator-interval *interval-value*	Specifies the timeout period of a translator.	The value is an integer ranging from 1 to 120, in seconds. The default value is 40.
zero-address-forwarding	Sets the FA of the generated NSSA LSAs to 0.0.0.0 when external routes are imported by the ABR in an NSSA.	-
translator-strict	Configures the translator to perform strict check on the P-bit flag. The translator determines whether to translate Type 7 LSAs into Type 5 LSAs based on the P-bit flag.	-

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An NSSA is configured in the scenario where AS external routes are to be imported but not forwarded to save system resources. AS external routes can be imported to an NSSA and transmitted to the entire NSSA.

All switches in the NSSA must be configured with NSSA attributes using the **nssa** command.

The **nssa** command is applicable to the following scenarios:

- The **default-route-advertise** parameter is configured to advertise Type 7 LSAs carrying the default route on the ASBR to the NSSA.

  Regardless of whether the default route 0.0.0.0/0 exists in the routing table on the ABR, Type 7 LSAs carrying the default route will be generated. However, Type 7 LSAs carrying the default route will be generated on the ASBR only when the default route 0.0.0.0/0 exists in the routing table on the ASBR.

- When the area to which the ASBR belongs is configured as an NSSA, invalid Type 5 LSAs from other switches in the area where LSAs are flooded will be reserved. These LSAs will be deleted only when the aging time reaches 3600s. The switch performance is affected because the forwarding of a large number of LSAs consumes the memory resources. To resolve such a problem, you can set the parameter **flush-waiting-timer** to the maximum value 3600s for Type 5 LSAs. This ensures that the invalid Type 5 LSAs from other switches can be deleted in time.

NOTE

- When the LS age field value (aging time) in the header of an LSA reaches 3600s, the LSA is deleted.
- If an ASBR also functions as an ABR, **flush-waiting-timer** does not take effect. This prevents Type 5 LSAs in the non-NSSAs from being deleted.

- If an ASBR also functions as an ABR, the **no-import-route** parameter is configured to prevent external routes imported using the **import-route** command from being advertised to the NSSA.
- The **no-summary** parameter is configured on an ABR to reduce the number of LSAs that are transmitted to the NSSA. This implementation prevents the ABR from transmitting Type 3 LSAs to the NSSA.

  NOTE

  After the **nssa default-route-advertise backbone-peer-ignore no-summary** command is run, the ABR generates default Type 7 and Type 3 LSAs as long as an interface that is Up exists in the backbone area. The default Type 3 LSAs preferentially take effect.
- After the **set-n-bit** parameter is configured, the N-bit is set in the database description (DD) packets during the synchronization between the switch and neighboring switches.
- If multiple ABRs are deployed in the NSSA, the system automatically selects an ABR (generally the switch with the largest router ID) as a translator to convert Type 7 LSAs into Type 5 LSAs. You can configure the **translator-always** parameter on an ABR to specify the ABR as an all-the-time translator. To specify two ABRs for load balancing, configure the **translator-always** parameter on the chosen ABRs to specify the ABRs as all-the-time translators. You can use this command to pre-configure a fixed translator to prevent LSA flooding caused by translator role changes.
- The **translator-interval** parameter is used to ensure uninterrupted services when translator roles change. The value of *interval-value* must be greater than the flooding period.

Configuration Impact

Configuring or deleting NSSA attributes will trigger routing updates in the area. A second configuration of NSSA attributes can be implemented or canceled only after a routing update is complete.

Precautions

It is recommended that a loopback address be configured for a device in the NSSA and be enabled in the corresponding OSPF area, so that the loopback address can be automatically selected as the FA. If other switches have routes of the same cost to the switch in the NSSA, load balancing is performed.

When the last ordinary area (other than a stub area or NSSA) under an OSPF process is deleted, useless Type 5 LSAs originated by the local switch in the area where LSAs are flooded will be deleted immediately. The local switch still reserves useless Type 5 LSAs from other switches. These useless Type 5 LSAs will be deleted only when the aging time reaches 3600s.

Example

Configure area 1 as an NSSA.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] area 1
[HUAWEI-ospf-1-area-0.0.0.1] nssa
```

7.4.69 opaque-capability enable

Function

The **opaque-capability enable** command enables the Opaque-LSA capability so that an OSPF process can generate Opaque LSAs and receive Opaque LSAs from neighbors.

The **undo opaque-capability** command disables the Opaque-LSA capability.

By default, the Opaque-LSA capability is disabled.

Format

opaque-capability enable

undo opaque-capability

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Opaque LSAs provide a generic mechanism for OSPF extension:

- OSPF supports GR using Type 9 LSAs.
- OSPF supports TE using Type 10 LSAs.

Before configuring OSPF GR or OSPF TE, you must enable opaque LSA capability running the **opaque-capability enable** command.

Configuration Impact

Enabling or disabling the opaque LSA function may delete and re-establish all sessions and instances.

Example

Enable OSPF opaque-lsa.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] opaque-capability enable
```

7.4.70 ospf

Function

The **ospf** command creates and runs an OSPF process.

The **undo ospf** command terminates an OSPF process.

By default, OSPF is disabled, that is, no OSPF process runs.

Format

ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

undo ospf *process-id* [**flush-waiting-timer** *time*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535. By default, it is 1.
router-id *router-id*	Specifies a router ID.	The value is in dotted decimal notation.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
flush-waiting-timer *time*	Indicates the interval for generating aged LSAs. The parameter takes effect only when it is set.	The value is an integer that ranges from 1 to 40, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can set OSPF parameters only after creating an OSPF process.

OSPF supports multi-process. More than one OSPF process can run on the same device and are independent of each other. Route interaction between different OSPF processes is similar to route interaction between different routing protocols.

An OSPF router ID can be manually configured or automatically selected. To ensure OSPF stability, you are advised to manually configure the IP address of a loopback interface as the router ID.

If no OSPF router ID is manually configured for a router, the router selects the global router ID as its OSPF router ID. If both the OSPF router ID and global router ID are not configured, the router selects a router ID based on IP addresses of current interfaces:

- If there are loopback interfaces that have IP addresses configured, the device selects the largest IP address among loopback interface addresses as the global router ID.
- If no loopback interface is configured or loopback interfaces do not have IP addresses configured, the device selects the largest IP address among interface addresses as the global router ID without considering the Up/Down state of interfaces.

In any of the following situations, the router ID is re-selected:

- The **ospf** command is run to re-configure an OSPF router ID, and the OSPF process is restarted.
- The global router ID is re-configured, and the OSPF process is restarted.
- The IP address of the original global router ID is deleted, and the OSPF process is restarted.

Configuration Impact

After an OSPF process is disabled using **undo ospf** command, the receive end still maintains the LSAs generated by this OSPF process. These invalid LSAs occupy the system memory and are deleted only when the LS age field (aging time) reaches 3600 seconds. When the **undo ospf** *process-id* **flush-waiting-timer** *time* command is used to delete an OSPF process, the switch regenerates an LSA in the set time and sets the LS age field to 3600 seconds. After other switches receive the LSA with the LS age field as 3600 seconds, they delete the LSA immediately. If the host does not send all the LSAs in the set time, other switches still reserve invalid LSAs.

NOTE

When the LS age field (aging time) in the LSA header reaches 3600 seconds, this LSA is deleted.

Precautions

An interface on a device belongs to only one OSPF process.

If a VPN instance is specified, the OSPF process specified in this command belongs to this VPN instance. If no VPN instance is specified, the OSPF process specified in this command belongs to the global VPN instance. *vpn-instance-name* cannot be changed after being specified.

NOTE

The router ID of each OSPF process must be unique on the entire network; otherwise, the OSPF neighbor relationship cannot be set up and routing information is incorrect. Configuring a unique router ID for each OSPF process on each OSPF device is recommended.

Example

Run an OSPF process.

```
<HUAWEI> system-view
[HUAWEI] ospf 100 router-id 10.10.10.1 vpn-instance test
```

7.4.71 ospf authentication-mode

Function

The **ospf authentication-mode** command sets an authentication mode and password used between neighboring nodes.

The **ospf authentication-mode null** command configures the null authentication mode on an interface.

The **undo ospf authentication-mode** command deletes the authentication mode on an interface.

By default, an interface does not authenticate OSPF packets.

Format

ospf authentication-mode { **simple** [**plain** *plain-text* | [**cipher**] *cipher-text*] | **null** }

ospf authentication-mode { **md5** | **hmac-md5** | **hmac-sha256** } [*key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* }]

ospf authentication-mode keychain *keychain-name*

undo ospf authentication-mode

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Indicates simple authentication. **NOTICE** Simple authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	In simple authentication, the password type is **cipher** by default.
plain	Indicates plain authentication. Only plain text can be entered, and only plain text is displayed when the configuration file is viewed. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This carries security risks. Selecting **cipher** to save the password in cipher text is recommended.	-
plain-text	Specifies a plain text password.	*plain-text* is a string of 1 to 8 characters without spaces when **simple** is configured, and is a string of 1 to 255 characters without spaces when **md5**, **hmac-md5** or **hmac-sha256** is configured.
cipher	Indicates cipher authentication. Either plain text or cipher text can be entered, and cipher text is displayed when the configuration file is viewed.	When **cipher** is configured, enter only the password in cipher text. Then, the password is displayed in cipher text in configuration files. MD5 authentication, HMAC-SHA256 authentication or HMAC-MD5 authentication uses the password in cipher text by default.

Parameter	Description	Value
cipher-text	Specifies a cipher text password.	The value is a string of characters without spaces. In simple authentication, a plain text password is a string of 1 to 8 characters and a cipher text password is a string of 24 or 32 or 48 characters. In MD5 authentication, HMAC-SHA256 authentication or HMAC-MD5 authentication, a plain text password is a string of 1 to 255 characters and a cipher text password is a string of 20 to 392 characters.
md5	Indicates MD5 authentication. **NOTICE** MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-md5	Indicates HMAC-MD5 authentication. **NOTICE** HMAC-MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-sha256	Indicates HMAC-SHA256 authentication.	-
key-id	Specifies the authentication key ID of the interface's cipher authentication. The key ID must be consistent with that of the peer.	The value is an integer that ranges from 1 to 255.

Parameter	Description	Value
keychain	Indicates keychain authentication. **NOTE** Before configuring this parameter, run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, OSPF authentication will fail. Currently, OSPF supports only HMAC-MD5 and HMAC-SHA256 algorithms.	-
keychain-name	Specifies the keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
null	Indicates null authentication.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Due to the defects and non-strict implementation of the TCP/IP protocol suite and increasing attacks on TCP/IP networks, the impact generated by attacks on the network may become more serious. Attacks on network devices may lead to a network crash. To improve OSPF network security, configure authentication.

Configuration Impact

Interface authentication is used to set the authentication mode and password used between neighboring devices. It takes precedence over area authentication.

Precautions

Null authentication is an authentication method. It does not indicate that no authentication is configured.

The authentication mode and password configured for interfaces on the same network segment must be the same.

OSPF does not support the configuration on a null interface.

An authentication password cannot contain spaces.

Example

Configure OSPF HMAC-SHA256 authentication on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf authentication-mode hmac-sha256
```

Configure OSPF HMAC-SHA256 authentication on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf authentication-mode hmac-sha256
```

7.4.72 ospf bfd

Function

The **ospf bfd** command enables BFD on an OSPF interface or sets parameter values for a BFD session.

The **undo ospf bfd** command deletes BFD on an OSPF interface or restores the default parameter values of a BFD session.

By default, BFD is not enabled on any OSPF interfaces.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ospf bfd enable

undo ospf bfd enable

ospf bfd { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* | **frr-binding** } *

undo ospf bfd { **min-rx-interval** [*receive-interval*] | **min-tx-interval** [*transmit-interval*] | **detect-multiplier** [*multiplier-value*] | **frr-binding** } *

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **frr-binding** parameter.

Parameters

Parameter	Description	Value
enable	Enables BFD.	-
min-rx-interval *receive-interval*	Indicates the minimum interval at which BFD packets are received from the remote end.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *transmit-interval*	Indicates the minimum interval at which BFD packets are sent to the remote end.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Specifies the local detection multiplier.	The value is an integer ranging from 3 to 50. By default, it is 3.

Parameter	Description	Value
frr-binding	Binds the BFD status to the link status of an interface. That is, when the BFD status goes Down, the link status of the interface also goes Down. This enables traffic to be switched to the backup path.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A link failure or topology change causes devices to recalculate routes. Therefore, the convergence of routing protocols must be sped up to improve network performance.

Link faults are unavoidable. Therefore, a feasible solution is required to detect faults faster and notify routing protocols of the faults immediately. If BFD is associated with routing protocols and a link fault occurs, BFD can speed up the convergence of routing protocols.

Prerequisites

The configured parameters of the BFD session are valid on an interface only when BFD is enabled on the interface.

Procedure

The *receive-interval* is obtained through the negotiation between the local end and peer end by comparing the values of the local **min-rx-interval** and the peer **min-tx-interval**. If the local end fails to receive a BFD packet from the peer end within an interval of *receive-interval* x *multiplier-value*, it considers that the neighbor is Down.

Configuration Impact

If global BFD is not enabled, you can enable BFD on an interface but cannot set up BFD sessions. Similarly, if only parameters of a BFD session are set but the **ospf bfd enable** command is not used, the BFD session cannot be set up.

BFD configured on an interface takes precedence over BFD configured in a process. If BFD is enabled on an interface, the BFD parameters on the interface are used to establish BFD sessions.

Precautions

- After BFD is enabled, BFD sessions can be created only between the two ends that have set up an OSPF neighbor relationship and the relationship is in the Exstart state.
- The **ospf bfd enable** command and the **ospf bfd block** command are mutually exclusive.
- After BFD is disabled from an interface through the **undo ospf bfd enable** command, the parameters for setting up BFD sessions remain on this interface but do not take effect.

Example

Enable BFD on VLANIF100 and set the minimum interval for receiving BFD packets to 400 ms and the local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf bfd enable
[HUAWEI-Vlanif100] ospf bfd min-rx-interval 400 detect-multiplier 4
```

Enable BFD on GE0/0/1 and set the minimum interval for receiving BFD packets to 400 ms and the local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf bfd enable
[HUAWEI-GigabitEthernet0/0/1] ospf bfd min-rx-interval 400 detect-multiplier 4
```

7.4.73 ospf bfd block

Function

The **ospf bfd block** command prevents an interface from dynamically setting up a BFD session.

The **undo ospf bfd block** command cancels the configuration.

By default, the device does not prevent an interface from dynamically setting up a BFD session.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ospf bfd block

undo ospf bfd block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **bfd all-interfaces enable** command is used for an OSPF process, BFD sessions are created on all OSPF interfaces whose neighbor status is Full. If you do not want some interfaces to have BFD sessions created, run the **ospf bfd block** command to prevent these interfaces from dynamically setting up BFD sessions.

Prerequisites

BFD has been enabled on interfaces.

Precautions

The **ospf bfd enable** command and the **ospf bfd block** command are mutually exclusive.

Example

Prevent VLANIF100 from dynamically setting up a BFD session.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf bfd block
```

Prevent GE0/0/1 from dynamically setting up a BFD session.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf bfd block
```

7.4.74 ospf cost

Function

The **ospf cost** command sets a cost for an OSPF on an interface.

The **undo ospf cost** command restores the default cost for OSPF.

By default, OSPF automatically calculates its cost based on its interface bandwidth. The default cost of the loopback interface is 0.

Format

ospf cost *cost*

undo ospf cost

Parameters

Parameter	Description	Value
cost	Specifies the cost of an OSPF-enabled interface.	The value is an integer ranging from 1 to 65535. By default, it is 1.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, OSPF automatically calculates the link cost for an interface based on the bandwidth of the interface. You can modify the interface cost using the **ospf cost** command. For example, when you configure load balancing, you can run this command to modify the interface cost of the routes if conditions are satisfied for load balancing.

If no cost is set for an OSPF interface using the **ospf cost** command, OSPF automatically calculates its cost based on the interface bandwidth. The calculation formula is as follows: Cost of the interface = Bandwidth reference value/Interface bandwidth. The integer of the calculated result is the cost of the interface. If the calculated result is smaller than 1, the cost is 1. Changing the bandwidth reference value or interface bandwidth change the cost of an interface:

- To use the bandwidth reference value to determine the interface cost, run the **bandwidth-reference** command.
- To use the interface bandwidth to determine the interface cost, run the **bandwidth** command to set configuration bandwidth for an interface, and then run the **bandwidth-config enable** command to enable the device to calculate the cost for the interface based on the configuration bandwidth of the interface.
- To use both the bandwidth reference value and interface bandwidth to determine the interface cost, run the preceding three commands.

Precautions

- The **ospf cost** command cannot run on null interfaces.
- No default cost is configured for trunk interfaces, because a trunk interface has multiple member interfaces that are in constant change.

Example

Set the cost of VLANIF100 that runs OSPF to 65.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf cost 65
```

Set the cost of GE0/0/1 that runs OSPF to 65.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf cost 65
```

7.4.75 ospf dr-priority

Function

The **ospf dr-priority** command sets a priority for an interface that participates in the DR election.

The **undo ospf dr-priority** command restores the default setting.

By default, the priority is 1.

Format

ospf dr-priority *priority*

undo ospf dr-priority

Parameters

Parameter	Description	Value
priority	Specifies the priority of an interface that participates in the DR or BDR election. A larger value indicates a higher priority.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DR priority of an interface determines whether it is qualified to be a DR. The interface with the highest DR priority is elected as the DR. If the DR priority of an interface on a device is 0, the device cannot be elected as a DR or a BDR. On a broadcast or NBMA network, you can set a DR priority for an interface to determine whether it is qualified to be a DR or a BDR.

Configuration Impact

When the DR and BDR are elected on a network segment, they send DD packets to all neighboring nodes and set up adjacencies with all neighboring nodes.

Precautions

NOTICE

Restarting or shutting down an interface will interrupt the OSPF adjacency between devices. Therefore, perform the operation with caution.

If the DR priority of a device is re-configured, the DR or BDR on the network will not be re-elected. You can re-elect a DR or a BDR by using either of the following methods. This, however, will interrupt the OSPF adjacency between devices. Therefore, use the following methods with caution.

- Restart the OSPF processes on all devices.
- Run the **shutdown** and then **undo shutdown** commands on the interfaces where OSPF adjacencies are set up.

In OSPF, the DR priority cannot be configured for null interfaces.

Example

Set the priority of VLANIF100 that participates in the DR election to 8.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf dr-priority 8
```

Set the priority of GE0/0/1 that participates in the DR election to 8.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf dr-priority 8
```

7.4.76 ospf enable

Function

The **ospf enable** command enables OSPF on an interface.

The **undo ospf enable** command disables OSPF on an interface.

By default, the interface does not run OSPF.

Format

ospf enable [*process-id*] **area** *area-id*

undo ospf enable [*process-id*] **area** *area-id*

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535. The default value is 1.
area *area-id*	Specifies an area ID.	The value can be a decimal integer or an IP address. When the value is an integer, the value ranges from 0 to 4294967295.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ospf enable** command configuration takes precedence over the **network** command configuration.

After the **undo ospf enable** command is run to disable OSPF on an interface, the **network** configuration takes effect on the interface automatically.

Configuration Impact

The interface will alternate between Up and Down when the **ospf enable** command and the **network** command are run on the interface repeatedly.

Precautions

An interface can be configured with only one OSPF process.

The configured interface and the OSPF process must be in the same VPN.

- The **ospf enable** command can be configured on an interface before an OSPF process is created. The interface specified by the **ospf enable** command and the created OSPF process must be in the same VPN.
- If a process is created before the **ospf enable** command is run on an interface, the process of the interface and existing process must belong to the same VPN. Otherwise, the **ospf enable** command cannot be run.
- If no OSPF process is created, interfaces that belong to different VPN instances cannot be added to the same OSPF process.

Example

Enable VLANIF100 in the specified OSPF area.

```
<HUAWEI> system-view
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf enable 1 area 0
```

Enable GE0/0/1 in the specified OSPF area.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf enable 1 area 0
```

7.4.77 ospf filter-lsa-out

Function

The **ospf filter-lsa-out** command configures an OSPF interface to filter outgoing LSAs.

The **undo ospf filter-lsa-out** command disables an OSPF interface from filtering outgoing LSAs.

By default, outgoing LSAs are not filtered.

Format

ospf filter-lsa-out { **all** | { **summary** [**acl** { *acl-number* | *acl-name* }] | **ase** [**acl** { *acl-number* | *acl-name* }] | **nssa** [**acl** { *acl-number* | *acl-name* }] } * }

undo ospf filter-lsa-out

Parameters

Parameter	Description	Value
all	Filters all outgoing LSAs except grace LSAs.	-
summary	Filters outgoing network summary LSAs (Type3).	-
ase	Filters outgoing AS external LSAs (Type5).	-
nssa	Filters outgoing NSSA LSAs (Type7).	-
acl *acl-number*	Specifies the number of the basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple links exist between two switches, you can run the **ospf filter-lsa-out** command to configure the local switch to filter the outgoing LSAs based on the filtering policy before the device sends these LSAs along specified links. This reduces the unnecessary retransmission of LSAs and saves bandwidth resources.

Configuration Impact

Filtering the outgoing LSAs on the specified OSPF interface can prevent useless LSAs from being sent to neighbors. This can reduce the size of the LSDB of neighbors and speed up the network convergence.

NOTE

- After the command is configured on an interface, the OSPF neighbor relationship of the interface will automatically re-establish.
- When the rule in the ACL changes, the OSPF neighbor relationship of the interface will automatically re-establish.

Precautions

When the **rule** command is used to configure the filtering rules for an ACL configured using the **acl** command, only the source address range that is specified by the **source** parameter and the period of time that is specified by the **time-range** parameter take effect.

Grace LSAs are used to inform the neighbor of the Graceful Restart (GR) time, cause, and interface instance ID when GR starts and ends. The command is not used to filter the grace LSAs.

Example

Configure VLANIF100 to filter all outgoing LSAs except grace LSAs.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf filter-lsa-out all
```

Configure GE0/0/1 to filter all outgoing LSAs except grace LSAs.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf filter-lsa-out all
```

7.4.78 ospf frr block

Function

The **ospf frr block** command disables the OSPF IP FRR function on a specified interface.

The **undo ospf frr block** command restores the OSPF IP FRR function on the specified interface.

By default, the OSPF IP FRR function is enabled on a specific interface.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ospf frr block

undo ospf frr block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

OSPF IP FRR can be disabled using the **ospf frr block** command on an interface of a specific device that is running important services and resides on an FRR backup link. This setting prevents the device connected to this interface from being a part of a backup link and being burdened after FRR switches traffic to the backup link.

Example

Disable the OSPF IP FRR function on the interface VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ospf frr block
```

7.4.79 ospf maxage-lsa auto-protect disable

Function

The **ospf maxage-lsa auto-protect disable** command disables master/slave board switching triggered by abnormal OSPF LSA aging.

The **undo ospf maxage-lsa auto-protect disable** command enables master/slave board switching triggered by abnormal OSPF LSA aging.

By default, master/slave board switching triggered by abnormal OSPF LSA aging is enabled.

Format

ospf maxage-lsa auto-protect disable

undo ospf maxage-lsa auto-protect disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If the local device clock is faster than usual and the aging timer expires abnormally, the local device incorrectly clears all Router LSAs from the peer device, which causes route flapping and service interruptions. To resolve this issue, master/slave board switching triggered by abnormal OSPF LSA aging is automatically enabled. Master/Slave board switching is triggered to restore network connections and service traffic when the following condition is met:

(Number of incorrectly cleared Router LSAs/Total number of Router LSAs) x 100% ≥ 80% (Router LSAs are those sent by the peer device to the local device)

Example

Disable master/slave board switching triggered by abnormal OSPF LSA aging.

```
<HUAWEI> system-view
```

```
[HUAWEI] ospf maxage-lsa auto-protect disable
```

7.4.80 ospf mib-binding

Function

The **ospf mib-binding** command binds an OSPF process to SNMP and enables OSPF to respond to SNMP requests.

The **undo ospf mib-binding** command cancels the binding.

By default, OSPF processes are not bound to SNMP.

Format

ospf mib-binding *process-id*

undo ospf mib-binding

Parameters

Parameter	Description	Value
process-id	Specifies an OSPF process ID.	The value is an integer ranging from 1 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The OSPF MIB is a virtual database of the device status maintained by the managed devices.

Before performing read and write operations on the OSPF MIB, you must run the **ospf mib-binding** *process-id* command to bind a specified OSPF process to SNMP.

Prerequisites

An OSPF process has been created using the **ospf** command in the system view.

Example

Bind OSPF process 100 to SNMP.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] quit
```

```
[HUAWEI] ospf mib-binding 100
```

Cancel the binding.

```
<HUAWEI> system-view
[HUAWEI] undo ospf mib-binding
```

7.4.81 ospf mtu-enable

Function

The **ospf mtu-enable** command enables an interface to add its actual MTU in DD packets to be sent and check whether the MTU in a received DD packet is greater than the local MTU.

The **undo ospf mtu-enable** command restores the default settings.

By default, an interface adds the MTU 0 (not the actual MTU) in DD packets to be sent and does not check the MTUs in received DD packets.

Format

ospf mtu-enable

undo ospf mtu-enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve compatibility with a non-Huawei device, an OSPF-enabled Huawei device adds the MTU 0 in DD packets to be sent and does not check the MTUs in received DD packets, allowing an OSPF neighbor relationship to be set up even if the two ends have different MTU settings.

However, under the default configuration, the non-Huawei device may discard an OSPF packet received from the Huawei device if the packet's actual MTU is greater than the MTU of the non-Huawei device. If the discarded packet is an LSU, an OSPF neighbor relationship can still be set up, but the route carried in the LSU fails to be learned, causing service interruptions.

To resolve this issue, run the **ospf mtu-enable** command to configure an interface to add the actual MTU in DD packets to be sent and check whether the MTU in a received DD packet is greater than the local MTU. If the interface MTU settings of the local and remote ends are different, an OSPF neighbor relationship cannot enter the Full state. In this manner, MTU inconsistency can then be identified in time.

Precautions

OSPF does not support the configuration on a null interface.

After the command is configured, the system automatically restarts the OSPF process.

Example

Set Vlanif100 to fill in the MTU field when sending DD packets.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf mtu-enable
```

Set GigabitEthernet0/0/1 to fill in the MTU field when sending DD packets.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf mtu-enable
```

7.4.82 ospf network-type

Function

The **ospf network-type** command sets a network type for an OSPF interface.

The **undo ospf network-type** command restores the default network type of the OSPF interface.

By default, the network type of an interface is determined by the physical interface. The network type of Ethernet interfaces is **broadcast**.

Format

ospf network-type { **broadcast** | **nbma** | **p2mp** | **p2p** [**peer-ip-ignore**] }

undo ospf network-type

Parameters

Parameter	Description	Value
broadcast	Indicates that the network type of the interface is changed to broadcast.	-
nbma	Indicates that the network type of the interface is changed to NBMA.	-
p2mp	Indicates that the network type of the interface is changed to point-to-multipoint.	-

Parameter	Description	Value
p2p	Indicates that the network type of the interface is changed to point-to-point.	-
peer-ip-ignore	Disables network segment check when IP address unnumbered is not configured for a P2P interface changed from a broadcast interface and the interface tries to establish an OSPF neighbor relationship. By default, if **peer-ip-ignore** is not specified in the command, OSPF checks the network segment of the two ends during which an OSPF neighbor relationship is to be established. Specifically, OSPF performs an AND operation on the local subnet mask and the local IP address, and on the local subnet mask and the remote IP address. An OSPF neighbor relationship can be established only when the results on the two ends are the same.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When link layer protocols remain unchanged, you can change network types and configure OSPF features to flexibly build networks.

- In the broadcast network, if there is a device that does not support multicast address, you can change the network type of the interface to NBMA.
- If the network type of the interface is NBMA, when the interface type is changed to broadcast, neighbor relationships do not need to be configured.

The condition for changing an NBMA network to broadcast network is that there must be a direct virtual circuit between any two devices, and the network must be a full mesh network.

If a network does not meet the preceding conditions, you must change the type of network to point-to-multipoint. In this manner, two indirect devices can communicate with the help of one device directly connected to the two devices. Instead of configuring the neighboring device, you can change the network type of the interface to point-to-multipoint.

If there are only two devices that run OSPF in the same network segment, the network type of an interface can be changed to p2p.

Precautions

- OSPF does not support the configuration on a null interface.
- When the network type of an interface is NBMA or the network type of an interface is changed to NBMA manually, you must run the **peer** command to configure the neighbor.
- If the network type of an OSPF interface is NBMA, OSPF does not advertise the interface's information to RSVP-TE, and TE tunnels passing through this interface fail to go Up.
- Generally, the network type of two OSPF interfaces on both ends of the link must be identical. Otherwise, the two interfaces cannot set up the neighbor relationship.

  Only when the network type of one OSPF interface is broadcast and the network type of the other OSPF interface is P2P or P2MP, the two interfaces can still set up the neighbor relationship, but cannot learn the OSPF routing information each other.

Example

Set network type of VLANIF100 to NBMA.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf network-type nbma
```

Set network type of GE0/0/1 to NBMA.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf network-type nbma
```

7.4.83 ospf p2mp-mask-ignore

Function

The **ospf p2mp-mask-ignore** command disables a device from checking the network mask on a Point-to-Multipoint (P2MP) network.

The **undo ospf p2mp-mask-ignore** command configures the device to check the network mask on a P2MP network.

By default, devices on a P2MP network do not check the network mask.

Format

ospf p2mp-mask-ignore

undo ospf p2mp-mask-ignore

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPF checks the network masks carried in Hello packets. If the network mask carried in a received Hello packet is not the same as the network mask of the local device, the Hello packet is discarded.

On a P2MP network, when the mask lengths of devices are different, you can use the **ospf p2mp-mask-ignore** command on devices to disable them from checking the network mask in Hello packets. In this manner, the OSPF neighbor relationship can be established.

Prerequisites

Because P2MP is not a link layer protocol, each P2MP network is forcibly changed from a network of another type. A common P2MP network is changed from a non-fully connected non-broadcast multiple access (NBMA) network through the **ospf network-type p2mp** command.

Example

Disable a device from checking the network mask on a P2MP network.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf network-type p2mp
[HUAWEI-Vlanif100] ospf p2mp-mask-ignore
```

Disable a device from checking the network mask on a P2MP network.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf network-type p2mp
[HUAWEI-GigabitEthernet0/0/1] ospf p2mp-mask-ignore
```

7.4.84 ospf router-id auto-recover disable

Function

The **ospf router-id auto-recover disable** command disables a device from performing automatic recovery after detecting router ID conflict.

The **undo ospf router-id auto-recover disable** command enables a device to perform automatic recovery after detecting router ID conflict.

By default, a device performs automatic recovery after detecting router ID conflict.

Format

ospf router-id auto-recover disable

undo ospf router-id auto-recover disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If router ID conflict occurs in an OSPF area, the system can define a new router ID, preventing route flapping and reducing route calculation operations. Other protocols will not go Down when the CPU usage is controlled.

NOTE

- If the automatic recovery function is enabled and a router ID conflict occurs between indirectly connected routers in one OSPF area, the system replaces the conflicted router ID with a newly calculated one. The automatic recovery function takes effect on both configured and automatically generated router IDs.
- The system can replace a router ID in a maximum of three attempts in case the router ID conflict persists.

Example

Disable a device from performing automatic recovery after detecting router ID conflict.

```
<HUAWEI> system-view
[HUAWEI] ospf router-id auto-recover disable
```

7.4.85 ospf smart-discover

Function

The **ospf smart-discover** command enables smart-discover on an interface.

The **undo ospf smart-discover** command disables smart-discover on an interface.

By default, smart-discover is disabled on interfaces.

Format

ospf smart-discover

undo ospf smart-discover

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In normal situations, devices periodically send Hello packets through OSPF interfaces. By sending Hello packets, devices set up and maintain neighbor relationships, and elect the DR and BDR on the multi-access network (broadcast or NBMA network). When setting up neighbor relationships or electing the DR and BDR on the multi-access network, interfaces send Hello packets only when the Hello timer expires. This slows down the establishment of neighbor relationships and election of the DR and BDR.

After smart-discover is configured, when the status of the neighbor relationship changes or the DR and BDR on the multi-access network changes, the device sends Hello packets to its neighbor immediately without waiting for the expiration of the Hello timer.

Procedure

On broadcast and NBMA networks, neighbor relationships can be rapidly set up and a DR and a BDR can be rapidly elected.

- When the neighbor status becomes 2-way for the first time or returns to Init from the 2-way or higher state, the smart-discover-enabled interface sends Hello packets to a neighbor without waiting for the expiration of the Hello timer when detecting that the neighbor status changes.
- When the status of the interface functioning as the DR or BDR on the multi-access network changes, the smart-discover-enabled interface actively sends Hello packets on the network segment and then participates in the DR or BDR election.

The principle of setting up adjacencies rapidly on P2P or P2MP networks is the same as that on broadcast and NBMA networks.

Configuration Impact

The interval for sending Hello packets on an interface is determined by the interval for sending Hello packets set on the interface.

Precautions

The default interval for sending Hello packets varies with the network type.

Example

Enable smart-discover on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf smart-discover
```

Enable smart-discover on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf smart-discover
```

7.4.86 ospf suppress-flapping peer

Function

The **ospf suppress-flapping peer** command configures detection parameters for OSPF neighbor relationship flapping suppression.

The **undo ospf suppress-flapping peer** command restores the default detection parameters.

By default, the detection interval of OSPF neighbor relationship flapping suppression is 60s, the suppression threshold is 10, and the interval for exiting from suppression is 120s.

Format

ospf suppress-flapping peer { **detecting-interval** *detecting-interval* | **threshold** *threshold* | **resume-interval** *resume-interval* } *

undo ospf suppress-flapping peer { **detecting-interval** *detecting-interval* | **threshold** *threshold* | **resume-interval** *resume-interval* } *

Parameters

Parameter	Description	Value
detecting-interval *detecting-interval*	Specifies a detection interval for OSPF neighbor relationship flapping suppression. Each OSPF interface on which OSPF neighbor relationship flapping suppression is enabled starts a flapping counter. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping_event is recorded, and the flapping_count is incremented by 1.	The value is an integer ranging from 1 to 300, in seconds. The default value is 60s.
threshold *threshold*	Specifies the threshold of OSPF neighbor relationship flapping suppression. When the flapping-count reaches or exceeds *threshold*, flapping suppression takes effect.	The value is an integer ranging from 1 to 1000. The default value is 10.

Parameter	Description	Value
resume-interval *resume-interval*	Specifies an interval for exiting from OSPF neighbor relationship flapping suppression. If the interval between two successive neighbor status changes from Full to a non-Full state is longer than *resume-interval*, the flapping-count is reset. **NOTE** The value of *resume-interval* must be greater than that of *detecting-interval*.	The value is an integer ranging from 2 to 1000, in seconds. The default value is 120s.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure detection parameters for OSPF neighbor relationship flapping suppression on an interface, run the **ospf suppress-flapping peer** command. However, keeping the default configurations is recommended.

Prerequisites

OSPF neighbor relationship flapping suppression must have been enabled globally before you configure detection parameters for it. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure the detection parameters.

Example

Set the detection interval of OSPF neighbor relationship flapping suppression to 5s, the suppression threshold to 40, and the interval for exiting from suppression to 20s on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf suppress-flapping peer detecting-interval 5 threshold 40 resume-interval 20
```

7.4.87 ospf suppress-flapping peer disable

Function

The **ospf suppress-flapping peer disable** command disables OSPF neighbor relationship flapping suppression on an interface.

The **undo ospf suppress-flapping peer disable** command enables OSPF neighbor relationship flapping suppression on an interface.

By default, OSPF neighbor relationship flapping suppression is enabled on all interfaces.

Format

ospf suppress-flapping peer disable

undo ospf suppress-flapping peer disable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, OSPF neighbor relationship flapping suppression is enabled on all interfaces in the same OSPF process. To disable the function on one of the interfaces, run the **ospf suppress-flapping peer disable** command.

NOTE

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

Prerequisites

OSPF neighbor relationship flapping suppression must have been enabled globally before you enable the function on an interface using the **undo ospf suppress-flapping peer disable** command. By default, the function is enabled globally. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it.

Example

Disable OSPF neighbor relationship flapping suppression on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf suppress-flapping peer disable
```

7.4.88 ospf suppress-flapping peer hold-down

Function

The **ospf suppress-flapping peer hold-down** command configures the Hold-down mode and sets a duration for this mode.

The **undo ospf suppress-flapping peer hold-down** command cancels the Hold-down mode.

By default, the Hold-down mode is disabled.

Format

ospf suppress-flapping peer hold-down *interval*

undo ospf suppress-flapping peer hold-down [*interval*]

Parameters

Parameter	Description	Value
interval	Specifies a duration for the Hold-down mode.	The value is an integer ranging from 1 to 600, in seconds. The default value is 60.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set a duration for this mode, run the **ospf suppress-flapping peer hold-down** command.

Prerequisites

OSPF neighbor relationship flapping suppression must have been enabled globally before you configure the Hold-down mode and set a duration for this mode. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it.

Example

Configure the Hold-down mode and set its duration to 200s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf suppress-flapping peer hold-down 200
```

7.4.89 ospf suppress-flapping peer hold-max-cost disable

Function

The **ospf suppress-flapping peer hold-max-cost disable** command disables the Hold-max-cost mode.

The **undo ospf suppress-flapping peer hold-max-cost disable** command enables the Hold-max-cost mode.

By default, the Hold-max-cost mode is enabled.

Format

ospf suppress-flapping peer hold-max-cost disable

undo ospf suppress-flapping peer hold-max-cost disable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set a duration for this mode, run the **ospf suppress-flapping peer hold-down** *interval* command.

Prerequisites

OSPF neighbor relationship flapping suppression must have been enabled globally before you configure duration for the Hold-max-cost mode. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it.

Precautions

The Hold-max-cost mode takes effect only unidirectionally. If a remote device does not support OSPF neighbor relationship flapping suppression, bidirectional traffic between the local and remote devices may travel along different paths.

Example

Disable the Hold-max-cost mode on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf suppress-flapping peer hold-max-cost disable
```

7.4.90 ospf suppress-reachability

Function

The **ospf suppress-reachability** command suppresses the advertisement of the IP addresses of a specified interface.

The **undo ospf suppress-reachability** command restores the default configuration.

By default, all OSPF interfaces advertise their IP addresses.

Format

ospf suppress-reachability [**disable**]

undo ospf suppress-reachability [**disable**]

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To suppress the advertisement of the IP addresses of a specified interface so that the IP addresses can be reused, run the **ospf suppress-reachability** command.

Configuration Impact

Suppressing the advertisement of the IP addresses of all interfaces in an OSPF process reduces the number of IP prefixes carried in LSAs and the number of OSPF routes on the network, and improves network security and OSPF performance.

Precautions

If the advertisement of the IP addresses of virtual-link interfaces is suppressed, involved virtual-link neighbors cannot reach the Full state.

The interface IP addresses whose advertisement is suppressed are not used as the forwarding addresses (FAs) of the routes imported by OSPF. As a result, external routes may fail to be calculated.

Running the **ospf suppress-reachability** command suppresses the advertisement of primary and secondary IP addresses, without affecting the advertisement of loopback interfaces' IP addresses.

Example

Suppress the advertisement of IP addresses on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf suppress-reachability
```

7.4.91 ospf timer dead

Function

The **ospf timer dead** command sets a dead interval after which an interface considers its OSPF neighbor invalid.

The **undo ospf timer dead** command restores the default dead interval of the neighbor.

By default, for a P2P or broadcast interface, the dead interval for OSPF neighbors is 40 seconds; for an NBMA or P2MP interface, it is 120 seconds.

Format

ospf timer dead *interval*

undo ospf timer dead

Parameters

Parameter	Description	Value
interval	Specifies the dead interval of the OSPF neighbors.	The value is an integer ranging from 1 to 235926000, in seconds. Setting the dead interval of an OSPF neighbor to be longer than 20s is recommended.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an interface does not receive any Hello packet from its neighbor within the dead interval, the interface considers its neighbor invalid. The dead interval on an OSPF interface must be greater than the transmission interval of Hello messages. In addition, the dead intervals of devices on the same network segment must be the same.

By default, the dead interval of OSPF neighbors is four times the transmission interval of Hello messages.

Precautions

OSPF does not support the configuration on a null interface.

If the dead interval of an OSPF neighbor is shorter than 20s, the session may be closed. Therefore, if **dead** *interval* is shorter than 20s, the actual dead interval of an OSPF neighbor is not shorter than 20s.

Example

Set the dead interval on VLANIF100 to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf timer dead 60
```

Set the dead interval on GE0/0/1 to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf timer dead 60
```

7.4.92 ospf timer hello

Function

The **ospf timer hello** command sets an interval for sending Hello packets on an interface.

The **undo ospf timer hello** command restores the default value of the interval.

By default, for a P2P or broadcast interface, the interval for sending Hello packets is 10 seconds; for an NBMA or P2MP interface, it is 30 seconds.

Format

ospf timer hello *interval* [**conservative**]

undo ospf timer hello

Parameters

Parameter	Description	Value
interval	Specifies an interval for sending the Hello packet on an interface.	The value is an integer ranging from 1 to 65535, in seconds. Setting *interval* to be longer than or equal to 5s is recommended.
conservative	Indicates the conservative mode of the dead timer. If the conservative mode is configured, the value configured for the dead timer using the **ospf timer dead** command takes effect even when the value is less than 20s.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Hello packets are periodically sent on OSPF interfaces to establish and maintain neighbor relationships. A Hello packet contains information about timers, DRs, BDRs, and known neighbors.

The smaller the **hello** *interval* is, the faster the changing speed of the network topology is. The cost of routes, however, becomes greater. Ensure that the parameters of this interface and the adjacent routers are consistent.

Precautions

OSPF does not support the configuration on a null interface.

If **hello** *interval* is set but a dead interval is not set using the **ospf timer dead** command, the dead interval of an OSPF neighbor is four times the value of **hello** *interval*. If the dead interval of an OSPF neighbor is shorter than 20s, the session may be closed. Therefore, if **hello** *interval* is shorter than 5s, the actual dead interval of an OSPF neighbor is not shorter than 20s.

Example

Set the interval for sending Hello packets on VLANIF100 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf timer hello 20
```

Set the interval for sending Hello packets on GE0/0/1 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf timer hello 20
```

7.4.93 ospf timer poll

Function

The **ospf timer poll** command sets a poll interval for sending Hello packets on NBMA networks.

The **undo ospf timer poll** command restores the default poll interval.

By default, it is 120 seconds.

Format

ospf timer poll *interval*

undo ospf timer poll

Parameters

Parameter	Description	Value
interval	Specifies the poll interval for sending Hello packets.	The value is an integer ranging from 1 to 3600, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an NBMA network, after a device's neighbor becomes invalid, the device periodically sends Hello packets to the neighbor according to the poll interval set in the **ospf timer poll** command. The poll interval should be at least 4 times that of the **Hello** interval.

Precautions

OSPF does not support the configuration on a null interface.

Example

Set the poll interval for sending Hello packets on VLANIF100 to 130 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf timer poll 130
```

Set the poll interval for sending Hello packets on GE0/0/1 to 130 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf timer poll 130
```

7.4.94 ospf timer retransmit

Function

The **ospf timer retransmit** command sets an interval for retransmitting LSA on an interface.

The **undo ospf timer retransmit** command restores the default interval for retransmitting LSA on an interface.

By default, the interval time is 5 seconds.

Format

ospf timer retransmit *interval*

undo ospf timer retransmit

Parameters

Parameter	Description	Value
interval	Specifies interval for retransmitting LSA on an interface.	The value is an integer ranging from 1 to 3600, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a device transmits an LSA to its neighbor, it has to wait for the ACK packet from the neighbor. If no ACK packet is received from the neighbor in the LSA retransmission interval, this LSA is retransmitted.

Do not set LSA retransmission intervals too short between adjacent routers. Otherwise, it leads to unnecessary retransmission.

Precautions

OSPF does not support the configuration on a null interface.

Example

Specify the interval for retransmitting LSAs between VLANIF100 and the adjacent device to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf timer retransmit 8
```

Specify the interval for retransmitting LSAs between GE0/0/1 and the adjacent device to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf timer retransmit 8
```

7.4.95 ospf trans-delay

Function

The **ospf trans-delay** command adds a transmission delay to LSAs before they are sent by an interface.

The **undo ospf trans-delay** command restores the default transmission delay of LSAs on an interface.

By default, the transmission delay is 1 second.

Format

ospf trans-delay *interval*

undo ospf trans-delay

Parameters

Parameter	Description	Value
interval	Specifies a transmission delay to be added to LSAs before they are sent by an interface.	The value is an integer ranging from 1 to 500, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

LSAs age (increase by 1 each second) in LSDBs but do not age during transmission in the network. To ensure that the aging time of LSAs transmitted to the remote device is correct, run the **ospf trans-delay** command to add a transmission delay to LSAs before they are sent by a local interface. This configuration is especially important to low-speed networks.

Precautions

OSPF does not support the configuration on a null interface.

Example

Add a transmission delay of 3 seconds to LSAs before they are sent by a VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf trans-delay 3
```

Add a transmission delay of 3 seconds to LSAs before they are sent by a GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf trans-delay 3
```

7.4.96 ospf valid-ttl-hops

Function

The **ospf valid-ttl-hops** command enables OSPF GTSM and sets a TTL value to be checked.

The **undo ospf valid-ttl-hops** command disables OSPF GTSM.

By default, OSPF GTSM is disabled.

Format

ospf valid-ttl-hops *hops* [**nonstandard-multicast**] [**vpn-instance** *vpn-instance-name*]

undo ospf valid-ttl-hops [*hops* [**nonstandard-multicast**]] [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
hops	Specifies a TTL value to be checked.	The value is an integer that ranges from 1 to 255. The default value is 255.
nonstandard-multicast	Specifies the GTSM configuration is also valid for multicast packets. When the **nonstandard-multicast** parameter is configured: ● The TTL values of the multicast packets which will be sent are set as 255. ● The received multicast packets will be checked for the TTL value 1 or in the range of [255-*hops*+1, 255].	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance. If the parameter is specified, only the TTL value of the packets in the specified VPN instance needs to be checked.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a network demanding higher security, you can enable GTSM to improve the security of the OSPF network. GTSM defends against attacks by checking the TTL value. If an attacker simulates and keeps sending OSPF unicast packets to a switch, the switch receives and directly sends the packets to the main control board for OSPF processing, without checking the validity of the packets. In this case, the switch is busy processing these packets, causing high CPU usage. GTSM protects the switches and enhances the system security by checking whether the TTL value in the IP packet header is within a pre-defined range.

The **ospf valid-ttl-hops** command is used to enable OSPF GTSM. To check the TTL value of packets that match the GTSM policy, the **vpn-instance** parameter must be specified in the command.

For example, running the **ospf valid-ttl-hops** command enables OSPF GTSM on both the public network and the private network. If you run the **ospf valid-ttl-hops 5 vpn-instance** *vpn1* command:

- OSPF GTSM is enabled on both the public network and the private network.
- The TTL value of OSPF packets in the VPN instance named *vpn1* is detected.
- The default action is performed for packets that are from the public network and other VPN instances and do not match the GTSM policy.

Precautions

- If a VPN instance is specified in the **ospf valid-ttl-hops** command and the interface is bound to the VPN instance, all the unicast packets sent to this interface are dropped when the set number of TTL hops is smaller than the actual number of hops on the network.
- If a virtual link or sham link is configured, the actual TTL value and the configured TTL value must be the same. That means that the number of virtual links or sham links that pass through the switch is calculated. Otherwise, packets sent from neighbors of a virtual link or a sham link will be dropped.
- GTSM only checks the TTL values of the packets that match the GTSM policy. If the packets do not match the GTSM policy, you can set the **pass** parameter or **drop** parameter in the **gtsm default-action** command to pass or drop these packets.
- If only a private or public network policy is configured, run the **gtsm default-action** command to set the default behavior for processing the packets unmatched with the GTSM policy to **pass** to prevent the OSPF packets of other instances from being discarded.

Example

Enable OSPF GTSM. Set the maximum number of TTL hops to 5 for the packets that can be received from the public network.

```
<HUAWEI> system-view
[HUAWEI] ospf valid-ttl-hops 5
```

7.4.97 p2mp-peer

Function

The **p2mp-peer** command sets a cost for an OSPF route to a specified neighbor on a P2MP network.

The **undo p2mp-peer** command restores the default value.

By default, the cost of an OSPF route to a neighbor in a P2MP network equals the interface cost.

Format

p2mp-peer *ip-address* **cost** *cost*

undo p2mp-peer *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a neighbor on a P2MP network.	The value is in dotted decimal notation.
cost *cost*	Sets a cost for an OSPF route to a specified neighbor on a P2MP network.	The value is an integer ranging from 1 to 65535.

Views

OSPF process view

Default Level

2: Configuration level

Usage Guidelines

By default, the cost of an OSPF route to a neighbor equals the interface cost on a P2MP network. If this default cost is not suitable, run the **p2mp-peer** command to set a desired cost.

The interface cost calculation formula is as follows: Cost of an interface = Bandwidth reference value/Interface bandwidth. The integer of the calculated result is used as the interface cost, and 1 is used as the interface cost if the calculated result is smaller than 1. The bandwidth reference value is set using the **bandwidth-reference** command, with the default value being 100 Mbit/s.

Example

Set the cost to 100 for the OSPF route to the neighbor 10.1.1.1 in OSPF process 100 on a P2MP network.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] p2mp-peer 10.1.1.1 cost 100
```

7.4.98 peer (OSPF)

Function

The **peer** command sets an IP address and a DR priority for the adjacent switch on an NBMA network.

The **undo peer** command cancels the IP address of the adjacent switch on an NBMA network.

By default, the IP address and DR priority for the adjacent switch on an NBMA network are not set.

Format

peer *ip-address* [**dr-priority** *priority*]

undo peer *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies an IP address for the adjacent switch.	The value is in dotted decimal notation.
dr-priority *priority*	Sets a DR priority for the adjacent switch.	The value of the priority is an integer that ranges from 0 to 255. By default, it is 1.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

On an NBMA network (such as an X.25 or FR network), the entire network can be fully meshed based on the mapping configuration. This means that there is a virtual link between any two devices. In this case, the network running OSPF can be considered as a broadcast network where a DR or a BDR can be selected. However, you must run the **peer** command to manually specify an IP address and a DR priority for an adjacent switch. This is necessary because it is impossible to find the adjacent devices dynamically by broadcasting Hello packets.

Example

Set the IP address of the adjacent switch to 10.1.1.1 on an NBMA network.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] peer 10.1.1.1
```

7.4.99 preference (OSPF)

Function

The **preference** command sets a preference for an OSPF route.

The **undo preference** command restores the default preference of OSPF routes.

By default, the preference of OSPF routes is 10 and that of ASE routes is 150.

Format

preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

undo preference [**ase**]

Parameters

Parameter	Description	Value
ase	Indicates the preference of an AS external route.	-
preference	Specifies the preference of an OSPF route. The smaller the preference value, the higher the preference.	The value is an integer ranging from 1 to 255.
route-policy *route-policy-name*	Specifies the name of a route policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Multiple dynamic routing protocols can run on a switch at the same time. This creates a problem of route sharing and selecting among routing protocols. The system sets a default preference for each routing protocol. If different protocols have routes to the same destination, the protocol with a higher preference is selected to forward IP packets. To set a preference for an OSPF route, run the **preference** command.

You can create a route-policy to set a preference for a specific route by setting the **route-policy** parameter in the **preference** command:

- If the **apply preference** clause is configured for the route-policy, route preference is determined as follows:
  - Route matching the route-policy: Its preference is determined by the **apply** clause.

  - Route that does not match the route-policy: Its preference is determined by the **preference** command.

  In the following example, the preference of the route matching the route-policy **abc** is set to 50 and the preference of the route that does not match the route-policy is set to 30.

```
#
route-policy abc permit node 1
 if-match cost 20
 apply preference 50
#
ospf 1
 preference 30 route-policy abc
```

- If the **apply preference** clause is not included in the route-policy, the preference of routes is set by the **preference** command.

  In the above example, if the **apply preference 50** clause is not included in the policy **abc**, the preference of all routes is set to 30.

Configuration Impact

When there are routes discovered by multiple routing protocols on the same switch, you can make the switch prefer OSPF routes by setting a high preference for them.

Precautions

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured priority applies to all OSPF routes.

Example

Set the preference of routes in OSPF process 100 to 150.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] preference 150
```

Set the preference of external routes in OSPF process 200 to 130.

```
<HUAWEI> system-view
[HUAWEI] ospf 200
[HUAWEI-ospf-200] preference ase 130
```

7.4.100 prefix-priority (OSPF)

Function

The **prefix-priority** command sets a convergence priority for OSPF routes.

The **undo prefix-priority** command restores the default convergence priority of OSPF routes.

By default, the convergence priority of public 32-bit host routes is **medium**, and the convergence of other OSPF routes is **low**.

Format

prefix-priority { **critical** | **high** | **medium** } **ip-prefix** *ip-prefix-name*

undo prefix-priority { **critical** | **high** | **medium** }

Parameters

Parameter	Description	Value
critical	Sets the convergence priority of OSPF routes to critical.	-
high	Sets the convergence priority of OSPF routes to high.	-
medium	Sets the convergence priority of OSPF routes to medium.	-
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **prefix-priority** command sets a convergence priority for OSPF routes according to a specified IP prefix list name. It takes effect on the public network only.

After the **prefix-priority** command is run in the OSPF view, OSPF route calculation, link-state advertisement (LSA) flooding, and LSDB synchronization can be implemented according to the configured priority, which accelerates route convergence.

Prerequisites

An IP prefix list has been created using the **ip ip-prefix** command in the system view.

Configuration Impact

When an LSA meets multiple priorities, the highest priority takes effect.

With the **prefix-priority** command, OSPF can calculate and flood LSAs, and synchronize LSDBs according to priorities. This speeds up route convergence. OSPF calculates LSAs in the sequence of intra-area routes, inter-area routes, and AS external routes. This command makes OSPF calculate the three types of routes separately according to the specified route calculation priorities. Convergence priorities are critical, high, medium, and low. To speed up the processing of LSAs with the higher priority, during LSA flooding, the LSAs need to be placed into the corresponding critical, high, medium, and low queues according to priorities.

Precautions

By default, the convergence priorities of public OSPF host routes, direct routes, static routes, and other protocol (such as BGP and RIP) routes are **medium**, **high**, **medium**, and **low** respectively. In the public network, OSPF 32-bit host routes are uniformly identified as **medium**.

Example

Set the convergence priority of OSPF routes of 10.0.0.0/8 to critical.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix critical-prefix index 10 permit 10.0.0.0 8
[HUAWEI] ospf 1
[HUAWEI-ospf-1] prefix-priority critical ip-prefix critical-prefix
```

7.4.101 reset gtsm statistics

Function

The **reset gtsm statistics** command clears GTSM statistics.

Format

reset gtsm statistics all

Parameters

Parameter	Description	Value
all	Clears GTSM statistics.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Before collecting the GTSM statistic within a certain period, you need to clear the existing statistics.

Example

Clear GTSM statistics.

```
<HUAWEI> reset gtsm statistics all
```

7.4.102 reset ospf counters

Function

The **reset ospf counters** command resets OSPF counters.

Format

reset ospf [*process-id*] **counters** [**neighbor** [*interface-type interface-number*] [*router-id*]]

Parameters

Parameter	Description	Value
process-id	Indicates an OSPF process ID. If the parameter is not specified, all OSPF processes are restarted.	The value is an integer ranging from 1 to 65535.
neighbor	Specifies neighbor information of an interface.	-
interface-type interface-number	Specifies the type and the number of an interface.	-
router-id	Specifies the router ID of the neighbor.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

When the switch restarts an OSPF process, the neighboring switch always reserves invalid LSAs. This occupies the memory of the system. These LSAs are deleted only when they expire, which happens when the LS age field in the LSA reaches 3600 seconds. After the **reset ospf** is used to restart an OSPF process and only when the router ID is changed, the switch generates an LSA in the set time and sets the LS age field to 3600 seconds. After receiving the LSA, other switches delete the LSA immediately from their LSDBs. If a switch does not send all the LSAs within the set time, other neighboring switches still store some invalid LSAs.

Clearing OSPF statistics does not affect the normal operation of OSPF services.

NOTICE

Once deleted, statistics cannot be restored. Therefore, exercise caution when deleting statistics.

Example

Reset OSPF counters.

```
<HUAWEI> reset ospf counters
```

7.4.103 reset ospf process

Function

The **reset ospf process** command restarts an OSPF process.

Format

reset ospf [*process-id*] **process** [**flush-waiting-timer** *time* | **graceful-restart**]

Parameters

Parameter	Description	Value
process-id	Indicates an OSPF process ID. If the parameter is not specified, all OSPF processes are restarted.	The value is an integer ranging from 1 to 65535.
flush-waiting-timer *time*	Specified the time when the LSA is generated. The parameter takes effect only when it is set.	The value is an integer that ranges from 1 to 40, in seconds.
graceful-restart	Indicates that graceful restart is enabled.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset ospf process** command can be used to clear OSPF information to reset the board.

NOTICE

If OSPF connections are reset, OSPF neighbor relationships will be interrupted and the original information cannot be restored. Exercise caution before running the **reset ospf process** command.

Configuration Impact

After the **reset ospf process** command is used to restart OSPF, the following situations may occur:

- If a router ID is changed, a new router ID will take effect after the command is run.
- Re-elect a DR and BDR.
- OSPF configuration will not be lost after OSPF restarts.

Precautions

Configuring the **flush-waiting-timer** parameter when OSPF starts allows you to clear invalid LSAs within the set time before LSAs time out.

Whether all invalid LSAs on other switches can be deleted depends on the set time.

When the switch restarts an OSPF process, the neighboring switch always reserves invalid LSAs. This occupies the memory of the system. These LSAs are deleted only when they expire, which happens when the LS age field in the LSA reaches 3600 seconds. After the **reset ospf** is used to restart an OSPF process and only when the router ID is changed, the switch generates an LSA in the set time and sets the LS age field to 3600 seconds. After receiving the LSA, other switches delete the LSA immediately from their LSDBs. If a device does not send all the LSAs within the set time, other neighboring switches still store some invalid LSAs.

Example

Restart all OSPF processes.

```
<HUAWEI> reset ospf process
Warning: The OSPF process will be reset. Continue? [Y/N]: y
```

7.4.104 reset ospf redistribution

Function

The **reset ospf redistribution** command re-imports OSPF routes.

Format

reset ospf [*process-id*] **redistribution**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process. If this parameter is not specified, all OSPF processes are restarted.	The value is an integer that ranges from 1 to 65535.

Views

User view

Default Level

3: Management level

Usage Guidelines

The **reset ospf redistribution** command re-imports OSPF routes to generate Type 5 or Type 7 LSAs.

Example

Re-import OSPF routes in OSPF process 1.

```
<HUAWEI> reset ospf 1 redistribution
```

7.4.105 reset ospf suppress-flapping peer

Function

The **reset ospf suppress-flapping peer** command forces an interface to exit from OSPF neighbor relationship flapping suppression.

Format

reset ospf *process-id* **suppress-flapping peer** [*interface-type interface-number*] [**notify-peer**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPF process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies an interface type and number.	-
notify-peer	Instructs neighbors to exit from OSPF neighbor relationship flapping suppression too.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Interfaces exit from flapping suppression in any of the following scenarios:

- The suppression timer expires.
- The corresponding OSPF process is reset.
- The **reset ospf suppress-flapping peer** command is run.
- OSPF neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable** command in the OSPF view.

If **notify-peer** is specified when the **reset ospf suppress-flapping peer** command is run on a device, the device sends Hello packets in which **HelloInterval** and **RouterDeadInterval** are 0s to its neighbors to instruct the neighbors to exit from OSPF neighbor relationship flapping suppression too. If the neighbors fail to receive such Hello packets, the function of **notify-peer** does not take effect. To force the neighbors to exit from OSPF neighbor relationship flapping suppression, run the **reset ospf suppress-flapping peer** command on them.

Example

Force interfaces to exit from OSPF neighbor relationship flapping suppression.

```
<HUAWEI> reset ospf 1 suppress-flapping peer
```

7.4.106 retransmission-limit

Function

The **retransmission-limit** command enables retransmission limit and sets the maximum number of retransmissions.

The **undo retransmission-limit** command disables retransmission limit.

By default, retransmission limit is disabled.

Format

retransmission-limit [*max-number*]

undo retransmission-limit

Parameters

Parameter	Description	Value
max-number	Indicates the maximum number of retransmissions.	The value is an integer that ranges from 2 to 255. The default value is 30.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **retransmission-limit** command can be used to enable Retransmission Limitation for OSPF (RL-for OSPF) to prevent dead loops caused by repeated transmissions if neighbors cannot receive packets.

Configuration Impact

The OSPF retransmission limit can be used in the following packets:

- DD packets
- LSU packets
- LSR packets

Limit the maximum number of retransmissions. If the preceding three types of packets cannot be responded within the allowed retransmission times, disconnect neighbor relationships.

Example

Enable OSPF retransmission limit and set the maximum number of retransmissions to 40.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] retransmission-limit 40
```

7.4.107 route-tag

Function

The **route-tag** command sets a tag value for imported VPN routes.

The **undo route-tag** command restores the default setting.

By default, the tag value of a VPN route is calculated based on the AS number of BGP. If no BGP is configured, the default tag value is 0.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

route-tag { *tag* | **disable** }

undo route-tag

Parameters

Parameter	Description	Value
tag	Specifies the tag value of the imported VPN routes.	The value is an integer ranging from 0 to 4294967295.
disable	Disables a device from using a VPN route tag to detect loops.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **route-tag** command can be used only in VPN scenarios to prevent loops on Type-5 and Type-7 LSAs when a CE is dual-homed to two PEs.

In a networking where a CE is dual-homed to two PEs, PE1 generates Type-5 and Type-7 LSAs based on the imported BGP routes and sends the LSAs to the CE, then to PE2. Because OSPF routes have higher priorities over BGP routes, OSPF routes will replace BGP routes on PE2, causing loops. After the **route-tag** command is run, if the tag value of the PE and an LSA are the same, the PE will neglect the LSA, and a loop is prevented.

By default, the first two bytes of the tag value are fixed as 0xD000, while the last two bytes are the AS number of the local BGP. If a BGP AS number is greater than 65535, the default tag 0 is used. You can use the command to change the tag in this case.

Precautions

- Configuring the same VPN route tag on the PEs within the same area is recommended.
- Different OSPF processes can be configured with the same VPN route tag.

The tags set by the **route-tag** command or other commands are different only in preference.

1. The preference of the tag configured using the **import-route** command is the highest.
2. The preference of the tag configured using the **route-tag** command is medium.
3. The preference of the tag configured using the **default tag** command is the lowest.

Example

Set the route tag for OSPF process 100 to 100 in a VPN instance named **test**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv4] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospf 100 vpn-instance test
[HUAWEI-ospf-100] route-tag 100
```

7.4.108 rfc1583 compatible

Function

The **rfc1583 compatible** command converts rules defined in RFC 2328 into rules defined in RFC 1583.

The **undo rfc1583 compatible** command converts rules defined in RFC 1583 into rules defined in RFC 2328.

By default, OSPF supports the routing rule of RFC 1583.

Format

rfc1583 compatible

undo rfc1583 compatible

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

RFC 2328 and RFC 1583 define different OSPF route selection rules. When enabling OSPF, configure the same route selection rules on all devices in the same OSPF area. For example, in scenarios where an OSPF device uses the default route selection rules defined in RFC 1583, if the other switches in the same OSPF area use route selection rules defined in RFC 2328, you need to run the **undo rfc1583 compatible** command.

Example

Converts rules defined in RFC 1583 into rules defined in RFC 2328.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] undo rfc1583 compatible
```

7.4.109 sham-hello enable (OSPF)

Function

The **sham-hello enable** command enables the sham-hello function of OSPF.

The **undo sham-hello** command disables the sham-hello function.

By default, the sham-hello feature is disabled.

Format

sham-hello enable

undo sham-hello

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

After this command is executed, the device maintains neighbor relationships through both the Hello packets and also all OSPF protocol packets. This accurately senses the existence of OSPF neighbors and stabilizes neighboring relations.

Example

Enable the sham-hello function.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] sham-hello enable
```

7.4.110 sham-link (OSPF Area)

Function

The **sham-link** command configures a sham link or sets parameter values for a sham link.

The **undo sham-link** command deletes a sham link or restores the default parameter values of a sham link.

By default, no sham link is configured for OSPF.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

sham-link *source-ip-address destination-ip-address* [[**simple** [**plain** *plain-text* | [**cipher**] *cipher-text*] | { **md5** | **hmac-md5** | **hmac-sha256** } [*key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* }] | **authentication-null** | **keychain** *keychain-name*] | **smart-discover** | **cost** *cost* | **dead** *dead-interval* | **hello** *hello-interval* | **retransmit** *retransmit-interval* | **trans-delay** *trans-delay-interval*] *

undo sham-link *source-ip-address destination-ip-address* [[**simple** | **md5** | **hmac-md5** | **hmac-sha256** | **authentication-null** | **keychain**] | **smart-discover** | **cost** | **dead** | **hello** | **retransmit** | **trans-delay**] *

Parameters

Parameter	Description	Value
source-ip-address	Specifies the source IP address.	The value is in dotted decimal notation.
destination-ip-address	Specifies the destination IP address.	The value is in dotted decimal notation.
smart-discover	Indicates that Hello packets are sent automatically and immediately.	-
simple	Indicates simple authentication. In simple authentication, the password type is **cipher** by default. **NOTICE** Simple authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
plain	Indicates plain authentication. Only plain text can be entered, and only plain text is displayed when the configuration file is viewed. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This carries security risks. You are advised to select **cipher** to save the password in cipher text.	-
plain-text	Specifies a plain text password.	● In **simple** authentication, the value is a string of 1 to 8 characters without spaces. ● In **md5**, **hmac-sha256** or **hmac-md5** authentication, the value is a string of 1 to 255 characters.

Parameter	Description	Value
cipher	Indicates cipher authentication. Either plain text or cipher text can be entered, and cipher text is displayed when the configuration file is viewed.	-
cipher-text	Specifies a cipher text password.	- In **simple** authentication, the value is a string of 1 to 8 plain text characters and 48 cipher text characters. - In **md5**, **hmac-sha256** or **hmac-md5** authentication, the value is a string of 1 to 255 plain text characters and 20 to 392 cipher text characters.
md5	Indicates MD5 authentication. **NOTICE** MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-md5	Indicates **hmac-md5** authentication. **NOTICE** HMAC-MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-sha256	Indicates **HMAC-SHA256** authentication.	-
key-id	Specifies the authentication key ID of the interface's cipher authentication. The key ID must be consistent with that of the peer.	The value is an integer that ranges from 1 to 255.
authentication-null	Indicates that no authentication is used.	-

Parameter	Description	Value
keychain	Indicates keychain authentication. **NOTE** Before configuring this parameter, run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, OSPF authentication will fail. Currently, only the **HMAC-MD5**, **SM3**, and **HMAC-SHA256** algorithms can be used in OSPF.	-
keychain-name	Specifies the keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
cost *cost*	Specifies the cost of the sham link.	The value of the cost is an integer that ranges from 1 to 65535. The default value is 1.
dead *dead-interval*	Specifies the dead interval. This value must be equal to *dead-interval* of the switch that sets up a virtual link with the local switch, and must be at least four times that of *hello-interval*.	The value of the interval is an integer that ranges from 1 to 235926000, in seconds.
hello *hello-interval*	Specifies an interval for transmitting Hello packets on an interface. This value must be equal to *hello-interval* of the switch that sets up a virtual link with the local switch.	The value is an integer that ranges from 1 to 65535, in seconds.

Parameter	Description	Value
retransmit *retransmit-interval*	Specifies an interval for retransmitting the LSA packets on an interface.	The value is an integer that ranges from 1 to 3600, in seconds.
trans-delay *trans-delay-interval*	Specifies the delay in transmitting LSA packets on an interface.	The value is an integer that ranges from 1 to 3600, in seconds.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **sham-link** command can be used only in VPN scenarios.

This command can create a sham link to allow VPN traffic to be preferentially forwarded through routes within the backbone area. This prevents traffic from the same VPN in the same OSPF area from being forwarded through intra-area OSPF routes.

Before enabling neighbors of a sham link to set up adjacencies quickly, configure the **smart-discover** parameter to actively send Hello packets immediately.

Configuration Impact

After a sham link is configured between two PEs, the sham link is considered as an intra-area OSPF route. This configuration enables a route passing through an MPLS VPN backbone network to become an intra-area OSPF route, preventing VPN traffic from being transmitted through this route. A 32-bit loopback interface address is specified as the source and destination addresses of the sham link. The loopback interface must be bound to a VPN instance and advertised using BGP.

Precautions

The route to the endpoint address of a sham link cannot be advertised to the remote PE using an OSPF process in a private network. Otherwise, two routes to the endpoint address of the sham link exist on the remote PE. One route is learned from the OSPF process and the other is learned using MP-BGP. OSPF routes have higher priorities over BGP routes. As such, the remote PE selects an incorrect OSPF route. As a result, the sham link cannot be created.

Example

Create a sham link with the source address 10.1.1.1 and destination address 10.2.2.2 in a VPN instance named **test**.

```
<HUAWEI> system-view
[HUAWEI] ospf 1 vpn-instance test
[HUAWEI-ospf-1] area 1
[HUAWEI-ospf-1-area-0.0.0.1] sham-link 10.1.1.1 10.2.2.2
```

7.4.111 silent-interface (OSPF)

Function

The **silent-interface** command disables an interface from receiving and sending OSPF packets.

The **undo silent-interface** command restores the default setting.

By default, the interface is permitted to receive or send OSPF packet.

Format

silent-interface { **all** | *interface-type interface-number* }

undo silent-interface { **all** | *interface-type* [*interface-number*] }

Parameters

Parameter	Description	Value
all	Indicates all interfaces in a specified process.	-
interface-type interface-number	Specifies the interface type and interface number.	-

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To ensure that OSPF routing information is not obtained by the devices of a certain network and the local device does not receive routing update information advertised by other devices, you can run the **silent-interface** command to disable an interface from receiving and sending OSPF packets, thereby preventing routing loops.

Configuration Impact

After an OSPF interface is set to be in the silent state, the interface can still advertise its direct routes. Hello packets on the interface, however, will be blocked and no neighbor relationship can be established on the interface. This can enhance the networking adaptability of OSPF and reduce the consumption of system resources.

Example

Disable VLANIF200 from sending or receiving OSPF packets.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] silent-interface vlanif 200
```

7.4.112 spf-schedule-interval

Function

The **spf-schedule-interval** command sets an interval for OSPF to calculate routes.

The **undo spf-schedule-interval** command restores the default setting.

By default, the intelligent timer is enabled. The interval for the SPF calculation is expressed in milliseconds. The maximum interval for the SPF calculation is 10000 ms, the initial interval is 500 ms, and the Holdtime interval is 1000 ms.

Format

spf-schedule-interval { *interval1* | **intelligent-timer** *max-interval start-interval hold-interval* | **millisecond** *interval2* }

undo spf-schedule-interval

Parameters

Parameter	Description	Value
interval1	Specifies an interval for OSPF to perform the SPF calculation.	The value is an integer ranging from 1 to 10, in seconds.
intelligent-timer	Sets an interval for OSPF SPF calculation through an intelligent timer.	-
max-interval	Specifies a maximum interval for OSPF to perform the SPF calculation.	The value is an integer ranging from 1 to 120000, in milliseconds. The default value is 10000.
start-interval	Specifies the initial interval for OSPF to perform the SPF calculation.	The value is an integer ranging from 1 to 60000, in milliseconds. The default value is 500.

Parameter	Description	Value
hold-interval	Specifies the Holdtime interval for OSPF to perform the SPF calculation.	The value is an integer ranging from 1 to 60000, in milliseconds. The default value is 1000.
millisecond *interval2*	Specifies an interval for OSPF to perform the SPF calculation.	The value is an integer ranging from 1 to 10000, in milliseconds.

Views

2: Configuration level

Usage Guidelines

Usage Scenario

Based on the LSDB, the device that runs OSPF calculates the SPT with itself as the root based on the SPF arithmetic, and determines the next hop to the destination network according to the SPT. When the OSPF LSDB changes, the shortest path needs to be recalculated. Frequent network changes and continual calculation of the shortest path consume many system resources and affect the efficiency of the devices. You can configure an intelligent timer and set a proper interval for the SPF calculation to prevent the excessive consumption of device memory and bandwidth resources.

On a network where the convergence time of routes is required to be shorter, set millisecond as the unit of interval to increase the frequency of calculating routes. This increases route convergence. In other networking environments, the default value is recommended.

Configuration Impact

After this command is configured, the interval for the SPF calculation is as follows:

1. The initial interval for the SPF calculation is specified by the parameter *start-interval*.
2. The interval for the SPF calculation for the nth (n≥2) time is equal to *hold-interval* x $2^{(n-2)}$.
3. When the interval specified by *hold-interval* x $2^{(n-2)}$ reaches the maximum interval specified by *max-interval*, OSPF performs SPF calculation at the maximum interval until *max-interval* expires without flapping or the OSPF process is restarted.

Example

Set the interval for OSPF to calculate routes to 6 seconds.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] spf-schedule-interval 6
```

7.4.113 stub (OSPF area)

Function

The **stub** command sets an area to a stub area.

The **undo stub** command cancels the settings.

By default, no area is set to a stub area.

Format

stub [**no-summary** | **default-route-advertise backbone-peer-ignore**] *

undo stub

Parameters

Parameter	Description	Value
no-summary	Disables an ABR from sending non-default Type 3 LSAs to the stub area. This parameter applies only to ABRs of stub areas. If the parameter is configured on an ABR, the ABR advertises only one default Type 3 LSA (no other Type 3 LSAs) to the stub area. In this case, this area is also called a totally stub area.	-
default-route-advertise	Configures an ABR to advertise a default Type 3 LSA to the stub area. This parameter applies only to ABRs of stub areas.	-
backbone-peer-ignore	Prevents an ABR from checking the neighbor status when the ABR generates a default Type 3 LSA and advertises it to the stub area. This parameter applies only to ABRs of stub areas. If the parameter is configured on an ABR, the ABR generates a default Type 3 LSA and advertises it to the stub area as long as an interface is Up in the backbone area.	-

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

There are two configuration commands for stub areas: **stub** and **default-cost**. The stub area attribute must be configured on all switches in a stub area using the **stub** command.

The **default-cost** command takes effect only when it is configured on an ABR. The command is used to specify the cost of the default summary route transmitted by the ABR to the stub area.

- If the **stub** command is run on an ABR, without parameters specified, the ABR advertises a default Type 3 LSA and advertises it to the stub area as long as an OSPF neighbor in the full state exists in the backbone area.
- If the **stub no-summary** command is run on an ABR, the ABR is disabled from sending non-default Type 3 LSAs to the stub area connected to the ABR.
- If the **stub default-route-advertise backbone-peer-ignore** command is run on an ABR, the ABR generates a default Type 3 LSA and advertises it to the stub area as long as an interface is Up in the backbone area.

Precautions

The backbone area (area 0) cannot be configured as a stub area.

Example

Set OSPF area 1 as a stub area.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] stub
```

7.4.114 stub-router (OSPF)

Function

The **stub-router** command configures a stub router.

The **undo stub-router** command restores the default configuration.

By default, no device is configured as a stub router.

Format

stub-router [**on-startup** [*interval*]]

undo stub-router

Parameters

Parameter	Description	Value
on-startup [*interval*]	Specifies the interval during which a device acts as a stub router when the device is restarted or faulty. ● If **on-startup** is not specified, the device is always a stub router, even if the cost of all routes advertised by the device is 65535. ● If **on-startup** is specified, the device works as a stub router only when it restarts or is faulty. The hold time of the stub router state is determined by *interval* parameter. If the *interval* parameter is not configured, the default interval (500 seconds) is used.	The value is an integer that ranges from 5 to 65535, in seconds. By default, the value is 500 seconds.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

After the **stub-router** command is configured on a device, the device informs other devices not to use this stub router to forward data by increasing the metric to 65535 of the links in the LSA that is generated by the device. As the metric is not infinite, there can still be a route to this stub router. The metric of the LSA links that are generated by the stub router is very high.

Example

Configure the device as a stub router.

```
<HUAWEI> system-view
[HUAWEI] ospf 1
[HUAWEI-ospf-1] stub-router
```

7.4.115 suppress-flapping peer disable (OSPF)

Function

The **suppress-flapping peer disable** command disables OSPF neighbor relationship flapping suppression globally.

The **undo suppress-flapping peer disable** command enables OSPF neighbor relationship flapping suppression globally.

By default, OSPF neighbor relationship flapping suppression is enabled globally.

Format

suppress-flapping peer disable

undo suppress-flapping peer disable

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

If an OSPF interface alternates between Up and Down, OSPF neighbor relationship flapping occurs on the interface. During the flapping, OSPF frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPF services, and other OSPF-dependent services, such as LDP and BGP. OSPF neighbor relationship flapping suppression can address this problem by delaying OSPF neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

By default, OSPF neighbor relationship flapping suppression is enabled globally. To disable this function globally, run the **suppress-flapping peer disable** command.

Example

Disable neighbor relationship flapping suppression globally.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] suppress-flapping peer disable
```

7.4.116 suppress-reachability (OSPF)

Function

The **suppress-reachability** command suppresses the advertisement of the IP addresses of all interfaces in an OSPF process.

The **undo suppress-reachability** command restores the default configuration.

By default, all interfaces in an OSPF process advertise their IP addresses.

Format

suppress-reachability

undo suppress-reachability

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To suppress the advertisement of the IP addresses of all interfaces in an OSPF process so that the IP addresses can be reused, run the **suppress-reachability** command.

Configuration Impact

Suppressing the advertisement of the IP addresses of all interfaces in an OSPF process reduces the number of IP prefixes carried in LSAs and the number of OSPF routes on the network, and improves network security and OSPF performance.

Precautions

If the advertisement of the IP addresses of virtual-link interfaces is suppressed, involved virtual-link neighbors cannot reach the Full state.

The interface IP addresses whose advertisement is suppressed are not used as the forwarding addresses (FAs) of the routes imported by OSPF. As a result, external routes may fail to be calculated.

Running the **suppress-reachability** command suppresses the advertisement of primary and secondary IP addresses, without affecting the advertisement of loopback interfaces' IP addresses.

Example

Suppress the advertisement of the IP addresses of all interfaces in OSPF process 100.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] suppress-reachability
```

7.4.117 vlink-peer (OSPF area)

Function

The **vlink-peer** command creates and configures a virtual link.

The **undo vlink-peer** command deletes the virtual link or restores the default setting.

By default, no virtual link is configured for OSPF.

Format

vlink-peer *router-id* [**dead** *dead-interval* | **hello** *hello-interval* | **retransmit** *retransmit-interval* | **smart-discover** | **trans-delay** *trans-delay-interval* | [**simple** [**plain** *plain-text* | [**cipher**] *cipher-text*] | { **md5** | **hmac-md5** | **hmac-sha256** } [*key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* }] | **authentication-null** | **keychain** *keychain-name*]] *

undo vlink-peer *router-id* [**dead** | **hello** | **retransmit** | **smart-discover** | **trans-delay** | **simple** | **md5** | **hmac-md5** | **hmac-sha256** | **authentication-null** | **keychain**]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
router-id	Specifies the switch ID of virtual link neighbor.	-
dead *dead-interval*	Specifies a dead interval. This value must be equal to *dead-interval* of the Switch that sets up a virtual link with the interface and must be at least 4 times that of *hello-interval*.	The value is an integer that ranges from 1 to 235926000, in seconds. The default value is 40 seconds.
hello *hello-interval*	Specifies an interval for transmitting Hello packets on an interface. This value must be equal to *hello-interval* value of the Switch that sets up a virtual link with the interface. The default value is 10 seconds.	The value ranges from 1 to 65535 seconds. The default value is 10 seconds.
retransmit *retransmit-interval*	Specifies an interval for retransmitting the LSA packets on an interface.	The value is an integer that ranges from 1 to 3600, in seconds. The default value is 5 seconds.
smart-discover	Automatically sends Hello packets	-

Parameter	Description	Value
trans-delay *trans-delay-interval*	Specifies the delay in transmitting LSA packets on an interface.	The value is an integer that ranges from 1 to 3600, in seconds. The default value is 1 second.
simple	Indicates simple authentication. In simple authentication, the password type is **cipher** by default. **NOTICE** Simple authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
plain	Indicates plain authentication. Only plain text can be entered, and only plain text is displayed when the configuration file is viewed. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This carries security risks. Select **cipher** to save the password in cipher text for increased security.	-
plain-text	Specifies a plain text password.	● In **simple** mode, the value is a string of 1 to 8 characters without spaces. ● In **md5**, **hmac-sha256** or **hmac-md5** mode, the value is a string of 1 to 255 characters without spaces.
cipher	Indicates cipher authentication. Either plain text or cipher text can be entered, and cipher text is displayed when the configuration file is viewed.	-

Parameter	Description	Value
cipher-text	Specifies a cipher text password.	- In **simple** mode, the value is a string of 1 to 8 characters (plaintext password) or 48 characters (ciphertext password) without spaces. - In **md5**, **hmac-sha256** or **hmac-md5** mode, the value is a string of 1 to 255 (plain text password) and 20 to 392 characters (cipher text password) without spaces.
md5	Indicates MD5 authentication. In MD5 authentication, the password type is **cipher** by default. **NOTICE** MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-md5	Indicates HMAC-MD5 authentication. In HMAC-MD5 authentication, the password type is **cipher** by default. **NOTICE** HMAC-MD5 authentication carries potential security risks. As such, HMAC-SHA256 authentication is recommended.	-
hmac-sha256	Indicates HMAC-SHA256 authentication. In HMAC-SHA256 authentication, the password type is **cipher** by default.	-
key-id	Specifies the authentication key ID of the interface's cipher authentication. The key ID must be consistent with that of the peer.	The value is an integer that ranges from 1 to 255.

Parameter	Description	Value
authentication-null	Indicates that no authentication is used.	-
keychain	Indicates keychain authentication. **NOTE** Before configuring this parameter, run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, OSPF authentication will fail. Currently, only the **HMAC-MD5**, **SM3**, and **HMAC-SHA256** algorithms can be used in OSPF.	-
keychain-name	Specifies the keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

Usage Guidelines

After OSPF areas are defined, OSPF route updates between non-backbone areas are transmitted through a backbone area. Therefore, OSPF requires that all non-backbone areas be directly connected to the backbone area and devices within the backbone area keep connected as well. However, these requirements may not be met due to various limitations. OSPF virtual links can be configured to solve the problem.

Follow-up Procedure

After virtual links are established, devices provided by different vendors may use different default MTUs. To ensure consistent MTUs on the devices, run the **undo**

ospf mtu-enable command to set the default MTU in DD packets sent by interfaces to 0.

NOTICE

Configuring the MTU in DD packets will cause the neighbor relationship to be re-established.

Precautions

When configuring parameters, pay attention to the following:

- A smaller **hello** value indicates faster detection of changes in network topology and higher network resource usage.
- A **retransmit** value that is too small leads to unnecessary retransmission of LSAs. On a low-speed network, set a large **retransmit** value.
- The authentication mode of a virtual link must be the same as that in the backbone area.

Example

Configure a virtual link with the peer device's router ID 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] area 2
[HUAWEI-ospf-100-area-0.0.0.2] vlink-peer 10.1.1.1
```

7.4.118 vpn-instance-capability simple (OSPF)

Function

The **vpn-instance-capability simple** command directly calculates a route instead of conducting the routing loop detection.

The **undo vpn-instance-capability** command detects the DN bit to avoid routing loops.

By default, the routing-loop check is enabled.

Format

vpn-instance-capability simple

undo vpn-instance-capability

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If OSPF VPN multi-instance is deployed on a Multi-VPN-Instance CE (MCE), routes cannot be calculated based on Type3, Type5, or Type7 LSAs with the DN bit. Therefore, OSPF detects routing loops when calculating routes. In this case, the **vpn-instance-capability simple** command is used to disable OSPF routing loop detection and enable OSPF to calculate routes based on received LSAs without checking the DN bit and route-tag in the LSAs. The route-tag is restored to the default value 1.

Prerequisites

OSPF VPN multi-instance has been deployed on an MCE using the **ospf** *process-id* **vpn-instance** *vpn-instance-name* command.

Configuration Impact

- If there is no ABR and the **vpn-instance-capability simple** command is run on an MCE, the MEC cannot become an ABR.
- After the **vpn-instance-capability simple** command is run, OSPF routes that have been imported by BGP do not carry any OSPF domain ID, route tag, or router ID.
- By default, when BGP imports an OSPF route, it uses the cost of the OSPF route plus 1 as the MED value. The MED in BGP is similar to the cost in an IGP in terms of functions. After the **vpn-instance-capability simple** command is run, BGP uses the cost of an OSPF route as the MED when it imports the OSPF route. Therefore, MED values change after the command is run, which may affect the route selection result.

Precautions

NOTE

The **undo vpn-instance-capability** command cannot be used to enable OSPF routing loop detection in a scenario without MCEs.

Example

Disable the OSPF routing-loop check.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] vpn-target 3:3 export-extcommunity
[HUAWEI-vpn-instance-vrf1-af-ipv4] vpn-target 4:4 import-extcommunity
[HUAWEI-vpn-instance-vrf1-af-ipv4] quit
[HUAWEI-vpn-instance-vrf1] quit
[HUAWEI] ospf 100 vpn-instance vrf1
[HUAWEI-ospf-100] vpn-instance-capability simple
```

7.5 OSPFv3 Configuration Commands

7.5.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

7.5.2 abr-summary (OSPFv3 Area)

Function

The **abr-summary** command configures IPv6 route summarization on an ABR.

The **undo abr-summary** command cancels IPv6 route summarization on an ABR.

By default, IPv6 route summarization is not configured on ABRs.

Format

abr-summary *ipv6-address prefix-length* [**cost** *cost* | **not-advertise**] *

undo abr-summary *ipv6-address prefix-length*

Parameters

Parameter	Description	Value
ipv6-address	Specifies the address range of IPv6 routes to be summarized.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the prefix length.	The value is an integer that ranges from 1 to 128.
cost *cost*	Specifies the cost of a summarized route. By default, the cost of a summarized route is the maximum cost among those of routes that are summarized.	The value is an integer that ranges from 1 to 16777214.
not-advertise	Indicates that the summarized IPv6 routes that match a specified IPv6 address prefix or prefix length are not advertised.	-

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

This command applies only to the ABR of the current area. The ABR transmits only one summarized route to other areas.

An area can be configured with multiple summarized network segments. Thus OSPFv3 can summarize multiple network segments.

Example

Summarize two routes FC00:0:0:1::/64 and FC00:0:0:2::/64 of OSPFv3 area 1 into route FC00:0:0::/48 with the cost being 400, and advertise it to other areas.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 1
[HUAWEI-ospfv3-1-area-0.0.0.1] abr-summary fc00:0:0:: 48 cost 400
```

7.5.3 area (OSPFv3)

Function

The **area** command displays the OSPFv3 area view.

Format

area *area-id*

Parameters

Parameter	Description	Value
area-id	Specifies an OSPFv3 area ID.	The value can be an integer in the decimal format or in the IPv4 address format. If the value is a decimal integer, it ranges from 0 to 4294967295. If the value is an IPv4 address, it specifies the matched IP address in dotted decimal notation.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The number of devices increases with the expansion of the network. This leads to a large LSDB on every OSPFv3-enabled device on a large-scale network. Consequently, route flapping frequently occurs and thus a large number of OSPF packets are transmitted on the network, which wastes bandwidth resources.

OSPFv3 addresses the preceding problem by logically partitioning an AS into different areas.

Prerequisites

The OSPFv3 process view has been entered.

Precautions

After an AS is partitioned into different areas, not all areas are equal. The area with ID 0 is a backbone area. The backbone area is responsible for forwarding inter-area routes. In addition, the routing information between non-backbone areas must be forwarded through the backbone area.

The first time the **area** command is run, an OSPFv3 area is created, and the OSPFv3 area view is displayed. Running the **area** command later enters the OSPFv3 area view only.

Example

Enter the OSPFv3 area 0 view.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 0
[HUAWEI-ospfv3-1-area-0.0.0.0]
```

7.5.4 asbr-summary (OSPFv3)

Function

The **asbr-summary** command enables an autonomous system border router (ASBR) to summarize the routes imported by OSPFv3.

The **undo asbr-summary** command disables an ASBR from summarizing the routes imported by OSPFv3.

By default, ASBRs do not summarize the routes imported by OSPFv3.

Format

asbr-summary *ipv6-address prefix-length* [**cost** *cost* | **tag** *tag* | **distribute-delay** *dist-delay-interval* | **not-advertise**] *

undo asbr-summary *ipv6-address prefix-length*

Parameters

Parameter	Description	Value
ipv6-address prefix-length	Specifies the IPv6 address and prefix length of a summary IPv6 route.	● The IPv6 address is a 32-digit hexadecimal number in the X:X:X:X:X:X:X:X format. ● The prefix length ranges from 1 to 128.
cost *cost*	Specifies the cost of a summary route. By default, for Type 1 external routes, the cost of the summarized route is the highest cost of specific routes; for Type 2 external routes, the cost of the summarized route equals the highest cost of specific routes plus 1.	The value is an integer in the range from 1 to 16777214.
tag *tag*	Indicates the tag used to control route advertisement based on routing policies.	The value is an integer in the range from 0 to 4294967295. The default value is 1.
distribute-delay *dist-delay-interval*	Specifies the delay in advertising summary routes.	The value is an integer in the range from 1 to 65535, in seconds.
not-advertise	Indicates that the summary IPv6 routes that match a specified IPv6 address prefix or prefix length are not advertised.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

An ASBR connects to more than one autonomous system (AS) and generates AS external LSAs.

You can run the **asbr-summary** command to enable an ASBR to summarize the imported routes with the same prefix into a single summary route and advertise the summary route.

Multiple summary routes can be configured on an ASBR. Therefore, multiple network segments can be summarized in OSPFv3.

Example

Enable an ASBR to summarize the routes imported by OSPFv3.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] asbr-summary fc00::1 64 cost 20 tag 100
```

7.5.5 authentication-mode (OSPFv3)

Function

The **authentication-mode** command configures an authentication mode and a password for an OSPFv3 process or area.

The **undo authentication-mode** command deletes the authentication mode and password configured for an OSPFv3 process or area.

By default, no authentication mode or password is configured for any OSPFv3 process or area.

Format

authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* }

authentication-mode keychain *keychain-name*

undo authentication-mode hmac-sha256 key-id *key-id*

undo authentication-mode keychain

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
hmac-sha256	Configures HMAC-SHA256 authentication.	-
key-id *key-id*	Specifies the key ID for authentication, which must be the same as the one configured at the other end.	The value is an integer that ranges from 1 to 65535.

Parameter	Description	Value
plain	Configures the plaintext password type. Only a plaintext password can be entered, and the password is displayed in plaintext in the configuration file. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	-
plain-text	Specifies a plaintext password.	The value is a string of 1 to 255 characters without spaces.
cipher	Configures the ciphertext password type. You can enter either a plaintext or ciphertext password, but the password is displayed in ciphertext in the configuration file.	-
cipher-text	Specifies a ciphertext password.	The value can be a string of 1 to 255 characters for plaintext passwords and 20 to 392 characters for ciphertext passwords without spaces.
keychain	Configures keychain authentication. **NOTE** Before configuring this parameter, you must run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, the OSPF authentication will fail.	-
keychain-name	Specifies a keychain name.	The value is a string of 1 to 47 case-insensitive characters without spaces.

Views

OSPFv3 view, OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Due to inherent defects and flawed implementation of the TCP/IP protocol suite, there are an increasing number of attacks, which poses greater threats on TCP/IP networks than ever before. The attacks on network devices may lead to network failures. To configure an authentication mode and a password for an OSPFv3 process or area to improve OSPFv3 network security, run the **authentication-mode** command.

Precautions

If you use area authentication, the authentication and password configurations on the interfaces of all the routers in the area must be the same.

OSPFv3 area authentication has a lower priority than OSPFv3 interface authentication.

To configure OSPFv3 interface authentication, run the **ospfv3 authentication-mode** command.

Example

Configure HMAC-SHA256 authentication for OSPFv3 process 100.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 100
[HUAWEI-ospfv3-100] authentication-mode hmac-sha256 key-id 10 cipher test
```

Configure HMAC-SHA256 authentication for OSPFv3 area 0.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 100
[HUAWEI-ospfv3-100] area 0
[HUAWEI-ospfv3-100-area-0.0.0.0] authentication-mode hmac-sha256 key-id 10 cipher test
```

7.5.6 bandwidth-reference (OSPFv3)

Function

The **bandwidth-reference** command sets a bandwidth reference value for link cost calculation.

The **undo bandwidth-reference** command restores the default setting.

By default, the bandwidth reference value of the link cost is 100 Mbit/s. That is, the link cost is 100000000/bandwidth.

Format

bandwidth-reference *value*

undo bandwidth-reference

Parameters

Parameter	Description	Value
value	Specifies a bandwidth reference value for link cost calculation.	The value is an integer that ranges from 1 to 2147483648, in Mbit/s. The default value is 100 Mbit/s.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

To set a cost for an interface that runs OSPFv3, you can run the **ospfv3 cost** command. If the link cost is not set, OSPFv3 calculates the link cost according to the link bandwidth (Cost = Reference Value/Bandwidth). The priority of the cost set using the **ospfv3 cost** command is higher than that set using the **bandwidth-reference** command.

The **bandwidth-reference** command has the same function on Eth-Trunk interfaces and physical interfaces. If the command is run on an Eth-Trunk interface, the bandwidth of the Eth-Trunk interface is the total bandwidth of all its member interfaces.

The **bandwidth** *bandwidth* command can only set an interface bandwidth obtained by the NMS from the MIB. It cannot change an interface actual bandwidth and interface cost.

Example

Set the bandwidth reference value of the link cost to 1000.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] bandwidth-reference 1000
```

7.5.7 bfd all-interfaces (OSPFv3)

Function

The **bfd all-interfaces** command enables BFD for OSPFv3 or configures BFD parameters for OSPFv3.

The **undo bfd all-interfaces** command disables BFD for OSPFv3 or deletes the configured BFD parameters for OSPFv3.

By default, BFD is not enabled or configured for OSPFv3 processes.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

bfd all-interfaces { **enable** | { **min-transmit-interval** *min-transmit-value* | **min-receive-interval** *min-receive-value* | **detect-multiplier** *detect-multiplier-value* } * }

undo bfd all-interfaces { **enable** | { **min-transmit-interval** [*min-transmit-value*] | **min-receive-interval** [*min-receive-value*] | **detect-multiplier** [*detect-multiplier-value*] } * }

Parameters

Parameter	Description	Value
enable	Enables BFD for OSPFv3.	-
min-transmit-interval *min-transmit-value*	Specifies the minimum interval for sending BFD packets to the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. • After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. • After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Parameter	Description	Value
min-receive-interval *min-receive-value*	Specifies the minimum interval for receiving BFD packets from the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *detect-multiplier-value*	Indicates the local detection multiplier.	The value is an integer in the range from 3 to 50. The default value is 3.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- To allow OSPFv3 to quickly detect device faults and recalculate routes, run the **bfd all-interfaces** command to enable BFD and configure BFD session parameters for OSPFv3. This speeds up OSPFv3 route convergence. If an OSPFv3 neighbor relationship goes Down, the BFD session between the OSPFv3 neighbors is dynamically deleted.

After OSPFv3 establishes a BFD session, the default parameter values are used. BFD session parameters can also be modified as required.

- Actual interval at which BFD packets are transmitted on the local device = Max { configured interval *min-transmit-value* at which BFD packets are transmitted on the local device, configured interval *min-receive-value* at which BFD packets are received on the peer device }
- Actual interval at which BFD packets are received on the local device = Max { configured interval *min-transmit-value* at which BFD packets are transmitted on the peer device, configured interval *min-receive-value* at which BFD packets are received on the local device }
- Actual period for BFD detection on the local device = Actual interval at which BFD packets are received on the local device x Detection multiplier *detect-multiplier-value* configured on the peer device

For example:

- On the local device, the configured interval at which BFD packets are transmitted is 200 ms; the interval at which BFD packets are received is 300 ms; the detection multiplier is 4.
- On the peer device, the configured interval at which BFD packets are transmitted is 100 ms; the interval at which BFD packets are received is 600 ms; the detection multiplier is 5.

Then:

- On the local device, the actual interval at which BFD packets are transmitted is 600 ms calculated by using the formula max {200 ms, 600 ms}; the interval at which BFD packets are received is 300 ms calculated by using the formula max {100 ms, 300 ms}; the detection period is 1500 ms calculated by multiplying 300 ms by 5.
- On the peer device, the actual interval at which BFD packets are transmitted is 300 ms calculated by using the formula max {100 ms, 300 ms}, the actual interval at which BFD packets are received is 600 ms calculated by using the formula max {200 ms, 600 ms}, and the detection period is 2400 ms calculated by multiplying 600 ms by 4.

Prerequisites

BFD has been enabled globally using the **bfd** command.

After BFD in the OSPFv3 process is enabled using the **bfd all-interfaces enable** command, OSPFv3 establish BFD sessions only with neighbors whose status is Full.

Follow-up Procedure

- Configure a BFD session on a specified interface.

  If you need to configure BFD on a specified interface, or if global BFD for OSPFv3 is configured but you want a specific interface to detect link faults faster, run the **ospfv3 bfd** command to configure BFD on the specified interface.
- Prevent an interface from dynamically creating a BFD session.

  If you do not want to enable BFD on a specified interface, run the **ospfv3 bfd block** command to disable the interface from dynamically creating a BFD session.

Precautions

The **bfd all-interfaces** command and the **ospfv3 bfd block** command are mutually exclusive.

BFD cannot be enabled on VBDIF interfaces.

Example

Enable BFD for OSPFv3 process 1.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] bfd all-interfaces enable
```

7.5.8 default (OSPFv3)

Function

The **default** command sets default parameters for the external routes that are imported by OSPFv3. The default parameters include the cost, tag and type (Type 1 or Type 2).

The **undo default** command restores the default values of the parameters of the external routes that are imported by OSPFv3.

By default, the cost, tag value, and type of the external routes is 1, 1, and Type 2, respectively.

Format

default { **cost** *cost* | **tag** *tag* | **type** *type* } *

undo default { **cost** [*cost*] | **tag** [*tag*] | **type** [*type*] } *

Parameters

Parameter	Description	Value
cost *cost*	Specifies the default cost of the external route that is imported by OSPFv3.	The value is an integer that ranges from 1 to 16777214. By default, the value is 1.
tag *tag*	Specifies the tag value of the external route that is imported by OSPFv3.	The value is an integer that ranges from 0 to 4294967295. By default, the value is 1.
type *type*	Specifies the type of the external route that is imported by OSPFv3.	The value is an integer that ranges from 1 to 2. By default, it is 2. ● 1: Type 1 external route ● 2: Type 2 external route

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Since OSPFv3 can import external routes and advertise them to the entire AS, it is necessary to specify a default cost for these external routes.

If multiple OSPFv3 processes are enabled, the **default** command takes effect only on the present process.

Example

Set the default cost of the external routes that are imported by OSPFv3 to 10.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] default cost 10
```

7.5.9 default-cost (OSPFv3 Area)

Function

The **default-cost** command specifies a cost for the default route that is sent to the stub area by OSPFv3.

The **undo default-cost** command restores the default cost of the default route.

By default, the cost of the Type 3 default route transmitted to the stub area is 1.

Format

default-cost *cost*

undo default-cost

Parameters

Parameter	Description	Value
cost	Specifies the cost of the default route that is sent to the stub area by OSPFv3.	The value ranges from 0 to 16777214. By default, the value is 1.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

The **default-cost** command applies only to the ABR that is connected to the stub area.

Before setting the cost of the default route that is transmitted to the stub area by OSPFv3, run the **stub** command to configure the local area as a stub area.

If multiple OSPFv3 processes are enabled, the **default-cost** command takes effect only on the present process.

Example

Set area 1 as the stub area and the cost of the default route that is sent to the stub area to 60.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 1
[HUAWEI-ospfv3-1-area-0.0.0.1] stub
[HUAWEI-ospfv3-1-area-0.0.0.1] default-cost 60
```

7.5.10 default-route-advertise (OSPFv3)

Function

The **default-route-advertise** command advertises default routes into an OSPFv3 routing domain.

The **undo default-route-advertise** command cancels advertising default routes.

Format

default-route-advertise [**always** | **cost** *cost* | **type** *type* | **tag** *tag* | **route-policy** *route-policy-name* [**match-any**]]*

undo default-route-advertise [**always** | **cost** [*cost*] | **type** [*type*] | **tag** [*tag*] | **route-policy** [*route-policy-name*] [**match-any**]]*

Parameters

Parameter	Description	Value
always	Generates and advertises an LSA that describes a default route, regardless of whether the local device has active default routes from processes other than the local OSPFv3 process. The switch that has **always** configured does not calculate default routes of other switches. If **always** is not specified, an LSA is generated only when there are active non-OSPFv3 default routes in the routing table of the local device.	-
cost *cost*	Specifies the cost of an advertised default route.	The value is an integer that ranges from 1 to 16777214. The default value is 1.
type *type*	Specifies the type of an external route.	The value is 1 or 2. The default value is 2. ● 1: Type 1 external route ● 2: Type 2 external route

Parameter	Description	Value
tag *tag*	Specifies the tag value of an advertised default route.	The value is an integer that ranges from 0 to 4294967295. The default value is 1.
route-policy *route-policy-name*	Specifies the name of a route-policy. The device advertises default routes according to the parameters configured in the route-policy when there are matched non-OSPFv3 default routes in the routing table.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
match-any	Indicates that through a route-policy, the device advertises default routes according to the parameters configured in the route-policy when there are matched routes in the routing table.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a static default route has been configured on an OSPFv3-capable switch, OSPFv3 compares the preferences of default routes before advertising a default route. To add the default route advertised by OSPFv3 to the current routing table, ensure that the preference of the static default route is lower than that of the default route advertised by OSPFv3.

Default routes that are imported using the **import-route** command cannot be advertised. To advertise default routes, run the **default-route-advertise** command. The cost of a generated default route is determined by the **cost** and **type** parameters in the **default-route-advertise** command, and the default **tag** value is 1. If the local routing table does not contain non-OSPFv3 default routes, specify the **always** parameter to generate an ASE LSA of a default route.

A route-policy is only used to filter existing active non-OSPFv3 default routes of the local device, and match routes according to the following rules:

- If a default route matches the policy, the local device generates a default route according to the parameters configured in the route-policy, such as the cost, tag, and type.

- If a default route does not match the policy and **always** is not specified, the local device does not generate any default route.
- If a default route does not match the policy and **always** is specified, the switch generates a default route. The parameters of the generated default route are determined by the **default-route-advertise** [**always** | **cost** *cost* | **type** *type* | **tag** *tag* | **route-policy** *route-policy-name*]* command.

NOTE

The preferences of parameters of the default route configured in a route-policy are higher than those of parameters configured in the **default-route-advertise** [**always** | **cost** *cost* | **type** *type* | **tag** *tag* | **route-policy** *route-policy-name*] * command.

Precautions

Creating a route-policy before it is referenced is recommended. If a nonexistent route-policy is referenced using the command, the device advertises the default IPv6 route as long as a default IPv6 route that is not generated by the current OSPFv3 process exists in the local routing table.

Example

Advertise the ASE LSA that describes a default route into an OSPFv3 routing domain. The local device does not have a default route.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] default-route-advertise always
```

7.5.11 description (OSPFv3 Area)

Function

The **description** command configures a description for an OSPFv3 area.

The **undo description** command deletes the configured description of an OSPFv3 area.

By default, there is no description for any OSPFv3 areas.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies a description for an OSPFv3 area.	The value is a string of 1 to 80 case-sensitive characters, spaces supported.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

By configuring a description for an OSPFv3 area, you can identify different OSPFv3 areas easily.

Example

Configure a description for OSPFv3 area 0.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 0
[HUAWEI-ospfv3-1-area-0.0.0.0] description main area
```

7.5.12 description (OSPFv3)

Function

The **description** command configures a description for an OSPFv3 process.

The **undo description** command deletes the configured description of an OSPFv3 process.

By default, there is no description for any OSPFv3 processes.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies a description for an OSPFv3 process.	The value is a string of 1 to 80 case-sensitive characters, spaces supported.

```

Table 7-62 Description of the **display default-parameter ospfv3** command output

Item	Description
OSPFv3 Default Values	Default values of OSPFv3
Process View	Process view
Area View	Area view
Interface View	Interface view
Maximum ECMP Count	Maximum number of equal-cost routes
SPF Delay Time(sec)	Default delay for SPF calculation
SPF Hold Time(sec)	Hold time interval between two consecutive SPF calculations
SPF Max Time(millisec)	Maximum delay time between two consecutive SPF calculations
SPF Start Time(millisec)	Initial SPF schedule delay

Item	Description
SPF ExpHold Time(millisec)	Minimum hold time between two consecutive SPF calculations
LSA Reorig Time(sec)	Interval at which LSAs are updated
Wait Interval for stub-router on-startup	Default period during which a router remains to be a stub router during master/slave switchover
Grace Period(sec)	GR period
Retransmit-Interval for Grace LSAs(sec)	Default interval for retransmitting Grace LSAs, in seconds
Ack wait-time for Grace LSAs(sec)	Default time during which a router waits to reply the received Grace LSA with an LSAck message If the switch does not receive any Grace LSA within the default waiting time, the switch does not send the LSAck message.
Helper Max Grace Period Support(sec)	Default GR period of the helper router
Bandwidth-Reference(Mbps)	Default bandwidth reference value used to calculate the link cost, in Mbit/s
Default Metric	Default metric of the imported external route
Default Type	Default type of the imported external route
Route Preference for Internal Routes	Default preference of the internal route
Route Preference for External Routes	Default preference of the external route
Default Stub Cost	Default cost of a stub area
NSSA Translator Stability Index(sec)	Default dead time of a translator
Hello Interval(sec)	Default interval for sending Hello packets on a P2P or a broadcast network
NBMA Hello Interval(sec)	Default interval for sending Hello packets on an NBMA network
Dead Interval(sec)	Default interval for declaring a neighbor to be Down after no Hello packets are received on a P2P or broadcast network

Item	Description
NBMA Dead Interval(sec)	Default interval for declaring a neighbor to be Down after no Hello packets are received on an NBMA network
Poll Interval(sec)	Default poll interval for sending Hello packets on an NBMA network
Retransmit Interval(sec)	Default interval for retransmitting packets
Transmit Delay(sec)	Default estimated time for transmitting an LSU over this interface Before packet transmission, the estimated time needs to be added to the time limit of each LSA. The estimated time should be added to the transmission delay of the inbound interface.
Router DR Priority	Default priority of the DR
Suppress flapping peer	Whether OSPFv3 neighbor relationship flapping suppression is enabled
Suppress flapping detect interval	Default detection interval of OSPFv3 neighbor relationship flapping suppression
Suppress flapping detect threshold	Default threshold of OSPFv3 neighbor relationship flapping suppression
Suppress flapping Resume interval	Default interval for exiting from OSPFv3 neighbor relationship flapping suppression
Suppress flapping mechanism	Default mode of OSPFv3 neighbor relationship flapping suppression
Hold-max-cost interval	Default duration of the Hold-max-cost mode

7.5.14 display ospfv3

Function

The **display ospfv3** command displays brief information about OSPFv3.

Format

display ospfv3 [*process-id*]

Parameters

Parameter	Description	Value
process-id	Identifies the OSPFv3 process ID. If process-id is not specified, the brief information of all OSPFv3 processes is displayed in the ascending order of the process ID.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3** command to check brief information about OSPFv3. The information helps learn about the OSPFv3 configuration and status.

Example

Display brief information about OSPFv3.

```
<HUAWEI> display ospfv3

 Routing Process "OSPFv3 (1)" with ID 0.0.0.0
 Route Tag: 0
 Multi-VPN-Instance is not enabled
 SPF schedule delay 5 secs, Hold time between SPFs 10 secs
 LSA Origination interval 5 secs
 LSA Arrival interval 1 sec
 Default ASE parameters: Metric: 1 Tag: 1 Type: 2
 Stub router capability: enabled
 Number of AS-External LSA 0. AS-External LSA's Checksum Sum 0x0000
 Number of AS-Scoped Unknown LSA 0. AS-Scoped Unknown LSA's Checksum Sum 0x0000
 Number of FULL neighbors 0
 Number of Exchange and Loading neighbors 0
 Number of LSA originated 0
 Number of LSA received 0
 SPF Count          : 0
 Non Refresh LSA    : 0
 Non Full Nbr Count : 0
 Number of areas in this router is 0
```

Table 7-63 Description of the **display ospfv3** command output

Item	Description
Route Tag	Tag value for the imported VPN route.
Multi-VPN-Instance is not enabled	The current process does not support Multi-VPN instance.

Item	Description
SPF schedule delay	Delay of SPF calculation after the SPF calculation is scheduled.
Hold time between SPFs	Interval between two SPF calculation.
LSA Origination interval	Minimum interval for producing the same LSA.
LSA Arrival interval	Minimum interval for receiving the same LSA.
Default ASE parameters	Default parameters for AS external LSA: ● Metric: cost of the route ● Tag: tag value ● Type: type of LSA (1 or 2)
Stub router capability	Stub router capability. If **on-startup** is not specified when the **stub-router** command is run, information about this field is always displayed. If **on-startup** is specified when the stub-router command is run, information about this field is displayed only in the valid period during which the device keeps serving as a stub router after being restarted.
Number of AS-External LSA	Number of LSA originated for routes outside an AS.
AS-External LSA's Checksum Sum	Checksum of LSA originated for routes outside an AS.
Number of AS-Scoped Unknown LSA	Number of unknown LSA with the flooding range of an entire AS.
AS-Scoped Unknown LSA's Checksum Sum	Checksum of unknown LSA with the flooding range of an entire AS.
Number of FULL neighbors	Number of Full neighbors.
Number of Exchange and Loading neighbors	Number of neighbors in the Exchange state and neighbors in the Loading state.
Number of LSA originated	Number of generated LSAs.
Number of LSA received	Number of received LSAs.
SPF Count	Number of the events triggered by the SPF calculation.
Non Refresh LSA	Number of LSAs that are not updated in the retransmission list during GR.

Item	Description
Non Full Nbr Count	Number of neighbors in the Exchange state and neighbors in the Loading state during GR.
Number of areas in this router is	Number of areas on a switch.

7.5.15 display ospfv3 abr-summary-list

Function

The **display ospfv3 abr-summary-list** command displays information about the summarization of the routes imported by OSPFv3.

If the IP address and mask are not specified, information about the summarization of all the routes imported by OSPFv3 is displayed.

Format

display ospfv3 [*process-id*] **abr-summary-list** [*ipv6-address prefix-length*]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
ipv6-address	Specifies the matched IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
prefix-length	Specifies the length of the route prefix.	The value is an integer ranging from 1 to 128.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 abr-summary-list** command to check information about the summarization of the routes imported by an ABR. If the IP address and mask are not specified, information about the summarization of all the routes imported by the ABR is displayed.

Example

Display information about the summarization of all the routes imported by OSPFv3.

```
<HUAWEI> display ospfv3 abr-summary-list
OSPFv3 Process (1)
Area ID  :  0.0.0.1
Prefix           Prefix-Len  Matched       Status
FC00:0:0:2001::  16          2[Active]     Advertise
FC00:0:0:3001::  16          0[NotActive]  Advertise
FC00:0:0:4001::  16          0[NotActive]  Advertise
```

Table 7-64 Description of the **display ospfv3 abr-summary-list** command output

Item	Description
OSPFv3 Process (1)	OSPFv3 process ID
Area ID	Area ID
Prefix	IPv6 prefix
Prefix-Len	Length of the prefix
Matched	Status of the summarized routes
Status	Advertisement status of the summarized routes: ● Advertise: Advertise after the summarization. ● NotAdvertise: Do not advertise after the summarization.

7.5.16 display ospfv3 area

Function

The **display ospfv3 area** command displays OSPFv3 area information.

Format

display ospfv3 [*process-id*] **area** [*area-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID for an OSPFv3 process.	The value is an integer ranging from 1 to 65535.

Parameter	Description	Value
area-id	Specifies the area ID for the area to be displayed.	If the value is a decimal integer, it ranges from 0 to 4294967295. If the value is an IPv4 address, it specifies the matched IP address in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 area** command to check OSPFv3 area information. The information helps determine the status and parameters of each area.

Example

Display OSPFv3 area information.

```
<HUAWEI> display ospfv3 area
OSPFv3 Process (1)

Area 0.0.0.0(BACKBONE)  InActive
Number of interfaces in this area is 1
 SPF algorithm executed 0 times
 Number of LSA 0. Checksum Sum 0x0000
 Number of Unknown LSA 0
 Area Bdr Router count: 0
 Area ASBdr Router count: 0
 Next SPF Trigger Time 500 millisecs
 Router ID conflict state : Normal
```

Table 7-65 Description of the display ospfv3 area command output

Item	Description
Number of interfaces in this area	Number of active interfaces.
SPF algorithm executed	Number of SPF calculations.
Number of LSA	Number of LSAs in this area.
Checksum	Area checksum.
Number of Unknown LSA	Number of unknown LSAs in the area.
Area Bdr Router count	Number of ABRs in the area.
Area ASBdr Router count	Number of ASBRs in the area.
Next SPF Trigger Time	Interval for SPF calculations in the area.

Item	Description
Router ID conflict state	Status of the automatic recovery function. The value can be one of the following: ● Normal: The automatic recovery function is properly detecting router ID conflict. ● Wait select: The automatic recovery function delays defining a new router ID if the device starts after an unexpected delay (two hours by default). ● Selecting: The automatic recovery function restarts the OSPF process with the router ID and waits for the restarted OSPF process to take effect. ● RtrId Changed: The automatic recovery function determines whether router ID conflict occurs after the new router ID takes effect and returns to the Normal state if no new router ID conflict is detected. ● Suspend: If the maximum number of conflict times is reached, automatic recovery function does not define a new router ID any longer. The maximum number of conflict times is three by default.

7.5.17 display ospfv3 asbr-summary

Function

The **display ospfv3 asbr-summary** command displays OSPFv3 route summarization information.

Format

display ospfv3 [*process-id*] **asbr-summary** [*ipv6-address prefix-length*] [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies an OSPFVv3 process ID.	The value is an integer in the range from 1 to 65535.

Parameter	Description	Value
ipv6-address prefix-length	Specifies an IPv6 address and route prefix length. If both *ipv6-address* and *prefix-length* are not specified, all OSPFv3 route summarization information is displayed.	- The IPv6 address is a 32-digit hexadecimal number in the X:X:X:X:X:X:X:X format. - The prefix length ranges from 1 to 128.
verbose	Displays detailed information about OSPFv3 route summarization.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view OSPFv3 route summarization information, run the **display ospfv3 asbr-summary** command.

Example

Display detailed information about OSPFv3 route summarization.

```
<HUAWEI> display ospfv3 asbr-summary verbose

      OSPFv3 Process (1)
 Total summary address count :1

          Summary Address

 Prefix        : 10::
 Prefix length : 32
 Tag           : 0 (Not Configured)
 Status        : Advertised
 Cost          : 10 (Configured)
 Delay         : (Not Configured)
 Type          : 2 (Larger than any link state path)
 The Count of Route is: 3

Destination      Mask        Protocol      Proc       Type     Metric
    10::0         64         Static        0          2        1
    10::2         128        Static        0          2        1
    10::3         128        Static        0          2        1
```

Table 7-66 Description of the **display ospfv3 asbr-summary** command output

Item	Description
OSPFv3 Process	OSPFv3 process ID.

Item	Description
Total Summary address count	Number of summary routes. To configure summary routes, run the **asbr-summary** command.
Summary Address	Detailed information about summary routes.
Prefix	Prefix of a summary route.
Prefix length	Prefix length.
Tag	Tag of a summary route.
Status	Whether summary routes are advertised: ● Advertised: Summary routes will be advertised. ● NotAdvertised: Summary routes will not be advertised.
Cost	Cost of a summary route.
Delay	Delay in advertising summary routes.
Type	AS external route type: ● 1: Type 1 external route ● 2: Type 2 external route
The Count of Route is	Number of routes that are summarized.
Destination	Destination address of a summary route.
Mask	Mask of a summary route.
Protocol	Protocol of a summary route.
Proc	Protocol process ID of a summary route.
Metric	Cost of a summary route.

7.5.18 display ospfv3 bfd session

Function

The **display ospfv3 bfd session** command displays bidirectional forwarding detection (BFD) session information of all OSPFv3 processes.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

display ospfv3 [*process-id*] **bfd session** [*interface-type interface-number*] [*neighbor-id*] [**verbose** | **all**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID for an OSPFv3 process. If the process number is not specified, information about all OSPFv3 processes is displayed in an ascending order.	The value is an integer that ranges from 1 to 65535.
interface-type interface-number	Specifies the name, type and the number of the interface.	-
neighbor-id	Specifies router ID of the neighbor.	-
verbose	Displays detailed information of the neighbor.	-
all	Displays all the BFD sessions configured in OSPFv3.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

BFD can provide millisecond-level fault detection. BFD can work with OSPFv3 to rapidly detect faults on neighboring devices, and instruct OSPFv3 to recalculate routes for correct packet forwarding. You can run the command to check BFD session parameters in OSPFv3 processes.

Example

Display BFD session information of all OSPFv3 processes.

```
<HUAWEI> display ospfv3 bfd session
```

```
* - STALE

OSPFv3 Process (1)
 Neighbor-Id      Interface                    BFD-Status
 10.3.3.3         GE0/0/1                     Up
 10.1.1.1         GE0/0/2                     Up
```

Table 7-67 Description of the **display ospfv3 bfd session** command output

Item	Description
* - STALE	Stale BFD session
OSPFv3 Process	ID of the OSPFv3 process
Neighbor-Id	Neighbor ID
Interface	Interface to which this session is associated
BFD-Status	BFD session status: ● Up ● Down

Display the BFD session information for process 1.

```
<HUAWEI> display ospfv3 1 bfd session verbose

* - STALE

OSPFv3 Process (1)

 Neighbor-Id: 10.3.3.3
 BFD Status: Up
 Interface: GE0/0/1
 IPv6-Local-Address: FE80::201:FF:FE01:1
 IPv6-Remote-Address: FE80::225:9EFF:FEFB:BFF1
 BFD Module preferred timer values
     Transmit-Interval(ms): 100
     Receive-Interval(ms): 100
     Detect-Multiplier: 4
 OSPFv3 Module preferred timer values
     Transmit-Interval(ms): 100
     Receive-Interval(ms): 100
     Detect-Multiplier: 4
 Configured timer values
     Transmit-Interval(ms): 100
     Receive-Interval(ms): 100
     Detect-Multiplier: 4
```

Table 7-68 Description of the **display ospfv3 bfd session** command output

Item	Description
IPv6-Local-Address	Local IPv6 address to which this session is associated

Item	Description
IPv6-Remote-Address	Remote IPv6 address to which this session is associated
BFD Module preferred timer values	Actual BFD parameter values which are negotiated by BFD Module for the established session
Transmit-Interval(ms)	Minimum interval for sending BFD packets
Receive-Interval(ms)	Minimum interval between received BFD packets
Detect-Multiplier	Detection multiplier
OSPFv3 Module preferred timer values	Preferred BFD parameter values across the processes sharing the session
Configured timer values	Configured BFD parameter values for the neighbor

Display all the BFD sessions in OSPFv3.

```
<HUAWEI> display ospfv3 bfd session all

* - STALE

BFD Session (1)
 BFD Status: Up
 Interface: GE0/0/1
 IPv6-Local-Address: FE80::201:FF:FE01:1
 IPv6-Remote-Address: FE80::225:9EFF:FEFB:BFF1
 Process-Id  Neighbor-Id
      1      10.3.3.3

BFD Session (2)
 BFD Status: Up
 Interface: GE0/0/2
 IPv6-Local-Address: FE80::201:FF:FE01:1
 IPv6-Remote-Address: FE80::200:13FF:FE82:4569
 Process-Id  Neighbor-Id
      1      10.1.1.1
```

Table 7-69 Description of the **display ospfv3 bfd session all** command output

Item	Description
BFD Session	BFD session number configured in OSPFv3
Process-Id	Configured OSPFv3 process ID
Neighbor-Id	Neighbor ID

7.5.19 display ospfv3 black-box neighbor-down

Function

The **display ospfv3 black-box neighbor-down** command displays detailed information about OSPFv3 neighbors in the Down state.

Format

display ospfv3 black-box neighbor-down [*number*]

Parameters

Parameter	Description	Value
number	Specifies the number of OSPFv3 neighbors in the Down state to be displayed.	The value is an integer ranging from 1 to 10.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If *number* is not specified, the **display ospfv3 black-box neighbor-down** command displays detailed information about the latest 10 OSPFv3 neighbors in the Down state.

Example

Display the latest 2 OSPFv3 neighbors in the Down state.

```
<HUAWEI> display ospfv3 black-box neighbor-down 2
 Neighbor Router-id                    : 10.11.11.99
 Interface                             : Vlanif10
 Process ID                            : 99
 Instance ID                           : 1
 Reason for Neighbor down              : Interface down
 Time at which neighbor went down      : 2010-12-28 12:45:20+08:00
 Neighbor Router-id                    : 10.11.11.99
 Interface                             : Vlanif10
 Process ID                            : 99
 Instance ID                           : 1
 Reason for Neighbor down              : One-way received
 Time at which neighbor went down      : 2010-12-28 12:45:20+08:00
```

Table 7-70 Description of the **display ospfv3 black-box neighbor-down** command output

Item	Description
Neighbor Router-id	Router ID of a neighbor whose neighbor relationship becomes Down
Interface	Interface of a device involved in a neighbor relationship
Process ID	ID of the OSPFv3 process to which the neighbor relationship belongs
Instance ID	ID of the OSPFv3 instance to which the neighbor relationship belongs
Reason for Neighbor down	Reason why a neighbor relationship becomes Down: ● Interface down ● Dead timer expired ● Sequence number mismatch ● One-way received ● Forced down ● Bad LS request ● DR or BDR has changed
Time at which neighbor went down	Date and time at which the neighbor went Down.

7.5.20 display ospfv3 error

Function

The **display ospfv3 error** command displays the OSPFv3 errors.

Format

display ospfv3 [*process-id*] **error** [**lsa**]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID. If no OSPFv3 process number is specified, errors of all OSPFv3 processes are displayed.	The value ranges from 1 to 65535.
lsa	Display the OSPFv3 LSA errors	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

While analyzing the faults of OSPFv3, you can obtain information of errors using the command. You can then diagnose the faults of OSPFv3 according to information.

Example

Display the errors of OSPFv3.

```
<HUAWEI> display ospfv3 error
         OSPFv3 Process 1 with Router ID 0.0.0.0
                 OSPFv3 Error Statistics

General Packet Errors :
 0          : Bad packet                    0          : Bad version
 0          : Bad area ID                   0          : Bad virtual link
 0          : Packet too small              0          : Transmit error
 0          : Bad Instance ID               0          : Interface down
 0          : Unknown neighbor              0          : Authentication failure
 0          : AuthSeqNum mismatch           0          : AuthKeyId mismatch
 0          : IPv6: received my own packet  0          : Bad Checksum

Hello Packet Errors :
 0          : Hello timer mismatch          0          : Dead timer mismatch
 0          : Extern option mismatch        0          : Router ID confusion
 0          : Virtual neighbor unknown

DD Packet Errors :
 0          : Neighbor state low            0          : Extern option mismatch
 0          : Unknown LSA Type              0          : MTU option mismatch
 0          : Router ID confusion

LS ACK packet Errors :
 0          : Neighbor state low            0          : Bad ACK
 0          : Duplicate ACK                 0          : Unknown LSA type

LS REQ packet Errors :
 0          : Neighbor state low            0          : Bad request
 0          : Empty Request

LS UPD packet Errors :
 0          : Neighbor state low            0          : LSA checksum bad
 0          : Received less recent LSA      0          : Unknown LSA type
 0          : Newer self-generate LSA
 0          : Received LSA within LSA Arrival interval

Receive Grace LSA errors :
 0          : Number of invalid LSAs
 0          : Number of policy failed LSAs
 0          : Number of wrong period LSAs

License Errors :
 0          : Max external routes reached   0          : Max NBRs reached
```

Table 7-71 Description of the **display ospfv3 error** command output

Item	Description
General Packet Errors	General packet errors.
Bad packet	The analyzed packet errors, including the verification of the length field.
Bad version	OSPFv3 version errors, that is, it is not version 3.
Bad area ID	Area ID in the received packet does not match. That is, when the area IDs in the received packets are different from the local area ID, except area 0, other area IDs are considered incorrect.
Bad virtual link	V-link receives illegal packets.
Packet too small	Length of the received packet is less than the sum of length of IP header and the length field of the packet.
Transmit error	Transmitting packets to socket fails.
Bad Instance ID	The Instance ID errors
Interface down	Times that the OSPFv3 interface goes Down.
Unknown neighbor	For NBMA, sham-link, and V-link networks, the device receives OSPFv3 packets from neighbors that are not enabled with OSPFv3.
Authentication failure	Times that the authentication fails.
AuthSeqNum mismatch	Number of packets with a sequence number different from the local one
AuthKeyId mismatch	Number of packets with key IDs different from the local one
IPv6: received my own packet	Number of IPv6 packets received from self.
Bad Checksum	Number of packets that fail in the check and calculation
Hello Packet Errors	Hello packet errors.
Hello timer mismatch	The Hello interval is not consistent.
Dead timer mismatch	The Dead interval is not consistent.
Extern option mismatch	The extension attributes of Hello packets are not consistent.
Router ID confusion	Router id is configured to the same.

Item	Description
Virtual neighbor unknown	Router id of the packet is inconsistent with that of the neighbor that is configured by the V-link.
DD Packet Errors	DD packet errors.
Neighbor state low	Cases of error: ● DD packet is received but its neighbor status is lower than 2-way. ● LSR packet is received but its neighbor status is lower than Exchange. ● LSU packet is received but its neighbor status is lower than Exchange. ● ACK packet is received but its neighbor status is lower than Exchange.
Extern option mismatch	Option of the DD packets is not matched.
Unknown LSA Type	The router receives unknown LSA type from neighbors that are not enabled with OSPFv3.
MTU option mismatch	MTU check of the interface on which OSPFv3 is enabled. The MTU value of the DD packet that is received on the interface is greater than that of this interface.
LS ACK packet Errors	LS ACK packet errors.
Bad ACK	The count of receiving incorrect ACK packets.
Duplicate ACK	The count of receiving repeat ACK packets.
LS REQ packet Errors	Title bar: LS REQ packet errors.
Bad request	BadRequest event in the protocol.
Empty Request	Number of Empty Request.
LS UPD packet Errors	LS UPD packet error.
LSA checksum bad	LSA checksum not proper
Received less recent LSA	Receiving older LSA than the local copy.
Newer self-generate LSA	LSA recently generated by self.
Received LSA within LSA Arrival interval	Received LSA within arrival interval.
Receive Grace LSA errors	Title bar: Grace LSA error.
Number of invalid LSAs	Number of LSAs that are invalid.
Number of policy failed LSAs	Number of LSAs with policy failure.

Item	Description
Number of wrong period LSAs	Number of LSAs with wrong period.
License Errors	License errors.
Max external routes reached	Number of external routes reached the maximum value.
Max NBRs reached	Number of neighbors reached the maximum value.

7.5.21 display ospfv3 graceful-restart-information

Function

The **display ospfv3 graceful-restart-information** command displays the status of OSPFv3 GR.

Format

display ospfv3 [*process-id*] **graceful-restart-information**

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process number. If the process number is not specified, brief information about all OSPFv3 processes is displayed in an ascending order.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 graceful-restart-information** command to check the status of OSPFv3 GR.

Example

Display the status of OSPFv3 GR.

```
<HUAWEI> display ospfv3 graceful-restart-information
```

```
          OSPFv3 Router with ID (10.0.0.0) (Process 1)

Graceful-restart capability      : enabled
Graceful-restart support         : planned and unplanned, strict lsa check
Grace-Period Configured            : 120 Sec
Last Restart-exit Reason         : none

Helper capability                : enabled
  Last Helper-exit Reason          : none
```

Table 7-72 Description of the **display ospfv3 graceful-restart-information** command output

Item	Description
Graceful-restart capability	Whether GR is enabled: ● enabled ● disabled
Graceful-restart support	GR configuration feature. ● planned: indicates that only the planned GR is supported. ● unplanned: indicates that only the unplanned GR is supported. ● strict lsa check: indicates that the Helper supports strict external LSA check.
Grace-Period Configured	GR period.

Item	Description
Last Restart-exit Reason	Reason for the Restart device exiting from GR last time: ● none: indicates that no GR is performed. ● successful: indicates that the device is successfully restarted through GR, and then exits from GR. ● topology change: indicates that the network topology changes. ● grace lsa not recv: indicates that no Grace-LSAs are received. ● grace period exp: indicates that the GR period expires. ● process reset: indicates that a parameter of the OSPFv3 process is reset during GR. ● hold timer expire: indicates that the hold timer expires. ● interface address deleted: indicates that the interface address is deleted. ● interface down: indicates that the interface goes Down. ● DR/BDR change on network: indicates that the DR or BDR on the network changes. ● Received route uninstall notification: indicates that the message indicating that OSPFv3 routes are not installed to the RM is received.
Helper capability	Whether Helper is enabled: ● enabled ● disabled

Item	Description
Last Helper-exit Reason	Reason for the Helper device exiting from GR last time: ● none: indicates that the switch never enters the Helper mode since it starts. ● successful: indicates that the Helper successfully exits from GR. ● topology change: indicates that the network topology changes. ● interface id change: indicates that the interface ID changes. ● grace period exp: indicates that GR period expires. ● hold timer expire: indicates that the hold timer expires. ● interface address deleted: indicates that the interface address is deleted.

7.5.22 display ospfv3 interface

Function

The **display ospfv3 interface** command displays information about OSPFv3 interfaces.

Format

display ospfv3 [*process-id*] **interface** [**area** *area-id*] [*interface-type interface-number*]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the OSPFv3 area ID. The value of the area ID can be a decimal integer or in the IPv4 address format.	If the value is a decimal integer, it ranges from 0 to 4294967295. If the value is an IPv4 address, it specifies the matched IP address in dotted decimal notation.

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of the interface. If the interface is not specified, information of all OSPFv3 interfaces is displayed.	-

Views

Usage Guidelines

You can run the **display ospfv3 interface** command to check information about OSPFv3 interfaces.

Example

Display information about OSPFv3 VLANIF 10.

```
<HUAWEI> display ospfv3 interface vlanif 10
 Vlanif10 is up, line protocol is up
 Interface ID 0x45
 Interface MTU 1500
 IPv6 Prefixes
 FE80::2E0:13FF:FE96:1600 (Link-Local Address)
 FC00:0:0:4000::1/64
 OSPFv3 Process (1), Area 0.0.0.0, Instance ID 0
       Router ID 10.5.5.5, Network Type BROADCAST, Cost: 1
   Transmit Delay is 1 sec, State Backup, Priority 1
   No designated router on this link
   No backup designated router on this link
   Timer interval configured, Hello 10, Dead 40, Wait 40, Retransmit 5
      Hello due in 00:00:08
   Neighbor Count is 1, Adjacent neighbor count is 1
   Interface Event: 2, Lsa Count: 2, Lsa Checksum: 0x9b74
   Interface Physical BandwidthHigh 0, BandwidthLow 1000000000
```

Display information about VLANIF 10 after OSPFv3 neighbor relationship flapping suppression is configured.

```
<HUAWEI> display ospfv3 interface Vlanif 10
 Vlanif10 is up, line protocol is up
  Interface ID 0x7
  Interface MTU 1500
  IPv6 Prefixes
    FE80::2E0:74FF:FE00:8201 (Link-Local Address)
    FC00:3::1/64
  OSPFv3 Process (1), Area 0.0.0.0, Instance ID 0
    Router ID 1.1.1.1, Network Type BROADCAST, Cost: 1
    Transmit Delay is 1 sec, State Backup, Priority 1
    Designated Router (ID) 4.4.4.4
    Interface Address FE80::2E0:4FF:FE09:8201
    Backup Designated Router (ID) 1.1.1.1
    Interface Address FE80::2E0:74FF:FE00:8201
    Timer interval configured, Hello 10, Dead 40, Wait 40, Retransmit 5
       Hello due in 00:00:09
```

```
  Neighbor Count is 1, Adjacent neighbor count is 1
  Interface Event 3, Lsa Count 2, Lsa Checksum 0x15084
  Interface Physical BandwidthHigh 0, BandwidthLow 100000000
  Suppress flapping peer: enable(flapping-count: 0, threshold: 3)
```

Table 7-73 Description of the **display ospfv3 interface** command output

Item	Description
Interface ID	Interface ID
Interface MTU	MTU value
IPv6 Prefixes	IPv6 prefixes
Link-Local Address	Address of local link
OSPFv3 Process	OSPFv3 process ID
Area	Area that the interface belongs to
Instance ID	ID of the instance that the interface belongs to
Router ID	Router ID
Network Type	Network type of the interface that can be displayed as Point-to-Point, NBMA, Point-To-Multipoint and Broadcast
Cost	Cost of the interface. To set the cost of the interface in different instances, run the **ospfv3 cost** command.
Transmit Delay	Transmission delay
State	State of the interface
Priority	Priority of the interface
Designated Router (ID)	Designated router on the link
Backup Designated Router (ID)	Backup designated router on the link

Item	Description
Timer interval configured	Configured interval - Hello: Interval for sending Hello packets. To set the interval for sending Hello packets on the interface instance, run the **ospfv3 timer hello** command. - Dead: Interval of the Dead timer. To set the dead interval of the OSPFv3 neighbor of the instance on the interface, run the **ospfv3 timer dead** command. - Wait: Interval of the Wait timer - Retransmit: Retransmission interval. To set interval for retransmitting the LSA on the interface instance, run the **ospfv3 timer retransmit** command.
Hello due in	Time remaining to send Hello packet
Neighbor Count	Number of neighbors
Adjacent neighbor count	Number of adjacency
Interface Event	Number of events on this interface
Lsa Count	Total number of LSA in the interface scope database
Lsa Checksum	Checksum of all the LSAs in the database
Interface Physical BandwidthHigh	Maximum physical bandwidth on the interface
BandwidthLow	Minimum physical bandwidth on the interface

Item	Description

Suppress flapping peer	Status of OSPFv3 neighbor relationship flapping suppression:
	● enable: OSPFv3 neighbor relationship flapping suppression is enabled.
	– flapping-count: number of valid flapping_events
	If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping_event is recorded, and the flapping_count is incremented by 1. To change *detecting-interval*, run the **ospfv3 suppress-flapping peer detecting-interval** *detecting-interval* command.
	– threshold: flapping suppression threshold
	When the flapping_count reaches or exceeds **threshold**, flapping suppression takes effect. To configure the threshold, run the **ospfv3 suppress-flapping peer threshold** *threshold* command.
	● disable: OSPFv3 neighbor relationship flapping suppression is disabled. In this case, the following information is displayed, without flapping-count or threshold:
	`Suppress flapping peer: disable`
	● hold-down: OSPFv3 neighbor relationship flapping suppression works in Hold-down mode. In this case, an example of the displayed information is as follows:
	`Suppress flapping peer: hold-down(start: 2016-01-29 12:09:36-08:00, remain-interval: 500s)`
	– start: time when the flapping suppression started
	– remain-interval: remaining time of the flapping suppression
	● hold-max-cost: OSPFv3 neighbor relationship flapping suppression works in Hold-max-cost mode. In this case, an example of the displayed information is as follows:
	`Suppress flapping peer: hold-max-cost(start: 2016-01-29 12:09:36-08:00, remain-interval: 476s)`

7.5.23 display ospfv3 lsdb

Function

The **display ospfv3 lsdb** command displays the OSPFv3 LSDB.

Format

display ospfv3 [*process-id*] **lsdb** [**area** *area-id*] [**originate-router** *advertising-router-id* | **self-originate**] [{ **router** | **network** | **inter-router** [**asbr-router** *asbr-router-id*] | { **inter-prefix** | **nssa** } [*ipv6-address prefix-length*] | **link** | **intra-prefix** | **grace** } [*link-state-id*]]

display ospfv3 [*process-id*] **lsdb** [**originate-router** *advertising-router-id* | **self-originate**] **external** [*ipv6-address prefix-length*] [*link-state-id*]

display ospfv3 [*process-id*] **lsdb statistics**

Parameters

Parameter	Description	Value
process-id	Identifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the OSPFv3 area ID. The value of the area ID can be a decimal integer or in the IPv4 address format.	If the value is a decimal integer, it ranges from 0 to 4294967295. If the value is an IPv4 address, it specifies the matched IP address in dotted decimal notation.
external	Displays the AS-external LSA in the LSDB. If the **area** parameter is selected, the **external** parameter cannot be selected.	-
grace	Displays the Grace-LSA in the LSDB.	-
inter-prefix	Displays the Inter-area-prefix LSA in the LSDB.	-
nssa	Displays the NSSA in the LSDB.	-
inter-router	Displays the Inter-area-router LSA in the LSDB.	-

Parameter	Description	Value
intra-prefix	Displays the Intra-area-prefix LSA in the LSDB.	-
link	Displays the Link-local LSA in the LSDB.	-
network	Displays the Network-LSA in the LSDB.	-
router	Displays the Router-LSA in the LSDB.	-
link-state-id	Indicates the link state ID.	The value is in dotted decimal notation.
originate-router *advertising-router-id*	Specifies the Router ID of the switch that advertises LSA packet.	The value is in dotted decimal notation.
asbr-router *asbr-router-id*	Specifies the router ID of the ASBR.	The value is in dotted decimal notation.
self-originate	Displays LSAs in the LSDB that are advertised by the local switch.	-
ipv6-address prefix-length	Specifies the IPv6 destination address and the length of the prefix.	*ipv6-address* is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X. *prefix-length* is an integer ranging from 0 to 128.
statistics	Indicates the statistics of the LSDB.	-

Usage Guidelines

You can run the **display ospfv3 lsdb** command to check the OSPFv3 LSDB.

Example

Display the OSPFv3 LSDB.

```
<HUAWEI> display ospfv3 lsdb
* indicates STALE LSA

         OSPFv3 Router with ID (10.5.5.5) (Process 1)

Table 7-74 Description of the **display ospfv3 lsdb** command output

Item	Description
Link-LSA	Description of the Link-LSA
Router-LSA	Description of the Router-LSA
Network-LSA	Description of the Network-LSA
Inter-Area-Prefix-LSA	Description of the Inter-Area-Prefix-LSA
NSSA-external-LSA	Description of the NSSA-external-LSA
Intra-Area-Prefix-LSA	Description of the Intra-Area-Prefix-LSA
AS-External-LSA	Description of the AS-external-LSA
Link State ID	Link state ID in LSA header
Origin Router	switch that generates LSA
Age	Aging time of LSA
Seq#	Sequence number of LSA (from LSA header)
CkSum	Checksum of LSA
Link	Number of links in router LSA
Prefix	Number of prefixes in Link LSA
Reference	The Reference for Intra Area Prefix LSA, including Router-LSA and Network-LSA
Type	The type of the external routes: ● E1: Type 1 external route ● E2: Type 2 external route

Display the Link-local LSA in the LSDB.

```
<HUAWEI> display ospfv3 lsdb link
          OSPFv3 Router with ID (10.2.2.2) (Process 1)

             Link-LSA (Interface Vlanif10)
 LS age: 11
 LS Type: Link-LSA
 Link State ID: 0.0.2.6
 Originating Router: 10.2.2.2
 LS Seq Number: 0x80000002
 Retransmit Count: 0
 Checksum: 0xEFFA
 Length: 56
 Priority: 1
 Options: 0x000013 (-|R|-|-|E|V6)
 Link-Local Address: FE80::1441:0:E213:1
```

```
Number of Prefixes: 1

  Prefix: 2000:1::/64
   Prefix Options: 0 (-|-|-|-|-)
```

Table 7-75 Description of the **display ospfv3 lsdb link** command output

Item	Description
LS age	Aging time of LSA
LS Type	Type of LSA: - Router-LSA - Network-LSA - Inter-Area-Prefix-LSA - Inter-Area-Router-LSA - AS-external-LSA - Link-LSA - Intra-Area-Prefix-LSA - NSSA-LSA
Link State ID	Link state ID in LSA header
Originating Router	Router that generates LSA
LS Seq Number	Sequence number of LSA (from LSA header)
Retransmit Count	Total number of nodes in the retransmission list
Checksum	Checksum of LSA
Length	Length of the LSA
Priority	Priority of the interface that corresponds to the link
Options	Value of options of the link
Link-Local Address	Link local address
Number of Prefixes	Number of IPv6 prefixes in the LSA
Prefix	IPv6 prefix
Prefix Options	Value of options of the prefix

7.5.24 display ospfv3 next-hop

Function

The **display ospfv3 next-hop** command displays the next-hop routing table of OSPFv3.

Format

display ospfv3 [*process-id*] **next-hop**

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 next-hop** command to check the next-hop routing table of OSPFv3.

Example

Display the next-hop routing table of OSPFv3 process 1.

```
<HUAWEI> display ospfv3 1 next-hop
OSPFv3 Process (1)
Neighbor-Id     Next-Hop                          Interface   RefCount
10.3.3.9        FE80::2E0:FCFF:FE01:814F             Vlanif10    1
```

Table 7-76 Description of the **display ospfv3 next-hop** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
Neighbor-Id	Neighbor ID
Next-Hop	Next hop address
Interface	Egress
RefCount	Number of routes using the next hop

7.5.25 display ospfv3 path

Function

The **display ospfv3 path** command displays the paths to a destination address.

Format

display ospfv3 [*process-id*] **path**

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPFv3 process.	The value is an integer ranging from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the process ID is not specified, paths in all processes are displayed.

Example

Display all OSPFv3 paths.

```
<HUAWEI> display ospfv3 path
OSPFv3 Process (1)
Type        AreaId/LSACost   PathCost
Intra       0.0.0.1          2
Inter       0.0.0.1          2
External    0.0.0.10              1
```

Table 7-77 Description of the **display ospfv3 path** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
Type	Path type: ● Intra: indicates the intra-area routes. ● Inter: indicates the inter-area routes. ● External: indicates the AS-external routes.
AreaId/LSACost	● Area ID in case of an intra-area or inter-area path. ● LSA cost in case the path type is External. ● Cost in case of a path to a destination outside an AS
PathCost	Cost of the path

7.5.26 display ospfv3 peer

Function

The **display ospfv3 peer** command displays the qualified OSPFv3 neighbor.

Format

display ospfv3 [*process-id*] [**area** *area-id*] **peer** [*interface-type interface-number* | *neighbor-id*] [**verbose**]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the neighbor of the specific area.	*area-id* can be a decimal integer or in IPv4 address format. The integer ranges from 0 to 4294967295.
interface-type interface-number	Indicates the type and the number of the interface.	-
neighbor-id	Specifies router ID of the neighbor.	The value is in dotted decimal notation.
verbose	Displays detailed information of the neighbor of each area.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 peer** command to check qualified OSPFv3 neighbor information.

Example

Display neighbor information about OSPFv3 process 1 on Vlanif10.

```
<HUAWEI> display ospfv3 1 peer vlanif 10
```

```
OSPFv3 Process (1)
OSPFv3 Area (0.0.0.0)
Neighbor ID     Pri  State           Dead Time Interface           Instance ID
10.1.1.1          1  Full/DR         00:00:30  Vlanif10                  0
```

Display the detailed neighbor information of OSPFv3 process 100 on Vlanif10.

```
<HUAWEI> display ospfv3 100 peer vlanif 10 verbose
OSPFv3 Process (100)
 Neighbor 10.1.1.1 is Full, interface address FE80::3D43:0:8C14:1
    In the area 0.0.0.1 via interface Vlanif10
    DR Priority is 1 DR is 0.0.0.0 BDR is 0.0.0.0
    Options is 0x000013 (-|R|-|-|E|V6)
    Dead timer due in 00:00:29
    Neighbour is up for 18:40:40
    Database Summary Packets List 0
    Link State Request List 0
    Link State Retransmission List 0
    Neighbour Event: 6
    Neighbour If Id: 0x1017
```

Table 7-78 Description of the **display ospfv3 peer** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process.
OSPFv3 Area	ID of the OSPFv3 area.
Neighbor ID	Neighbor ID.
Pri	Priority of the neighbor switch.
State	State of the neighbor / DR or BDR. State of the neighbor: includes Down, Attempt, Init, 2-Way, ExStart, Exchange, Loading, and Full. DR or BDR: includes DR and Backup.
Dead Time	Dead time of the neighbor.
Interface	Interface that connects with the neighbor.
Instance ID	ID of the instance that the neighbor belongs to.
Neighbor	Neighbor ID.
interface address	Link address of the neighbor interface.
In the area 0.0.0.1 via interface Vlanif10	Vlanif10 of the neighbor is in Area 1.
DR Priority	Priority of DR.
DR	Designated router.
BDR	Backup designated router.
Options	Options of the neighbor.
Dead timer due in 00:00:29	The time before the neighbor dies.

Item	Description
Neighbour is up for 18:40:40	The up time of the neighbour.
Database Summary Packets List	Number of packets in the database summary list of the neighbor.
Link State Request List	Number of LSAs in the request list of the neighbor.
Link State Retransmission List	Number of LSAs in the retransmission list of the neighbor.
Neighbour Event	Number of times NFSM (Neighbor Finite State Machine) state changed.
Neighbour If Id	Interface ID of the neighbor.

7.5.27 display ospfv3 request-list

Function

The **display ospfv3 request-list** command displays the statistics of the request list of OSPFv3.

Format

display ospfv3 [*process-id*] **request-list** [[**area** *area-id* | **interface** *interface-type interface-number* | **peer** *router-id*]* | **statistics**]

Parameters

Parameter	Description	Value
process-id	Specifies the process ID of OSPFv3.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the OSPFv3 area ID.	The integer ranges from 0 to 4294967295. The value of the area ID can be a decimal integer or in the IPv4 address format.
interface *interface-type interface-number*	Specifies the type and number of the interface.	-
peer *router-id*	Indicates the Router ID of a neighbor.	It is in dotted decimal notation.

Parameter	Description	Value
statistics	Displays the statistics of the request list of OSPFv3.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The display of the command is used to diagnose faults.

Example

Display the statistics of the request list in OSPFv3.

```
<HUAWEI> display ospfv3 request-list
   OSPFv3 Process (1)
   Interface  FC00:0:0:1::2        Area-ID   0.0.0.1
   Nbr-ID   10.254.255.255
   LS-Type               LS-ID           AdvRouter       SeqNum       Age
   Link-LSA              0.0.2.2         10.254.255.255  0x80000001   151
   Router-LSA            0.0.0.0         10.254.255.255  0x80000005   46
   Intra-Area-Prefix-LSA 0.0.0.1         10.254.255.255  0x80000001   45
   AS-External-LSA       0.0.0.1         10.254.255.255  0x80000001   113
   AS-External-LSA       0.0.0.2         10.254.255.255  0x80000001   113
```

Table 7-79 Description of the **display ospfv3 request-list** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
Interface	Interface that connects with the neighbor
Area-ID	ID of the area that the interface belongs to
Nbr-ID	Router ID of the neighbor

Item	Description
LS-Type	LSA type: ● Link-LSA: is generated by the switch for each link and is advertised in the local link. ● Router-LSA: is generated by each switch and advertised in the area whether the switch resides. It describes the link state and cost of the switch. ● Intra-Area-Prefix-LSA: – An LSA generated on a router describes the IPv6 address prefix associated with the Router LSA. – An LSA generated on a DR describes the IPv6 address prefix associated with the network LSA. ● AS-External-LSA: is generated by the ASBR and is advertised to the entire AS (except the stub area). It describes the routes that reach other ASs.
LS-ID	Link State ID (from LSA header)
AdvRouter	Advertising router (from LSA header)
SeqNum	Sequence number (from LSA header)
Age	Aging time (from LSA header)

7.5.28 display ospfv3 retrans-list

Function

The **display ospfv3 retrans-list** command displays the statistics of the retransmission list in OSPFv3.

Format

display ospfv3 [*process-id*] **retrans-list** [[**area** *area-id* | **interface** *interface-type interface-number* | **peer** *router-id*]* | **statistics**]

Parameters

Parameter	Description	Value
process-id	Specifies the process ID of OSPFv3.	The value is an integer ranging from 1 to 65535.

Parameter	Description	Value
area *area-id*	Specifies the OSPFv3 area ID.	The integer ranges from 0 to 4294967295. The value of the area ID can be a decimal integer or in the IPv4 address format.
interface *interface-type interface-number*	Specifies the type and number of the interface.	-
peer *router-id*	Indicates the Router ID of a neighbor.	It is in dotted decimal notation.
statistics	Displays the statistics of the retransmission list in OSPFv3.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The display of the command is used to diagnose faults.

Example

Display the statistics of the retransmission list in OSPFv3.

```
<HUAWEI> display ospfv3 retrans-list

    OSPFv3 Process (1)
    Interface  FC00:0:0:1::2        Area-ID   0.0.0.1
    Nbr-ID   10.22.2.255
    LS-Type                LS-ID           AdvRouter       SeqNum       Age
    Network-LSA            0.0.2.2         10.254.255.255  0x80000002   1
    Intra-Area-Prefix-LSA 0.0.0.2          10.254.255.255  0x80000002   1
```

Table 7-80 Description of the **display ospfv3 retrans-list** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
Interface	Interface that connects with the neighbor
Area-ID	ID of the area that the interface belongs to

Item	Description
Nbr-ID	Router ID of the neighbor
LS-Type	LSA type: ● Network-LSA: is generated by the DR of a broadcast network or an NBMA network and is advertised in the area where the DR resides. It describes the link state of the network segment. ● Intra-Area-Prefix-LSA: – An LSA generated on a router describes the IPv6 address prefix associated with the Router LSA. – An LSA generated on a DR describes the IPv6 address prefix associated with the network LSA.
LS-ID	Link State ID (from the LSA header)
AdvRouter	Advertising router (from LSA header)
SeqNum	Sequence number (from LSA header)
Age	Aging time (from LSA header)

7.5.29 display ospfv3 routing

Function

The **display ospfv3 routing** command displays the OSPFv3 routing table.

Format

display ospfv3 [*process-id*] **routing** [*ipv6-address prefix-length* | **abr-routes** | **asbr-routes** | **intra-routes** | **inter-routes** | **ase-routes** | **nssa-routes** | [**statistics**] [**uninstalled**]]

Parameters

Parameter	Description	Value
process-id	Identifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
ipv6-address	Indicates the IPv6 address.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
prefix-length	Specifies the length of the prefix.	The value is an integer ranging from 0 to 128.
abr-routes	Displays the routing table of ABR in OSPFv3.	-
asbr-routes	Displays routing table of ASBR in OSPFv3.	-
intra-routes	Displays the statistics of OSPFv3 routes in an area.	-
inter-routes	Displays the statistics of OSPFv3 routes between areas.	-
ase-routes	Displays the statistics of OSPFv3 routes outside an AS.	-
nssa-routes	Displays the statistics of OSPFv3 routes in an NSSA.	-
statistics	Displays the statistics of all routing tables.	-
uninstalled	Displays the routes are not installed into the RM.	-

Views

Default Level

1: Monitoring level

Usage Guidelines

By using this command with different parameters, you can view the routes of a specified interface or next hop.

The command output can help you troubleshoot OSPFv3 faults.

Example

Display the OSPFv3 routing table.

```
<HUAWEI> display ospfv3 routing
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,
        N - NSSA, U - Uninstalled, D - Denied by Import Policy
```

```
OSPFv3 Process (1)
   Destination                                              Metric
     Next-hop
     FC00:0:0:3::1/128                                        0
      directly connected, LoopBack1
  IA FC00:0:0:4::1/128                                        1
       via FE80::200:FF:FE00:DC00, Vlanif1002
  IA FC00:0:0:5::1/128                                        1
       via FE80::200:FF:FE00:DC00, Vlanif1002
     FC00:0:0:6::/64                                            1
      directly connected, Vlanif1002
```

Table 7-81 Description of the **display ospfv3 routing** command output

Item	Description
Codes	The following information provides the full spelling and explanation: ● E2: Type 2 external route ● E1: Type 1 external route ● IA: Inter-area route ● N: NSSA route ● U: OSPFv3 routes that are not advertised to the IPv6 routing table ● D: OSPFv3 routes denied by import route policy
OSPFv3 Process	OSPFv3 process
Destination	Destination address
Metric	Metric to the destination
Next-hop	Next hop to the destination

Displays the routes are not installed into the RM.

```
<HUAWEI> display ospfv3 routing uninstalled
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,N - NSSA, U - Uninstalled

OSPFv3 Process (1)
   Destination                                                Metric
     Next-hop
  N    via FE80:1000:2000:3000:4000:5000:6000:7000, Vlanif10
  U E2 FC00:0:0:1::1/128                                        5
```

Table 7-82 Description of the **display ospfv3 routing uninstalled** command output

Item	Description
N	NSSA

Display statistics about the OSPFv3 routes that are not installed into the RM.

```
<HUAWEI> display ospfv3 routing statistics uninstalled
OSPFv3 Process (1) UNINSTALLED ROUTES STATISTICS
     Intra-area-routes   :   2
     Inter-area-routes   :   0
     External-routes     :   1
```

Table 7-83 Description of the **display ospfv3 routing statistics uninstalled** command output

Item	Description
Intra-area-routes	Number of intra-area routes
Inter-area-routes	Number of inter-area routes
External-routes	Number of external routes

7.5.30 display ospfv3 sham-link

Function

The **display ospfv3 sham-link** command displays information about sham links in an OSPFv3 area.

Format

display ospfv3 [*process-id*] **sham-link** [**area** *area-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPFv3 process.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the OSPFv3 area ID.	The integer ranges from 0 to 4294967295. The value of the area ID can be a decimal integer or in the IPv4 address format.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the process ID and area ID are not specified, information about all the configured sham links is displayed.

Example

Display all sham link information of OSPFv3.

```
<HUAWEI> display ospfv3 sham-link
 OSPFv3 Process (10)
 Sham Link SHAM-LINK1 to router 0.0.0.0 is down
 Area 0.0.0.1, via Interface *, Instance ID 0, cost 1
 Source address 2001:db8:1::1
 Destination address 2001:db8:2::1
 Interface ID 0x80000001
 Sham-Link Interface Events: 24
 Sham-Link Interface LsaCount: 0
 Sham-Link Interface Lsa Checksum: 0x0
 Transmit Delay is 1 sec, State Down
 Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
 Hello due in 00:00:00
 Adjacency state Down
 IP security association configured: sa1
 IP security association applied: sa1
```

Table 7-84 Description of the **display ospfv3 sham-link** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
Area	ID of the OSPFv3 area to which the sham link belongs
via Interface	Interface of the sham link
Instance ID	ID of the instance
cost	Cost of the sham link
Source address	Source IPv6 address of the sham link
Destination address	Destination IPv6 address of the sham link
Interface ID	Interface ID
Sham-Link Interface Events	Number of interface events of the sham-link
Sham-Link Interface LsaCount	Number of LSAs sent from all sham-link interfaces
Sham-Link Interface Lsa Checksum	Checksum of the LSA sent from the sham-link interface
Transmit Delay	Delay for an interface to send Update packets
State	Interface status of the sham link ● Down ● Point-To-Point

Item	Description
Timer intervals configured	Values of the following timers: ● Hello ● Dead ● Retransmit ● Wait
Adjacency state	Adjacency of the sham link ● Down ● Init ● Exch ● Start ● Exchange ● Loading ● Full
IP security association configured	IP security association configured on a sham link
IP security association applied	IP security association applied on a sham link

7.5.31 display ospfv3 topology

Function

The **display ospfv3 topology** command displays the OSPFv3 area topology.

Format

display ospfv3 [*process-id*] **topology** [**area** *area-id*]

Parameters

Parameter	Description	Value
process-id	Identifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the area ID.	The value of the area ID can be a decimal integer or in the IPv4 address format. The integer ranges from 0 to 4294967295.

Views

All views

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 topology** command to check the OSPFv3 area topology.

Example

Display the topology of OSPFv3 area 1.

```
<HUAWEI> display ospfv3 topology area 1
OSPFv3 Process (1)
OSPFv3 Area (0.0.0.1) topology
Type  ID(If-Index)       Bits      Metric    Next-Hop        Interface
Rtr   1.1.1.1                   --
Rtr   10.2.2.2                   1         10.2.2.2        Vlanif10
Net   10.2.2.2(268435842)          1         0.0.0.0         Vlanif10
```

Table 7-85 Description of the **display ospfv3 topology** command output

Item	Description
OSPFv3 Process	ID of the OSPFv3 process
OSPFv3 Area	ID of the OSPFv3 area
Type	SPF type: ● Rtr: Router ● Net: Network
ID (If-Index)	Router ID (If-Index) is the interface ID of the DR in the network type.
Bits	B bit and E bit indicate the switch type: ● B bit: ABR ● E bit: ASBR
Metric	Metric of path to the node
Next-Hop	Next hop of the path to the node
Interface	Egress of the path to the node

7.5.32 display ospfv3 vlink

Function

The **display ospfv3 vlink** command displays the OSPFv3 virtual links.

Format

display ospfv3 [*process-id*] **vlink**

Parameters

Parameter	Description	Value
process-id	Identifies the OSPFv3 process ID.	The value ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ospfv3 vlink** command to check the OSPFv3 virtual links.

Example

Display OSPFv3 virtual links.

```
<HUAWEI> display ospfv3 vlink
OSPFv3 Process (100)

Virtual Link VLINK1 to router 10.2.2.2 is up
 Transit area 0.0.0.1 via interface Vlanif10, instance ID 0
 Local address FC00:0:0:2000::1
 Remote address FC00:0:0:1001::2
 Interface ID 0x80000001
 VirtualInterface Event: 1
 VirtualInterface LsaCount: 0
 VirtualInterface Lsa Checksum: 0x0
 Transmit Delay is 1 sec, State Point-To-Point, Cost 1562
 Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
      Hello due in 00:00:04
   Adjacency state Init
```

Table 7-86 Description of the **display ospfv3 vlink** command output

Item	Description
Transit area	If the current interface is the V-link interface, the transfer area ID is displayed
via interface	Interface of the V-link
instance ID	Instance ID
Local address	Local address
Remote address	Remote address
Interface ID	Interface ID

Item	Description
VirtualInterface Event	Number of interface events of the V-link
VirtualInterface LsaCount	Number of LSAs sent from all V-link interfaces
VirtualInterface Lsa Checksum	Checksum of the LSA sent from the V-link interface
Transmit Delay	Transmission delay of the interface
State	Interface state: - Down - Point-To-Point
Cost	Cost
Timer intervals configured	Timers: - Hello: Hello interval - Dead: Interval of Dead timer - Wait: Interval of Wait timer. It is pointless to use a virtual link. - Retransmit: Retransmission interval
Adjacency state	State of the V-link: - Down - Init - Exch - Start - Exchange - Loading - Full

7.5.33 domain-id (OSPFv3)

Function

The **domain-id** command sets an OSPFv3 domain ID.

The **undo domain-id** command restores the default setting.

By default, the domain ID is null.

Format

domain-id { **null** | *domain-id* [**type** *type* **value** *value* | **secondary**] * }

undo domain-id { *domain-id* [**type** *type* **value** *value*] }

Parameters

Parameter	Description	Value
null	Specifies that the OSPFv3 domain ID is null.	-
domain-id	Specifies an OSPFv3 domain ID.	The value can be an integer or expressed in dotted decimal notation. If the domain ID is an integer, its value ranges from 0 to 4294967295; it is converted to the dotted decimal notation and carried 1 with 256 when being displayed. If the domain ID is in dotted decimal notation format, it is displayed as originally entered.
type *type*	Specifies the type of the OSPFv3 domain ID.	The value is an integer that can be 0005, 0105, 0205, or 8005. The default value is 0005.
value *value*	Specifies the value of the OSPFv3 domain ID type.	The value is a hexadecimal number that ranges from 0 to FFFF. The default value is 0.
secondary	Specifies the ID of a secondary domain.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Generally, the routes that are imported from a PE are advertised as External-LSAs. However, such routes that belong to different nodes of the same OSPFv3 domain should be advertised as Type 3 LSAs (intra-domain routes). This requires that different nodes in the same OSPFv3 domain have the same domain ID.

Values 0 and null indicate different meanings.

The maximum number of secondary domain IDs in each OSPFv3 process is 10. The maximum number of secondary domain IDs may vary with products.

The parameter **secondary** can be configured only when the primary domain ID is configured. When the **undo domain-id** command is run, if no parameter is specified, the primary domain ID is deleted.

Example

Set the VPN domain ID in OSPFv3 VPN extension.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] ipv6-family
[HUAWEI-vpn-instance-test-af-ipv6] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv6] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospfv3 1 vpn-instance test
[HUAWEI-ospfv3-1] domain-id 234
```

7.5.34 filter export (OSPFv3)

Function

The **filter export** command filters the outgoing Type3 LSAs of the local area.

The **undo filter export** command restores the default setting.

By default, the outgoing Type3 LSAs of the local area are not filtered.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

filter { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **export**

undo filter [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **export**

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The command can be used to filter out invalid LSAs sent to neighbors to reduce the size of neighbors' LSDBs and speed up network convergence.

Configuration Impact

After filtering conditions are set for the outgoing Type3 LSAs to be advertised using the **filter export** command, only the outgoing Type3 LSAs that pass the filtering can be advertised.

Precautions

- The command can be configured only on ABRs.
- When the **rule** command is used to configure a filtering rule for an ACL, only the source address range specified by the parameter **source** and the time range specified by the parameter **time-range** in the **rule** command take effect.
- To set filtering conditions for the incoming Type3 LSAs to be advertised, run the **filter import (OSPFv3)** command.
- Creating an ACL6, IPv6 prefix list, or route-policy before it is referenced is recommended. If a nonexistent ACL6, IPv6 prefix list, or route-policy is referenced using the command, OSPFv3 advertises all Type 3 LSAs.

Example

Configure OSPFv3 to filter the outgoing Type3 LSAs.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 100
[HUAWEI-ospfv3-100] area 1
```

```
[HUAWEI-ospfv3-100-area-0.0.0.1] filter 2000 export
```

7.5.35 filter import (OSPFv3)

Function

The **filter import** command filters the incoming Type3 LSAs of the local area.

The **undo filter import** command restores the default setting.

By default, the incoming Type3 LSAs are not filtered.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

filter { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name* } **import**

undo filter [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* | **route-policy** *route-policy-name*] **import**

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a routing policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **filter import** command can be used to filter out invalid LSAs sent to neighbors to reduce the size of the neighbors' LSDBs and speed up network convergence.

Configuration Impact

After filtering conditions are set for the incoming Type3 LSAs to be advertised using the **filter import** command, only the incoming Type3 LSAs that pass the filtering can be received and advertised.

Precautions

- The command can be configured only on ABRs.
- When the **rule** command is used to configure a filtering rule for an ACL, only the source address range specified by the parameter **source** and the time range specified by the parameter **time-range** in the **rule** command take effect.
- To set filtering conditions for the outgoing Type3 LSAs to be advertised, run the **filter export (OSPFv3)** command.
- Creating an ACL6, IPv6 prefix list, or route-policy before it is referenced is recommended. If a nonexistent ACL6, IPv6 prefix list, or route-policy is referenced using the command, OSPFv3 receives all Type 3 LSAs.

Example

Configure OSPFv3 to filter the incoming Type3 LSAs within the local area.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 100
[HUAWEI-ospfv3-100] area 1
[HUAWEI-ospfv3-100-area-0.0.0.1] filter ipv6-prefix my-prefix-list import
```

7.5.36 filter-policy export (OSPFv3)

Function

The **filter-policy export** command filters imported routes.

The **undo filter-policy export** command restores the default setting.

By default, imported routes are not filtered.

Format

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **export** [*protocol* [*process-id*]]

undo filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name*] **export** [*protocol* [*process-id*]]

Parameters

Parameter	Description	Value
acl6-number	Specifies the ACL6 number.	The value is an integer that ranges from 2000 to 2999.
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of the IPv6 address prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol	Specifies the protocol from which the route is imported. You can use this parameter to filter the imported routes of specific protocols. If this parameter is not specified, all imported routes are filtered.	The value may be **bgp, direct**, **isis, ospfv3, ripng**, **static**, or **unr**. The specific value varies depending on the routing protocol supported by the device.
process-id	Specifies the process ID of the protocol.	The value is an integer ranging from 1 to 65535.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **filter-policy export** command is only valid for the routes that are imported using the **import-route** command.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Precautions

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all external routes imported to OSPFv3 are converted to Type 5 LSAs (AS-external-LSAs) or Type 7 LSAs (NSSA-external-LSAs) and then are advertised to neighbors.

Example

Filter the imported routes based on the rule defined by ACL6 2002.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] filter-policy 2002 export
```

7.5.37 filter-policy import (OSPFv3)

Function

The **filter-policy import** command filters received routes.

The **undo filter-policy import** command restores the default setting.

By default, received routes are not filtered.

Format

filter-policy { *acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name* } **import**

undo filter-policy [*acl6-number* | **acl6-name** *acl6-name* | **ipv6-prefix** *ipv6-prefix-name*] **import**

Parameters

Parameter	Description	Value
acl6-number	Specifies the ACL6 number.	The value is an integer ranging from 2000 to 2999.

Parameter	Description	Value
acl6-name *acl6-name*	Specifies the name of an IPv6 named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ipv6-prefix *ipv6-prefix-name*	Specifies the name of the IPv6 address prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **filter-policy import** command only filters the routes calculated by OSPFv3. Routes that do not pass the filtering are neither added to the OSPFv3 routing table nor advertised.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Precautions

Creating an ACL6 or IPv6 prefix list before it is referenced is recommended. If a nonexistent ACL6 or IPv6 prefix list is referenced using the command, all IPv6 routes received by OSPFv3 are delivered to the IPv6 routing table.

Example

Filter the received routes based on the IPv6 address prefix list named **abc**.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] filter-policy ipv6-prefix abc import
```

7.5.38 frr (OSPFv3)

Function

The **frr** command creates and then displays the OSPFv3 FRR view.

The **undo frr** command deletes the OSPFv3 FRR view.

By default, the OSPFv3 FRR view does not exist.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

frr

undo frr

Parameters

None

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPFv3 IP FRR allows devices to fast switch traffic from faulty links to back up links without interrupting traffic. This function protects traffic and greatly improves the reliability of OSPFv3 networks. OSPFv3 IP FRR must be configured in the OSPFv3 FRR view. The **frr** command run in the OSPFv3 view creates and displays the OSPFv3 FRR view.

Follow-up Procedure

The **frr** command run in the OSPFv3 view creates and displays the OSPFv3 FRR view only, but cannot enable the OSPFv3 IP FRR function. Run the **loop-free-alternate** command in the OSPFv3 view to enable OSPFv3 IP FRR to create the loop-free backup route.

Example

Create and display the OSPFv3 FRR view.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] frr
[HUAWEI-ospfv3-1-frr]
```

7.5.39 frr-policy route (OSPFv3)

Function

The **frr-policy route** command configures a filtering policy for the OSPFv3 IP FRR backup routes. The filtering policy determines what kind of OSPFv3 backup route can be added to the routing table.

The **undo frr-policy route** command cancels the filtering function.

By default, the filtering function is disabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

frr-policy route route-policy *route-policy-name*

undo frr-policy route

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of the policy used to filter OSPFv3 backup routes.	The value must be an existing route-policy.

Views

OSPFv3 FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

OSPFv3 IP FRR allows devices to fast switch traffic on fault links to back up links without interrupting traffic. This protects traffic and greatly improves the reliability of OSPFv3 networks.

After the filtering policy is configured using the **frr-policy route** command, only the OSPFv3 backup route that satisfies filtering rules can be delivered to the forwarding table.

Configuration Impact

To protect the traffic over a specific OSPFv3 route, you can configure a filtering policy *route-policy-name* that the OSPFv3 route matches to ensure that the backup route can be added to the forwarding table. When this route fails, OSPFv3 can fast switch the traffic to a backup route.

Precautions

The **frr-policy route** command is cyclic in nature, and only the latest configuration takes effect.

If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, OSPFv3 adds all backup routes to the IPv6 routing table.

Example

Configure OSPFv3 to add the OSPFv3 backup routes that match the named ACL **abc** to the IPv6 routing table.

```
<HUAWEI> system-view
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] frr
[HUAWEI-ospfv3-1-frr] loop-free-alternate
[HUAWEI-ospfv3-1-frr] frr-policy route route-policy abc
```

7.5.40 graceful-restart (OSPFv3)

Function

The **graceful-restart** command enables GR of the OSPFv3 process.

The **undo graceful-restart** command disables GR of the OSPFv3 process.

By default, OSPFv3 GR is not enabled.

Format

graceful-restart [**period** *period* | **ack-time** *time* | **retransmit-interval** *interval* | **lsa-checking-ignore** | **planned-only**] *

undo graceful-restart [**period** [*period*] | **ack-time** [*time*] | **retransmit-interval** [*interval*] | **lsa-checking-ignore** | **planned-only**] *

Parameters

Parameter	Description	Value
period *period*	Specifies the GR period.	The value is an integer ranging from 1 to 1800, expressed in seconds. By default, the value is 120 seconds.
ack-time *time*	Specifies the period during which a switch waits for the Grace-LSA Ack message from its neighbor.	The value is an integer ranging from 1 to 30, expressed in seconds. By default, the value is 15 seconds.
retransmit-interval *interval*	Specifies the interval for retransmitting Grace-LSAs.	The value is an integer ranging from 1 to 5, expressed in seconds. By default, the value is 5 seconds.
lsa-checking-ignore	Indicates that strict check is not performed on LSAs. By default, switches perform strict check on received LSAs.	-
planned-only	Indicates that switches support Planned-GR only. By default, switches support Planned-GR and Unplanned-GR.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

ack-time is an optional parameter. After the parameter is specified, the restarter can discover more neighbors in *ack-time* period.

Example

Enable GR of the OSPFv3 process.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] graceful-restart
```

7.5.41 helper-role (OSPFv3)

Function

The **helper-role** command configures a switch to support the GR Helper mode.

The **undo helper-role** command cancels GR Helper mode.

By default, the switch is not enabled to support GR Helper mode.

Format

helper-role [{ **ip-prefix** *ip-prefix-name* | **acl-number** *acl-number* | **acl-name** *acl-name* } | **max-grace-period** *period* | **planned-only** | **lsa-checking-ignore**]*

undo helper-role [[**ip-prefix** [*ip-prefix-name*] | **acl-number** [*acl-number*] | **acl-name** [*acl-name*]] | **max-grace-period** *period* | **planned-only** | **lsa-checking-ignore**]*

Parameters

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
acl-number *acl-number*	Specifies the number of the basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a IPv6 Named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
max-grace-period *period*	Specifies the permitted maximum restart period.	The value is an integer ranging from 1 to 1800, expressed in seconds. By default, the value is 1800 seconds.
planned-only	Indicates that switches support Planned-GR only. By default, switches support Planned-GR and Unplanned-GR.	-

Parameter	Description	Value
lsa-checking-ignore	Indicates that strict check is not performed on LSAs. By default, switches perform strict check on received LSAs.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Switches cannot use the helper mode during the GR process.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Example

Configure a switch to support the helper mode.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] helper-role acl-number 2001 max-grace-period 250 planned-only lsa-checking-
ignore
```

7.5.42 import-route (OSPFv3)

Function

The **import-route** command imports an external route. Before the routes are imported, the OSPFv3 process of the route must be active.

The **undo import-route** command stops importing external routes.

By default, no route of other protocols is imported.

Format

import-route { **bgp** [**permit-ibgp**] | **unr** | **direct** | **ripng** *help-process-id* | **static** | **isis** *help-process-id* | **ospfv3** *help-process-id* } [{ **cost** *cost* | **inherit-cost** } | **type** *type* | **tag** *tag* | **route-policy** *route-policy-name*]*

undo import-route { **bgp** | **unr** | **direct** | **ripng** *help-process-id* | **static** | **isis** *help-process-id* | **ospfv3** *help-process-id* }

Parameters

Parameter	Description	Value
bgp	Specifies the protocol from which routes are imported, as **bgp**.	-
permit-ibgp	IBGP routes that are permitted to be imported. The import of IBGP routes may cause route loops. Therefore, this command must not be configured unless it is necessary.	-
unr	Specifies the imported source routing protocol as **unr**. User Network Route (UNR) is allocated if dynamic routing protocols cannot be used when users are getting online.	-
direct	Specifies the imported source routing protocol as **direct**.	-
ripng	Specifies the protocol from which routes are imported, as **ripng**.	-
static	Specifies the imported source routing protocol as **static**.	-
isis	Specifies the protocol from which routes are imported, as **isis**.	-
ospfv3	Specifies the protocol from which routes are imported, as **ospfv3**.	-
help-process-id	Specifies the process ID of the imported source protocol.	The value is an integer ranging from 1 to 65535.
cost *cost*	Indicates the cost of the imported route.	The value is an integer ranging from 1 to 16777214. For details about the default value, see **default (OSPFv3)**.
inherit-cost	Indicates the original cost of the imported routes.	-

Parameter	Description	Value
type *type*	Specifies the type of the external routes.	The value is an integer ranging from 1 to 2. For details about the default value, see **default (OSPFv3)**. - 1: Type 1 external route - 2: Type 2 external route
tag *tag*	Specifies the tag value of the imported routes.	The value is an integer that ranges from 0 to 4294967295. For details about the default value, see **default (OSPFv3)**.
route-policy *route-policy-name*	Specifies the name of the routing policy. Only the routes that match the *route-policy-name* are imported.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a non-PE device, only EBGP routes are imported after the **import-route bgp** command is configured. IBGP routes are also imported after the **import-route bgp permit-ibgp** command is configured. If IBGP routes are imported, routing loops may occur. In this case, run the **preference (OSPFv3)** and **preference (BGP)** commands to prevent loops by specifying preferences of OSPFv3 and BGP routes. If IBGP routes need to be imported, configure the **import-route bgp permit-ibgp** command, and run the **preference (OSPFv3)** and **preference (BGP)** commands to set the preference of OSPFv3 ASE routes lower than that of IBGP routes (preference value of OSPFv3 ASE routes larger than that of IBGP routes).

On a PE, configuring the **import-route bgp** command imports both EBGP routes and IBGP routes, no matter whether the **import-route bgp permit-ibgp** command is configured or not. If the **import-route bgp permit-ibgp** command and the **default-route-advertise (OSPFv3)** command are both configured, the active IBGP default routes can be imported into OSPFv3.

NOTE

After the **import-route direct** command is executed, routes to the network segment where the IPv6 address of the management interface belongs are also imported in the OSPFv3 routing table. Therefore, use this command with caution.

Precautions

Creating a route-policy before it is referenced is recommended. If a nonexistent route-policy is referenced using the command, all the routes learned by the specified protocol are imported to the OSPFv3 routing table.

Example

Import the RIPng route of type 2. The cost of the route is 50.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] import-route ripng 1 type 2 cost 50
```

OSPFv3 process 100 imports the routes discovered by OSPFv3 process 160.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 100
[HUAWEI-ospfv3-100] import-route ospfv3 160
```

7.5.43 ipsec sa (OSPFv3)

Function

The **ipsec sa** command configures a Security Association (SA) in the OSPFv3 area or OSPFv3 process.

The **undo ipsec sa** command deletes the SA configured in the OSPFv3 area or OSPFv3 process.

By default, no SA is configured in the OSPFv3 area or OSPFv3 process.

Format

ipsec sa *sa-name*

undo ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of an SA.	The value is an existing SA name.

Views

OSPFv3 view or OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An SA defines a set of security algorithms and keys to ensure IP security. Incoming and outgoing OSPFv3 packets are authenticated and encrypted based on the rules defined by the SA.

The **ipsec sa** *sa-name* command run in the OSPFv3 process view is used to authenticate packets of the OSPFv3 process. An SA applied in an OSPFv3 process is used to authenticate the packets of the process. After an OSPFv3 process is associated with an OSPFv3 area, the SA applied in the OSPFv3 process is also applied to the OSPFv3 area.

The **ipsec sa** *sa-name* command run in the OSPFv3 area view is used to authenticate packets of the OSPFv3 area.

NOTE

- The SA applied in an OSPFv3 area takes precedence over that applied in an OSPFv3 process.
- If the SA applied in the OSPFv3 area is deleted, the SA applied in the OSPFv3 process is used to authenticate packets.

Example

Configure an SA named **sa1** in the OSPFv3 process. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] ipsec sa sa1
```

Configure an SA named **sa2** in the OSPFv3 area. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 10.0.0.0
[HUAWEI-ospfv3-1-area-10.0.0.0] ipsec sa sa2
```

7.5.44 loop-free-alternate (OSPFv3)

Function

The **loop-free-alternate** command enables OSPFv3 IP FRR to enable the device to use the LFA algorithm to calculate the nexthop and outbound interface for the dynamic backup link.

The **undo loop-free-alternate** command disables OSPFv3 IP FRR.

By default, this function is disabled.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

loop-free-alternate

undo loop-free-alternate

Parameters

None

Views

OSPFv3 FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **frr** command run in the OSPFv3 view creates and displays the OSPFv3 FRR view only, but cannot enable the OSPFv3 IP FRR function. You must run the **loop-free-alternate** command in the OSPFv3 view to enable OSPFv3 IP FRR use the LFA algorithm to calculate the nexthop and outbound interface for the dynamic backup link to create the loop-free backup route.

Follow-up Procedure

Run the **frr-policy route** command in the OSPFv3 view to configure a filtering policy for OSPFv3 IP FRR. Only the OSPFv3 backup route that satisfies specific rules can be delivered to the forwarding table.

Example

Enable OSPFv3 IP FRR to create the loop-free backup route.

```
<HUAWEI> system-view
[HUAWEI] ospfv3
```

```
[HUAWEI-ospfv3-1] frr
[HUAWEI-ospfv3-1-frr] loop-free-alternate
```

7.5.45 lsa-forwarding-address

Function

The **lsa-forwarding-address** command enables the OSPFv3 forwarding address (FA) function.

The **undo lsa-forwarding-address** command disables the OSPFv3 FA function.

By default, the OSPFv3 FA function is disabled.

Format

lsa-forwarding-address { **standard** | **zero-translate** }

undo lsa-forwarding-address

Parameters

Parameter	Description	Value
standard	Indicates that the function is compatible with RFC 3101.	-
zero-translate	Allows the Type 7 LSAs with the P-bit set and the FA being 0 to be translated to Type 5 LSAs.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For an OSPFv3 Type 5 or Type 7 LSA:

- When there is no FA, other switches consider how to reach the ASBR (the switch that generates this LSA) and then reach an external network through this ASBR.
- When there is an FA, other switches consider how to reach the device to which this FA belongs and then reach an external network through this device.

In this situation, if no FA is available, an additional next hop may be generated when a switch within an OSPF domain first reaches an ASBR before reaching an external network.

Therefore, the FA in an OSPFv3 Type 5 or Type 7 LSA provides a faster next hop to reach an external network.

Precautions

If the FA in an OSPFv3 Type 5 or Type 7 LSA is not 0, the corresponding route is calculated only when the **lsa-forwarding-address** command is configured.

Example

Enable the OSPFv3 FA function that is compatible with RFC 3101.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] lsa-forwarding-address standard
```

7.5.46 maximum load-balancing (OSPFv3)

Function

The **maximum load-balancing** command sets the maximum number of equal-cost routes for carrying out load balancing.

The **undo maximum load-balancing** command restores the default setting.

The default maximum number of equal-cost OSPFv3 routes for carrying out load balancing is 8.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

maximum load-balancing *number*

undo maximum load-balancing

Parameters

Parameter	Description	Value
number	Specifies the maximum number of equal-cost routes.	The value is an integer ranging from 1 to 8.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Applicable Environment

If a routing protocol discovers multiple routes with the same cost to a single destination, they can carry out load balancing. The **maximum load-balancing** command sets the maximum number of equal-cost routes that can carry out load balancing. This optimizes the routing policy and ensures traffic forwarding on a complex network.

Effect

Packets will be load-balanced by multiple equal-cost routes to a single destination.

NOTE

Load balancing is performed in either per-flow or per-packet mode. By default, packets are load-balanced in per-flow mode.

Follow-up Procedure

If more existing equal-cost OSPFv3 routes than the value set using the **maximum load-balancing** command are available, valid routes are selected for load balancing based on the following criteria:

- Route preference: Routes with lower preferences are selected for load balancing.
- Interface index: If routes have the same priorities, routes with higher interface index values are selected for load balancing.
- Next hop IP address: If routes have the same priorities and interface index values, routes with larger IP address are selected for load balancing.

The **nexthop** command allows routes with a specified weight to carry out load balancing.

Precautions

To disable load balancing, set the value of *number* to 1.

Example

Set the maximum number of equal-cost routes that OSPFv3 can support to 3.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] maximum load-balancing 3
```

Restore the default maximum number of equal-cost routes for carrying out load balancing.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] undo maximum load-balancing
```

7.5.47 nexthop (OSPFv3)

Function

The **nexthop** command sets the preference for equal-cost routes.

The **undo nexthop** command cancels the preference of equal-cost routes.

By default, the preference is not set for equal-cost routes. That is, equal-cost routes forward packets at the same time for load balancing.

Format

nexthop *router-id interface-type interface-number* **weight** *value*

undo nexthop *router-id interface-type interface-number*

Parameters

Parameter	Description	Value
router-id	Specifies the router ID of a neighbor.	It is in dotted decimal notation.
interface-type interface-number	Specifies the type and number of an interface.	-
weight *value*	Specifies the weight of the next hop. The smaller the weight is, the higher the route preference is.	It is an integer ranging from 1 to 254.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

After OSPFv3 calculates equal-cost routes, you can run the **nexthop** command to select the route with the highest preference from the equal-cost routes as the next hop. OSPFv3 selects a next hop from these equal-cost routes according to the weight. The smaller the weight is, the higher the route preference is.

Example

Set the preference for equal-cost routes in OSPFv3.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] quit
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] nexthop 10.2.2.2 vlanif 10 weight 240
```

7.5.48 nssa (OSPFv3 Area)

Function

The **nssa** command configures an OSPFv3 area as an NSSA.

The **undo nssa** command cancels the configuration.

By default, no OSPFv3 area is configured as an NSSA.

Format

nssa [**default-route-advertise** [**cost** *cost* | **type** *type* | **tag** *tag*] * | **no-import-route** | **no-summary** | **translator-always** | **translator-interval** *translator-interval* | **set-n-bit** | **suppress-forwarding-address**] *

undo nssa

Parameters

Parameter	Description	Value
default-route-advertise	Generates default Type7 LSAs on the ASBR and then advertises them to the NSSA. **NOTE** The ABR generates a default NSSA LSA (Type7 LSA) automatically and advertises it in the NSSA.	-
cost *cost*	Specifies the default cost of Type 7 LSAs.	It is an integer ranging from 1 to 16777214. The default value is 1.

Parameter	Description	Value
type *type*	Specifies the type of the external routes.	The value is an integer ranging from 1 to 2. By default, it is 2. - 1: Type 1 external route - 2: Type 2 external route
tag *tag*	Specifies the tag value of the OSPFv3 route imported to an NSSA.	It is an integer ranging from 0 to 4294967295. The default value is 0.
no-import-route	Indicates that no external routes are imported to NSSAs.	-
no-summary	Disables ABRs from sending summary LSAs to NSSAs.	-
translator-always	Specifies the ABR in an NSSA as the translator. Multiple ABRs in an NSSA can be configured as translators.	-
translator-interval *translator-interval*	Specifies the timeout period of a translator.	It is an integer ranging from 1 to 120, in seconds. The default value is 40 seconds.
set-n-bit	Indicates that the N-bit is set in DD packets.	-
suppress-forwarding-address	Enables the device to suppress the forwarding address of a Type 5 LSA translated from a Type 7 LSA.	-

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

If an area is configured to the nssa area, all switches of the area must be configured with the NSSA attribute.

The area will be updated after NSSA attributes are configured or deleted. Thus, the NSSA attributes can be re-configured or deleted only after the last update of NSSA attributes is complete.

The keyword **default-route-advertise** is used to generate default Type 7 LSAs. Regardless of whether there is route ::/0 in the routing table on an ABR, a Type 7 LSA default route is generated. A Type 7 LSA default route can be generated only when there is route ::/0 in the routing table on an ASBR.

When an ASBR is also an ABR, you can specify **no-import-route** to disable OSPFv3 from advertising the external routes imported through the **import-route** command to NSSAs. To reduce the number of LSAs to be transmitted to NSSAs, you can specify **no-summary** on an ABR to disable the ABR from transmitting summary LSAs (Type 3 LSAs) to NSSAs.

NOTE

- When the LS age field (aging time) in the LSA header reaches 3600 seconds, this LSA is deleted.
- After the keyword **set-n-bit** is set, a switch re-establishes neighbor relationships with switches directly connected to it in the NSSA.

Example

Configure Area 1 as an NSSA, and set the timeout period of the translator to 20s.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 1
[HUAWEI-ospfv3-1-area-0.0.0.1] nssa translator-interval 20
```

7.5.49 ospfv3

Function

The **ospfv3** command enables an OSPFv3 process.

The **undo ospfv3** command disables the OSPFv3 process.

By default, the system does not support OSPFv3.

Format

ospfv3 [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo ospfv3 *process-id*

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535. By default, it is 1.
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Only when you configure the Route ID in the OSPFv3 view, the OSPFv3 process can run normally. Otherwise, the OSPFv3 process can be viewed but cannot generate LSAs.

If a VPN instance is specified, the OSPFv3 process belongs to the VPN instance. If no VPN instance is specified, the OSPFv3 process is a global instance.

NOTE

Before configuring OSPFv3-related parameters, you must enable OSPFv3.

Example

Enable the OSPFv3 protocol.

```
<HUAWEI> system-view
[HUAWEI] ospfv3
```

7.5.50 ospfv3 area

Function

The **ospfv3 area** command enables the OSPFv3 process on an interface and specifies the area the process belongs to.

The **undo ospfv3 area** command disables the OSPFv3 process on the interface.

By default, the OSPFv3 protocol is not enabled on the interface.

Format

ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

undo ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value is an integer ranging from 1 to 65535.
area *area-id*	Specifies the OSPFv3 area ID.	The value of the area ID can be a decimal integer or in the IPv4 address format. The integer ranges from 0 to 4294967295.
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Before running this command on an interface, run the **ipv6 enable** command to enable IPv6 in the interface view.

Example

Enable OSPFv3 on an interface and enable OSPFv3 in area 1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
```

Enable OSPFv3 in GE0/0/1, and enable OSPFv3 in area 1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
```

7.5.51 ospfv3 authentication-mode

Function

The **ospfv3 authentication-mode** command configures an authentication mode and a password for an OSPFv3 interface.

The **undo ospfv3 authentication-mode** command deletes the authentication mode and password configured for an OSPFv3 interface.

By default, no authentication mode or password is configured for any OSPFv3 interface.

Format

ospfv3 authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* } [**instance** *instance-id*]

ospfv3 authentication-mode keychain *keychain-name* [**instance** *instance-id*]

undo ospfv3 authentication-mode hmac-sha256 key-id *key-id* [**plain** *plain-text* | **cipher** *cipher-text*] [**instance** *instance-id*]

undo ospfv3 authentication-mode keychain [*keychain-name*] [**instance** *instance-id*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
hmac-sha256	Configures the HMAC-SHA256 authentication mode.	N/A
key-id *key-id*	Specifies the key ID for authentication, which must be the same as the one configured at the other end.	The value is an integer ranging from 1 to 65535.

Parameter	Description	Value
plain	Configures the plaintext password type. Only a plaintext password can be entered, and the password is displayed in plaintext in the configuration file. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	N/A
plain-text	Specifies a plaintext password.	The value is a string of 1 to 255 characters, spaces not supported.
cipher	Configures the ciphertext password type. You can enter either a plaintext or ciphertext password, but the password is displayed in ciphertext in the configuration file.	N/A
cipher-text	Specifies a ciphertext password.	The value can be a string of 1 to 255 characters for plaintext passwords and 20 to 392 characters for ciphertext passwords, spaces not supported.
keychain	Configures keychain authentication. **NOTE** Before you configure keychain authentication, run the **keychain** command to configure a keychain, the **key-id** command to configure a key ID, the **key-string** command to configure a password, and the **algorithm** command to configure an algorithm. If these commands are not run, OSPFv3 authentication fails.	N/A

Parameter	Description	Value
keychain-name	Specifies a keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
instance *instance-id*	Specifies the ID of a VLAN to which the specified interface belongs.	The value ranges from 0 to 255, with default value 0.

Views

Interface view

2: Configuration level

Usage Guidelines

Usage Scenario

Due to inherent defects and flawed implementation of the TCP/IP protocol suite, there are an increasing number of attacks, which poses greater threats on TCP/IP networks than ever before. The attacks on network devices may lead to network failures. To configure an authentication mode and a password for an OSPFv3 interface to improve OSPFv3 network security, run the **ospfv3 authentication-mode** command.

Precautions

OSPFv3 interface authentication takes precedence over OSPFv3 area authentication.

To configure OSPFv3 area authentication, run the **authentication-mode** command.

Example

Configure OSPFv3 HMAC-SHA256 authentication on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] ospfv3 1 area 0
```

```
[HUAWEI-Vlanif100] ospfv3 authentication-mode hmac-sha256 key-id 10 cipher test
```

Configure OSPFv3 HMAC-SHA256 authentication on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 0
[HUAWEI-GigabitEthernet0/0/1] ospfv3 authentication-mode hmac-sha256 key-id 10 cipher test
```

7.5.52 ospfv3 bfd

Function

The **ospfv3 bfd** command enables the bidirectional forwarding detection (BFD) on the specified interface enabled with OSPFv3, or sets the parameter values of a BFD session.

The **undo ospfv3 bfd** command deletes the BFD on the specified interface, or restores the default parameter values of a BFD session.

By default, BFD is not enabled on OSPFv3 interfaces.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

ospfv3 bfd enable [**instance** *instance-id*]

ospfv3 bfd { **min-transmit-interval** *min-transmit-value* | **min-receive-interval** *min-receive-value* | **detect-multiplier** *detect-multiplier-value* } * [**instance** *instance-id*]

undo ospfv3 bfd enable [**instance** *instance-id*]

undo ospfv3 bfd { **min-transmit-interval** [*min-transmit-value*] | **min-receive-interval** [*min-receive-value*] | **detect-multiplier** [*detect-multiplier-value*] } * [**instance** *instance-id*]

Parameters

Parameter	Description	Value
enable	Enables BFD for OSPFv3 on the specified interface.	-
min-transmit-interval *min-transmit-value*	Specifies the minimum interval for sending BFD packets to the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-receive-interval *min-receive-value*	Specifies the minimum interval for receiving BFD packets from the peer.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *detect-multiplier-value*	Indicates the local detection multiplier.	The value is an integer in the range from 3 to 50. The default value is 3.
instance *instance-id*	Specifies an interface instance ID.	The value is an integer in the range from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A link fault or a topology change causes devices to recalculate routes. Therefore, the convergence of routing protocols must be as fast as possible to improve network performance.

Link faults are inevitable. Therefore, quickly detecting faults and notifying routing protocols of the faults is a feasible solution to immediately rectify link faults. If BFD is associated with routing protocols, BFD can speed up the convergence of routing protocols when a link fault occurs.

After OSPFv3 establishes a BFD session, the default parameter values are used. BFD session parameters can also be modified as required.

- Actual interval at which BFD packets are transmitted on the local device = Max { configured interval *min-transmit-value* at which BFD packets are transmitted on the local device, configured interval *min-receive-value* at which BFD packets are received on the peer device }
- Actual interval at which BFD packets are received on the local device = Max { configured interval *min-transmit-value* at which BFD packets are transmitted on the peer device, configured interval *min-receive-value* at which BFD packets are received on the local device }
- Actual period for BFD detection on the local device = Actual interval at which BFD packets are received on the local device x Detection multiplier *detect-multiplier-value* configured on the peer device

For example:

- On the local device, the configured interval at which BFD packets are transmitted is 200 ms; the interval at which BFD packets are received is set to 300 ms; the detection multiplier is 4.
- On the peer device, the configured interval at which BFD packets are transmitted is 100 ms; the interval at which BFD packets are received is 600 ms; the detection multiplier is 5.

Then:

- On the local device, the actual interval at which BFD packets are transmitted is 600 ms calculated by using the formula max {200 ms, 600 ms}; the interval at which BFD packets are received is 300 ms calculated by using the formula max {100 ms, 300 ms}; the detection period is 1500 ms calculated by multiplying 300 ms by 5.
- On the peer device, the actual interval at which BFD packets are transmitted is 300 ms calculated by using the formula max {100 ms, 300 ms}, the actual interval at which BFD packets are received is 600 ms calculated by using the formula max {200 ms, 600 ms}, and the detection period is 2400 ms calculated by multiplying 600 ms by 4.

Prerequisites

The set BFD session parameters take effect only when BFD is enabled on the interface.

Configuration Impact

If the global BFD is not configured, BFD on the interface can be configured but the BFD session cannot be set up. Similarly, if the parameters of a BFD session are set but the **ospfv3 bfd enable** command is not configured, the BFD session cannot be set up.

The priority of BFD configured on an interface is higher than that configured in a process. If the BFD is enabled on the interface, the BFD session is set up by using the parameters of the BFD configured on the interface.

Precautions

- After BFD is configured, OSPFv3 establishes BFD sessions only with neighbors.
- The **ospfv3 bfd enable** command and the **ospfv3 bfd block** command are mutually exclusive.
- After BFD is disabled on the interface using the **undo ospfv3 bfd enable** command, the configurations of the parameters of the BFD session on the interface still exist.
- BFD cannot be enabled on VBDIF interfaces.

Example

Enable BFD for OSPFv3 on interface Vlanif10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ospfv3 bfd enable instance 1
```

Configure BFD parameters for OSPFv3 on interface Vlanif10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ospfv3 bfd min-transmit-interval 100 min-receive-interval 100 detect-multiplier 3
instance 1
```

7.5.53 ospfv3 bfd block

Function

The **ospfv3 bfd block** command blocks the bidirectional forwarding detection (BFD) dynamically created by an interface.

The **undo ospfv3 bfd block** command cancels the feature.

By default, BFD is not blocked.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ospfv3 bfd block [**instance** *instance-id*]

undo ospfv3 bfd block [**instance** *instance-id*]

Parameters

Parameter	Description	Value
instance *instance-id*	Indicates the interface instance id.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the **bfd all-interfaces enable** command is run in the OSPFv3 process, all neighbors that enable OSPFv3 and the neighbor relationship is in Full state create BFD sessions. To prevent specific interfaces from being enabled with BFD, you can disable their interfaces from dynamically creating BFD sessions.

Prerequisites

BFD has been enabled on these interfaces.

Before configuring this command, you must run the **ipv6 enable** command in the interface view to enable IPv6.

Precautions

The **ospfv3 bfd enable** command and the **ospfv3 bfd block** command are mutually exclusive.

Example

Block the BFD dynamically created by Vlanif100 when configured the BFD for OSPF3 of all interfaces in the OSPF3 process.

```
<HUAWEI> system-view
[HUAWEI] interface Vlanif100
[HUAWEI-Vlanif100] ospfv3 bfd block instance 1
```

7.5.54 ospfv3 cost

Function

The **ospfv3 cost** command sets the cost of the interface in different instances.

The **undo ospfv3 cost** command restores the default cost of the interface in different instances.

By default, the cost of an interface running OSPF is calculated using the following formula: **Interface cost = Bandwidth reference value/Interface bandwidth** where, the bandwidth reference value can be changed using the **bandwidth-reference** command.

Format

ospfv3 cost *cost* [**instance** *instance-id*]

undo ospfv3 cost [*cost*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
cost	Specifies the cost for running OSPFv3.	The value is an integer ranging from 1 to 65535.
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the cost for public instances to run OSPFv3 on VLANIF 10 to 33.

```
<HUAWEI> system-view
[HUAWEI] ipv6
```

```
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 cost 33
```

Set the cost for public instances to run OSPFv3 on GE0/0/1 to 33.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 cost 33
```

7.5.55 ospfv3 dr-priority

Function

The **ospfv3 dr-priority** command sets the priority of an interface that takes part in the DR or BDR election.

The **undo ospfv3 dr-priority** command restores the default value.

By default, the priority of an interface that takes part in the DR or BDR election is 1.

Format

ospfv3 dr-priority *priority* [**instance** *instance-id*]

undo ospfv3 dr-priority [*priority*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
priority	Specifies the priority of the interface that candidates for DR or BDR.	The value is an integer ranging from 0 to 255. The default value is 1.
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The priority of the interface determines the qualification of the interface when electing DR or BDR. The interface with the higher priority is preferred. The router whose priority is 0 cannot be elected as a DR or a BDR.

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the priority of public instance for electing DR or BDR to 8 on Vlanif10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 dr-priority 8
```

Set the priority of public instance for electing DR or BDR to 8 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 dr-priority 8
```

7.5.56 ospfv3 frr block

Function

The **ospfv3 frr block** command disables the OSPFv3 IP FRR function on a specified interface.

The **undo ospfv3 frr block** command restores the OSPFv3 IP FRR function on the specified interface.

By default, the OSPFv3 IP FRR function is enabled on a specific interface.

Product	Support
S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
S1720GW-E, S1720GWR-E, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S500, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, and S5720S-LI	Not supported

Format

ospfv3 frr block [**instance** *instance-id*]

undo ospfv3 frr block [**instance** *instance-id*]

Parameters

Parameter	Description	Value
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

OSPFv3 IP FRR can be disabled using the **ospfv3 frr block** command on an interface of a specific device that is running important services and resides on an FRR backup link. This setting prevents the device connected to this interface from being a part of a backup link and being burdened after FRR switches traffic to the backup link.

Example

Disable the OSPFv3 IP FRR function on the interface VLANIF 10.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ospfv3 frr block
```

7.5.57 ospfv3 ipsec sa

Function

The **ospfv3 ipsec sa** command configures an SA in the OSPFv3 interface.

The **undo ospfv3 ipsec sa** command deletes the SA configured in the OSPFv3 interface.

By default, no SA is configured in the OSPFv3 interface.

Format

ospfv3 ipsec sa *sa-name*

undo ospfv3 ipsec sa

Parameters

Parameter	Description	Value
sa-name	Specifies the name of an SA.	The value is an existing SA name.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an SA is configured on an interface, OSPFv3 uses the SA to authenticate and encrypt packets sent and received by the interface.

If no SA is configured on the interface or the configured SA is deleted from the interface, OSPFv3 uses the SA configured in the process or the area where the interface resides to authenticate packets sent and received by the interface.

NOTE

- The SA configured in the interface view takes precedence over that configured in the OSPFv3 area view or the OSPFv3 process view.
- The **ospfv3 ipsec sa** command can be used on all the OSPFv3 instances of an interface.

Example

Configure an SA named **sa3** for the interface VLANIF10. (This SA has been created.)

```
<HUAWEI> system-view
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 0
[HUAWEI-Vlanif10] ospfv3 ipsec sa sa3
```

7.5.58 ospfv3 mib-binding

Function

The **ospfv3 mib-binding** command binds an OSPFv3 process to SNMP and makes OSPFv3 respond to SNMP requests.

The **undo ospfv3 mib-binding** command disables the binding.

By default, there is no binding between the OSPFv3 process and SNMP.

Format

ospfv3 mib-binding *process-id*

undo ospfv3 mib-binding

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process ID.	The value ranges from 1 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When multiple OSPFv3 processes are enabled, you can bind OSPFv3 MIB to a process so that this process can be processed.

Before running this command, run the **ospfv3** command in the system view to create an OSPFv3 process.

NOTE

Only after **ospfv3 mib-binding** *process-id* command is run on a device, can the trap associated with the specified process ID be triggered on the device.

Example

Bind OSPFv3 process to SNMP.

```
<HUAWEI> system-view
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] quit
[HUAWEI] ospfv3 mib-binding 100
```

Disable the binding.

```
<HUAWEI> system-view
```

```
[HUAWEI] undo ospfv3 mib-binding
```

7.5.59 ospfv3 mtu-ignore

Function

The **ospfv3 mtu-ignore** command disables the MTU check on DD packets.

The **undo ospfv3 mtu-ignore** command restores the default value.

By default, the MTU check on DD packets is enabled.

Format

ospfv3 mtu-ignore [**instance** *instance-id*]

undo ospfv3 mtu-ignore [**instance** *instance-id*]

Parameters

Parameter	Description	Value
instance *instance-id*	Specifies the interface instance ID.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Disable OSPFv3 from checking the MTU of the DD packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 mtu-ignore
```

Disable OSPFv3 from checking the MTU of the DD packets.

```
<HUAWEI> system-view
[HUAWEI] ipv6
```

```
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 mtu-ignore
```

7.5.60 ospfv3 network-type

Function

The **ospfv3 network-type** command sets the network type of the OSPFv3 interface.

The **undo ospfv3 network-type** command restores the default network type of the OSPFv3 interface.

By default, the network type of an interface is determined by the physical interface. The network type of Ethernet interface is **broadcast**.

Format

ospfv3 network-type { **broadcast** | **nbma** | **p2mp** [**non-broadcast**] | **p2p** } [**instance** *instance-id*]

undo ospfv3 network-type [**broadcast** | **nbma** | **p2mp** [**non-broadcast**] | **p2p**] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
broadcast	Indicates that the network type of the interface is changed to broadcast.	-
nbma	Indicates that the network type of the interface is changed to NBMA.	-
p2mp	Indicates that the network type of the interface is changed to point-to-multipoint.	-
non-broadcast	Indicates that the network type of the interface is changed to non-broadcast point-to-multipoint.	-
p2p	Indicates that the network type of the interface is changed to point-to-point.	-
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

None

Example

Set network type of Vlanif10 to NBMA.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 network-type nbma
```

Set network type of GE0/0/1 to NBMA.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 network-type nbma
```

7.5.61 ospfv3 peer router-id

Function

The **ospfv3 peer router-id** command sets the DR priority and IPv6 addresses for adjacent switches on an NBMA network.

The **undo ospfv3 peer router-id** command cancels the setting.

By default, IPv6 addresses are not configured for the adjacent switches on an NBMA network.

Format

ospfv3 peer router-id *router-id ipv6-address* [**dr-eligible** | **cost** *cost* | **poll** *interval* | **instance** *instance-id*]*

undo ospfv3 peer router-id *router-id* [*ipv6-address*] [**dr-eligible** | **cost** [*cost*] | **poll** [*interval*] | **instance** *instance-id*]*

Parameters

Parameter	Description	Value
router-id	Specifies the router ID of the adjacent switch.	The value is in dotted decimal notation.
ipv6-address	Specifies the link-local address of the adjacent node.	The value is a 32-digit hexadecimal number, in the format of X:X:X:X:X:X:X:X.
dr-eligible	Specifies the neighbor switch that can take part in DR election on the NBMA network.	-
cost *cost*	Specifies the cost of the interface on the neighbor switch of the NBMA network.	The value is an integer ranging from 1 to 65535.
poll *interval*	Specifies the interval for sending polling Hello packets on the neighbor switch on the NBMA network.	The value is an integer ranging from 1 to 65535.
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

You can run the **ospfv3 peer router-id** command to set the DR priority and IPv6 addresses for adjacent switches on an NBMA network.

Example

On Vlanif10, specify the peer end to take part in DR selection.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
```

```
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 peer router-id 10.1.1.1 FE80::1 dr-eligible
```

On GE0/0/1, specify the peer end to take part in DR selection.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 peer router-id 10.1.1.1 FE80::1 dr-eligible
```

7.5.62 ospfv3 router-id auto-recover disable

Function

Using the **ospfv3 router-id auto-recover disable** command, you can disable automatic recovery that will take effect after router ID conflict is detected.

Using the **undo ospfv3 router-id auto-recover disable** command, you can enable automatic recovery that will take effect after router ID conflict is detected.

By default, automatic recovery takes effect after router ID conflict occurs.

Format

ospfv3 router-id auto-recover disable

undo ospfv3 router-id auto-recover disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If router ID conflict occurs in an OSPFv3 area, the system can define a new router ID, preventing route flapping and reducing route calculation operations. Other protocols will not go Down when the CPU usage is controlled.

NOTE

- After the automatic recovery function is restored and router ID conflict occurs in an OSPFv3 area, the switch changes the conflicted router ID to its own IP address. Even the router ID that is manually configured will be changed.
- After the router ID is changed, the system defines a new router ID for a maximum of three times by default if router ID conflict persists.

Example

Disable automatic recovery that will take effect after router ID conflict is detected.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 router-id auto-recover disable
```

7.5.63 ospfv3 suppress-flapping peer

Function

The **ospfv3 suppress-flapping peer** command configures detection parameters for OSPFv3 neighbor relationship flapping suppression.

The **undo ospfv3 suppress-flapping peer** command restores the default detection parameters.

By default, the detection interval of OSPFv3 neighbor relationship flapping suppression is 60s, the suppression threshold is 10, and the interval for exiting from suppression is 120s.

Format

ospfv3 suppress-flapping peer { **detecting-interval** *detecting-interval* | **threshold** *threshold* | **resume-interval** *resume-interval* } * [**instance** *instance-id*]

undo ospfv3 suppress-flapping peer { **detecting-interval** *detecting-interval* | **threshold** *threshold* | **resume-interval** *resume-interval* } * [**instance** *instance-id*]

Parameters

Parameter	Description	Value
detecting-interval *detecting-interval*	Specifies the detection interval of OSPFv3 neighbor relationship flapping suppression. Each OSPFv3 interface on which OSPFv3 neighbor relationship flapping suppression is enabled starts a flapping counter. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping_event is recorded, and the flapping_count is incremented by 1.	The value is an integer ranging from 1 to 300, in seconds. The default value is 60s.

Parameter	Description	Value
threshold *threshold*	Specifies the threshold of OSPFv3 neighbor relationship flapping suppression. When the flapping_count reaches or exceeds *threshold*, flapping suppression takes effect.	The value is an integer ranging from 1 to 1000. The default value is 10.
resume-interval *resume-interval*	Specifies the interval for exiting from OSPFv3 neighbor relationship flapping suppression. If the interval between two successive neighbor status changes from Full to a non-Full state is longer than *resume-interval*, the flapping_count is reset. **NOTE** The value of *resume-interval* must be greater than that of *detecting-interval*.	The value is an integer ranging from 2 to 1000, in seconds. The default value is 120s
instance *instance-id*	Specifies the ID of the instance to which an interface belongs.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure detection parameters for OSPFv3 neighbor relationship flapping suppression on an interface, run the **ospfv3 suppress-flapping peer** command. However, keeping the default configurations is recommended.

Prerequisites

OSPFv3 neighbor relationship flapping suppression must have been enabled globally before you configure detection parameters for it. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure the detection parameters.

Example

Set the detection interval of OSPFv3 neighbor relationship flapping suppression to 5s, the suppression threshold to 40, and the interval for exiting from suppression to 20s on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospfv3 suppress-flapping peer detecting-interval 5 threshold 40 resume-interval
20
```

7.5.64 ospfv3 suppress-flapping peer disable

Function

The **ospfv3 suppress-flapping peer disable** command disables OSPFv3 neighbor relationship flapping suppression from an interface.

The **undo ospfv3 suppress-flapping peer disable** command enables OSPFv3 neighbor relationship flapping suppression on an interface.

By default, OSPFv3 neighbor relationship flapping suppression is enabled on all interfaces.

Format

ospfv3 suppress-flapping peer disable [**instance** *instance-id*]

undo ospfv3 suppress-flapping peer disable [**instance** *instance-id*]

Parameters

Parameter	Description	Value
instance *instance-id*	Specifies the ID of the instance to which an interface belongs.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, OSPFv3 neighbor relationship flapping suppression is enabled on all interfaces in the same OSPFv3 process. To disable the function from one of the interfaces, run the **ospfv3 suppress-flapping peer disable** command.

NOTE

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

Prerequisites

OSPFv3 neighbor relationship flapping suppression must have been enabled globally before you enable the function on an interface using the **undo ospfv3**

suppress-flapping peer disable command. By default, the function is enabled globally. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it first.

Example

Disable OSPFv3 neighbor relationship flapping suppression from VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospfv3 suppress-flapping peer disable
```

7.5.65 ospfv3 suppress-flapping peer hold-down

Function

The **ospfv3 suppress-flapping peer hold-down** command configures the Hold-down mode and sets duration for this mode.

The **undo ospfv3 suppress-flapping peer hold-down** command cancels the Hold-down mode.

By default, the Hold-down mode is disabled.

Format

ospfv3 suppress-flapping peer hold-down *interval* [**instance** *instance-id*]

undo ospfv3 suppress-flapping peer hold-down *interval* [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Specifies the duration of the Hold-down mode.	The value is an integer ranging from 1 to 600, in seconds.
instance *instance-id*	Specifies the ID of the instance to which an interface belongs.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set duration for this mode, run the **ospfv3 suppress-flapping peer hold-down** *interval* command.

Prerequisites

OSPFv3 neighbor relationship flapping suppression must have been enabled globally before you configure the Hold-down mode and set duration for this mode. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure the Hold-down mode and set duration for this mode.

Example

Configure the Hold-down mode and set its duration to 200s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospfv3 suppress-flapping peer hold-down 200
```

7.5.66 ospfv3 suppress-flapping peer hold-max-cost disable

Function

The **ospfv3 suppress-flapping peer hold-max-cost disable** command disables the Hold-max-cost mode.

The **undo ospfv3 suppress-flapping peer hold-max-cost disable** command enables the Hold-max-cost mode.

By default, the Hold-max-cost mode is enabled.

Format

ospfv3 suppress-flapping peer hold-max-cost disable [**instance** *instance-id*]

undo ospfv3 suppress-flapping peer hold-max-cost disable [**instance** *instance-id*]

Parameters

Parameter	Description	Value
instance *instance-id*	Specifies the ID of the instance to which an interface belongs.	The value is an integer ranging from 0 to 255.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set duration for this mode, run the **ospfv3 suppress-flapping peer hold-down** *interval* command.

NOTE

The Hold-max-cost mode can prevent a device from being isolated from the network. If a device on a key path is isolated from the network due to OSPFv3 neighbor relationship flapping, the network is separated into two isolated parts. To prevent this problem, use the Hold-max-cost mode on the key path.

Prerequisites

OSPFv3 neighbor relationship flapping suppression must have been enabled globally before you configure duration for the Hold-max-cost mode. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure duration for the Hold-max-cost mode.

Precautions

The Hold-max-cost mode takes effect only unidirectionally. If a remote device does not support OSPFv3 neighbor relationship flapping suppression, bidirectional traffic between the local and remote devices may travel along different paths.

Example

Disable the Hold-max-cost mode on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospfv3 suppress-flapping peer hold-max-cost disable
```

7.5.67 ospfv3 timer dead

Function

The **ospfv3 timer dead** command sets the dead interval of the OSPFv3 neighbor of the instance on the interface.

The **undo ospfv3 timer dead** command restores the default value.

By default, the dead interval of OSPFv3 neighbor is 40 seconds for the interface of P2P or Broadcast type. The dead interval of OSPFv3 neighbor is 120 seconds for the interface of P2MP or NBMA type.

Format

ospfv3 timer dead *interval* [**instance** *instance-id*]

undo ospfv3 timer dead [*interval*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Indicates the dead interval of OSPFv3.	The value is an integer ranging from 1 to 65535, in seconds.
instance *instance-id*	Specifies the interface instance ID.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Dead interval of OSPFv3 neighbor refers to that the neighbor is invalid if the neighbor does not receive the Hello packets from its neighbor in the interval. The dead interval of switches in the same network segment must be consistent.

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

By default, the dead interval of OSPF neighbors is four times the Hello packet interval. After the Hello packet interval is configured in the instance of the interface using the **ospfv3 timer hello** command, the default dead interval of the OSPFv3 neighbor of the instance on the interface is changed to be four times the Hello packet interval.

Example

Set the dead interval of the neighbor to 80 seconds for Vlanif10.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 timer dead 80
```

Set the dead interval of the neighbor to 80 seconds for GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 timer dead 80
```

7.5.68 ospfv3 timer hello

Function

The **ospfv3 timer hello** command specifies the interval for sending Hello packets on the interface instance.

The **undo ospfv3 timer hello** command restores the default interval.

By default, for the interface of the P2P and broadcast type, the interval for sending Hello packets is 10 seconds. For the interface of the P2MP and NBMA type, the interval for sending Hello packets is 30 seconds.

Format

ospfv3 timer hello *interval* [**conservative**] [**instance** *instance-id*]

undo ospfv3 timer hello [*interval* [**conservative**]] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Indicates the interval for an interface to send the Hello packets.	The value is an integer ranging from 1 to 65535, in seconds.
conservative	Indicates the conservative mode of the dead timer. If the conservative mode is configured, the value configured for the dead timer using the **ospfv3 timer dead** command takes effect even when the value is less than 10s.	-
instance *instance-id*	Specifies the interface instance ID.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the interval for sending Hello packets on Vlanif10 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 timer hello 20
```

Set the interval for sending Hello packets on GE0/0/1 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
```

```
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 timer hello 20
```

7.5.69 ospfv3 timer poll

Function

The **ospfv3 timer poll** command sets the polling interval for sending Hello packets on NBMA network.

The **undo ospfv3 timer poll** command restores the default polling interval.

By default, the polling interval for sending Hello packets on NBMA network is 120 seconds.

Format

ospfv3 timer poll *interval* [**instance** *instance-id*]

undo ospfv3 timer poll [*interval*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Specifies the polling interval of Hello packets.	The value is an integer ranging from 1 to 65535, in seconds.
instance *instance-id*	Specifies the instance ID of the interface.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

On the NBMA network, if a neighbor is invalid, you can configure switches to send Hello packet based on the polling interval that is set by the **ospfv3 timer poll** command. The polling interval should be at least 4 times that of the Hello interval.

OSPFv3 does not support the configuration on a null interface.

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the polling interval for sending Hello packets on the Vlanif10 to 130 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 timer poll 130
```

Set the polling interval for sending Hello packets on the GE0/0/1 to 130 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 timer poll 130
```

7.5.70 ospfv3 timer retransmit

Function

The **ospfv3 timer retransmit** command specifies the interval for retransmitting the LSA on the interface instance.

The **undo ospfv3 timer retransmit** command restores the default value.

By default, the interval for retransmitting LSAs is 5 seconds.

Format

ospfv3 timer retransmit *interval* [**instance** *instance-id*]

undo ospfv3 timer retransmit [*interval*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Indicates the interval for retransmitting LSAs.	The value is an integer ranging from 1 to 3600, in seconds.
instance *instance-id*	Specifies the interface instance ID.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

After sending an LSA to its neighbor, a switch needs to wait for the Ack packet from the neighbor. If the switch does not receive the Ack packet in the retransmission interval, the switch retransmits the LSA.

The interval for retransmitting LSA between the neighboring switches should not be set too short. Otherwise, it leads to unnecessary retransmission.

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the interval for retransmitting the LSA between VLANIF 10 and its neighboring switch to 12 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 timer retransmit 12
```

Set the interval for retransmitting the LSA between GE0/0/1 and its neighboring switch to 12 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] ospfv3 1 area 1
[HUAWEI-GigabitEthernet0/0/1] ospfv3 timer retransmit 12
```

7.5.71 ospfv3 trans-delay

Function

The **ospfv3 trans-delay** command sets the delay for transmitting LSA on an interface instance.

The **undo ospfv3 trans-delay** command restores the default value.

By default, the delay for transmitting LSA is 1 second.

Format

ospfv3 trans-delay *interval* [**instance** *instance-id*]

undo ospfv3 trans-delay [*interval*] [**instance** *instance-id*]

Parameters

Parameter	Description	Value
interval	Indicates the delay for transmitting LSA on an interface.	The value is an integer ranging from 1 to 800, in seconds. By default, it is 1 second.
instance *instance-id*	Specifies the interface instance ID.	The value is an integer ranging from 0 to 255. The default value is 0.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The LSA in the LSDB of the local switch ages with time. The aging of the LSA increases by 1 per second, but the aging of the LSA does not change in the transmission process. Therefore, it is necessary to add the delay to the aging time of the LSA before the LSA is sent.

Before running this command on an interface, run the **ospfv3 area** command on the interface to enable OSPFv3.

Example

Set the delay for transmitting LSA on VLANIF 10 to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6
[HUAWEI] ospfv3
[HUAWEI-ospfv3-1] router-id 10.1.1.1
[HUAWEI-ospfv3-1] quit
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipv6 enable
[HUAWEI-Vlanif10] ospfv3 1 area 1
[HUAWEI-Vlanif10] ospfv3 trans-delay 3
```

Set the delay for transmitting LSA on GE0/0/1 to 3 seconds.

```
<HUAWEI> system-view
[HUAWEI] ipv6

7.5.72 ospfv3 valid-ttl-hops

Function

The **ospfv3 valid-ttl-hops** command enables OSPFv3 GTSM and sets a TTL value.

The **undo ospfv3 valid-ttl-hops** command disables OSPFv3 GTSM.

By default, OSPFv3 GTSM is disabled.

Format

ospfv3 valid-ttl-hops *valid-ttl-hops-value* [**vpn-instance** *vpn-instance-name*]

undo ospfv3 valid-ttl-hops [*valid-ttl-hops-value*] [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
valid-ttl-hops-value	Specifies a TTL.	The value is an integer ranging from 1 to 255.
vpn-instance *vpn-instance-name*	Indicates the name of a VPN instance. If this parameter is specified, only the TTL values of the packets in the specified VPN instance are checked.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an OSPFv3 network requires high security, you can configure OSPFv3 GTSM and an authentication mode to improve network security. During network attacks, attackers may simulate OSPFv3 packets and continuously send them to a device. If the packets are destined for the device, it directly sends them to the control plane for processing without validating them. As a result, the increased processing workload on the control plane results in high CPU usage. GTSM protects devices against potential attacks and improves system security by checking whether the TTL value in each IP packet header is within a pre-defined range.

To enable OSPFv3 GTSM, run the **ospfv3 valid-ttl-hops**. To check the TTL values of packets that match a GTSM policy in a specified VPN instance, specify **vpn-instance** in the command.

The **ospfv3 valid-ttl-hops** command enables OSPFv3 GTSM on both the public network and VPNs. For example, if you run the **ospfv3 valid-ttl-hops 5 vpn-instance** *vpn1* command, OSPFv3 GTSM takes effect on both the public network and VPN 1, the TTL values of the OSPFv3 packets in the VPN 1 are checked, and the default action is performed on the packets that fail to match the GTSM policy.

Follow-up Procedure

GTSM checks the TTL values of only the packets that match a GTSM policy. For packets that do not match the GTSM policy, you can specify **pass** in the **gtsm default-action** command to allow these packets to pass the filtering or specify **drop** in the command to discard them.

Precautions

- If a VPN instance is specified in the **ospfv3 valid-ttl-hops** command and an interface is bound to the VPN instance, the interface discards all received unicast packets if the set TTL value is less than the actual hop count on the network.
- If a virtual link or sham link is deployed, configure a TTL value based on the actual hop count on the network (the number of routers through which the virtual link or sham link passes) to prevent the local switch from discarding packets from neighbors over the virtual link or sham link.
- Therefore, if you want to apply the configured TTL value to packets only in a VPN or the public network, specify **pass** in the **gtsm default-action** command to prevent the OSPFv3 packets in other instances from being discarded incorrectly.

Example

Enable OSPFv3 GTSM and set the maximum number of TTL hops to 5 for the packets that can be received from the public network.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 valid-ttl-hops 5
```

7.5.73 preference (OSPFv3)

Function

The **preference** command sets the preference for an OSPFv3 route.

The **undo preference** command restores the default setting.

By default, the preference of the OSPFv3 route is 10. When ASE is specified, the default value is 150.

Format

preference [**ase**] { *preference* | **route-policy** *route-policy-name* }*

undo preference [**ase**]

Parameters

Parameter	Description	Value
ase	Sets the preference for an AS external route or an NSSA route.	-
preference	Specifies the preference for OSPFv3 routes.	It is an integer ranging from 1 to 255.
route-policy *route-policy-name*	Specifies the name of a routing policy and sets the preference for specified routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The smaller the preference value, the higher the preference.

Multiple dynamic routing protocols may be run on a switch at the same time. Consequently, there is a problem of sharing and selecting routing information among routing protocols. Therefore, the system sets a default reference for each routing protocol. If different routing protocols find multiple routes to the same destination, the route discovered by the routing protocol with a higher preference is selected to forward IP packets.

Precautions

Creating a route-policy before it is referenced is recommended. If a nonexistent route-policy is referenced using the command, the configured priority applies to all OSPFv3 routes.

Example

Set the preference for OSPFv3 routes.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] preference 5
```

7.5.74 reset ospfv3

Function

The **reset ospfv3** command restarts the OSPFv3 process.

The **reset ospfv3 counters** command resets OSPFv3 statistics.

Format

reset ospfv3 { *process-id* | **all** } [**graceful-restart** [**extend-period** *period*]]

reset ospfv3 { *process-id* | **all** } **counters** [**neighbor** [*interface-type interface-number*] [*router-id*]]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPFv3 process number.	The value is an integer that ranges from 1 to 65535.
all	Restarts all OSPFv3 processes.	-
graceful-restart	Restarts the OSPFv3 process in GR mode.	-
extend-period *period*	Prolongs the current GR period.	The value is an integer that ranges from 1 to 1800, expressed in seconds.
neighbor	Resets neighbor statistics.	-
interface-type interface-number	Specifies the type and number of the interface.	-
router-id	Specifies the router ID of a neighbor.	It is in dotted decimal notation.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

You can choose general restart or graceful restart through the parameters.

By setting **extend-period**, you can prolong the current GR period. The prolonged GR period becomes invalid after the process restarts. This parameter takes effect for one time. That is, after the switch performs GR next time, the value of the period returns to the one set by using **graceful-restart** [**extend-period** *period*].

NOTICE

If OSPFv3 connections are reset, OSPFv3 neighbor relationships will be interrupted and the original information cannot be restored. Exercise caution before running the **reset ospfv3** command.

Example

Reset OSPFv3 statistics.

```
<HUAWEI> reset ospfv3 1 counters
```

7.5.75 reset ospfv3 suppress-flapping peer

Function

The **reset ospfv3 suppress-flapping peer** command forces an interface to exit from OSPFv3 neighbor relationship flapping suppression.

Format

reset ospfv3 *process-id* **suppress-flapping peer** [*interface-type interface-number*] [**notify-peer**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an OSPFv3 process.	The value is an integer ranging from 1 to 65535.
interface-type interface-number	Specifies an interface type and number.	-
notify-peer	Instructs neighbors to exit from OSPFv3 neighbor relationship flapping suppression.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Interfaces exit from flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPFv3 process is reset.
- An OSPFv3 neighbor is reset using the **reset ospfv3** command.
- The **reset ospfv3 suppress-flapping peer** command is run.
- OSPFv3 neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable (OSPFv3)** command in the OSPFv3 view.

If **notify-peer** is specified when the **reset ospfv3 suppress-flapping peer** command is run on a device, the device sends Hello packets in which **HelloInterval** and **RouterDeadInterval** are 0s to its neighbors to instruct the neighbors to exit from OSPFv3 neighbor relationship flapping suppression too. If the neighbors fail to receive such Hello packets, the function of **notify-peer** does not take effect. To force the neighbors to exit from OSPFv3 neighbor relationship flapping suppression, run the **reset ospfv3 suppress-flapping peer** command on them.

Example

Force interfaces to exit from OSPFv3 neighbor relationship flapping suppression.

```
<HUAWEI> reset ospfv3 1 suppress-flapping peer
```

7.5.76 rfc1583 compatible (OSPFv3)

Function

The **rfc1583 compatible** command converts rules defined in RFC 5340 into rules defined in RFC 1583.

The **undo rfc1583 compatible** command converts rules defined in RFC 1583 into rules defined in RFC 5340.

By default, OSPFv3 supports the routing rule of RFC 5340.

Format

rfc1583 compatible

undo rfc1583 compatible

Parameters

None

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

RFC 5340 and RFC 1583 define different OSPFv3 route selection rules. When enabling OSPFv3, configure the same route selection rules on all devices in the same OSPFv3 area. For example, an OSPFv3 device supports route selection rules defined in RFC 5340 by default. If the other routers in the same OSPFv3 area support route selection rules defined in RFC 1583, run the **rfc1583 compatible** command.

Example

Converts rules defined in RFC 5340 into rules defined in RFC 1583.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] rfc1583 compatible
```

7.5.77 route-tag (OSPFv3)

Function

The **route-tag** command sets the tag value for imported VPN routes.

The **undo route-tag** command restores the default setting.

By default, the first two bytes of the tag value are fixed as 0xD000, and the last two bytes are the local BGP AS number. For example, if the local BGP AS number is 100, the default tag value in decimal notation is 3489661028.

Format

route-tag *tag-value*

undo route-tag

Parameters

Parameter	Description	Value
tag-value	Specifies the tag value for the imported VPN route.	It is an integer ranging from 0 to 4294967295.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

On a PE, the VPN instance associated with an OSPFv3 instance is configured with a VPN route tag. This route tag must be carried in Type 5 or Type 7 LSAs. You are advised to configure the same route tag for PEs in the same area. Not transmitted in BGP extended community attributes, the VPN route tag is configured and takes effect only on the PEs that receive BGP routes and generate OSPFv3 LSAs. Different OSPFv3 processes can be configured with the same route tag.

If a BGP AS number is greater than 65535, the default tag 0 is used. You can use the command to change the tag in this case.

The only difference between the tag value set through the **route-tag** command and the tag value set through other commands is the preference:

- The preference of the tag value set through the **import-route** command is the highest.
- The preference of the tag value set through the **route-tag** command is medium.
- The preference of the tag value set through the **default tag** *tag* command is the lowest.

If a Type 5 or Type 7 LSA whose tag is the same as the local tag is received, this LSA is ignored during route calculation.

Example

Set the tag value of the imported VPN routes in OSPFv3 process 100 to 100.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance test
[HUAWEI-vpn-instance-test] ipv6-family
[HUAWEI-vpn-instance-test-af-ipv6] route-distinguisher 100:1
[HUAWEI-vpn-instance-test-af-ipv6] quit
[HUAWEI-vpn-instance-test] quit
[HUAWEI] ospfv3 100 vpn-instance test
[HUAWEI-ospfv3-100] route-tag 100
```

7.5.78 router-id (OSPFv3)

Function

The **router-id** command sets the Router ID for the switch that runs OSPFv3.

The **undo router-id** command deletes the Router ID that is set for OSPFv3 switch.

By default, there is no Router ID for the switch that runs OSPFv3.

Format

router-id *router-id*

undo router-id

Parameters

Parameter	Description	Value
router-id	Indicates the switch ID.	It is in dotted decimal notation.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

The Router ID of an OSPFv3 process is unique in an AS. If no Router ID is set, the OSPFv3 process does not run.

When you set a switch ID, ensure that the Router IDs of any two processes are different in an AS.

NOTE

Multiple OSPFv3 processes can run on a switch by setting the different process ID. In this case, you need to specify different Router IDs for different processes.

Example

Set the Router ID of the OSPFv3 process 1 to 10.1.1.3.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] router-id 10.1.1.3
```

7.5.79 sham-hello enable (OSPFv3)

Function

The **sham-hello enable** command enables OSPFv3 to regard the LSU packets and the LSAck packets the same as the Hello packets.

The **undo sham-hello** command disables the operation.

By default, the sham-hello feature is disabled.

Format

sham-hello enable

undo sham-hello

Parameters

none

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

The **sham-hello enable** command, OSPFv3 can regard the LSU packets and the LSAck packets the same as the Hello packets. After receiving this kind of packets, OSPFv3 refreshes the timeout timer of the neighbors to maintain the integrity of their relationship.

Example

Enable sham-hello.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] sham-hello enable
```

7.5.80 sham-link (OSPFv3)

Function

The **sham-link** command configures a sham link.

The **undo sham-link** command deletes a sham link or restores the default setting. If no optional parameters are specified, a sham link is deleted; if optional parameters are specified, the default values of the parameters are restored.

Format

sham-link *source-address destination-address* [**cost** *cost* | **dead** *dead-interval* | **hello** *hello-interval* | **instance** *instance-id* | **retransmit** *retransmit-interval* | **trans-delay** *trans-delay-interval* | { **authentication-mode** { **hmac-sha256 key-id** *key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* } | **keychain** *keychain-name* } | **ipsec sa** *sa-name* }] *

undo sham-link *source-address destination-address* [**cost** [*cost*] | **dead** [*dead-interval*] | **hello** [*hello-interval*] | **retransmit** [*retransmit-interval*] | **trans-delay** [*trans-delay-interval*] | { **authentication-mode** { **hmac-sha256 key-id** *key-id* | **keychain** } | **ipsec sa** [*sa-name*] }] *

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
source-address	Specifies the source IPv6 address.	-
destination-address	specifies the destination IPv6 address.	-
cost *cost*	Specifies the cost of a sham link	The value is an integer ranging from 1 to 65535. By default, it is 1.
dead *dead-interval*	Specifies the dead interval. This value must be equal to the *dead-interval* of the switch that sets up a sham link with the local switch, and must be at least four times that of *hello-interval*.	The value is an integer ranging from 1 to 65535, in seconds.
hello *hello-interval*	Specifies the interval for sending Hello packets on an interface. This value must be equal to the *hello-interval* of the switch that sets up the sham link with the local switch.	The value is an integer ranging from 1 to 65535, in seconds.
instance *instance-id*	Specifies the instance ID of a sham link.	The value is an integer ranging from 0 to 255.
retransmit *retransmit-interval*	Specifies the interval for retransmitting LSAs on an interface.	The value is an integer ranging from 1 to 3600, in seconds.
trans-delay *trans-delay-interval*	Specifies the delay for sending LSAs on an interface.	The value is an integer ranging 1 to 800, in seconds.
authentication-mode	Indicates the authentication mode over the sham link.	-
hmac-sha256	Sets the HMAC-SHA256 authentication mode.	-
key-id *key-id*	Specifies the key ID for authentication, which must be the same as the one configured at the other end.	The value is an integer ranging from 1 to 65535.

Parameter	Description	Value
plain	Configures the plaintext password type. Only a plaintext password can be entered, and the password is displayed in plaintext in the configuration file. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	-
plain-text	Specifies a plaintext password.	The value is a string of 1 to 255 characters, spaces not supported.
cipher	Configures the ciphertext password type. You can enter either a plaintext or ciphertext password, but the password is displayed in ciphertext in the configuration file.	-
cipher-text	Specifies a ciphertext password.	The value can be a string of 1 to 255 characters for plaintext passwords and 20 to 392 characters for ciphertext passwords, spaces not supported.
keychain	Configures keychain authentication. **NOTE** Before you configure keychain authentication, run the **keychain** command to configure a keychain, the **key-id** command to configure a key ID, the **key-string** command to configure a password, and the **algorithm** command to configure an algorithm. If these commands are not run, OSPFv3 authentication fails.	-

Parameter	Description	Value
keychain-name	Specifies a keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
ipsec sa *sa-name*	Specifies the name of an SA configured for an OSPFv3 sham link.	The value is an existing SA name.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

The **sham-link** command can be configured only in the OSPFv3 VPN process. If two PEs belong to the same area and have an intra-area route, you can set up a sham link between the two PEs so that the VPN backbone route is preferred over the intra-area route.

Example

Create an OSPFv3 sham link with the source address being FC00:0:0:1001::1 and destination address being FC00:0:0:2001::1.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1 vpn-instance vrf1
[HUAWEI-ospfv3-1] area 1
[HUAWEI-ospfv3-1-area-0.0.0.1] sham-link fc00:0:0:1001::1 fc00:0:0:2001::1
```

7.5.81 silent-interface (OSPFv3)

Function

The **silent-interface** command suppresses the specified interface from sending and receiving OSPFv3 packets.

The **undo silent-interface** command restores the default setting.

By default, the interface is permitted to send or receive OSPFv3 packets.

Format

silent-interface { **all** | *interface-type interface-number* }

undo silent-interface { **all** | *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Indicates all interfaces in a process.	-
interface-type interface-number	Indicates the interface type and interface number.	-

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

To prevent OSPFv3 routing information of a switch from being obtained by other switches on a certain network and prevent the switch from receiving routing information from other switches, you can disable an OSPFv3 interface on the switch from sending or receiving OSPFv3 packets.

After an interface on a switch is disabled from sending or receiving OSPFv3 packets, the direct route of the interface can still be advertised by the switch through an Intra-Area-Prefix-LSA, but no OSPFv3 neighbor relationship will be established on the interface. This enhances OSPFv3 adaptability.

In different processes, you can suppress the same interface from sending and receiving OSPFv3 packets. However, the **silent-interface** command takes effect only in the specified process of an interface, not all processes associated with the interface.

Example

Suppress Vlanif10 from sending and receiving OSPFv3 packets.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] silent-interface vlanif 10
```

7.5.82 spf timers

Function

The **spf timers** command sets the interval for calculating OSPFv3 routes by a common SPF timer.

The **undo spf timers** command restores the default setting.

By default, the interval for calculating OSPFv3 routes by a common SPF timer is not set.

Format

spf timers *delay-interval hold-interval*

undo spf timers

Parameters

Parameter	Description	Value
delay-interval	Specifies the delay for OSPFv3 from receiving network changes to performing SPF calculation.	The value is an integer ranging from 0 to 65535 seconds.
hold-interval	Specifies the holding interval between two consecutive SPF calculations.	The value is an integer ranging from 0 to 65535 seconds.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

According to the local LSDB, the switch that runs OSPFv3 can calculate an SPT with itself as the root and determines the next hop to the destination network according to the SPT. Adjusting SPF calculation interval can avoid the exhaustion of bandwidth and switch sources caused by frequent change of the network.

Precautions

- By default, the intelligent SPF timer takes effect.
- The **spf timers** *delay-interval hold-interval* and **spf-schedule-interval** *delay-interval hold-interval* commands have the same functions.
- The configurations of the **spf timers** *delay-interval hold-interval*, **spf-schedule-interval** *delay-interval hold-interval*, and **spf-schedule-interval intelligent-timer** *max-interval start-interval hold-interval-1* commands will override each other, and only the configuration of the last executed command takes effect.

Example

Set both the OSPFv3 route calculation interval and the hold interval to 6 seconds.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] spf timers 6 6
```

7.5.83 spf-schedule-interval (OSPFv3)

Function

The **spf-schedule-interval** command sets the interval for OSPFv3 to calculate routes.

The **undo spf-schedule-interval** command restores the default setting.

By default, the intelligent timer is enabled. The interval for the SPF calculation is expressed in milliseconds. The maximum interval for the SPF calculation is 10000 ms, the initial interval is 500 ms, and the Holdtime interval is 2000 ms.

Format

spf-schedule-interval { *delay-interval hold-interval* | **intelligent-timer** *max-interval start-interval hold-interval-1* }

undo spf-schedule-interval

Parameters

Parameter	Description	Value
delay-interval	Specifies the delay from the time when OSPFv3 receives a route change to the time when the SPF calculation is performed.	The value is an integer ranging from 0 to 65535, in seconds.
hold-interval	Specifies the hold interval between two consecutive SPF calculations.	The value is an integer ranging from 0 to 65535, in seconds.
intelligent-timer	Specifies the SPF calculation interval set through an intelligent timer.	-
max-interval	Specifies the maximum interval for performing the SPF calculation.	The value is an integer ranging from 1 to 20000, in milliseconds. The default value is 10000.
start-interval	Specifies the initial interval for performing the OSPFv3 SPF calculation.	The value is an integer ranging from 1 to 1000, in milliseconds. The default value is 500.

Parameter	Description	Value
hold-interval-1	Specifies the hold interval for performing the OSPFv3 SPF calculation.	The value is an integer ranging from 1 to 5000, in milliseconds. The default value is 2000.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Based on the local LSDB, a device that runs OSPFv3 uses the SPF algorithm to calculate the shortest path tree with itself as the root, and determines the next hop to the destination network based on the shortest path tree. Adjusting the interval at which the SPF calculation is performed can prevent too many bandwidth resources and device resources from being consumed due to frequent network changes.

Precautions

- The **spf timers** *delay-interval hold-interval* and **spf-schedule-interval** *delay-interval hold-interval* commands have the same functions.
- The configurations of the **spf timers** *delay-interval hold-interval*, **spf-schedule-interval** *delay-interval hold-interval*, and **spf-schedule-interval intelligent-timer** *max-interval start-interval hold-interval-1* commands will override each other, and only the configuration of the last executed command takes effect.

Configuration Impact

After the **spf-schedule-interval intelligent-timer** command is configured, the interval for the SPF calculation is as follows:

1. The initial interval for the SPF calculation is specified by the parameter *start-interval*.
2. The interval for the SPF calculation for the nth (n≥2) time is equal to *hold-interval-1*$\times 2^{(n-2)}$.
3. When the interval specified by *hold-interval-1*$\times 2^{(n-2)}$ reaches the maximum interval specified by *max-interval*, OSPFv3 performs SPF calculation at the maximum interval until *max-interval* expires without flapping or the OSPF process is restarted.

Example

Set the delay interval at which OSPFv3 route calculation is performed to 5s and the hold interval at which OSPFv3 route calculation is performed to 6s.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] spf-schedule-interval 5 6
```

Set the maximum interval for performing the SPF calculation to 10000 ms, the initial interval to 700 ms, and the hold interval to 4000 ms.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] spf-schedule-interval intelligent-timer 10000 700 4000
```

7.5.84 stub (OSPFv3 Area)

Function

The **stub** command sets an OSPFv3 area to the stub area.

The **undo stub** command cancels the settings.

By default, no area is set to the stub area.

Format

stub [**no-summary** | **default-route-advertise backbone-peer-ignore**] *

undo stub

Parameters

Parameter	Description	Value
no-summary	Disables an ABR from sending non-default Type 3 LSAs to the stub area. This parameter applies only to ABRs of stub areas. If the parameter is configured on an ABR, the ABR advertises only one default Type 3 LSA (no other Type 3 LSAs) to the stub area. In this case, this area is also called a totally stub area.	-
default-route-advertise	Configures an ABR to advertise a default Type 3 LSA to the stub area. This parameter applies only to ABRs of stub areas.	-
backbone-peer-ignore	Prevents an ABR from checking the neighbor status when the ABR generates a default Type 3 LSA and advertises it to the stub area. This parameter applies only to ABRs of stub areas. If the parameter is configured on an ABR, the ABR generates a default Type 3 LSA and advertises it to the stub area as long as an interface is Up in the backbone area.	-

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The stub area attribute must be configured on all switches in a stub area.

- If the **stub** command is run on an ABR, without parameters specified, the ABR advertises a default Type 3 LSA and advertises it to the stub area as long as an OSPFv3 neighbor in the full state exists in the backbone area.
- If the **stub no-summary** command is run on an ABR, the ABR is disabled from sending non-default Type 3 LSAs to the stub area connected to the ABR.
- If the **stub default-route-advertise backbone-peer-ignore** command is run on an ABR, the ABR generates a default Type 3 LSA and advertises it to the stub area as long as an interface is Up in the backbone area.

Precautions

The backbone area cannot be configured as a stub area.

Example

Set the OSPFv3 area 1 to the stub area.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] area 1
[HUAWEI-ospfv3-1-area-0.0.0.1] stub
```

7.5.85 stub-router (OSPFv3)

Function

The **stub-router** command configures a device as stub router.

The **undo stub-router** command restores the default configuration.

By default, no stub router exists.

Format

stub-router [**on-startup** [*interval*]]

undo stub-router

Parameters

Parameter	Description	Value
on-startup [*interval*]	Specifies the interval during which a device acts as a stub router when the device is restarted or faulty. ● If **on-startup** is not specified, the device is always a stub router, even if the cost of all routes advertised by the device is 65535. ● If **on-startup** is specified, the device works as a stub router only when it restarts or is faulty. The hold time of the stub router state is determined by *interval* parameter. If the *interval* parameter is not configured, the default interval (500 seconds) is used.	The value is an integer ranging from 5 to 65535, in seconds. By default, it is 500 seconds.

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

After the **stub-router** command is configured on a switch, the stub router informs other OSPFv3 devices not to use this stub router for data forwarding by increasing the metrics of the links in the Router-LSA generated by the switch. Since the metric is not infinite, the devices to this stub router still exist. The metrics of all links in the device Router-LSAs generated by the stub router are set to 65535.

Example

Configure the device as a stub router.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] stub-router
```

7.5.86 suppress-flapping peer disable (OSPFv3)

Function

The **suppress-flapping peer disable** command disables OSPFv3 neighbor relationship flapping suppression globally.

The **undo suppress-flapping peer disable** command enables OSPFv3 neighbor relationship flapping suppression globally.

By default, OSPFv3 neighbor relationship flapping suppression is enabled globally.

Format

suppress-flapping peer disable

undo suppress-flapping peer disable

Parameters

None

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

If an interface carrying OSPFv3 services alternates between Up and Down, OSPFv3 neighbor relationship flapping occurs on the interface. During the flapping, OSPFv3 frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPFv3 services, and other OSPFv3-dependent services, such as LDP and BGP. OSPFv3 neighbor relationship flapping suppression can address this problem by delaying OSPFv3 neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

By default, OSPFv3 neighbor relationship flapping suppression is enabled globally. To disable this function globally, run the **suppress-flapping peer disable** command.

Example

Disable neighbor relationship flapping suppression globally.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
[HUAWEI-ospfv3-1] suppress-flapping peer disable
```

7.5.87 vlink-peer (OSPFv3 Area)

Function

The **vlink-peer** command creates and configures a virtual link.

The **undo vlink-peer** command removes the existing virtual link.

By default, no virtual link is configured on OSPFv3.

Format

vlink-peer *router-id* [**hello** *hello-interval* | **retransmit** *retransmit-interval* | **trans-delay** *trans-delay-interval* | **dead** *dead-interval* | **instance** *instance-id* |

{ **authentication-mode** { **hmac-sha256 key-id** *key-id* { **plain** *plain-text* | [**cipher**] *cipher-text* } | **keychain** *keychain-name* } | **ipsec sa** *sa-name* }] *

undo vlink-peer *router-id* [**hello** [*hello-interval*] | **retransmit** [*retransmit-interval*] | **trans-delay** [*trans-delay-interval*] | **dead** [*dead-interval*] | { **authentication-mode** { **hmac-sha256 key-id** *key-id* | **keychain** } | **ipsec sa** [*sa-name*] }] *

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
router-id	Specifies the switch ID of a virtual link neighbor.	The value is in dotted decimal notation.
hello *hello-interval*	Specifies the interval for sending Hello packets on an interface. This value must be equal to the *hello-interval* value of the switch that sets up a virtual link with the interface.	The value is an integer ranging from 1 to 65535 seconds. By default, it is 10 seconds.
retransmit *retransmit-interval*	Specifies the interval for retransmitting the LSA packets on an interface.	The value is an integer ranging from 1 to 3600 seconds. By default, it is 5 seconds.
trans-delay *trans-delay-interval*	Specifies the delay for sending LSA packets on an interface.	The value is an integer ranging from 1 to 800 seconds. By default, it is 1 second.
dead *dead-interval*	Specifies the dead interval of the neighbor. This value must be equal to *dead-interval* of the switch that sets up the virtual link with it and must be at least four times that of the *hello-interval*.	The value is an integer ranging from 1 to 65535 seconds. By default, it is 40 seconds.
instance *instance-id*	Specifies the instance ID of the virtual link.	The value is an integer ranging from 0 to 255. By default, it is 0.
authentication-mode	Indicates the authentication mode over the virtual link.	N/A

Parameter	Description	Value
hmac-sha256	Sets the HMAC-SHA256 authentication mode.	N/A
key-id *key-id*	Specifies the key ID for authentication, which must be the same as the one configured at the other end.	The value is an integer ranging from 1 to 65535.
plain	Configures the plaintext password type. Only a plaintext password can be entered, and the password is displayed in plaintext in the configuration file. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	N/A
plain-text	Specifies a plaintext password.	The value is a string of 1 to 255 characters, spaces not supported.
cipher	Configures the ciphertext password type. You can enter either a plaintext or ciphertext password, but the password is displayed in ciphertext in the configuration file.	N/A
cipher-text	Specifies a ciphertext password.	The value can be a string of 1 to 255 characters for plaintext passwords and 20 to 392 characters for ciphertext passwords, spaces not supported.

Parameter	Description	Value
keychain	Configures keychain authentication. **NOTE** Before you configure keychain authentication, run the **keychain** command to configure a keychain, the **key-id** command to configure a key ID, the **key-string** command to configure a password, and the **algorithm** command to configure an algorithm. If these commands are not run, OSPFv3 authentication fails.	N/A
keychain-name	Specifies a keychain name.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
ipsec sa *sa-name*	Specifies the name of an SA configured for an OSPFv3 virtual link.	The value is an existing SA name.

Views

OSPFv3 area view

Default Level

2: Configuration level

Usage Guidelines

You can use the **vlink-peer** command to set up a logical connection for non-backbone area which does not connect to the backbone area directly or discontinuous backbone area.

The virtual link can be regarded as a common interface on which OSPFv3 is enabled, because the principles of **hello**, **retransmit,** and **trans-delay** that are configured on the virtual link are similar.

Example

Create an OSPFv3 virtual link to 10.110.0.3.

```
<HUAWEI> system-view
[HUAWEI] ospfv3 1
```

```
[HUAWEI-ospfv3-1] area 10.0.0.0
[HUAWEI-ospfv3-1-area-10.0.0.0] vlink-peer 10.110.0.3
```

7.5.88 vpn-instance-capability simple (OSPFv3)

Function

The **vpn-instance-capability simple** command disables loop detection and calculates routes directly.

The **undo vpn-instance-capability** command enables the DN-bit check to prevent routing loops.

By default, loop detection is enabled.

Format

vpn-instance-capability simple

undo vpn-instance-capability

Parameters

None

Views

OSPFv3 view

Default Level

2: Configuration level

Usage Guidelines

If a Multi-VPN-Instance CE (MCE) needs to support the VPN multi-instance, loop detection needs to be disabled. The **vpn-instance-capability simple** command takes effect only in the OSPFv3 VPN instance.

Example

Disable loop detection.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn1] ipv6-family
[HUAWEI-vpn1-af-ipv6] route-distinguisher 100:1
[HUAWEI-vpn1-af-ipv6] quit
[HUAWEI] ospfv3 100 vpn-instance vpn1
[HUAWEI-ospfv3-100] vpn-instance-capability simple
```

7.6 IPv4 IS-IS Configuration Commands

7.6.1 Command Support

Only the following switch models support IPv4 IS-IS:

S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S

7.6.2 adjacency-strict-check enable

Function

The **adjacency-strict-check enable** command enables IS-IS adjacency strict-check.

The **undo adjacency-strict-check enable** command disables IS-IS adjacency strict-check.

The **adjacency-strict-check disable** command disables IS-IS adjacency strict-check.

By default, IS-IS adjacency strict-check is disabled when IS-IS establishes neighbor relationships.

Format

adjacency-strict-check enable

undo adjacency-strict-check [**enable**]

adjacency-strict-check disable

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During the establishment of IS-IS neighbor relationships, if both IPv4 and IPv6 are configured at both ends, both IPv4 and IPv6 neighbors are established. By default, IPv4 and IPv6 share the standard topology. When the faulty link is restored, IPv4 goes Up faster than IPv6. After the IS-IS router receives a message indicating that IPv4 goes Up, it considers that both IPv4 and IPv6 neighbors are established. If IPv6 packets are being transmitted at that time, some of these IPv6 packets are discarded.

To resolve this problem, run the **adjacency-strict-check enable** command to enable IS-IS adjacency strict-check to ensure that an IS-IS neighbor is established only when both IPv4 and IPv6 go Up.

Prerequisites

You have created an IS-IS process and entered the IS-IS view using the **isis** command.

Configuration Impact

After you run the **adjacency-strict-check enable** command on a broadcast network, the basic topology becomes Down if the IP protocol enabled on the local router is different from that on its neighbors.

After you run the **adjacency-strict-check enable** command on a P2P network, neighbor relationships cannot be established if the IP protocol enabled on the local router is different from that on its neighbors and only the basic topology is available for the local router.

Precautions

undo adjacency-strict-check [**enable**] and **undo adjacency-strict-check** commands have the same function, **enable** is just provide convenience for users.

Example

Enable adjacency strict-check on IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] adjacency-strict-check enable
```

7.6.3 area-authentication-mode

Function

The **area-authentication-mode** command configures an IS-IS area to authenticate received Level-1 packets (LSPs and SNPs) using the specified authentication mode and password or adds authentication information to Level-1 packets to be sent.

The **undo area-authentication-mode** command restores the default configuration.

By default, the system neither encapsulates generated Level-1 packets with authentication information nor authenticates received Level-1 packets.

Format

area-authentication-mode { { **simple** { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } | **md5** { [**cipher**] *plain-cipher-text* | **plain** *plain-text* } } [**ip** | **osi**] | { **keychain** *keychain-name* } } [**snp-packet** { **authentication-avoid** | **send-only** } | **all-send-only**]

area-authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } [**snp-packet** { **authentication-avoid** | **send-only** } | **all-send-only**]

undo area-authentication-mode

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Transmits the password in plain text. NOTICE Simple authentication has potential risks. HMAC-SHA256 ciphertext authentication is recommended.	-
plain *plain-text*	Specifies the authentication password in plain text. You can enter only the password in plain text. When you view the configuration file, the password is displayed in plain text. NOTICE If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is a string of case-sensitive characters without spaces. The value contains digits and letters. When the authentication mode is **simple**, the value is a string of 1 to 16 characters. When the authentication mode is **md5** or **hmac-sha256**, the value is a string of 1 to 255 characters.
cipher *plain-cipher-text*	Specifies the authentication password in cipher text. You can enter the password in plain or cipher text. When you view the configuration file, the password is displayed in cipher text. By default, the password is in cipher text.	The value is a string of case-sensitive characters without spaces. The value contains digits and letters. When the authentication mode is **simple**, the value is a string of 1 to 16 characters in plain text or a string of 32 or 48 characters in cipher text. When the authentication mode is **md5** or **hmac-sha256**, the value is a string of 1 to 255 characters in plain text or a string of 20 to 392 characters in cipher text.

Parameter	Description	Value
md5	Transmits the password that is encrypted using MD5. **NOTICE** MD5 authentication has potential risks. HMAC-SHA256 cipher text authentication is recommended.	-
ip	Indicates the IP authentication password. This parameter cannot be configured when keychain authentication is used.	-
osi	Indicates the OSI authentication password. This parameter cannot be configured when keychain authentication is used. When neither **osi** nor **ip** is specified, the default parameter **osi** is used.	-
keychain *keychain-name*	Indicates the keychain that changes with time and is encrypted using MD5. This parameter takes effect only when *keychain-name* is set using the **keychain** command. Currently, IS-IS supports only HMAC-MD5 and HMAC-SHA256 algorithms.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.
snp-packet	Authenticates SNPs.	-
authentication-avoid	Encapsulates generated LSPs but not SNPs with authentication information and authenticates received LSPs but not SNPs.	-
send-only	Encapsulates generated LSPs and SNPs with authentication information, and authenticates received LSPs but not SNPs.	-

Parameter	Description	Value
all-send-only	Encapsulates generated LSPs and SNPs with authentication information, but does not authenticate received LSPs and SNPs.	-
hmac-sha256	Encapsulates generated packets with the HMAC-SHA256 authentication and a password encrypted by the HMAC-SHA256 algorithm and authenticates received packets.	-
key-id *key-id*	Indicates key ID of the HMAC-SHA256 algorithm.	The value is an integer ranging from 0 to 65535.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, the IS-IS packets to be sent are not encapsulated with authentication information, and the received packets are not authenticated. If a user sends malicious packets to attack a network, information on the entire network may be stolen. Therefore, you can configure IS-IS authentication to improve the network security.

The area authentication password is encapsulated into Level-1 IS-IS packets. Only the packets that pass the area authentication can be accepted. Therefore, you can configure IS-IS area authentication to authenticate the Level-1 area.

Precautions

The **area-authentication-mode** command is valid only on Level-1 or Level-1-2 routers.

By using this command enables IS-IS to discard all the Level-1 LSPs and SNPs whose area authentication passwords are not consistent with the one set by this command. At the same time, IS-IS inserts the configured area authentication password into all the Level-1 routing packets (LSPs and SNPs) sent from the local node. The establishment of the Level-1 neighbor relationship is not affected, regardless of whether the packets pass the area authentication.

The authentication takes effect only on the peer configured with authentication. The peer with no authentication configured can still receive the LSP and SNP packet with the password.

Example

Set the area authentication mode to keychain and keychain name to **test**.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] area-authentication-mode keychain test
```

7.6.4 attached-bit advertise

Function

The **attached-bit advertise** command configures a rule for setting the ATT bit in Link state Protocol Data Units (LSPs).

The **undo attached-bit advertise** command restores the default setting rule.

By default, the Level-1-2 device sets the ATT bit in LSPs using the default rule.

Format

attached-bit advertise { **always** | **never** }

undo attached-bit advertise

Parameters

Parameter	Description	Value
always	Indicates that the ATT bit is set to 1.	-
never	Indicates that the ATT bit is set to 0.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An ATT bit is a field in link state packets. An ATT bit identifies whether Level-1 area is attached to other areas. A Level-1-2 device sets the ATT bit to 1 to notify the devices in Level-1 area of its attachment to a Level-2 backbone area. After a Level-1 device receives the LSPs carrying the ATT bit 1 from the Level-1-2 device, the Level-1 device generates a route with the same destination address as the default route of the Level-1-2 device. Traffic can be forwarded along this route.

The preceding rule is the default rule for setting the ATT bit in the Intermediate System to Intermediate System (IS-IS) protocol. You can run the **attached-bit advertise** command to configure a rule for setting the ATT bit as required.

- If you want the ATT bit in LSPs to be set to 1, run the **attached-bit advertise always** command.
- If you want to disable the Level-1 device connected to the Level-1-2 device from advertising default routes when the ATT bit is set to 1, run either of the following commands:
  - Run the **attached-bit advertise never** command on the Level-1-2 device to disable the device from sending LSPs with the ATT bit 1.
  - Run the **attached-bit avoid-learning** command on the Level-1 device that is connected to the Level-1-2 device.

  Running the **attached-bit advertise never** command applies to all Level-1 devices that receive LSPs with the ATT bit 0. Therefore, it is more convenient.

Precautions

The ATT bit is defined in both Level-1 and Level-2 LSPs, but it can be set to 1 only in Level-1 LSPs. Additionally, only the Level-1-2 device can set the ATT bit. Therefore, running the **attached-bit avoid-learning** command takes effect only on the Level-1-2 device.

Example

Enable the Level-1-2 device to set the ATT bit to 1 in the LSPs sent in IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] attached-bit advertise always
```

7.6.5 attached-bit avoid-learning

Function

The **attached-bit avoid-learning** command disables a device from advertising default routes to a routing table when the ATT bit is set to 1.

The **undo attached-bit avoid-learning** command restores the device to generate default routes when the ATT bit is set to 1.

By default, a device advertises default routes when the ATT bit is set to 1.

Format

attached-bit avoid-learning

undo attached-bit avoid-learning

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

An ATT bit is a field in link state packets. An ATT bit identifies whether Level-1 area is attached to other areas. A Level-1-2 device sets the ATT bit to 1 to notify the devices in Level-1 area of its attachment to a Level-2 backbone area. After a Level-1 device receives the LSPs carrying the ATT bit 1 from the Level-1-2 device, the Level-1 device generates a route with the same destination address as the default route of the Level-1-2 device. Traffic can be forwarded along this route.

To prevent the Level-1 device from advertising the default route when the ATT bit is set to 1, run the **attached-bit avoid-learning** command.

To prevent the Level-1 device from advertising default routes to the routing table, run either of the following commands:

- Run the **attached-bit advertise never** command on the Level-1-2 device to disable the device from sending LSPs with the ATT bit 1.
- Run the **attached-bit avoid-learning** command on the Level-1 device that is connected to the Level-1-2 device.

The difference between the preceding commands lies in that the **attached-bit avoid-learning** command applies to a specified device.

Example

Disable IS-IS-enabled device from advertising default routes to a routing table when the ATT bit is set to 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] attached-bit avoid-learning
```

7.6.6 auto-cost enable

Function

The **auto-cost enable** command enables IS-IS to automatically calculate the interface cost based on the interface bandwidth.

The **undo auto-cost enable** command disables IS-IS from automatically calculating the interface cost based on the interface bandwidth.

By default, IS-IS is disabled from automatically calculating the interface cost based on the interface bandwidth.

Format

auto-cost enable [**compatible**]

undo auto-cost enable

Parameters

Parameter	Description	Value
compatible	Specifies the IS-IS to calculate the cost of an interface based on the bandwidth of the interface automatically in compatible.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this command is run, if the cost of an IS-IS interface is not set in the interface view and no cost is set in the IS-IS view, the system automatically calculates a cost for the interface.

If the cost style of the system is wide or wide-compatible:

When **auto-cost enable** command is configured, Interface cost = (Bandwidth-reference/Link-bandwidth) x 10.

The cost style is set by the **cost-style** command. The Bandwidth-reference is set by the **bandwidth-reference** command. The Link-bandwidth is the interface bandwidth.

If the cost style of the system is narrow, narrow-compatible or compatible, the cost of each interface is based on the following table.

Table 7-87 Relationship between the IS-IS interface cost and the bandwidth

Cost	Range of the Interface Bandwidth
60	Interface bandwidth =< 10 Mbit/s
50	10 Mbit/s < Interface bandwidth ≤ 100 Mbit/s
40	100 Mbit/s < Interface bandwidth ≤ 155 Mbit/s
30	155 Mbit/s < Interface bandwidth ≤ 622 Mbit/s

Cost	Range of the Interface Bandwidth
20	622 Mbit/s < Interface bandwidth ≤ 2.5 Gbit/s
10	2.5 Gbit/s < Interface bandwidth

Precautions

The priority of the cost value of the global configured by the **circuit-cost** command is higher than the auto cost value.

The **auto-cost enable** command cannot change the cost of the loopback interface.

Example

Enable IS-IS to automatically calculate the interface cost.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] auto-cost enable
```

7.6.7 bandwidth-reference (IS-IS)

Function

The **bandwidth-reference** command sets the bandwidth reference value that is used in automatic IS-IS interface cost calculation.

The **undo bandwidth-reference** command restores the default bandwidth reference value that is used in automatic IS-IS interface cost calculation.

By default, the bandwidth reference value is 100 Mbit/s.

Format

bandwidth-reference *value*

undo bandwidth-reference

Parameters

Parameter	Description	Value
value	Specifies the bandwidth reference value used in automatic IS-IS interface cost calculation.	The value is an integer that ranges from 1 to 2147483648, in Mbit/s.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To make the set link cost of IS-IS routes reflect the actual link cost, configure a proper link cost for all interfaces or enable automatic interface cost calculation. To enable automatic interface cost calculation, set a proper bandwidth reference value.

You can run the **bandwidth-reference** command to set a proper bandwidth reference value. After automatic interface cost calculation is enabled, and the cost type is wide or wide-compatible, the system calculates the cost of each interface with the following formula: Interface cost = (Bandwidth-reference/Interface bandwidth) x 10. If the interface cost calculated through this formula is greater than 16777214, 16777214 is used as the interface cost for route calculation. That is, the interface cost will never be greater than 16777214.

The **bandwidth** *bandwidth* command can only set an interface bandwidth obtained by the NMS from the MIB. It cannot change an interface actual bandwidth and interface cost.

After the **auto-cost enable** command enables automatic IS-IS interface cost calculation, the system automatically calculates the interface cost based on the bandwidth reference value set using the **bandwidth-reference** command.

The **bandwidth-reference** command can be operated on Eth-Trunk interfaces as same with on physical interfaces. If the command is run on an Eth-Trunk interface, the bandwidth of the Eth-Trunk interface is equal to the total bandwidth of all its member interfaces.

Precautions

Rules for automatically calculating the IS-IS interface cost vary according to the cost style of the IS-IS interface:

- The bandwidth reference value set using the **bandwidth-reference** command takes effect only when the cost style is wide or wide-compatible. In this case, the interface cost is calculated using the following formula:

  Interface cost = (Bandwidth-reference/Interface bandwidth) × 10.
- If the cost style of the system is narrow, narrow-compatible or compatible, the cost of each interface is based on the following table.

Table 7-88 Relationship between the IS-IS interface cost and the bandwidth

Cost	Range of the Interface Bandwidth
60	Interface bandwidth =< 10 Mbit/s
50	10 Mbit/s < Interface bandwidth =< 100 Mbit/s

Cost	Range of the Interface Bandwidth
40	100 Mbit/s < Interface bandwidth =< 155 Mbit/s
30	155 Mbit/s < Interface bandwidth =< 622 Mbit/s
20	622 Mbit/s < Interface bandwidth =< 2.5 Gbit/s
10	2.5 Gbit/s < Interface bandwidth

Example

Set the reference value of the system bandwidth to 1000 Mbit/s.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] bandwidth-reference 1000
```

7.6.8 bfd all-interfaces (IS-IS)

Function

The **bfd all-interfaces** command sets values for BFD session parameters used in BFD for IS-IS.

The **undo bfd all-interfaces** command restores the default values of BFD session parameters used in BFD for IS-IS.

By default, the minimum intervals for receiving and sending BFD packets are 1000 ms and the detection time multiplier is 3.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

bfd all-interfaces { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* | **frr-binding** } *

undo bfd all-interfaces { **min-rx-interval** [*receive-interval*] | **min-tx-interval** [*transmit-interval*] | **detect-multiplier** [*multiplier-value*] | **frr-binding** } *

Parameters

Parameter	Description	Value
min-rx-interval *receive-interval*	Specifies the minimum interval for receiving BFD packets from the peer end. The interval for receiving BFD packets between determines the BFD session detection time. On an unstable link, a smaller receive interval may result in BFD session flapping. To prevent BFD session flapping, increase the receive interval.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
min-tx-interval *transmit-interval*	Specifies the minimum interval for transmitting BFD packets to the peer end. The interval for transmitting BFD packets determines the BFD session detection time. On a stable link, you can increase the transmit interval to prevent frequent link status detection.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Specifies the local detection multiplier. On a stable link, you can increase the BFD detection multiplier to prevent frequent link status detection.	The value is an integer that ranges from 3 to 50. The default value is 3.

Parameter	Description	Value
frr-binding	Binds the BFD session status to IS-IS Auto FRR. When BFD detects a link fault on an interface, the BFD session goes Down, triggering FRR on the interface. Then traffic is switched from the faulty link to the backup link to ensure traffic forwarding.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During the establishment of a BFD session, you can adjust the interval for transmitting BFD packets, interval for receiving BFD packets, and local detection multiplier according to network and performance requirements.

Precautions

The value of *receive-interval* is obtained by negotiating the local **min-rx-interval** value and the remote **min-tx-interval** value. If a router does not receive any BFD packet from its peer in the *receive-interval* × *multiplier-value* period, the router advertises that its peer is Down.

If only parameters of a BFD session are set but the **bfd all-interfaces enable** command is not used, the BFD session cannot be set up.

NOTE

The BFD priority of the interface is higher than the BFD priority of the process. If BFD of the interface is enabled, the BFD session is set up based on the BFD parameters on the interface.

Example

Enable BFD in an IS-IS process and set the minimum interval for transmitting BFD packets to 600 ms.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] isis
[HUAWEI-isis-1] bfd all-interfaces enable
[HUAWEI-isis-1] bfd all-interfaces min-tx-interval 600
```

7.6.9 bfd all-interfaces enable

Function

The **bfd all-interfaces enable** command enables BFD in an IS-IS process.

The **undo bfd all-interfaces enable** command disables BFD in an IS-IS process.

By default, BFD is disabled in an IS-IS process.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

bfd all-interfaces enable

undo bfd all-interfaces enable

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If global BFD is not enabled, you can configure IS-IS BFD but cannot set up the BFD session. Before establishing BFD sessions, you need to enable BFD on the two ends.

Precautions

When BFD is enabled in the process using the **bfd all-interfaces enable** command, the interface does not set up a BFD session in the following cases:

- The **isis bfd block** command is used on the interface. The command suppresses the BFD capability of the interface. To set up a session on the interface, run the **undo isis bfd block** command.
- When the **isis bfd static** command is used on the interface, the interface does not set up the BFD session. To set up a session on the interface, run the **undo isis bfd static** command.

NOTE

The BFD priority of the interface is higher than the BFD priority of the process. If BFD of the interface is enabled, a BFD session is set up based on the BFD parameters on the interface.

Example

Enable BFD in an IS-IS process.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] isis
[HUAWEI-isis-1] bfd all-interfaces enable
```

7.6.10 circuit-cost

Function

The **circuit-cost** command sets the link cost for all IS-IS interfaces during SPF calculation.

The **undo circuit-cost** command deletes the configured link cost of all IS-IS interfaces.

By default, no link cost is set for IS-IS interfaces.

Format

circuit-cost { *cost* | **maximum** } [**level-1** | **level-2**]

undo circuit-cost [*cost* | **maximum**] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
cost	Specifies the interface cost used in SPF calculation.	If the IS-IS cost style is wide or wide-compatible, the cost of imported routes ranges from 1 to 1677721416777214; otherwise, the cost ranges from 1 to 63.
maximum	Sets the link cost of IS-IS interfaces to 16777215. **NOTE** You can configure this parameter only when the IS-IS cost style is wide or wide-compatible. After the interface cost is set to 16777215, the neighbor TLV generated on the link can only be used to transmit TE information but cannot be used for route calculation.	-
level-1	Specifies the link cost for all Level-1 interfaces. If no level is specified, the link cost is set for Level-1-2 interfaces.	-

Parameter	Description	Value
level-2	Specifies the link cost for all Level-2 interfaces. If no level is specified, the link cost is set for Level-1-2 interfaces.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large network, there are often multiple valid routes to the same destination. IS-IS can use the SPF algorithm to calculate the optimal route to forward traffic. This may cause the following problems:

- All traffic is forwarded along the optimal path, resulting in load unbalance.
- If the optimal path is intermittently disconnected, traffic is still forwarded along the optimal path, resulting in traffic loss.

To solve the preceding problems, run the **circuit-cost** command to change the cost of all IS-IS interfaces so that traffic can be forwarded along different physical links.

Precautions

The **isis cost** command takes precedence over the **circuit-cost** command. The **circuit-cost** command cannot change the cost of loopback interfaces.

Changing the link cost of interfaces will cause routes of the entire network to be recalculated and change the forwarding path of traffic.

Example

Set the default cost of all Level-1-2 interfaces to 30.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] circuit-cost 30
```

Set the link cost of all IS-IS interfaces to 16777215.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] circuit-cost maximum
```

7.6.11 circuit default-tag

Function

The **circuit default-tag** command sets the administrative tag value for all interfaces in an IS-IS process.

The **undo circuit default-tag** command restores the default administrative tag value for all interfaces in an IS-IS process.

By default, the administrative tag value of all IS-IS interfaces is 0.

Format

circuit default-tag *tag* [**level-1** | **level-2**]

undo circuit default-tag [*tag*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
tag	Specifies the administrative tag value for all interfaces in an IS-IS process.	The value is an integer that ranges from 1 to 4294967295.
level-1	Specifies the administrative tag value for all Level-1 interfaces in an IS-IS process. If no interface level is specified, the administrative tag values of Level-1 and Level-2 interfaces are set.	-
level-2	Specifies the administrative tag value for all Level-2 interfaces in an IS-IS process. If no interface level is specified, the administrative tag values of Level-1 and Level-2 interfaces are set.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The administrative tag carries management information about IP address prefixes to control the import of routes of different levels and areas. You can use the administrative tag to control the advertisement of IP address prefixes in an IS-IS routing domain to simplify route management.

The **circuit default-tag** command allows you to set the administrative tag value for all routes in an IS-IS process. You can filter routes based on the configured administrative tag value.

The administrative tag for an interface is advertised along with routing information.

- When the cost style of IS-IS is narrow or narrow-compatible, the administrative tag value is neither advertised nor takes effect in the LSP.
- When the cost style of IS-IS is wide, wide-compatible, or compatible, the administrative tag value is advertised in the LSP.

Precautions

The value of the administrative tag configured through the**circuit default-tag** command is the global administrative tag. The priority of the interface administrative tag configured by the **isis tag-value** command is higher than the priority of the global administrative tag.

Example

Set the administrative tag value of Level-1 interfaces to 30.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] circuit default-tag 30 level-1
```

7.6.12 cost-style

Function

The **cost-style** command sets the cost style of routes received and sent by an IS-IS device.

The **undo cost-style** command restores the default cost style of routes received and sent by an IS-IS device.

By default, the cost style of routes received and sent by an IS-IS device is narrow.

Format

cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }

undo cost-style

Parameters

Parameter	Description	Value
narrow	Configures an IS-IS device to receive and send only routes with cost style narrow. When the cost style is narrow, the cost of routes ranges from 1 to 63.	-
wide	Configures an IS-IS device to receive and send only routes with cost style wide. When the cost style is wide, the cost of routes ranges from 1 to 16777215.	-
wide-compatible	Configures an IS-IS device to receive routes with cost style narrow or wide and sent only routes with cost style wide.	-
compatible	Configures an IS-IS device to receive and send routes with cost style narrow or wide.	-

Parameter	Description	Value
narrow-compatible	Configures an IS-IS device to receive routes with cost style narrow or wide and sent only routes with cost style narrow.	-
relax-spf-limit	Configures an IS-IS device to receive routes with cost higher than 1023. If this parameter is specified, there is no restriction on the link costs of interfaces or route costs. The cost of a received route is the actual cost. If this parameter is not specified, the following situations occur: ● If the cost of a route is smaller than or equal to 1023, and the link cost of each interface through which the route passes is smaller than or equal to 63: The cost of the route is the sum of link costs of all interfaces through which the route passes. ● If the cost of a route is smaller than or equal to 1023, and the link costs of certain interfaces through which the route passes are larger than 63: An IS-IS device can learn only the routes imported by the interfaces and direct routes of the network segment where the interfaces reside. The costs of these routes are the actual cost. ● If the cost of a route is larger than 1023: The device can receive only the routes of the network segment where the interface with link cost smaller than 1023 resides. If the cost of a route is larger than 1023, the cost is calculated as 1023.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the cost style of IS-IS routes is narrow, indicating that only routes with the cost ranging from 1 to 63 can be received and sent. LSPs carrying tag information to be filtered by a routing policy cannot be flooded when the cost style is narrow. The **cost-style** command can be used to change the cost style of IS-IS routes so that they can be transmitted successfully.

To implement extended IS-IS functions, setting the cost style of IS-IS routes to **wide** is recommended.

Precautions

When the cost style of a route is changed from wide to narrow, transmission of the route may be interrupted.

If you want to change the cost style of IS-IS routes, running the command while configuring basic IS-IS functions is recommended. If the cost style of IS-IS routes is changed during network operation, the IS-IS process is restarted and neighbors are disconnected.

Example

Configure an IS-IS device to send only the packets with cost style narrow and to receive the packets with cost style narrow or wide.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] cost-style narrow-compatible
```

7.6.13 default-route-advertise (IS-IS)

Function

The **default-route-advertise** command configures IS-IS devices to generate default routes.

The **undo default-route-advertise** command disables IS-IS devices from generating default routes.

By default, IS-IS devices do not generate default routes.

Format

default-route-advertise [**always** | **match default** | **route-policy** *route-policy-name*] [**cost** *cost* | **tag** *tag* | [**level-1** | **level-1-2** | **level-2**]] * [**avoid-learning**]

undo default-route-advertise

Parameters

Parameter	Description	Value
always	Configures an IS-IS device to unconditionally advertise default routes with itself as the next hop.	-
match default	Advertises a default route through an LSP if the default route is generated by other routing protocols or other IS-IS processes in the routing table. If this default route is deleted from the routing table, it is not advertised through an LSP.	-

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy. A Level-1-2 device advertises default routes to the IS-IS routing domain only when there are external routes matching the route-policy in the routing table of the device. This prevents routing blackhole when link faults make some important external routes unavailable but default routes are still advertised. This route-policy does not affect external route import in IS-IS.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
cost *cost*	Specifies the cost of default routes.	The value is an integer. The value range varies according to the cost style. When the cost style is narrow, narrow-compatible, or compatible, the value ranges from 0 to 63. When the cost style is wide or wide-compatible, the value ranges from 0 to 4261412864.
tag *tag*	Specifies the tag value of advertised default routes. Advertised LSPs carry the tag value only when the IS-IS cost style is wide, wide-compatible, or compatible.	The value is an integer that ranges from 1 to 4294967295.
level-1	Sets the level of default routes to Level-1. If no level is specified, Level-2 default routes are generated by default.	-
level-2	Sets the level of default routes to Level-2. If no level is specified, Level-2 default routes are generated by default.	-
level-1-2	Sets the level of default routes to Level-1-2. If no level is specified, Level-2 default routes are generated by default.	-
avoid-learning	Prevents an IS-IS process from learning default routes or adding them to the routing table. If existing default routes in the routing table are active, set the default route that needs to be added to the routing table to inactive.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When IS-IS and other routing protocols are running on a network, use either of the following methods to allow the traffic within the IS-IS domain to be transmitted to other routing domains:

- Configure a boundary router in the IS-IS domain to advertise default routes to the IS-IS domain.
- Configure a boundary router in the IS-IS domain to import routes from the other routing domains to the IS-IS domain.

The first method is simpler, because the routers in the IS-IS domain do not need to learn routes imported form the other routing protocols.

Precautions

You can specify **always** to allow default routes to be advertised unconditionally; in this case, the device still calculates default routes from other devices.

NOTE

If **always** is configured on multiple devices within the same area, a routing loop may occur.

After this command is run on an IS-IS router, all traffic in an IS-IS domain will be forwarded by this IS-IS router to a destination outside the domain. Compared with configuring a static default route on each router in an IS-IS domain, running this command simplifies configurations, because this command only needs to be run on a boundary router in the IS-IS domain. In addition, you can specify different parameters to allow default routes to be advertised in different ways.

If this command is run on a Level-1 router, the router advertises default routes only to the Level-1 area.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, an ABR advertises the default route to the IS-IS domain as long as the local routing table contains external routes.

Example

Configure the current IS-IS device to advertise the IPv4 default routes that match route-policy **filter** and set the cost of these default routes to 15.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] default-route-advertise route-policy filter cost 15
```

7.6.14 description (IS-IS)

Function

The **description** command configures a description for an IS-IS process.

The **undo description** command deletes the description of an IS-IS process.

By default, no description is configured for an IS-IS process.

Format

description *description*

undo description

Parameters

Parameter	Description	Value
description	Configures a description for an IS-IS process.	The value is a string of 1 to 80 case-sensitive characters. Spaces are supported.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Configuring descriptions for IS-IS processes helps identify and maintain IS-IS processes.

IS-IS process description that is configured through the **description** command is not advertised in an LSP.

IS-IS process description that is configured through the **is-name** command is advertised in an LSP.

Precautions

If you run the **description** command multiple times, only the latest configuration takes effect.

Example

Configure description for IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
```

```
[HUAWEI-isis-1] description this process configure the area-authentication-mode
```

7.6.15 display default-parameter isis

Function

The **display default-parameter isis** command displays the default IS-IS configuration.

Format

display default-parameter isis

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display default-parameter isis** command to check the default IS-IS configuration in IS-IS initialization.

Example

Display the default IS-IS configuration.

```
<HUAWEI> display default-parameter isis

```

Table 7-89 Description of the display default-parameter isis command output

Item	Description
Default Configurations For Process	Default configuration of an IS-IS process.
Cost-Style	IS-IS cost style: ● narrow ● wide ● wide-compatible ● compatible ● narrow-compatible To set the IS-IS cost style, run the **cost-style** command.
Circuit-Cost <IPv4>	Cost of all IS-IS IPv4 interfaces. To set the cost of IS-IS IPv4 interfaces, run the **circuit-cost** command.
Circuit-Cost <IPv6>	Cost of all IS-IS IPv6 interfaces. To set the cost of IS-IS IPv6 interfaces, run the **ipv6 circuit-cost** command.
IS-Level	Level of an IS-IS device: ● L1: Level-1 device ● L2: Level-2 device ● L12: Level-1-2 device To set the level of an IS-IS device, run the **is-level** command.
LSP-Originate-Length	Maximum length of an LSP generated by IS-IS. To set the maximum length of an LSP generated by IS-IS, run the **lsp-length** command.
LSP-Receive-Length	Maximum length of an LSP received by IS-IS. To set the maximum length of an LSP received by IS-IS, run the **lsp-length** command.

Item	Description
LSP-Max-Age <s>	Maximum lifetime of an LSP generated by an IS-IS process, in seconds. To set the maximum lifetime of an LSP generated by an IS-IS process, run the **timer lsp-max-age** command.
LSP-Generation-IntelliTimer <s,ms,ms>	Delay in generating LSPs: ● L1: delay for a Level-1 router to generate LSPs ● L2: delay for a Level-2 router to generate LSPs ● Max: maximum delay in generating LSPs, in seconds ● Init: initial delay in generating LSPs, in milliseconds ● Incr: incremental delay in generating LSPs, in milliseconds To set the delay in generating LSPs, run the **timer lsp-generation** command.
LSP-Refresh-Interval <s>	Interval for refreshing LSPs, in seconds. To set the interval for refreshing LSPs, run the **timer lsp-refresh** command.
Preference	Protocol preference of IS-IS routes. To set the protocol preference of IS-IS routes, run the **preference** command.
SPF-IntelliTimer <s,ms,ms>	Delay in SPF calculation: ● Max: maximum delay in SPF calculation, in seconds ● Init: initial delay in SPF calculation, in milliseconds ● Incr: incremental delay in SPF calculation, in milliseconds To set the delay in SPF calculation, run the **timer spf** command.
Default Configurations For Interfaces	Default configuration of IS-IS interfaces.
Circuit-Level	IS-IS interface level. To set the IS-IS interface level, run the **isis circuit-level** command.
CSNP-Interval <s>	Interval for sending CSNPs, in seconds. To set the interval for sending CSNPs, run the **isis timer csnp** command.

Item	Description
Cost <IPv4>	Cost of IS-IS interfaces in an IPv4 topology. To set the cost of IS-IS interfaces in an IPv4 topology, run the **isis cost** command.
Cost <IPv6>	Cost of IS-IS interfaces in an IPv6 topology. To set the cost of IS-IS interfaces in an IPv6 topology, run the **isis ipv6 cost** command.
DIS-Priority	Priority for DIS election. To set the priority for DIS election, run the **isis dis-priority** command.
Hello-Interval <s>	Interval for sending Hello packets, in seconds. To set the interval for sending Hello packets, run the **isis timer hello** command.
Holding-Multiplier	Number of consecutive Hello packets that are not received before the neighbor is declared Down. To set this value, run the **isis timer holding-multiplier** command.
LSP-Retransmit <s>	Interval for retransmitting LSPs on a P2P link, in seconds. To set the retransmit interval, run the **isis timer lsp-retransmit** command.
LSP-Throttle <ms>	Interval for sending LSPs or CSNPs, in milliseconds, and number of LSPs or CSNPs that are sent each time. To set the two values, run the **isis timer lsp-throttle** command.
PPP-Negotiation	PPP negotiation type during the establishment of IS-IS adjacencies: ● 2-way ● 3-way ● only To set the PPP negotiation type during the establishment of IS-IS adjacencies, run the **isis ppp-negotiation** command.

Item	Description
Peer Suppress-Flapping <s>	Detection parameters for IS-IS neighbor relationship flapping suppression on an interface: ● Detect-Interval: detection interval of IS-IS neighbor relationship flapping suppression ● Resume-Interval: interval for exiting from IS-IS neighbor relationship flapping suppression ● Threshold: threshold of IS-IS neighbor relationship flapping suppression

7.6.16 display isis cost interface

Function

The **display isis cost interface** command displays costs of an interface and how they are generated.

Format

display isis cost interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis cost interface** command to check costs of an IS-IS interface, including the link cost and route prefix cost that the interface uses in each topology, and how the costs are generated.

Example

Display costs of VLANIF 100 and how they are generated.

```
<HUAWEI> display isis cost interface vlanif 100
Interface: Vlanif 100
                            Level-2 interface cost
 Topology base(0):
  Link effective cost: 10(A)                          enabled by circuit cost
  IP prefix effective cost:
   10.10.7.0/24                    cost: 10           enabled by circuit cost
   10.10.8.0/24                    cost: 10           enabled by circuit cost
   10.10.9.0/24                    cost: 10           enabled by circuit cost
 Topology red(7):
  Link effective cost: 87(A)                          enabled by circuit cost
  IP prefix effective cost:
   10.10.7.0/24                    cost: 87           enabled by circuit cost
   10.10.8.0/24                    cost: 87           enabled by circuit cost
   10.10.9.0/24                    cost: 87           enabled by circuit cost

                   Flags: R-Relative cost  A-Absolute cost
```

Table 7-90 Description of the **display isis cost interface** command output

Item	Description
Interface	Type and ID of an interface on which IS-IS is enabled
Link effective cost	Link cost
IP prefix effective cost	Cost of an IPv4 route
cost	Interface cost
enabled by circuit cost	Default cost or cost configured in the **isis cost** command
enabled by auto cost	Cost configured in the **auto-cost enable** command
enabled by global cost	Cost configured in the **circuit cost** command
enabled by igp ldp	The interface cost is configured by LDP
enabled by rui cost	Cost that inherits the cost of the RUI route
enabled by silent cost	Cost configured in the **isis silent** command in the interface view
enabled by tunnel cost	Cost generated after the TE Tunnel is configured
IPv6 prefix effective cost	Cost of an IPv6 route
Flags	Cost flag ● R-Relative cost: relative cost ● A-Absolute cost: absolute cost

7.6.17 display isis bfd interface

Function

The **display isis bfd interface** command displays information about BFD-enabled IS-IS interfaces.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display isis [*process-id*] **bfd interface**

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

BFD can provide millisecond-level fault detection. It can work with IS-IS to fast detect faults on neighboring devices and instruct IS-IS to recalculate routes for correct packet forwarding. You can run the **display isis bfd interface** command to check information about BFD-enabled IS-IS interfaces.

Example

Display information about BFD-enabled IS-IS interfaces.

```
<HUAWEI> display isis 1 bfd interface

                    BFD information of interface for ISIS(1)
                   -----------------------------------------
 Interface                  BFD.State      Min-Tx       Min-Rx        Mul
 Vlanif101                   enable         1000         1000         3
 Total interfaces: 1                       Total bfd enabled interfaces: 1
```

Table 7-91 Description of the display isis bfd interface command output

Item	Description
Interface	BFD-enabled IS-IS interface. To enable BFD on an IS-IS interface, run the **bfd all-interfaces enable** or **isis bfd enable** command.
BFD.State	BFD status on the IS-IS interface: ● enable: BFD is enabled on the interface. ● disable: BFD is disabled on the interface. To enable BFD on an IS-IS interface, run the **bfd all-interfaces enable** or **isis bfd enable** command.
Min-Tx	Minimum interval for transmitting BFD packets. To set the minimum interval, run the **bfd all-interfaces** or **isis bfd** command.
Min-Rx	Minimum interval for receiving BFD packets. To set the minimum interval, run the **bfd all-interfaces** or **isis bfd** command.
Mul	Local detection multiplier. To set the local detection multiplier, run the **bfd all-interfaces** or **isis bfd** command.

7.6.18 display isis bfd session

Function

The **display isis bfd session** command displays information about dynamic BFD sessions.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

display isis [*process-id* | **vpn-instance** *vpn-instance-name*] **bfd session** { **all** | **peer** *ip-address* | **interface** *interface-type interface-number* }

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
all	Specifies all IS-IS interfaces in the IS-IS process.	-
peer *ip-address*	Specifies the IP address of a neighbor.	The value is in dotted decimal notation.
interface *interface-type interface-number*	Specifies the interface on which BFD session statistics need to be collected.	-

Usage Guidelines

BFD can provide millisecond-level fault detection. It can work with IS-IS to fast detect faults on neighboring devices and instruct IS-IS to recalculate routes for correct packet forwarding. You can run the **display isis bfd session** command to check information about dynamic BFD sessions.

Example

Display information about dynamic BFD sessions.

```
<HUAWEI> display isis bfd session all
                    BFD session information for ISIS(1)
                    -----------------------------------
Peer System ID : 0000.0000.0002          Interface : Vlanif10
TX : 1000          BFD State : up        Peer IP Address : 10.1.1.2
RX : 1000          LocDis : 8194         Local IP Address: 10.1.1.1
Multiplier : 3     RemDis : 8197          Type : L1
Diag : No diagnostic information
Total BFD session(s) : 1
```

Table 7-92 Description of the display isis bfd session all command output

Item	Description
Peer System ID	System ID of the neighbor.

Item	Description
Interface	Local IS-IS interface connected to the neighbor.
TX	Negotiated minimum interval for transmitting BFD packets.
BFD State	BFD session status: Up or Down.
Peer IP Address	IP address of the remote IS-IS interface.
RX	Negotiated minimum interval for receiving BFD packets.
LocDis	Local discriminator dynamically assigned by BFD.
Local IP Address	IP address of the local IS-IS interface.
Multiplier	Remote detection multiplier.
RemDis	Remote identifier dynamically assigned by BFD.
Type	Level of the neighbor: ● L1: Level-1 ● L2: Level-2 ● L1L2: Level-1-2
Diag	Diagnostic information. "No diagnostic information" indicates that BFD runs properly and no diagnostic information is displayed.
Total BFD session (s)	Total number of BFD sessions.

7.6.19 display isis brief

Function

The **display isis brief** command displays brief information about IS-IS.

Format

display isis brief [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis [*process-id*] **brief**

Parameters

Parameter	Description	Value
process-id	Display brief information about a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Display brief information about the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis brief** command to check brief information about IS-IS.

Example

Display brief information about IS-IS.

```
<HUAWEI> display isis brief

                   ISIS Protocol Information for ISIS(1)
                   ------------------------------------
SystemId: 0000.0000.0001      System Level: L1
Area-Authentication-mode: NULL
Domain-Authentication-mode: NULL
Ipv6 is not enabled
ISIS is in starting status
ISIS is in protocol hot standby state: Real-Time Backup
Flush Protect Mode: False

Interface: (Vlanif10)
Cost: L1 10        L2 10               Ipv6 Cost: L1 10   L2 10
State: IPV4 Down                        IPV6 Down
Type: BROADCAST                           MTU: 1497
Priority: L1 64   L2 64
Timers:     Csnp: L1 10    L2 10    ,Retransmit: L12 5   , Hello: L1 10 L2 10  ,

Hello Multiplier: L1 3    L2 3     , LSP-Throttle Timer: L12 50
```

Table 7-93 Description of the display isis brief command output

Item	Description
ISIS Protocol Information for ISIS(1)	Information about IS-IS process 1. To create an IS-IS process, run the **isis** command.

Item	Description
SystemId	System ID of the current IS-IS device. To set the system ID, run the **network-entity** command.
System Level	Level of an IS-IS device: - L1: Level-1 - L2: Level-2 - L12: Level-1-2 To set the level of an IS-IS device, run the **is-level** command.
Area-Authentication-mode	IS-IS area authentication mode. To set the IS-IS area authentication mode and password, run the **area-authentication-mode** command.
Domain-Authentication-mode	IS-IS routing domain authentication mode. To set the IS-IS domain authentication mode and password, run the **domain-authentication-mode** command.
Ipv6 is not enabled	IPv6 is not enabled in the IS-IS process.
ISIS is in starting status	IS-IS is running.
ISIS is in protocol hot standby state: Real-Time Backup	IS-IS hot standby is real-time backup.
Flush Protect Mode	Indicates whether the process works in purge LSP protection mode.
Interface	Interface on which IS-IS is enabled. To enable IS-IS on an interface, run the **isis enable** command.
Cost	Cost of IS-IS IPv4 interfaces. To set the cost of IS-IS IPv4 interfaces, run the **circuit-cost** or **isis cost** command.
Ipv6 Cost	Cost of IS-IS IPv6 interfaces. To set the cost of IS-IS IPv6 interfaces, run the **ipv6 circuit-cost** or **isis ipv6 cost** command.
State	Status of the IS-IS interface.
Type	Network type of the IS-IS interface: P2P or broadcast. To set the network type of an IS-IS interface, run the **isis circuit-type** command.
MTU	MTU of the IS-IS interface.

Item	Description
Priority	Priority of the IS-IS interface. **NOTE** When the current interface is a virtual link interface, the priority field is not displayed.
Timers	IS-IS timer.
Csnp	Interval for sending CSNPs. To set the interval for sending CSNPs, run the **isis timer csnp** command.
Retransmit	Interval for retransmitting LSPs on a P2P link. To set the retransmit interval, run the **isis timer lsp-retransmit** command.
Hello	Interval for sending Hello packets. To set the interval for sending Hello packets, run the **isis timer hello** command.
Hello Multiplier	Number of consecutive Hello packets that are not received before the neighbor is declared Down. To set this value, run the **isis timer holding-multiplier** command.
LSP-Throttle Timer	Interval for sending LSPs or CSNPs and number of LSPs or CSNPs that are sent each time. To set the two values, run the **isis timer lsp-throttle** command.

7.6.20 display isis debug-switches

Function

The **display isis debug-switches** command displays the current IS-IS debugging status.

Format

display isis debug-switches [*process-id*]

display isis [*process-id*] **debug-switches**

Parameters

Parameter	Description	Value
process-id	Displays the current status of IS-IS debugging of specified IS-IS process ID. If *process-id* is not specified, display the current status of IS-IS debugging of all IS-IS process.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no IS-IS process is enabled or IS-IS debugging is not enabled, the **display isis debug-switches** command output is empty.

Example

Display the IS-IS debugging status.

```
<HUAWEI> display isis debug-switches 1
ISIS-1 SPF events related debugging switch is on
```

7.6.21 display isis error

Function

The **display isis error** command displays statistics about error LSPs and Hello packets that are received by IS-IS interfaces or processes.

Format

display isis error [{ *process-id* | **vpn-instance** *vpn-instance-name* } [**interface**]]

display isis error interface *interface-type interface-number*

Parameters

Parameter	Description	Value
process-id	Displays statistics about error packets received by a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about error packets received by the IS-IS process in a specified VPN instance.	The value must be an existing VPN instance name.
interface	Displays statistics about error packets received on all interfaces in a specified IS-IS process or VPN instance.	-
interface-type interface-number	Displays statistics about error packets received by a specified interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis error** command to check statistics about error LSPs and Hello packets that are received by IS-IS interfaces or processes.

Example

Display statistics about error LSPs and Hello packets received on all interfaces in IS-IS process 1.

```
<HUAWEI> display isis error 1
                   Statistics of error packets for ISIS(1)
                   ---------------------------------------
LSP packet errors:
Longer LSP              : 0          Smaller LSP             : 0
Mismatched Level        : 0          Invalid Sysid           : 0
Zero Sequence Number    : 0          Illegal IS Type         : 0
Zero Checksum           : 0          Incorrect Checksum      : 0
Bad Authentication      : 0          Bad Auth Count          : 0

More IPv6 IF Addr       : 0           Duplicate IPv6 Addr     : 0
More Optional Checksum  : 0           Bad Optional Checksum   : 0
-------------------------------------------------------------------
```

Table 7-94 Description of the display isis error command output

Item	Description
LSP packet errors	LSP errors.
Longer LSP	The LSP length is greater than the value set using the **lsp-length receive** command.
Smaller LSP	The LSP header length is smaller than the fixed length.
Mismatched Level	The level of received LSPs mismatches the local IS-IS level.
Invalid Sysid	The system ID in an LSP is invalid.
Zero Sequence Number	The sequence number of an LSP is 0.
Illegal IS Type	The IS type is invalid.
Zero Checksum	The checksum of an LSP is 0.
Incorrect Checksum	The checksum of an LSP is incorrect.
Bad Authentication	The authentication field of an LSP is incorrect.
Bad Auth Count	The number of authentication fields carried in an LSP is incorrect, that is, it is greater than 1.
More Protocol TLV	The number of protocol TLVs in an LSP is greater than 1.
Bad Nbr TLV	The neighbor TLV is incorrect.
Bad Extended IS TLV	The extended IS TLV is incorrect.
Bad IF Addr TLV	The interface address TLV is incorrect.
Bad Reach TLV	The reachability TLV is incorrect.
Bad Inter Domain TLV	The inter-domain TLV is incorrect. The correct TLV is 0x83.
Mismatched Area Id(L1)	Mismatched Level-1 area ID.
Bad TLV Length	The TLV length is incorrect.
Bad Alias TLV	The Alias TLV is incorrect.

Item	Description
Bad Area TLV	The area TLV is incorrect.
Bad SRLG TLV	The SRLG TLV is incorrect.
Unknown Adjacency	LSPs are received from unknown adjacency.
Bad Protocol ID	The protocol ID is incorrect.
Bad Version	The version is incorrect.
Zero Lifetime	The remaining lifetime of an LSP is 0.
Bad Ext Reach TLV	The Ext Reach TLV is incorrect.
Bad TE Router ID TLV	The TE Router ID TLV is incorrect.
Bad TE Sub TLV	The TE sub-TLV is incorrect.
Hello packet errors	Hello packet errors.
Bad Packet Length	The Hello packet length is incorrect.
Reserved CircType	The reserved link type is incorrect.
Repeated System ID	The system ID is repeated.
Bad Circuit Type	The link type is incorrect.
Longer packet	The Hello packet length is greater than the larger value between the interface MTU and the value set using the **lsp-length originate** command.
More Area Addr	Area addresses are superfluous.
Longer Area Addr	The area address is too long.
Bad Area Addr TLV	The area address TLV is incorrect.
More IF Addr	Interface addresses are superfluous.
Bad Formatted IF TLV	The format of the interface TLV is incorrect.
More Nbr SNPA(LAN)	Sub-network Points of Attachment (SNPAs) of a neighbor on a broadcast network are superfluous.
Invalid Sysid	The system ID length field is not 0 or 6.
Bad TLV Length	The TLV length is incorrect.
Zero HoldingTime	The neighbor holdtime is 0.
Unusable IP Addr	The IP address is on a different network segment than the peer end.
Repeated IPv4 Addr	The IPv4 address is repeated.
Mismatched Area Addr(L1)	Mismatched Level-1 area address.
Mismatched Proto	Mismatched protocol.

Item	Description
SNPA Conflicted(LAN)	Conflicting SNPA on a broadcast network.
Mismatched Level	The level of received Hello packets mismatches the local IS-IS level.
Mismatched Max Area Addr	The maximum area address is incorrect.
Bad Authentication	The authentication field of a Hello packet is incorrect.
More Auth TLV	Authentication TLVs are superfluous.
3-Way Option Error(P2P)	3-way information is incorrect.
No Area Addr TLV	The received Hello packet has no area address TLV.
Bad Protocol ID	The protocol ID is incorrect.
Bad Version	The version is incorrect.
Invalid IPv6 Addr	An IPv6 address is invalid.
More IPv6 IF Addr	A Hello packet carries more than 11 IPv6 addresses.
Duplicate IPv6 Addr	The IPv6 address is repeated.
More Optional Checksum	More than one optional checksum TLV is contained in a packet.
Bad Optional Checksum	Error optional checksum TLV.

7.6.22 display isis graceful-restart status

Function

The **display isis graceful-restart status** command displays the IS-IS GR status.

Format

display isis *process-id* **graceful-restart status** [**level-1** | **level-2**]

display isis graceful-restart status [**level-1** | **level-2**] [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
level-1	Displays the Level-1 IS-IS GR status.	-
level-2	Displays the Level-2 IS-IS GR status.	-

Parameter	Description	Value
process-id	Displays the IS-IS GR status of a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays the IS-IS GR status of the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis graceful-restart status** command to check the IS-IS GR status.

Example

Display the IS-IS GR status.

```
<HUAWEI> display isis graceful-restart status
                      Restart information for ISIS(1)
                        -------------------------------
IS-IS(1) Level-1 Restart Status
Restart Interval: 300
SA Bit Supported
  Total Number of Interfaces = 1
  Restart Status: RESTART COMPLETE
IS-IS(1) Level-2 Restart Status
Restart Interval: 300
SA Bit Supported
  Total Number of Interfaces = 1
  Restart Status: RESTART COMPLETE
```

Table 7-95 Description of the display isis graceful-restart status command output

Item	Description
Restart Interval	Expected restart time of the device. This parameter is configured using the **graceful-restart interval** command.
SA Bit Supported	Whether the device supports SA.
Total Number of Interfaces = 1	Number of interfaces on which IS-IS is enabled. IS-IS is enabled using the **isis enable** command on an interface.

Item	Description
Restart Status:	Restart status of the current device. RESTART COMPLETE indicates that the restart is complete.

7.6.23 display isis interface

Function

The **display isis interface** command displays information about IS-IS interfaces.

Format

display isis interface [[**verbose** | **traffic-eng**] * | **te-tunnel**] [*process-id* | **vpn-instance** *vpn-instance-name*] (supported only by the S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display isis *process-id* **interface** [**te-tunnel** | [**traffic-eng** | **verbose**] *] (supported only by the S5731-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H)

display isis interface *interface-type interface-number* [**verbose**]

display isis interface *interface-type interface-number* [**verbose**]

display isis interface

display isis interface *process-id*

display isis *process-id* **interface**

display isis interface vpn-instance *vpn-instance-name*

Parameters

Parameter	Description	Value
verbose	Displays detailed information about IS-IS interfaces.	-
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
traffic-eng	Displays Traffic Engineering information of IS-IS.	-

Parameter	Description	Value
te-tunnel	Displays information on the MPLS TE tunnel of IS-IS.	-
vpn-instance *vpn-instance-name*	Display IS-IS interface information in the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
interface-type interface-number	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to view IS-IS interface information, including the interface name, IP address, link status of the interface. If **verbose** is specified, the command output also includes the configuration of IS-IS parameters for the interface, such as the CSNP broadcast interval, Hello packet broadcast interval, and number of IS-IS Hello packets that fail to be received before IS-IS declares the neighbor Down.

Example

Display information about IS-IS interfaces.

```
<HUAWEI> display isis interface

                       Interface information for ISIS(1)
                       ---------------------------------
 Interface       Id      IPV4.State          IPV6.State      MTU  Type  DIS
 Vlanif10        001        Up                  Down         1497 L1/L2 No/No
```

Display detailed information about IS-IS interfaces.

```
<HUAWEI> display isis interface verbose
                       Interface information for ISIS(1)
                       ---------------------------------
 Interface       Id      IPV4.State          IPV6.State      MTU  Type  DIS
 Vlanif10       001         Up                Down         1497 L1/L2 No/No
  Circuit MT State            : Standard
  Description                 :
  SNPA Address                : 0000-1382-4569
  IP Address                  : 10.1.1.5

Suppress flapping peer      :  enable (flapping-count: 0, threshold: 10)
```

Table 7-96 Description of the display isis interface command output

Item	Description
Interface	IS-IS interface type and number.
Id	Link ID.
IPV4.State	IPv4 link status.
MTU	Interface MTU. An IS-IS neighbor relationship can be established only when two interfaces on both ends of a link have the same MTU.
Type	Interface type: - L1: Level-1 interface - L2: Level-2 interface - L1/L2: Level-1-2 interface
DIS	Whether the interface is a DIS. **NOTE** Only an interface with network type broadcast can be selected as the DIS. If an interface is a P2P interface, "--" is displayed in this field.

Item	Description
Circuit MT State	Topology status on the interface: ● Standard: – IPv4 is enabled on the interface, but IPv6 is not. – IPv6 is enabled on the interface, but IPv4 is not. In addition, the topology type is standard. – Both IPv4 and IPv6 are enabled on the interface. In addition, the topology type is standard. ● IPv6: IPv6 is enabled on the interface, but IPv4 is not. In addition, the topology type is IPv6. ● Standard IPv6: – IPv6 is enabled on the interface, but IPv4 is not. In addition, the topology type is compatible. – Both IPv4 and IPv6 are enabled on the interface. In addition, the topology type is compatible or IPv6. To configure the IPv6 topology type, run the **ipv6 enable** command in the IS-IS view.
SNPA Address	MAC address.
IP Address	IPv4 address of the interface.
IPV6 Link Local Address	IPv6 link-local address.
IPV6 Global Address(es)	IPv6 global address.
Csnp Timer Value	Interval for sending CSNPs. To set the interval for sending CSNPs, run the **isis timer csnp** command.
Hello Timer Value	Interval for sending Hello packets. To set the interval for sending Hello packets, run the **isis timer hello** command.
DIS Hello Timer Value	Interval at which the DIS sends Hello packets, which is one third of **Hello Timer Value**. The field takes effect only when the interface functions as the DIS.
Hello Multiplier Value	Number of consecutive Hello packets that are not received before the neighbor is declared Down. To set this value, run the **isis timer holding-multiplier** command.

Item	Description
LSP-Throttle Timer	Interval for sending LSPs or CSNPs and number of LSPs or CSNPs that are sent each time. To set the two values, run the **isis timer lsp-throttle** command.
Cost	Cost of an IPv4 interface. This field value affects route selection.
Ipv6 Cost	Cost of an IPv6 interface. This field value affects route selection in IPv6 topologies.
Priority	Priority for DIS election. To set the priority for DIS election, run the **isis dis-priority** command.
Retransmit Timer Value	Interval for retransmitting LSPs on a P2P link. To set the retransmit interval, run the **isis timer lsp-retransmit** command.
Bandwidth-Value	Physical bandwidth of an interface. The value can be calculated using the following formula: **Bandwidth-Value** = 4294967296 x **high** + **low**. For example, if the value of **high** is 1 and the value of **low** is 705032704, Bandwidth-Value = 1 x 4294967296 + 705032704 = 5000000000. ● low: low bandwidth with the maximum value of 4294967295 ● high: high bandwidth with the maximum value of 4294967295
Static Bfd	Static BFD status: ● NO: Static BFD is not enabled. ● YES: Static BFD is enabled. To enable BFD on an interface, run the **isis bfd static** command.
Dynamic Bfd	Dynamic BFD status: ● NO: Dynamic BFD is not enabled. ● YES: Dynamic BFD is enabled. To enable dynamic BFD on an interface, run the **bfd all-interfaces enable** or **isis bfd enable** command.

Item	Description
Dynamic IPv6 Bfd	Status of dynamic IPv6 BFD: ● NO: Dynamic BFD is not enabled on the interface. ● YES: Dynamic BFD is enabled on the interface. To enable dynamic IPv6 BFD on an interface, run the **ipv6 bfd all-interfaces enable** or **isis ipv6 bfd enable** command.
Fast-Sense Rpr	Whether the fast sense RPR function is enabled.
Suppress flapping peer	Status of IS-IS neighbor relationship flapping suppression: ● NO: IS-IS neighbor relationship flapping suppression is disabled. ● YES (flapping-count: 3, threshold: 10): IS-IS neighbor relationship flapping suppression is enabled and IS-IS neighbor relationship is not suppressed. The flapping-count and threshold value. ● Hold-down(start: UTC 10:20:30, remain-interval: 7): IS-IS neighbor relationship flapping suppression works in Hold-down mode. The starting and remaining time of the flapping suppression. ● Hold-max-cost(start: UTC 10:20:30, remain-interval: 7): IS-IS neighbor relationship flapping suppression works in Hold-max-cost mode. The starting and remaining time of the flapping suppression. **NOTE** In the flapping suppression state, *remain-interval* is reset each time when the device detects a valid neighbor flapping event.

7.6.24 display isis last-peer-change

Function

The **display isis last-peer-change** command displays changes in IS-IS neighbor relationships.

Format

display isis *process-id* **last-peer-change**

display isis last-peer-change [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use the **display isis last-peer-change** command to view a maximum of 100 latest records in each IS-IS process.

Example

Display changes in IS-IS neighbor relationships.

```
<HUAWEI> display isis last-peer-change
                      Peer change information for ISIS(1)
                      -----------------------------------

Time      : 2011-03-28 09:30:34
System Id : 0000.0000.0002
Type      : L1 LAN
Interface : vlanif10
State     : IPv4 -> IPv4/IPv6
Details   : Protocol change
```

Table 7-97 Description of the display isis last-peer-change command output

Item	Description
Time	Time a neighbor relationship changes.
System Id	System ID of a neighbor.
Type	Neighbor type: • L1 LAN • L2 LAN • P2P
Interface	Interface connected to the neighbor.

Item	Description
State	Changes in the IS-IS neighbor relationship status: ● Init -> Up ● Up -> Down ● Up -> Init ● Down -> Up ● IPv4/IPv6 -> IPv4 ● IPv4/IPv6 -> IPv6 ● IPv4 -> IPv4/IPv6 ● IPv6 -> IPv4/IPv6 ● IPv4 -> IPv6 ● IPv6 -> IPv4 ● L12 -> L2 ● L2 -> L12
Details	Causes for IS-IS neighbor relationship changes: ● Circuit down ● BFD down ● Hold timer expired ● New adjacency created ● Clear neighbor ● Multiple P2P adjacency ● Adjacency usage mismatch ● Internal error ● Memory low ● P2P circuit ID conflict ● Area mismatch ● Three way down ● Three way init ● Three way up ● Protocol change ● Mt usage mismatch ● Peer state change ● Peer level change

7.6.25 display isis lsdb

Function

The **display isis lsdb** command displays information about IS-IS LSDBs.

Format

display isis *process-id* **lsdb** [{ **level-1** | **level-2** } | **verbose** | { **local** | *lsp-id* | **is-name** *symbolic-name* }] *

display isis lsdb [{ **level-1** | **level-2** } | **verbose** | { **local** | *lsp-id* | **is-name** *symbolic-name* }] * [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
level-1	Displays Level-1 LSDBs. If no level is specified, Level-1 and Level-2 LSDBs are displayed.	-
level-2	Displays Level-2 LSDBs. If no level is specified, Level-1 and Level-2 LSDBs are displayed.	-
verbose	Displays detailed information about IS-IS LSDBs.	-
local	Displays information about the local LSDB.	-
lsp-id	Specifies an LSP ID.	The value is in dotted decimal notation. The value ranges from 16 to 20 in ####.####.####.##-## format, such as 0050.0500.5004.00-00.
is-name *symbolic-name*	Specifies the dynamic host name in is-name or is-name.##-## format. ##-## indicates the pseudonode ID-LSP fragment ID.	The value is a string of 1 to 70 characters.

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays the LSDB of the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Table 7-99 Description of the display isis lsdb verbose command output

Item	Description
SOURCE	System ID of the source node.
ORG ID	Source system ID of the virtual system.
HOST NAME	Dynamic host name.
Auth	Authentication password.
Len	Authentication password length.
Type	Authentication type: ● Plain Text: indicates that the password is sent in plain text. ● MD5: indicates that the password is encrypted using the MD5 algorithm. ● CRYPTO_AUTH: The password is encrypted with the HMAC-SHA256 encryption algorithm.
NLPID	Supported network protocol. ● IPV4: supported the IPv4 network protocol. ● IPV6: supported the IPv6 network protocol.
AREA ADDR	Area address.
INTF ADDR	Interface IPv4 address.
INTF ADDR V6	Interface IPv6 address.
Topology	Topology type.
NBR ID	System ID of a neighbor.
+NBR ID	System ID of a neighbor, which can carry TE information.
+MT NBR ID	Neighbor ID in the MT topology.
COST	Route cost.
IP-Internal	Internal IPv4 routing information.
IP-External	External IPv4 routing information.

Item	Description
+IP-Extended	Extended IP routing information, which can carry TE information.
IPV6	Internal IPv6 routing information.

7.6.26 display isis mesh-group

Function

The **display isis mesh-group** command displays the configuration of the IS-IS mesh-group.

Format

display isis mesh-group [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **mesh-group**

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis mesh-group** command to check the configuration of the IS-IS mesh-group.

Example

Display information about the configured IS-IS mesh-group.

```
<HUAWEI> display isis mesh-group
              Mesh Group information for ISIS(1)
----------------------------------------------------------------------
Interface         Status
```

```
Vlanif10         100
Vlanif20         100
```

Table 7-100 Description of the display isis mesh group command output

Item	Description
Interface	Type and number of the interface in the mesh-group.
Status	Mesh-group number.

7.6.27 display isis name-table

Function

The **display isis name-table** command displays the mapping between the dynamic hostnames of IS-IS routers and the system IDs.

Format

display isis name-table [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **name-table**

Parameters

Parameter	Description	Value
process-id	Displays the mapping between dynamic hostnames of IS-IS routers and system IDs in a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays the mapping between dynamic hostnames of IS-IS routers and system IDs in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After dynamic hostnames are configured, you can run the **display isis name-table** command to check the mapping between the dynamic hostnames and system IDs.

Example

Configure a name for the local IS-IS system.

```
[Switch] isis
[Switch-isis-1] is-name RUTA
```

Configure a static name mapping for the remote IS-IS system (0000.0000.0041).

```
[Switch-isis-1] is-name map 0000.0000.0041 RUTB
```

Display the IS-IS system name table.

```
<Switch> display isis name-table
            Name table information for ISIS(1)
System ID               Hostname       Type
-------------------------------------------------------------------
6789.0000.0001          RUTA           DYNAMIC
0000.0000.0041          RUTB           STATIC
```

Table 7-101 Description of the display isis name-table command output

Item	Description
System ID	System ID of the current IS-IS device. To set the system ID, run the **network-entity** command.
Hostname	Host name of the device. To set a host name for the local or remote device, run the **is-name** or **is-name map** command.
Type	Type of the mapping between the host name and system ID: static or dynamic.

7.6.28 display isis peer

Function

The **display isis peer** command displays IS-IS neighbor information.

Format

display isis *process-id* **peer** [**verbose**]

display isis peer [**verbose**] [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis peer interface *interface-type interface-number* [**verbose**]

Parameters

Parameter	Description	Value
verbose	Displays detailed IS-IS neighbor information, including the area address, period during which the neighbor remains Up, and IP address of its directly connected interface.	-
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In an IS-IS area, if you need to check whether two devices can communicate properly, run the **display isis peer** command to view information about the neighbor, including the neighbor status, period during which the neighbor remains Up, and neighbor type.

Example

Display information about IS-IS neighbors.

```
<HUAWEI> display isis peer
                          Peer information for ISIS(1)

  System Id     Interface          Circuit Id       State HoldTime Type     PRI
-------------------------------------------------------------------------------
0000.0000.0001   Vlanif10         0000.0000.0001.01   Up    24s   L1(L1L2)  64
0000.0000.0001   Vlanif10         0000.0000.0001.01   Up    24s   L2(L1L2)  64

Total Peer(s): 2
```

Table 7-102 Description of the display isis peer command output

Item	Description
System Id	System ID of the neighbor.
Interface	Type and number of the interface.
Circuit Id	Circuit ID.
State	Neighbor status: ● Up: indicates that the neighbor is Up and the two ends can communicate. ● Init: indicates that the local end can receive packets from the remote end but the remote end cannot receive packets from the local end. This status is displayed when authentication is configured on the remote end. ● Down: indicates that the neighbor is Down. This is the initial status, indicating that no message is received from the neighbor. In most cases, this status is not displayed.
HoldTime	Neighbor holdtime.
Type	Neighbor type: ● L1: indicates that the neighbor type is Level-1 and interfaces on both ends are Level-1 interfaces. ● L2: indicates that the neighbor type is Level-2 and interfaces on both ends are Level-2 interfaces. ● L1(L1L2): indicates that the neighbor type is Level-1 and interfaces on both ends are Level-1-2 interfaces. ● L2(L1L2): indicates that the neighbor type is Level-2 and interfaces on both ends are Level-1-2 interfaces.
PRI	Priority of the neighbor in DIS election.

Display detailed information about IS-IS neighbor.

```
<HUAWEI> display isis peer verbose
                          Peer information for ISIS(1)

Total Peer(s): 2
```

Table 7-103 Description of the **display isis peer verbose** command output

Item	Description
MT IDs supported	IDs of topology instances supported by the remote interface.
Local MT IDs	IDs of topology instances supported by the local interface.
Area Address(es)	Area addresses of the neighbor.
Peer IP Address(es)	IP address of the remote interface.
Peer IPv6 Address(es)	IPv6 address of the remote interface.
Uptime	Period during which the neighbor remains Up.
Adj Protocol	Protocol used for establishing the adjacency.
Restart Capable	Whether GR is supported: ● YES: indicates that GR is supported. ● NO: indicates that GR is not supported.
Suppressed Adj	Whether neighbor suppression is supported: ● YES: indicates that neighbor suppression is supported. ● NO: indicates that neighbor suppression is not supported.
Peer System Id	The System ID of the IS-IS peer.
Total Peer(s)	Number of neighbors.

7.6.29 display isis purge packet

Function

The **display isis purge packet** command displays statistics about received IS-IS purge LSPs carrying the POI TLV.

Format

display isis *process-id* **purge packet** [*packet-number*]

display isis purge packet *process-id* [*packet-number*]

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer ranging from 1 to 65535.
packet-number	Specifies the number of purge LSPs whose statistics are to be displayed.	The value is an integer ranging from 1 to 20.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check statistics about received IS-IS purge LSPs carrying the POI TLV, run the **display isis purge packet** command. You can specify *packet-number* in the command to check statistics about a specified number of purge LSPs, and the maximum value of *packet-number* is 20. If its value is set to 20:

- The first two displayed purge LSPs are sent by the local source system, with fragment number 0, one of which is Level-1, and the other is Level-2.
- The first 10 displayed purge LSPs are generated locally, and the next 10 purge LSPs are from neighbors. The purge LSPs are displayed in reverse order of the time when they were received. If the LSP ID is followed by an asterisk (*), the purge LSP is generated locally.

Example

Display statistics about received IS-IS purge LSPs carrying the POI TLV.

```
<HUAWEI> display isis purge packet 1 10

                  Purge LSP packet for ISIS(1)
--------------------------------------------------------------
Packet information(Index 1):

Table 7-104 Description of the **display isis purge packet** command output

Item	Description
Received LSPID	ID of a received purge LSP
Source Interface	Source interface of a received purge LSP
Time	Time when a purge LSP was received
Level	Level of a received purge LSP
PDU Type	Type of received purge LSP
PDU Length	Length of a received purge LSP
Sequence Number	Sequence number (LSN) of a received purge LSP
Checksum	Checksum of a received purge LSP
POI NAME	POI TLV carried in a received purge LSP
POI NAME(Neighbor)	Neighbor system ID in the POI TLV carried in a received purge LSP
HOST NAME	Dynamic hostname carried in a received purge LSP
Auth Type	Authentication information carried in a received purge LSP

7.6.30 display isis route

Function

The **display isis route** command displays IS-IS routing information.

Format

display isis route [*process-id* | **vpn-instance** *vpn-instance-name*] [**ipv4**] [**verbose** | [**level-1** | **level-2**] | *ip-address* [*mask* | *mask-length*]] *

display isis route [*process-id* | **vpn-instance** *vpn-instance-name*] **ipv6** [**verbose** | [**level-1** | **level-2**] | *ipv6-address* [*prefix-length*]] *

display isis *process-id* **route** [**ipv4**] [**verbose** | [**level-1** | **level-2**] | *ip-address* [*mask* | *mask-length*]] *

display isis *process-id* **route ipv6** [**verbose** | [**level-1** | **level-2**] | *ipv6-address* [*prefix-length*]] *

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
ipv4	Displays IPv4 routes. If this parameter is not specified, both IPv4 and IPv6 IS-IS routes are displayed.	-
verbose	Displays detailed routing information.	-
level-1	Displays Level-1 IS-IS routes.	-
level-2	Displays Level-2 IS-IS routes.	-
ip-address	Displays the routes with the specified IPv4 destination address.	The value is in dotted decimal notation.
mask	Specifies the mask of an IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of an IP address.	The value is an integer that ranges from 0 or 32.
ipv6	Displays IPv6 routes. If this parameter is not specified, both IPv4 and IPv6 IS-IS routes are displayed.	-
ipv6-address	Displays the routes with the specified IPv6 destination address.	The value is a 32-digit hexadecimal number, in X:X:X:X:X:X:X:X format.
prefix-length	Specifies the prefix length of an IPv6 address.	The value is an integer that ranges from 0 to 128.

-------------------------------------------------------------------------------
10.2.1.0/24          10         NULL    Vlanif10        Direct          D/-/L/-
172.18.0.0/16        20         NULL    Vlanif10        10.2.1.1        A/-/L/-

 IPV6 Dest.          ExitInterface   NextHop                     Cost      Flags
-------------------------------------------------------------------------------
 FC00:0:0:200::/64    Vlanif10        Direct                      10        D/L/-

     Flags: D-Direct, A-Added to URT, L-Advertised in LSPs, S-IGP Shortcut,
                           U-Up/Down Bit Set

                        ISIS(1) Level-2 Forwarding Table
                        --------------------------------

IPV4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
10.2.1.0/24          10         NULL    Vlanif10        Direct          D/-/L/-
172.18.0.0/16        20         NULL    Vlanif10        10.2.1.1        A/-/L/-

 IPV6 Dest.          ExitInterface   NextHop                     Cost      Flags
-------------------------------------------------------------------------------
 FC00:0:0:200::/64    Vlanif10        Direct                      10        D/L/-

     Flags: D-Direct, A-Added to URT, L-Advertised in LSPs, S-IGP Shortcut,
                           U-Up/Down Bit Set
```

Table 7-105 Description of the display isis route command output

Item	Description
IPV4 Destination	IPv4 destination address and mask.
IPV6 Dest.	IPv6 destination address and mask.

Item	Description
IntCost	IPv4 internal cost or IS-IS route cost. To change the IS-IS IPv4 route cost, run the **circuit-cost** or **isis cost** command to set the link cost of an IS-IS IPv4 interface.
ExtCost	IPv4 external cost or cost of routes imported from other routing protocols. To set the cost of imported routes, run the **import-route** command. **NOTE** The costs of external routes imported using the **import-route cost-type external** command are displayed in this field to differentiate the costs of IS-IS routes.
Cost	IPv6 route cost. To change the IS-IS IPv6 route cost, run the **ipv6 circuit-cost** or **isis ipv6 cost** command to set the link cost of an IS-IS IPv6 interface.
ExitInterface	Outbound interface of a route.
NextHop	Next hop address of a route. This field displays Direct if the destination network segment is the direct network segment.
Flags	Route flag: ● D-Direct: indicates a direct route. ● A-Added to URT: indicates that a route is added to the unicast routing table. ● L-Advertised in LSPs: indicates that a route is advertised through an LSP. ● S-IGP Shortcut: indicates that the interface on which IGP-Shortcut is enabled exists on the path to the destination. ● U-Up/Down Bit Set: indicates the Up/ Down bit.

Display IS-IS IPv4 routes.

```
<HUAWEI> display isis route ipv4

                         Route information for ISIS(1)
                         -----------------------------

                        ISIS(1) Level-1 Forwarding Table

```

Table 7-106 Description of the display isis route verbose command output

Item	Description
IPV4 Dest	IPv4 destination address and mask.
Int.Cost	IPv4 internal cost, the cost of an IS-IS route.
Ext.Cost	IPv4 external cost, the cost of other protocol route imported by IS-IS. **NOTE** The costs of non-IS-IS routes imported by the **import-route cost-type external** command are displayed in this field so that the costs of non-IS-IS routes are kept independently from the costs of IS-IS routes.
Admin Tag	Administrative tag.
Src Count	Number of source addresses to the same destination.
Priority	Convergence priority of IS-IS routes: ● Critical ● High ● Medium ● Low To set the convergence priority of IS-IS routes, run the **prefix-priority** command.
NextHop	Next hop of a route. The next hop (B) tag of a route is a backup route tag.
Interface	Outbound interface of a route.
ExitIndex	Index of the outbound interface.
Flags	Flags of routing information

7.6.31 display isis spf-log

Function

The **display isis spf-log** command displays IS-IS SPF logs.

Format

display isis spf-log [*process-id* | **vpn-instance** *vpn-instance-name*] [[**level-1** | **level-2**] | **ipv6** | **verbose**]*

display isis *process-id* **spf-log** [[**level-1** | **level-2**] | **ipv6** | **verbose**]*

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
ipv6	Displays SPF logs in IPv6 topologies.	-
level-1	Displays Level-1 SPF logs.	-
level-2	Displays Level-2 SPF logs.	-
verbose	Displays detailed information about SPF logs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the SPT calculated by IS-IS is incorrect, you can run the **display isis spf-log** command to diagnose the fault. The command displays information about SPF calculation, such as the start time and duration of the SPF calculation, number of nodes, and events that trigger the SPF calculation. You can determine whether the events are the cause of the SPF calculation fault based on the start time of the SPF calculation.

Example

Display IS-IS SPF logs.

```
<HUAWEI> display isis spf-log

                        SPF Log information for ISIS(10)
                        --------------------------------

                            ISIS(10) Level-1 SPF Log
                            ------------------------

 StartTime  Duration  Nodes  Count  Last Trigger LSP      Trigger Event
-----------------------------------------------------------------------------
 2013-09-05 10:14:48+00:00
            0         1      1      NULL                  ISPF_CIRC_DR_CHANGE
 2013-09-05 10:13:23+00:00
            1         1      2      NULL                  FULL_SPF

                            ISIS(10) Level-2 SPF Log
                            ------------------------

 StartTime  Duration  Nodes  Count  Last Trigger LSP      Trigger Event
-----------------------------------------------------------------------------
 2013-09-05 10:14:48+00:00
            1         1      1      NULL                  ISPF_CIRC_DR_CHANGE
 2013-09-05 10:13:23+00:00
            1         1      2      NULL                  FULL_SPF
```

Table 7-107 Description of the display isis spf-log command output

Item	Description
StartTime	Start time of SPF calculation.
Duration	Duration of SPF calculation.
Nodes	Number of nodes in SPF calculation.
Count	Number of times SPF calculated is triggered.
Last Trigger LSP	LSP that triggers the last SPF calculation: ● NULL indicates that the LSP is local. ● LSP ID (specific ID) indicates that the LSP is not local.

Item	Description
Trigger Event	Event that triggers the last SPF calculation: ● NEWAREA indicates that a new NET is configured. ● TUNNEL_ADJ indicates that a tunnel neighbor relationship is established. ● ADJDOWN indicates that a tunnel neighbor goes Down. ● NEWLSP indicates that the router receives an LSP of a new process. ● LSPCHANGE indicates that the received LSP is different from local LSPs. ● RST_T2_CANCEL indicates that the GR T2 Timer is disabled. ● RST_T3_EXPIRE indicates that the GR T3 Timer expires. ● RESTART_COMPLETE indicates that the GR is over. ● CIRC_VLINK_CHANGE indicates that the status of the VLink interface changes. ● PRC_IPV4_PREFIX_ADD indicates that an IPv4 route is added. ● PRC_IPV4_PREFIX_DEL indicates that an IPv4 route is deleted. ● PRC_IPV4_PREFIX_MODIFY indicates that an IPv4 route is modified. ● PRC_IPV4_PREFIX_MIGP_ADD indicates that an MIGP IPv4 route is added. ● PRC_IPV4_PREFIX_MIGP_DEL indicates that an MIGP IPv4 route is deleted. ● PRC_IPV4_PREFIX_MIGP_MODIFY indicates that an MIGP IPv4 route is modified. ● PRC_IPV6_PREFIX_ADD indicates that an IPv6 route is added. ● PRC_IPV6_PREFIX_DEL indicates that an IPv6 route is deleted. ● PRC_IPV6_PREFIX_MODIFY indicates that an IPv6 route is modified. ● ISPF_ADJ_STATE_CHANGE indicates that the IS-IS neighbor status changes. ● ISPF_ADJ_USAGE_CHANGE indicates that the IS-IS neighbor level changes.

Item	Description
	• ISPF_ADJ_PROT_USAGE_CHANGE indicates that the protocol used by the IS-IS neighbor changes. • ISPF_ADJ_NEXTHOP_CHANGE indicates that the next hop of the IS-IS neighbor changes. • ISPF_CIRC_METRIC_CHANGE indicates that the cost on the interface changes. • ISPF_CIRC_DR_CHANGE indicates that the DIS changes. • ISPF_NODE_DEL indicates that the nodes in the SPT change. • ISPF_NODE_OLOAD_CHANGE indicates that the overload bit of the system changes. • ISPF_LINK_ADD indicates that a new link is added to the SPT. • ISPF_LINK_DEL indicates that a link is deleted from the SPT. • ISPF_LINK_METRIC_CHANGE indicates that the cost of a link changes. • FULL_SPF indicates that a full SPF calculation is triggered. • AREA_CFG_CHANGE indicates that the area of the process changes. • AREA_LEARNT_CHANGE indicates that the area of the IS-IS neighbor changes. • ISPF_TUNNEL_TYPE_CHANGE indicates that the tunnel type changes. • PRC_LEAVE_MAN_OVERLOAD indicates that the system exits the **set-overload** state that is set manually. • PRC_IPV4_SELFLSP_CHANGE indicates that the IPv4 route in the local LSP changes. • PRC_IPV6_SELFLSP_CHANGE indicates that the IPv6 route in the local LSP changes. • PRC_ALIAS_TLV_CHANGE indicates that the **ALIAS TLV** in the LSP changes. • LFA_LINK_ADD indicates that a link is added to the routes for FRR. • LFA_LINK_DEL indicates that a link is deleted from the routes for FRR.

Item	Description
	- LFA_LINK_CHANGE indicates that the links of the routes for FRR change. - LFA_NODE_ADD indicates that a node is added along the links of the routes for FRR. - LFA_NODE_DEL indicates that a node is deleted from the links of the routes for FRR. - LFA_NODE_CHANGE indicates that the nodes along the links of the routes for FRR change. - KEY_RESRORE indicates that the local device receives an indirect next hop key.

7.6.32 display isis spf-tree

Function

The **display isis spf-tree** command displays the topology of the SPF tree that is generated by IS-IS.

Format

display isis spf-tree [**systemid** *systemid* | **dname** *dname*] [[**level-1** | **level-2**] | **ipv6** | **verbose**] * [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **spf-tree** [**systemid** *systemid* | **dname** *dname*] [[**level-1** | **level-2**] | **ipv6** | **verbose**] *

display isis *process-id* **spf-tree statistics** [[**level-1** | **level-2**] | **ipv6**] *

display isis spf-tree statistics [[**level-1** | **level-2**] | **ipv6**] * [*process-id* | **vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
systemid *systemid*	Displays the SPF tree of the switch with a specified system ID or pseudonode ID.	The value is in XXXX.XXXX.XXXX[.XX] format.

Parameter	Description	Value
dname *dname*	Displays the SPF tree of the switch with a specified dynamic name.	The value is a string of 1 to 64 characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.
level-1	Displays Level-1 SPF tree.	-
level-2	Displays Level-2 SPF tree.	-
ipv6	Displays SPF tree in IPv6 topologies.	-
verbose	Displays detailed information about SPF tree.	-
process-id	Display SPF tree in a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays SPF tree of the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.
statistics	Displays SPF tree statistics, including information about links and nodes on the SPF tree.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify **statistics** to view the current status of the SPF tree. The generated SPF tree can be used to calculate routes only when the SPF calculation status is Completed, that is, incremental SPF (ISPF) calculation is complete.

Example

Display information about the SPF tree.

```
<HUAWEI> display isis spf-tree
                    Shortest Path Tree for ISIS(1)
                    ------------------------------
```

```
        Flags:   T-System is on SPF TREE  R-System is directly reachable
                 O-System is Overload     D-System or Link is to be deleted
                 C-Neighbor is child      P-Neighbor is parent
                 G-Cost gets greater      L-Cost gets lower
                 H-Nexthop is changed     U-Protocol usage is changed
                 V-Link is involved       N-Link is a new path
                 S-Link is IGP Shortcut   *-Relative cost
                      ISIS(1) Level-1 Shortest Path Tree

Table 7-108 Description of the display isis spf-tree command output

Item	Description
SpfNode	Node ID in the network topology.

Item	Description
NodeFlags	Node flag: ● T: The node is on the SPF tree. ● R: The node is directly reachable. ● O: The node is overloaded. ● D: The node is to be deleted.
NeighbourNode	ID of the neighboring node.
LinkCost	Link cost.
LinkFlags	Link flag: ● C: Neighbor is child ● P: Neighbor is parent ● G: Cost gets greater ● L: Cost gets lower ● H: Nexthop is changed ● U: Protocol usage is changed ● V: Link is involved ● N: Link is a new path ● S: Link is IGP Shortcut ● *: Relative cost
>	Mark of the local node.

Display detailed information about SPF tree.

Table 7-109 Description of the display isis spf-tree verbose command output

Item	Description
Distance	Cost of the shortest path from the root node to the destination node, excluding the TE tunnel link.
Distance-URT	Cost of the shortest path from the root node to the destination node, including the TE tunnel link.

Item	Description
Flags	Flag: - SPT: The node is in the tree. - Direct: The node is a direct node. - Shortcut: The node is on a shortcut link. - Oload: The node is in Overload state. - Isolate: The node is not in the tree. - MIGP_Islt: The node is not in the MIGP tree. - V6_Islt: The node is not in the IPv6 tree. - Del: The node will be deleted. - Remote: The node is on a tunnel.
IPv4 Nexthops-URT	IPv4 next hop of the node in the unicast routing table.
IPv6 Nexthops	IPv6 next hop of the node in the unicast routing table.
Neighbors	Information about all the neighbors of this node.
Cost	Cost of the link from the root node to this node.
Flags	Relationship with the neighbor: - Parent: The neighbor is a parent node. - Child: The neighbor is a child node.
IF	Name of the outbound interface.
NBR	System ID of the next hop.
TYPE	Traffic protection type: - LOOP-FREE: loop-free protection for the backup next hop
PROTECT	Traffic protection type of IS-IS Auto FRR: - NONE: indicates no protection. - LINK: indicates link protection. - NODE: indicates node protection. - LINK-NODE: indicates link and node protection.

Display the current status statistics of the SPF tree.

        Count of links from Parent to Son:   0
        Count of links from Son to Parent:   0
        Count of links that just changed:    0
Status of SPF:                          Completed
```

Table 7-110 Description of the display isis spf-tree statistics command output

Item	Description
Total (Nodes information)	Total number of nodes.
Count of nodes in SPT	Number of nodes in the SPF tree.
Count of isolate nodes in SPT	Number of isolated nodes in the network topology.
Count of IPv6 isolate nodes in SPT	Number of isolated IPv6 nodes in the network topology.
Max Distance of nodes in SPT	Maximum distance from the root node to the leaf node.
Total (Links information)	Total number of links.
Count of links from Parent to Son	Number of links from the parent node to the child node.
Count of links from Son to Parent	Number of links from the child node to the parent node.
Count of links that just changed	Number of links that just changed.
Status of SPF	Status of SPF calculation: ● Completed: indicates that SPF calculation is complete. ● Scheduled: indicates that SPF calculation is triggered but does not start. ● Running: indicates that SPF calculation is being performed.

7.6.33 display isis statistics

Function

The **display isis statistics** command displays IS-IS process statistics.

Format

display isis statistics packet [**interface** [*interface-type interface-number*]]

display isis statistics [**updated-lsp** [**history**]] [**level-1** | **level-2** | **level-1-2**] [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **statistics** [[[**updated-lsp** [**history**]] [**level-1** | **level-2** | **level-1-2**]] | **packet**]

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support **updated-lsp** and **history** parameters.

Parameters

Parameter	Description	Value
packet	Displays IS-IS packet statistics.	-
interface *interface-type interface-number*	Displays IS-IS packet statistics on a specified interface.	-
updated-lsp	Displays real-time data of received LSPs. By default, statistics about the LSPs received within the last 1 hour are displayed.	-
history	Displays historical data of received LSPs. By default, statistics about the LSPs received within the last 24 hours are displayed.	-
level-1	Displays IS-IS Level-1 statistics.	-
level-2	Displays IS-IS Level-2 statistics.	-
level-1-2	Displays IS-IS Level-1-2 statistics.	-
process-id	Displays statistics in a specified IS-IS process.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Displays statistics about the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

1: Monitoring level

Usage Guidelines

You can use the **display isis statistics** command to view IS-IS process statistics, including the number of routes learned from other IS-IS devices, number of routes imported from other routing protocols, number of locally generated LSPs, and convergence priorities of IS-IS routes.

Example

Display IS-IS process statistics.

```
<HUAWEI> display isis statistics
                       Statistics information for ISIS(1)
                       ----------------------------------
                               Level-1 Statistics
                               ------------------

Forwarding routes information:
         Total IPV4 Learnt Routes: 0
                         Critical: 0
                         High    : 0
                         Medium  : 0
                         Low     : 0
         Total IPv4 Forwarding Routes: 1
Total IPv6 Learnt Routes: 0
                        Critical: 0
                        High    : 0
                        Medium  : 0
                        Low     : 0
         Total IPv6 Forwarding Routes: 1

               LSP Source ID:          No. of used LSPs
               0000.0000.0002                001
```

Table 7-111 Description of the display isis statistics command output

Item	Description
Total IPV4 Learnt Routes ● Critical ● High ● Medium ● Low	Number of IPv4 routes learned by IS-IS: ● Critical: indicates the number of IPv4 routes with convergence priority critical. ● High: indicates the number of IPv4 routes with convergence priority high. ● Medium: indicates the number of IPv4 routes with convergence priority medium. ● Low: indicates the number of IPv4 routes with convergence priority low.
Total IPv4 Forwarding Routes	Number of IPv4 routes counted based on the destination address. If there are multiple routes to the same destination, these routes are counted as one route.
Total IPv6 Learnt Routes ● Critical ● High ● Medium ● Low	Number of IPv6 routes learned by IS-IS: ● Critical: indicates the number of IPv6 routes with convergence priority critical. ● High: indicates the number of IPv6 routes with convergence priority high. ● Medium: indicates the number of IPv6 routes with convergence priority medium. ● Low: indicates the number of IPv6 routes with convergence priority low.
Total IPv6 Forwarding Routes	Number of IPv6 routes counted based on the destination address. If there are multiple routes to the same destination, these routes are counted as one route.
IPv4 Imported Routes	Imported IPv4 routes.

Item	Description
Static	Number of imported static routes.
Direct	Number of imported direct routes.
ISIS	Number of imported IS-IS routes.
BGP	Number of imported BGP routes.
RIP	Number of imported RIP routes.
OSPF	Number of imported OSPF routes.
IPv6 Imported Routes	Imported IPv6 routes.
RIPng	Number of imported RIPng routes.
OSPFv3	Number of imported OSPFv3 routes.
LSP Source ID	System ID of the switch that generates the LSP.
No. of used LSPs	Number of used LSPs.
Number of advertised imported routes	Number of imported external routes that are advertised.

Display IS-IS packet statistics.

```
<HUAWEI> display isis statistics packet

                  PDUs information for ISIS(1)
                  ----------------------------
       Sent packets:
       PDU type              Total(packets)
       L1 IIH                2516
       L1 LSP                  84
       L1 CSNP                   8
       L1 PSNP                  44
       L2 IIH                5028
       L2 LSP                  80
       L2 CSNP                   8
       L2 PSNP                  46

       Received packets:
       PDU type              Total(packets)
       L1 IIH               12943
       L1 LSP                 216
       L1 CSNP                 3911
       L1 PSNP                  40
       L2 IIH               14907
       L2 LSP                 206
       L2 CSNP                 3900
       L2 PSNP                  41
```

Table 7-112 Description of the display isis statistics packet command output

Item	Description
PDU type	Packet type.

Item	Description
Total(packets)	Total number of packets.
L1 IIH	Level-1 Hello packets.
L1 LSP	Level-1 LSPs.
L1 CSNP	Level-1 CSNPs.
L1 PSNP	Level-1 PSNPs.
L2 IIH	Level-2 Hello packets.
L2 LSP	Level-2 LSPs.
L2 CSNP	Level-2 CSNPs.
L2 PSNP	Level-2 PSNPs.

7.6.34 display isis traffic-eng advertisements

Function

The **display isis traffic-eng advertisements** command displays latest advertised traffic engineering (TE) information.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

display isis traffic-eng advertisements [{ **level-1** | **level-2** | **level-1-2** } | { *lsp-id* | **local** }] * [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **traffic-eng advertisements** [{ **level-1** | **level-2** | **level-1-2** } | { *lsp-id* | **local** }] *

Parameters

Parameter	Description	Value
level-1	Displays TE information in a Level-1 LSDB.	-
level-2	Displays TE information in a Level-2 LSDB.	-

Parameter	Description	Value
level-1-2	Displays TE information in a Level-1 or Level-2 LSDB based on the local node type. That is, if the local node is a Level-1 or Level-2 node, TE information in a Level-1 or Level-2 LSDB is displayed. If the local node is a Level-1-2 node, TE information in Level-1 and Level-2 LSDBs is displayed.	-
lsp-id	Displays TE information in the specified LSP.	The value is in dotted decimal notation. The value ranges from 16 to 20 in ####.####.####.##-## format, such as 0050.0500.5004.00-00.
local	Displays locally advertised TE information.	-
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

```

Table 7-113 Description of the display isis traffic-eng advertisements command output

Item	Description
LSPID	LSP ID.
LSP Seq Num	LSP sequence number.
LSP Checksum	LSP checksum.
LSP Holdtime	LSP holdtime.

Item	Description
ATT/P/OL	● ATT: Attach bit ● P: partition bit ● OL: overload bit
NLPID	Network protocol.
AREA ADDR	Area address.
Router ID	Router ID of the switch.
+NBR	System ID of the neighbor with the cost style wide, wide-compatible, or compatible.
COST	Cost.
Affinity:	Affinity attribute of a link.
Interface IP Address	IP address of an interface.
Peer IP Address	Peer IP address of an interface.
Physical BW	Physical bandwidth of a link.
Reservable BW	Reservable bandwidth of a link.
Unreserved BW	Unreserved bandwidth.
Sub Unreserved BW for Class Type 1	Unreserved bandwidth for CT1.
BW Unresrv [x]	Unreserved bandwidth for the link with priority x.
TE Cost	TE cost of a link.
Bandwidth Constraint Model	Bandwidth constraint model used by a link.
Bandwidth Constraints	Bandwidth constraint.
BC[x]	Bandwidth constraint of BCx.
Local Overbooking Multiplier	Local overbooking multiplier.
LOM[x]	Local overbooking multiplier of BCx.
+SRLG NBR ID	System ID of a neighbor in a shared risk link group (SRLG).
Neighbor IP Address	IP address of the neighbor.
Shared Risk Link Group	Shared risk link group. **NOTE** When SRLG is enabled on an interface, TE information contains SRLG information.

7.6.35 display isis traffic-eng link

Function

The **display isis traffic-eng link** command displays IS-IS TE link information.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

display isis traffic-eng link [{ **level-1** | **level-2** | **level-1-2** } | **verbose**] * [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **traffic-eng link** [{ **level-1** | **level-2** | **level-1-2** } | **verbose**] *

Parameters

Parameter	Description	Value
level-1	Displays TE link information on a Level-1 switch.	-
level-2	Displays TE link information on a Level-2 switch.	-
level-1-2	Displays TE link information on a Level-1-2switch.	-
verbose	Displays detailed TE link information.	-
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

7.6.36 display isis traffic-eng network

Function

The **display isis traffic-eng network** command displays IS-IS TE network information.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

display isis traffic-eng network [**level-1** | **level-2** | **level-1-2**] [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **traffic-eng network** [**level-1** | **level-2** | **level-1-2**]

Parameters

Parameter	Description	Value
level-1	Displays TE network information on a Level-1 router.	-
level-2	Displays TE network information on a Level-2 router.	-
level-1-2	Displays TE network information on a Level-1-2 router.	-
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

 Total Number of TE Networks in Level-2 Area: 2, Num Active: 2
```

Table 7-116 Description of the display isis traffic-eng network command output

Item	Description
DIS Router ID	Router ID of the DIS.
DIS's Ip Address	IP address of the DIS.
Status In CSPF	Whether CSPF is enabled on the switch.
Attached Router Count	Number of connected switches, including the local switch.
List of Attached Routers	List of connected switches.
RouterId	Router ID of the local switch.
Nbr	IP address of the neighbor.
Link State	Link status.
Total Number of TE Networks in Level-2 Area	Total number of networks on which TE is enabled in a Level-2 area.

7.6.37 display isis traffic-eng statistics

Function

The **display isis traffic-eng statistics** command displays IS-IS TE statistics.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

display isis traffic-eng statistics [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **traffic-eng statistics**

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID. If no process ID is specified, TE statistics about all IS-IS processes are displayed.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

 IS-IS Level-1 Traffic Engineering Status   : Disabled
 IS-IS Level-2 Traffic Engineering Status   : Enabled
 IS-IS Router ID                            : 10.1.1.9
```

Table 7-117 Description of the display isis traffic-eng statistics command output

Item	Description
IS-IS System Type	IS level.
IS-IS Cost Style Status	Cost style of the switch.
IS-IS Level-1 Traffic Engineering Status	TE status of a Level-1 router.
IS-IS Level-2 Traffic Engineering Status	TE status of a Level-2 router.
IS-IS Router ID	Router ID of an IS-IS router.

7.6.38 display isis traffic-eng sub-tlvs

Function

The **display isis traffic-eng sub-tlvs** command displays the types of sub-TLVs carrying DS-TE parameters.

NOTE

Only the S5731-H, S5731S-H, S5731-S, S5731S-S, S6730-S, S6730S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support this command.

Format

display isis traffic-eng sub-tlvs [*process-id* | **vpn-instance** *vpn-instance-name*]

display isis *process-id* **traffic-eng sub-tlvs**

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display isis traffic-eng sub-tlvs** command to check the types of sub-TLVs carrying DS-TE parameters.

Example

Display the types of sub-TLVs carrying DS-TE parameters.

```
<HUAWEI> display isis traffic-eng sub-tlvs
IS-IS(1) SubTlv Information
---------------------------------
 Unreserved sub-pool bandwidth sub-tlv value : 251
 Bandwidth constraint sub-tlv value          : 252
 LO multiplier sub-tlv value                 : 253
```

Table 7-118 Description of the display isis traffic-eng sub-tlvs command output

Item	Description
IS-IS(1) SubTlv Information	Sub-TLV information about IS-IS process 1.
Unreserved sub-pool bandwidth sub-tlv value	Sub-TLV of the unreserved sub-pool bandwidth.
Bandwidth constraint sub-tlv value	Sub-TLV of the bandwidth constraint.
LO multiplier sub-tlv value	Sub-TLV of the local overbooking multiplier.

7.6.39 domain-authentication-mode

Function

The **domain-authentication-mode** command configures an IS-IS routing domain to authenticate received Level-2 packets using the specified authentication mode and password and adds authentication information to Level-2 packets to be sent.

The **undo domain-authentication-mode** command cancels authenticating Level-2 packets and deletes the added authentication information from Level-2 packets.

By default, the system neither encapsulates generated Level-2 packets with authentication information nor authenticates received Level-2 packets.

Format

domain-authentication-mode { **simple** { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } | **md5** { [**cipher**] *plain-cipher-text* | **plain** *plain-text* } } [**ip** | **osi**] [**snp-packet** { **authentication-avoid** | **send-only** } | **all-send-only**]

domain-authentication-mode keychain *keychain-name* [**snp-packet** { **authentication-avoid** | **send-only** } | **all-send-only**]

domain-authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } [**snp-packet** { **authentication-avoid** | **send-only** } | **all-send-only**]

undo domain-authentication-mode

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Transmits the password in plain text. **NOTICE** Simple authentication has potential risks. HMAC-SHA256 cipher text authentication is recommended.	-

Parameter	Description	Value
plain *plain-text*	Specifies the authentication password in plain text. You can enter only the password in plain text. When you view the configuration file, the password is displayed in plain text. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is a string of case-sensitive characters without spaces. The value contains digits and letters. When the authentication mode is **simple**, the value is a string of 1 to 16 characters. When the authentication mode is **md5** or **hmac-sha256**, the value is a string of 1 to 255 characters.
cipher *plain-cipher-text*	Specifies the authentication password in cipher text. You can enter the password in plain or cipher text. When you view the configuration file, the password is displayed in cipher text. By default, the password is in cipher text.	The value is a string of case-sensitive characters without spaces. The value contains digits and letters. When the authentication mode is **simple**, the value is a string of 1 to 16 characters in plain text or a string of 32 or 48 characters in cipher text. When the authentication mode is **md5** or **hmac-sha256**, the value is a string of 1 to 255 characters in plain text or a string of 20 to 392 characters in cipher text.
md5	Transmits the password that is encrypted using MD5. **NOTICE** MD5 authentication has potential risks. HMAC-SHA256 cipher text authentication is recommended.	-
keychain *keychain-name*	Specifies the keychain that changes with time. Currently, IS-IS supports only HMAC-MD5 and HMAC-SHA256 algorithms.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ip	Indicates the IP authentication password. When neither **ip** nor **osi** is specified, the default parameter **osi** is used.	-
osi	Indicates the OSI authentication password. When neither **ip** nor **osi** is specified, the default parameter **osi** is used.	-
snp-packet	Authenticates SNPs.	-
authentication-avoid	Encapsulates generated LSPs but not SNPs with authentication information and authenticates received LSPs but not SNPs.	-
send-only	Encapsulates generated LSPs and SNPs with authentication information, and authenticates received LSPs but not SNPs.	-
all-send-only	Encapsulates generated LSPs and SNPs with authentication information, but does not authenticate received LSPs and SNPs.	-
hmac-sha256	Encapsulates generated packets with the HMAC-SHA256 authentication and a password encrypted by the HMAC-SHA256 algorithm and authenticates received packets.	-
key-id *key-id*	Indicates key ID of the HMAC-SHA256 algorithm.	It is an integer ranging from 0 to 65535.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, the IS-IS packets to be sent are not encapsulated with authentication information, and the received packets are not authenticated. If a user sends malicious packets to attack a network, information on the entire network may be stolen. Therefore, you can configure IS-IS authentication to improve the network security.

The domain authentication password is encapsulated into Level-2 IS-IS packets. Only the packets that pass the domain authentication can be accepted. Therefore, you can configure IS-IS domain authentication to authenticate Level-2 area.

Precautions

This command is valid in all the topologies in the specified IS-IS process and is only valid for Level-2 or Level-1-2 routers.

By using this command, you can discard all the Level-2 packets whose domain authentication password does not contain the one set through this command. At the same time, IS-IS adds the configured domain authentication password in all the Level-2 packets carrying routing information sent from the local node.

The authentication takes effect on the interface with the password. The port without the password can still receive the LSP and SNP with password.

Example

Set the domain authentication mode to HMAC-SHA256, authentication password to **YsHsjx_202206**, and key ID to **33** to authenticate Level-2 packets.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] domain-authentication-mode hmac-sha256 key-id 33 cipher YsHsjx_202206
```

7.6.40 filter-policy export (IS-IS)

Function

The **filter-policy export** command configures a filtering policy to allow IS-IS to filter the imported routes to be advertised.

The **undo filter-policy export** command cancels the filtering function.

By default, IS-IS does not filter the imported routes to be advertised.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*]]

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name*] **export** [*protocol* [*process-id*]]

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix-list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy to filter routes based on tag and other protocol parameters.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
protocol	Specifies the imported routes that need to be filtered when the routes are advertised. If this parameter is not specified, all the imported routes to be advertised are filtered.	The value can be **direct**, **static**, **unr**, **rip**, **bgp, ospf**, or another **isis** process.
process-id	Specifies the process ID if *protocol* is **rip**, **ospf**, or another **isis** process.	The value is an integer that ranges from 1 to 65535.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When IS-IS and other routing protocols are running on the network, and a boundary router in the IS-IS routing domain has imported routes of other routing protocols, the boundary router will advertise all the imported routes to its IS-IS neighbors by default. To advertise some of the imported routes to neighbors, use the **filter-policy export** command.

Precautions

Running the **filter-policy export** command does not affect the routes on the local device, but only advertises specific imported routes to IS-IS neighbors.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all external routes of the specified routing domain that are imported by IS-IS are advertised to the specified neighbor.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all external routes of the specified routing domain that are imported by IS-IS are advertised to the specified neighbor.

Example

Configure IS-IS to filter the imported routes using ACL 2000 before advertising the routes to other switches.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] filter-policy 2000 export
```

7.6.41 filter-policy import (IS-IS)

Function

The **filter-policy import** command configures a filtering policy to allow IS-IS to filter the received routes to be added to the IP routing table.

The **undo filter-policy import** command cancels the filtering function.

By default, IS-IS does not filter the received routes to be added to the IP routing table.

Format

filter-policy { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy [*acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name*] **import**

Parameters

Parameter	Description	Value
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy to filter routes based on tag and other protocol parameters.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS routing entries need to be added to an IP routing table to guide IP packet forwarding. If an IS-IS routing table has routes destined for a specific network segment, but these routes are not expected to be added to an IP routing table, run the **filter-policy import** command with specified parameters to allow only the needed IS-IS routes to be added to the IP routing table.

Precautions

Running the **filter-policy import** command on a router does not affect LSP flooding and LSDB synchronization on the router, but affects the local IP routing table.

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes received by IS-IS are delivered to the IP routing table.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all routes received by IS-IS are delivered to the IP routing table.

Example

Configure IS-IS to filter the received routes using ACL 2000 and add the routes matching the filtering conditions to the IP routing table.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] filter-policy 2000 import
```

7.6.42 flash-flood

Function

The **flash-flood** command enables LSP fast flooding to speed up IS-IS network convergence.

The **undo flash-flood** command disables LSP fast flooding.

By default, LSP fast flooding is disabled.

Format

flash-flood [*lsp-count* | **max-timer-interval** *interval* | [**level-1** | **level-2**]] *

undo flash-flood [*lsp-count* | **max-timer-interval** *interval* | [**level-1** | **level-2**]] *

Parameters

Parameter	Description	Value
lsp-count	Specifies the maximum number of LSPs to be flooded at a time on an interface.	The value is an integer that ranges from 1 to 15. The default value is 5.
max-timer-interval *interval*	Specifies the maximum interval for LSP flooding.	The value is an integer that ranges from 10 to 50000, in milliseconds. The default value is 10 ms.
level-1	Enables LSP fast flooding in Level-1. If no level is specified, by default, LSP fast flooding is enabled in both Level-1 and Level-2.	-

Parameter	Description	Value
level-2	Enables LSP fast flooding in Level-2. If no level is specified, by default, LSP fast flooding is enabled in both Level-1 and Level-2.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In most cases, when an IS-IS router receives new LSPs from other routers, it updates the LSPs in its LSDB and periodically floods the updated LSPs according to a timer.

LSP fast flooding speeds up LSDB synchronization because it allows a device to flood fewer LSPs than the specified number before route calculation when the device receives one or more new LSPs. This mechanism also speeds up network convergence.

Precautions

You can specify the number of LSPs to be flooded each time. The number is valid for all IS-IS interfaces. If the number of LSPs to be flooded is greater than the specified value, the *lsp-count* number of the LSPs are sent. If the timer is configured and does not time out before route calculation, LSPs are flooded immediately; otherwise, LSPs are flooded when the timer times out.

Example

Enable LSP fast flooding, configure each interface to send a maximum of six LSPs at a time, and set the maximum interval for sending LSPs to 100 ms.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] flash-flood 6 max-timer-interval 100
```

7.6.43 frr (IS-IS)

Function

The **frr** command enables the IS-IS Auto FRR function and displays the IS-IS Auto FRR view.

The **undo frr** command disables the IS-IS Auto FRR function.

By default, the IS-IS Auto FRR function is disabled.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Format

frr

undo frr

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage scenario

With the development of networks, the Voice over IP (VoIP) and on-line video services require high-quality real-time transmission. Nevertheless, if an IS-IS fault occurs, multiple processes, including fault detection, LSP update, LSP flooding, route calculation, and FIB entry delivery, must be performed to switch traffic to a new link. This results in a lengthy traffic interruption, which cannot meet the requirement for real-time services.

IS-IS Auto FRR can fast switch traffic to a backup link, ensuring millisecond-level traffic interruption. This protects traffic and improves IS-IS network reliability.

Precautions

After running this command, run the **loop-free-alternate** command to calculate a loop-free backup route.

Example

Enter the IS-IS FRR view.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] frr
[HUAWEI-isis-1-frr] loop-free-alternate
```

7.6.44 frr-policy route

Function

The **frr-policy route** command configures a filtering policy to allow IS-IS to filter the IS-IS backup routes to be added in the IP routing table.

The **undo frr-policy route** command cancels the filtering function.

By default, IS-IS does not filter the IS-IS backup routes to be added in the IP routing table.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

frr-policy route route-policy *route-policy-name*

undo frr-policy route

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a route-policy to filter IS-IS backup routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IS-IS FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The filtering policy can be configured as required. In this case, the IS-IS backup route that satisfies specified rules can be added to the IP routing table and delivered to the forwarding table. When a fault occurs on the route, the system can fast switch the forwarded traffic to the IS-IS backup route to protect traffic.

You can use IP prefix lists or ACLs to filter IS-IS backup routes.

Precautions

If you run the **frr-policy route** command multiple times, only the latest configuration takes effect.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, IS-IS adds all backup routes to the IP routing table.

Example

Configure IS-IS to filter IS-IS backup routes using route-policy and add the routes matching the route-policy **abc** to the IP routing table.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] frr
[HUAWEI-isis-1-frr] frr-policy route route-policy abc
```

7.6.45 graceful-restart (IS-IS)

Function

The **graceful-restart** command enables the graceful restart (GR) function for an IS-IS process.

The **undo graceful-restart** command disables the GR function for an IS-IS process.

By default, the GR function is disabled for an IS-IS process.

Format

graceful-restart

undo graceful-restart

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command is valid for all topologies in an IS-IS process.

When an IS-IS process on a device is restarted, neighbors delete neighbor relationships with the device and delete LSPs from the device. As a result, routes of neighbors are calculated incorrectly and packets are lost. Consequently, the network is temporarily interrupted.

To solve this problem, you can enable GR of the IS-IS process by running the **graceful-restart** command.

After the **graceful-restart** command is run, the device can notify its restart status to neighbors and permit neighbors to maintain neighbor relationships. In this manner, nonstop packet forwarding is implemented.

Configuration Impact

If IS-IS GR is enabled on a router, the holdtimes of this router's neighbors are automatically changed to 60s if they are smaller than 60s, and the holdtimes of this router's neighbors are kept unchanged if they are equal to or greater than 60s. If a router is faulty in non-GR scenarios, its neighbors need to take 60 seconds to detect the fault. A large number of packets may be discarded within the 60 seconds.

To resolve this problem, run the **graceful-restart no-impact-holdtime** command to configure the holdtimes of the neighbors to remain unchanged after IS-IS GR is enabled.

Example

Enable the GR function for IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] graceful-restart
```

7.6.46 graceful-restart no-impact-holdtime

Function

The **graceful-restart no-impact-holdtime** command configures the holdtime of an IS-IS neighbor to remain unchanged after IS-IS GR is enabled.

The **undo graceful-restart no-impact-holdtime** command cancels the configuration.

By default, after IS-IS GR is enabled, the holdtime of an IS-IS neighbor is automatically changed to 60s if it is smaller than 60s, and the holdtime of an IS-IS neighbor is kept unchanged if it is equal to or greater than 60s.

Format

graceful-restart no-impact-holdtime

undo graceful-restart no-impact-holdtime

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If IS-IS GR is enabled on a router, the holdtimes of this router's neighbors are automatically changed to 60s if they are smaller than 60s, and the holdtimes of this router's neighbors are kept unchanged if they are equal to or greater than 60s. If a router is faulty in non-GR scenarios, its neighbors need to take 60 seconds to detect the fault. A large number of packets may be discarded within the 60 seconds.

To resolve this problem, run the **graceful-restart no-impact-holdtime** command to configure the holdtimes of the neighbors to remain unchanged after IS-IS GR is enabled. After you run this command, the router can still fast detect neighbor status, implementing rapid network convergence.

Prerequisites

You have run the **graceful-restart (IS-IS)** command in the IS-IS view.

Example

Configure the holdtime of an IS-IS neighbor to remain unchanged after IS-IS GR is enabled.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] graceful-restart
[HUAWEI-isis-1] graceful-restart no-impact-holdtime
```

7.6.47 graceful-restart interval

Function

The **graceful-restart interval** command sets the GR T3 timer.

The **undo graceful-restart interval** command restores the default T3 timer.

By default, the GR T3 timer is 300 seconds.

Format

graceful-restart interval *interval-value*

undo graceful-restart interval

Parameters

Parameter	Description	Value
interval-value	Specifies the GR T3 timer.	The value is an integer that ranges from 30 to 1800, in seconds. Setting a value greater than that of the GR T2 timer specified using the **graceful-restart t2-interval** command is recommended. If the value is smaller than that of the GR T2 timer, the GR may fail.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS GR can be classified into restarting GR and starting GR based on the restart type. The restarting GR is triggered by a master/slave main control board switchover or an IS-IS process restart, while the starting GR is triggered by a restart of the IS-IS-enabled router.

During a restarting GR, the restarter restarts the protocol and starts the T1, T2, and T3 timers at the same time. The value of the T1 timer indicates the longest time during which the GR restarter waits for the LSP from the GR helper. The value of the T2 timer indicates the longest time during which the system waits for the LSDB synchronization. The value of the T3 timer indicates the longest time that a GR lasts. A router disables the T3 timer after the LSDB synchronization ends in all areas. If LSDBs are not synchronized yet when the T3 timer expires, the GR fails.

You can run the **graceful-restart interval** command to adjust the value of the T3 timer so that the LSDB synchronization can end before the T3 timer expires, which prevents the GR failure.

Prerequisites

The GR of the IS-IS process has been enabled using the **graceful-restart** command.

Configuration Impact

If the **graceful-restart interval** command is run on an IS-IS-enabled router, *interval-value* is used as the holdtime of its neighbor during the GR.

Precautions

The **graceful-restart interval** command is applicable only to restarting GRs.

Example

Set the GR interval for IS-IS process 1 to 120 seconds (2 minutes).

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] graceful-restart
[HUAWEI-isis-1] graceful-restart interval 120
```

7.6.48 graceful-restart suppress-sa

Function

The **graceful-restart suppress-sa** command suppresses the suppress-advertisement (SA) bit of the restart TLV.

The **undo graceful-restart suppress-sa** command restores the default setting.

By default, the SA bit of the restart TLV is not suppressed.

Format

graceful-restart suppress-sa

undo graceful-restart suppress-sa

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch that starts for the first time (not including GR) does not maintain the forwarding status. If the switch does not start for the first time, the LSPs generated when the switch run last time may exist in the LSP database of other switches in the network.

The sequence number of the LSP fragment is reinitialized when the switch starts, so the LSPs stored in the LSP database of other switches seem to be newer than the LSPs generated after the switch starts. This leads to the black hole in the network, and the black hole lasts until the switch regenerates its LSPs and advertises the LSPs with the highest sequence number.

If the neighbor suppresses the advertisement of the adjacency relationship to this switch during the switch starting until the switch advertises the updated LSPs, the preceding case can be avoided.

Prerequisites

GR has been enabled for the IS-IS process using the **graceful-restart** command.

Example

Suppress the SA bit in the restart TLV of IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] graceful-restart
[HUAWEI-isis-1] graceful-restart suppress-sa
```

7.6.49 graceful-restart t2-interval

Function

The **graceful-restart t2-interval** command configures a value for the T2 timer during an IS-IS GR.

The **undo graceful-restart t2-interval** command restores the default value of the T2 timer.

By default, the GR T2 timer is 60 seconds.

Format

graceful-restart t2-interval *interval-value*

undo graceful-restart t2-interval

Parameters

Parameter	Description	Value
interval-value	Specifies the value of the T2 timer during the IS-IS GR.	The value is an integer that ranges from 30 to 1800, in seconds. Setting a value smaller than that of the GR T3 timer specified using the **graceful-restart interval** command is recommended.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS GR can be classified into restarting GR and starting GR based on the restart type. The restarting GR is triggered by a master/slave main control board switchover or an IS-IS process restart, while the starting GR is triggered by a restart of the IS-IS-enabled router.

A GR restarter starts the T1 and T2 timers during all GRs. The value of the T1 timer indicates the longest time during which the GR restarter waits for the LSP from the GR helper. The value of the T2 timer indicates the longest time during which the system waits for the LSDB synchronization. The T2 timer is disabled after the LSDB synchronization among Level-1 or Level-2 routers ends. If LSDBs are not synchronized yet when the T2 timer expires, the GR fails.

You can run the **graceful-restart t2-interval** command to adjust the value of the T2 timer so that the LSDB synchronization can end before the T2 timer expires, which prevents the GR failure.

Prerequisites

The GR of the IS-IS process has been enabled using the **graceful-restart** command.

Precautions

If the value of the T2 timer is too small, a GR may fail. Keeping the default value is recommended. If you want to adjust it, configure a value to meet the conditions on the live network.

Example

Set the GR T2 timer of IS-IS process 1 to 120 seconds (2 minutes).

```
<HUAWEI> system-view
```

```
[HUAWEI] isis 1
[HUAWEI-isis-1] graceful-restart
[HUAWEI-isis-1] graceful-restart t2-interval 120
```

7.6.50 import-route (IS-IS)

Function

The **import-route** command configures IS-IS to import routes from other routing protocols.

The **undo import-route** command restores the default setting.

By default, IS-IS does not import routes from other routing protocols.

Format

import-route { { **rip** | **isis** | **ospf** } [*process-id*] | **static** | **direct** | **unr** | **bgp** [**permit-ibgp**] } [**cost-type** { **external** | **internal** } | **cost** *cost* | **tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

import-route { { **rip** | **isis** | **ospf** } [*process-id*] | **direct** | **unr** | **bgp** [**permit-ibgp**] } **inherit-cost** [**tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

import-route limit *limit-number* [**threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*] { **level-1** | **level-2** | **level-1-2** }

undo import-route { { **rip** | **isis** | **ospf** } [*process-id*] | **static** | **direct** | **unr** | **bgp** [**permit-ibgp**] } [**cost-type** { **external** | **internal** } | **cost** *cost* | **tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

undo import-route { { **rip** | **isis** | **ospf** } [*process-id*] | **direct** | **unr** | **bgp** [**permit-ibgp**] } **inherit-cost** [**tag** *tag* | **route-policy** *route-policy-name* | [**level-1** | **level-2** | **level-1-2**]] *

undo import-route limit [*limit-number*] [**threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*] { **level-1** | **level-2** | **level-1-2** }

Parameters

Parameter	Description	Value
rip	Indicates that the routing protocol from which routes are imported is RIP.	-
isis	Indicates that the routing protocol from which routes are imported is IS-IS.	-
ospf	Indicates that the routing protocol from which routes are imported is OSPF.	-
process-id	Specifies a process ID. When *protocol* is **rip**, **ospf**, or **isis**, a process ID needs to be specified. The default process ID is 1.	The value is an integer that ranges from 1 to 65535.

Parameter	Description	Value
static	Indicates that the imported routes are active static routes.	-
direct	Indicates that the imported routes are direct routes.	-
unr	Specifies the imported source routing protocol as **unr**. User Network Route (UNR) is allocated if dynamic routing protocols cannot be used when users are getting online.	-
bgp	Indicates that the routing protocol from which routes are imported is BGP.	-
permit-ibgp	Specifies the imported source route as an IBGP route. If you do not configure this parameter, only the EBGP routes are imported.	-
cost-type { **external** | **internal** }	Indicates the cost type of the imported routes. By default, the cost type is **external**. The configuration of this parameter will affect the costs of imported routes. ● If the cost type of an imported route is configured as **external**, the cost of the imported route equals the cost of the original route plus 64. ● If the cost type of an imported route is configured as **internal**, the imported route inherits the cost of the original route. **NOTE** If the cost style of the switch is wide, compatible, or wide-compatible, the cost types of imported routes are not differentiated between **external** and **internal**.	-
cost *cost*	Specifies the cost value of imported routes.	If the cost style of the switch is wide or wide-compatible, the cost value of imported routes ranges from 0 to 4261412864. Otherwise, the value ranges from 0 to 63. The default value is 0.

Parameter	Description	Value
tag *tag*	Specifies the administrative tag of imported routes.	The value is an integer that ranges from 1 to 4294967295.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
level-1	Indicates that routes are imported into Level-1 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
level-2	Indicates that routes are imported into Level-2 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
level-1-2	Indicates that routes are imported into Level-1 and Level-2 routing tables. If no level is specified, routes are imported to Level-2 routing tables by default.	-
inherit-cost	Indicates that the original cost value of imported external routes is retained. When IS-IS is configured to retain the original cost value of imported routes, the cost style and cost value cannot be set for the imported routes.	-
limit *limit-number*	Specifies the maximum number of external routes allowed to be imported to the IS-IS area.	The value is an integer ranging from 1 to 10000000.
threshold-alarm	Specifies the alarm threshold for imported routes.	-
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for imported routes.	The value is an integer ranging from 1 to 100. The default value is 80.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for imported routes.	The value is an integer ranging from 1 to 100. The default value is 70.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When IS-IS and other routing protocols are deployed on a network, you can enable the traffic within an IS-IS routing domain to reach a destination outside the IS-IS routing domain using either of the following methods:

- Configure boundary devices in the IS-IS routing domain to advertise default routes to the IS-IS routing domain.
- Configure boundary devices in the IS-IS routing domain to import routes from other routing domains into the IS-IS routing domain.

If there are multiple boundary devices in the IS-IS routing domain, optimal routes destined for another routing domain need to be selected. This requires all devices in the IS-IS routing domain learn all or some external routes. Configure boundary devices in the IS-IS routing domain to import routes from other routing domains into the IS-IS routing domain. Alternatively, run the **route-policy** *route-policy-name* command to import some external routes from other routing domains.

Precautions

When the routes of the other protocols are imported, you can set the cost value and cost style for the imported route. You can also configure IS-IS to retain the original cost value of the imported external route. During route advertisement and route calculation, the original cost values of these routes are used. In this case, the cost style and cost value of the imported routes cannot be set, and static routes cannot be imported.

After the **import-route direct** command is executed, routes to the network segment where the IP address of the management interface belongs are also imported in the ISIS routing table. Therefore, use this command with caution.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, all routes of the specified routing domain are imported to the IS-IS routing table.

Example

Configure IS-IS to import static routes and set the cost value of the routes to 15.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] import-route static cost 15
```

Configure IS-IS to import OSPF routes and retain the original cost value of the routes.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] import-route ospf inherit-cost
```

7.6.51 import-route isis level-1 into level-2

Function

The **import-route isis level-1 into level-2** command configures route leaking from Level-1 areas to Level-2 areas.

The **undo import-route isis level-1 into level-2** command prohibits route leaking from Level-1 areas to Level-2 areas.

By default, all Level-1 routing information, excluding information about default routes, is leaked to Level-2 areas.

Format

import-route isis level-1 into level-2 [**filter-policy** { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct allow-filter-policy**] *

undo import-route isis level-1 into level-2 [**filter-policy** { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct allow-filter-policy**] *

Parameters

Parameter	Description	Value
filter-policy	Specifies a filtering policy.	-
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list. Only the routes that match the IP prefix can be leaked to Level-2 areas.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
tag *tag*	Specifies the administrative tag value of imported routes.	The value is an integer that ranges from 1 to 4294967295.
direct allow-filter-policy	Specifies the filtering policy to filter the direct routes. Only the IS-IS Level-1 area direct routing information that matches the filtering policy can be shared with the Level-2 area with this parameter, and all Level-1 area direct routing information will be shared with the Level-2 area without this parameter.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS is designed for a hierarchical network. This means that routes of Level-1 areas are leaked to Level-2 areas, whereas routes of Level-2 areas are not leaked to Level-1 areas.

The import-route isis level-1 into level-2 command can be run only on Level-1-2 routers to allow some or no Level-1 routes to be leaked to Level-2 areas. For example, there are two Level-1-2 routers in a Level-1 area. You can run the import-route isis level-1 into level-2 command on one Level-1-2 router to allow some Level-1 routes to be leaked to the Level-2 area, and run the import-route isis level-1 into level-2 command on the other Level-1-2 router to allow the remaining Level-1 routes to be leaked to the Level-2 area. Then, traffic that is sent from the Level-2 area and destined for different network segments in Level-1 area will be forwarded to different Level-1-2 routers. This allows route selection to be controlled.

Precautions

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes in the Level-1 area leak to the Level-2 area.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all routes in the Level-1 area leak to the Level-2 area.

Example

Control route leaking from Level-1 areas to Level-2 areas on Level-1-2 routers using filtering policy 2000.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] import-route isis level-1 into level-2 filter-policy 2000
```

7.6.52 import-route isis level-2 into level-1

Function

The **import-route isis level-2 into level-1** command configures route leaking from Level-2 areas to Level-1 areas.

The **undo import-route isis level-2 into level-1** command prohibits route leaking from Level-2 areas to Level-1 areas.

By default, Level-2 routing information is not leaked to Level-1 areas.

Format

import-route isis level-2 into level-1 [**filter-policy** { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct** { **allow-filter-policy** | **allow-up-down-bit** } *] *

undo import-route isis level-2 into level-1 [**filter-policy** { *acl-number* | **acl-name** *acl-name* | **ip-prefix** *ip-prefix-name* | **route-policy** *route-policy-name* } | **tag** *tag* | **direct** { **allow-filter-policy** | **allow-up-down-bit** } *] *

Parameters

Parameter	Description	Value
filter-policy	Specifies a filtering policy.	-
acl-number	Specifies the number of a basic ACL.	The value is an integer that ranges from 2000 to 2999.
acl-name *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list. Only the routes that match the specified IP prefix can be imported.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
tag *tag*	Specifies the administrative tag value of imported routes.	The value is an integer that ranges from 1 to 4294967295.
direct allow-filter-policy	Indicates the filtering policy to filter the direct routes. Only the IS-IS Level-1 area direct routing information that matches the filtering policy can leak to the Level-2 area with this parameter, and all Level-1 area direct routing information is available to the Level-2 area without this parameter.	-
direct allow-up-down-bit	Indicates that the Up or Down bit is used during the leak of directs routes. If **direct allow-up-down-bit** is specified, the direct routes that have already leaked to the Level-1 area have the lowest priority and cannot leak back.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multiple Level-1-2 switches in a Level-1 area are connected to a Level-2 area, Level-1 switches are unable to know the network topology of the Level-2 area, but forward traffic to the nearest Level-1-2 switch (based on the route with the smallest cost). For Level-2 switches, however, this route may not be the optimal one. Therefore, you need to allow some Level-2 routes to be leaked to the Level-1 area to help Level-1 switches select the optimal route for forwarding traffic to the Level 2 area.

To solve the preceding problem, IS-IS provides the route leaking function to enable Level-1 devices to choose the best path for traffic forwarding.

The **import-route isis level-2 into level-1** command can be run only on Level-1-2 routers to allow all or some Level-2 routes to be leaked to the Level-1 area.

Precautions

For an ACL, when the **rule** command is used to configure a filtering rule, the filtering rule is effective only with the source address range that is specified by the **source** parameter and with the time period that is specified by the **time-range** parameter.

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes in the Level-2 area leak to the Level-1 area.

Creating an IP prefix list or route-policy before it is referenced is recommended. By default, nonexistent IP prefix lists or route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list or route-policy is referenced using the current command, all routes in the Level-1 area leak to the Level-2 area.

Example

Configure IS-IS to perform route leaking from a Level-2 area to a Level-1 area using filtering policy 2000.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] import-route isis level-2 into level-1 filter-policy 2000
```

7.6.53 isis

Function

The **isis** command starts an IS-IS process and a specified VPN instance, and displays the IS-IS view.

The **undo isis** command deletes a specified IS-IS process.

By default, no IS-IS instance exists on the network.

Format

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

undo isis *process-id*

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before you configure IS-IS functions and interface-related features, run the **isis** command to create an IS-IS process and enable IS-IS on the interface.

On a large-scale network, if a large number of switches run IS-IS, there will be a huge number of routes, increasing maintenance costs, slowing down route convergence, and affecting network stability. To resolve the problem, you can run the **isis** *process-id* command to start multi-processes to reduce the number of routes to be maintained.

In addition, to ensure that different services are forwarded properly on the network, you can run the **isis vpn-instance** *vpn-instance-name* command to start multiple IS-IS processes on one device to isolate these services.

Follow-up Procedure

After the **isis** command is used to enable an IS-IS process, run the **network-entity** command to set a NET for the switch, and run the **isis enable** command to enable IS-IS on each interface that needs to run IS-IS. You can start IS-IS only when these configurations are completed.

Precautions

One IS-IS process can be bound to only one VPN instance. Multiple IS-IS interfaces can be bound to one VPN instance.

If a VPN instance is deleted, the IS-IS process bound to the VPN instance is deleted.

When creating an IS-IS process, bind it to a VPN instance. An existing IS-IS process cannot be bound to any VPN instance.

Example

Bind IS-IS process 2 to VPN instance **vpn1**.

```
<HUAWEI> system-view
[HUAWEI] isis 2 vpn-instance vpn1
```

7.6.54 isis authentication-mode

Function

The **isis authentication-mode** command configures an IS-IS interface to authenticate Hello packets using the specified mode and password.

The **undo isis authentication-mode** command cancels the authentication and deletes the authentication information in Hello packets.

By default, no authentication information is added to Hello packets and no authentication is performed on received Hello packets.

Format

isis authentication-mode { **simple** | **md5** } { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } [**level-1** | **level-2**] [**ip** | **osi**] [**send-only**]

isis authentication-mode keychain *keychain-name* [**level-1** | **level-2**] [**send-only**]

isis authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | [**cipher**] *plain-cipher-text* } [**level-1** | **level-2**] [**send-only**]

undo isis authentication-mode [**level-1** | **level-2**]

undo isis authentication-mode keychain *keychain-name* [**level-1** | **level-2**] [**send-only**]

undo isis authentication-mode { **simple** { **plain** *plain-text* | **cipher** *plain-cipher-text* } | **md5** { **cipher** *plain-cipher-text* | **plain** *plain-text* } } [**level-1** | **level-2**] [**ip** | **osi**] [**send-only**]

undo isis authentication-mode hmac-sha256 key-id *key-id* { **plain** *plain-text* | **cipher** *plain-cipher-text* } [**level-1** | **level-2**] [**send-only**]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the **keychain** *keychain-name* parameter.

Parameters

Parameter	Description	Value
simple	Indicates that the password is transmitted in plain text. **NOTICE** Simple authentication has potential risks. HMAC-SHA256 cipher text authentication is recommended.	-
plain *plain-text*	Indicates that the password is in plain text. Only a plain-text password can be entered. The password in the configuration file is displayed in plain text. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the password in cipher text.	The value is a string of case-sensitive characters. It contains letters and digits without spaces. In **simple** authentication mode, the value is a string of 1 to 16 characters. In **md5** or **hmac-sha256** authentication mode, the value is a string of 1 to 255 characters.
cipher *plain-cipher-text*	Indicates that the password is in cipher text. A plain-text or cipher-text password can be entered. The password in the configuration file is displayed in cipher text. By default, the password is in cipher text.	The value is a string of case-sensitive characters. It contains letters and digits without spaces. In **simple** authentication mode, the value is a string of 1 to 16 characters in plain text or a string of 32 characters in cipher text. In **md5** or **hmac-sha256** authentication mode, the value is a string of 1 to 255 characters in plain text or a string of 20 to 392 characters in cipher text.
md5	Indicates that the password to be transmitted is encrypted using MD5. **NOTICE** MD5 authentication has potential risks. HMAC-SHA256 cipher text authentication is recommended.	-

Parameter	Description	Value
level-1	Indicates Level-1 authentication. When the link type of an IS-IS interface is Level-1-2, if **level-1** and **level-2** are not specified, both Level-1 and Level-2 Hello packets are configured with the authentication mode and password.	-
level-2	Indicates Level-2 authentication. When the link type of an IS-IS interface is Level-1-2, if **level-1** and **level-2** are not specified, both Level-1 and Level-2 Hello packets are configured with the authentication mode and password.	-
ip	Indicates the IP authentication password. This parameter cannot be configured in keychain authentication mode. If parameters **ip** and **osi** are not specified, the parameter **osi** is used by default.	-
osi	Indicates the OSI authentication password. This parameter cannot be configured in **keychain** authentication mode. If parameters **ip** and **osi** are not specified, the parameter **osi** is used by default.	-
send-only	Encapsulates sent Hello packets with authentication information but does not authenticate received Hello packets.	-
keychain *keychain-name*	Indicates that the password is a keychain that changes with time. This parameter takes effect only when *keychain-name* is set using the **keychain** command. Currently, IS-IS supports only HMAC-MD5 and HMAC-SHA256 algorithms.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Parameter	Description	Value
hmac-sha256	Encapsulates generated packets with the HMAC-SHA256 authentication and a password encrypted by the HMAC-SHA256 algorithm and authenticates received packets.	-
key-id *key-id*	Indicates key ID of the HMAC-SHA256 algorithm.	It is an integer ranging from 0 to 65535.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve network security, authenticate received packets or encapsulate sent packets with authentication information. Only the packets that pass the authentication can be transmitted on the network.

You can use the **isis authentication-mode** command to discard the Hello packets whose authentication passwords are different from the authentication password configured using this command. At the same time, IS-IS adds the configured interface authentication password into all the Hello packets sent from the local node.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

If a broadcast interface is emulated as a P2P interface using the **isis circuit-type** command and then restored to the broadcast interface using the **undo isis circuit-type** command, the authentication configuration of the IS-IS area is restored to the default setting.

Example

Set HMAC-SHA256 authentication password **YsHsjx_202206** key id **33** on VLANIF100

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis authentication-mode hmac-sha256 key-id  33 cipher YsHsjx_202206
```

Set HMAC-SHA256 authentication password **YsHsjx_202206** key id **33** GE0/0/1

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis authentication-mode hmac-sha256 key-id  33 cipher YsHsjx_202206
```

7.6.55 isis bfd

Function

The **isis bfd** command sets values of BFD session parameters on a specified IS-IS interface.

The **undo isis bfd** command restores the default values of BFD session parameters on a specified IS-IS interface.

By default, BFD session parameters use default values.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis bfd { **min-rx-interval** *receive-interval* | **min-tx-interval** *transmit-interval* | **detect-multiplier** *multiplier-value* | **frr-binding** } *

undo isis bfd { **min-rx-interval** [*receive-interval*] | **min-tx-interval** [*transmit-interval*] | **detect-multiplier** [*multiplier-value*] | **frr-binding** } *

Parameters

Parameter	Description	Value
min-rx-interval *receive-interval*	Specifies the minimum interval for receiving BFD packets from the peer end.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.

Parameter	Description	Value
min-tx-interval *transmit-interval*	Specifies the minimum interval for transmitting BFD packets to the peer end.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-H, S5731-S, S5731S-H, and S5731S-S, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S, the value ranges from 3 to 1000.
detect-multiplier *multiplier-value*	Specifies the local detection multiplier.	The value is an integer that ranges from 3 to 50. The default value is 3.
frr-binding	Binds the BFD session status to IS-IS Auto FRR. When BFD detects the link fault on an interface, the BFD session goes Down, triggering FRR on the interface. After that, the traffic is switched from the faulty link to the backup link, which protects the traffic.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD can quickly detect faults on links. Configure proper parameters based on the actual network situation to improve the IS-IS convergence speed when network faults occur. You can use the **isis bfd** command to change BFD session parameters such as the minimum interval for sending BFD packets, minimum interval for receiving BFD packets, and local detection multiplier.

In an IS-IS process, after IS-IS establishes a BFD session, the value of *receive-interval* is obtained after the negotiation of the local **min-rx-interval** value and the remote **min-tx-interval** value. If no BFD packet is received from the peer end within the specified period (*receive-interval* x *multiplier-value*), the neighbor is considered Down.

Negotiation principle: Actual interval for the local device to receive BFD packets = MAX {local **min-rx-interval** value, remote **min-tx-interval** value}

Prerequisites

BFD has been enabled globally. In the interface view, IS-IS has been enabled and BFD has been enabled on the interface using the **isis bfd enable** command.

Precautions

The BFD priority of the interface is higher than that of the process. If BFD of the interface is enabled, the BFD session is set up based on the BFD parameters on the interface.

Example

Enable BFD on VLANIF100 and set the minimum receive interval to 600 ms and local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis bfd enable
[HUAWEI-Vlanif100] isis bfd min-rx-interval 600 detect-multiplier 4
```

Enable BFD on GE0/0/1 and set the minimum receive interval to 600 ms and local detection multiplier to 4.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis bfd enable
[HUAWEI-GigabitEthernet0/0/1] isis bfd min-rx-interval 600 detect-multiplier 4
```

7.6.56 isis bfd block

Function

The **isis bfd block** command prevents an IS-IS interface from dynamically establishing a BFD session.

The **undo isis bfd block** command restores the default setting.

By default, an interface can dynamically establish a BFD session.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis bfd block

undo isis bfd block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD can provide millisecond-level fault detection, help IS-IS rapidly detect the faults that occur on neighboring devices or links, and instruct IS-IS to recalculate routes for correct packet forwarding. If the network contains unstable links that do not require high reliability and BFD has been enabled, a link cannot transmit data normally when it flaps. You can use the **isis bfd block** command to prevent specified interfaces from dynamically establishing BFD sessions.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

If the **isis bfd block**, **isis bfd enable**, and **isis bfd static** commands are executed, only the last command takes effect.

Example

Prevent VLANIF100 from dynamically establishing a BFD session.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis bfd block
```

Prevent GE0/0/1 from dynamically establishing a BFD session.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis bfd block
```

7.6.57 isis bfd enable

Function

The **isis bfd enable** command enables BFD on a specified IS-IS interface.

The **undo isis bfd enable** command disables BFD on a specified IS-IS interface.

By default, BFD is not enabled on an IS-IS interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis bfd enable

undo isis bfd enable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD can provide millisecond-level fault detection, help IS-IS to detect the faults that occur on neighboring devices or links more rapidly, and instruct IS-IS to recalculate routes for correct packet forwarding. The **isis bfd enable** command can be used to enable BFD on a specified IS-IS interface and establish BFD sessions by using default parameters.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

If global BFD is not enabled, you can configure BFD parameters on an interface but cannot establish a BFD session.

The BFD priority of the interface is higher than the BFD priority of the process. If BFD of the interface is enabled, the BFD session is set up based on the BFD parameters on the interface.

If the **isis bfd block**, **isis bfd enable**, and **isis bfd static** commands are run, only the last command takes effect.

Example

Enable BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis bfd enable
```

Enable BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis bfd enable
```

7.6.58 isis bfd static

Function

The **isis bfd static** command enables static BFD on a specified IS-IS interface.

The **undo isis bfd static** command disables static BFD on a specified IS-IS interface.

By default, static BFD is disabled on an IS-IS interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

isis bfd static

undo isis bfd static

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In static BFD, BFD session parameters are set manually and BFD session establishment requests are delivered manually. Then static BFD can quickly detect faults on links. You can run the **isis bfd static** command to enable static BFD on a specified interface to establish static BFD sessions on specified links.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

If the **isis bfd block**, **isis bfd enable**, and **isis bfd static** commands are run, only the last command takes effect.

Example

Enable static BFD on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis bfd static
```

Enable static BFD on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis bfd static
```

7.6.59 isis circuit-level

Function

The **isis circuit-level** command sets the link type of an interface on a Level-1-2 router.

The **undo isis circuit-level** command restores the default link type of an interface on a Level-1-2 router.

By default, the link type of an interface on a Level-1-2 router is Level-1-2, and both Level-1 and Level-2 neighbor relationships can be established on the interface.

Format

isis circuit-level [**level-1** | **level-1-2** | **level-2**]

undo isis circuit-level

Parameters

Parameter	Description	Value
level-1	Specifies the Level-1 link type. That is, only Level-1 neighbor relationship can be established on the interface.	-
level-1-2	Specifies the Level-2 link type. That is, both Level-1 and Level-2 neighbor relationships can be established on the interface.	-
level-2	Specifies the Level-2 link type. That is, only Level-2 neighbor relationship can be established on the interface.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an adjacency is established between a Level-1-2 router and a remote device, the Level-1-2 router sends and receives both Level-1 and Level-2 Hello packets, wasting bandwidth and memory resources. To solve this problem, run the **isis circuit-level** command to set a specified link type for an interface.

Prerequisites

IS-IS has been enabled using the **isis enable** command in the interface view.

Precautions

Network flapping may occur if the link type of an IS-IS interface is changed during network operation. Therefore, setting a link type for an IS-IS interface on the switch when configuring IS-IS is recommended.

The configuration of the **isis circuit-level** command takes effect only when the IS-IS system type is Level-1-2. Otherwise, the level configured using the **is-level** command is used as the link type.

Example

If VLANIF100 is connected to a non-backbone router in the same area, set this interface to Level-1, and prohibit the interface from sending and receiving Level-2 Hello packets.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-level level-1
```

If GE0/0/1 is connected to a non-backbone router in the same area, set this interface to Level-1, and prohibit the interface from sending and receiving Level-2 Hello packets.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-level level-1
```

7.6.60 isis circuit-type

Function

The **isis circuit-type** command simulates the network type of an IS-IS broadcast interface to a P2P interface.

The **undo isis circuit-type** command restores the default network type of an IS-IS interface.

By default, the network type of an interface is determined by the physical type of the interface.

Format

isis circuit-type p2p [**strict-snpa-check**]

undo isis circuit-type

Parameters

Parameter	Description	Value
p2p	Sets the network type of an IS-IS interface to P2P.	-
strict-snpa-check	Enables IS-IS to check the SNPA address of each received LSP or SNP.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The network type of IS-IS interfaces at the ends of the link must be identical. Otherwise, the two interfaces cannot set up the neighbor relationship. In most cases, the network types of interfaces on a broadcast network and a P2P network are Ethernet and P2P respectively.

The **isis circuit-type** command sets the network type of an interface to simulate a P2P interface so that the network type of IS-IS interfaces at the ends of the link is identical and the neighbor relationship can be established between them.

When an IS-IS neighbor relationship is established between a P2P interface and a simulated P2P interface and the simulated P2P interface has direct neighbors, the P2P interface may receive unneeded packets from these direct neighbors. To prevent the P2P interface from accepting these unneeded packets, specify **strict-snpa-check** in the **isis circuit-type** command to enable IS-IS to check the SNPA address of each received LSP or SNP. After the command is run, the P2P interface accepts only the packets whose SNPA addresses are included in the local neighbor address list, which improves network security.

Precautions

For an interface enabled with IS-IS using the **isis enable** command, when the network type of an interface changes, the corresponding configurations change. Details are as follows:

- After a broadcast interface is simulated as a P2P interface using the **isis circuit-type** command, the interval for sending Hello packets, the number of Hello packets that IS-IS does not receive from a neighbor before the neighbor is declared Down, interval for resending LSP packets on a P2P link, and various IS-IS authentication modes are restored to the default settings; other configurations such as the DIS priority, DIS name, and interval for sending CSNP packets on a broadcast network become invalid.
- After the **undo isis circuit-type** command is run to restore the network type of an IS-IS interface, the interval for sending Hello packets, the number of Hello packets that IS-IS does not receive from a neighbor before the neighbor is declared Down, interval for resending LSP packets on a P2P link, various IS-IS authentication modes, DIS priority, and interval for sending CSNP packets on a broadcast network are restored to the default settings.

Example

Set the network type of VLANIF100 to P2P.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-type p2p
```

Set the network type of GE0/0/1 to P2P.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-type p2p
```

7.6.61 isis cost

Function

The **isis cost** command sets the link cost value of an IS-IS interface.

The **undo isis cost** command restores the default link cost value of an IS-IS interface.

By default, the link cost value of an IS-IS interface is 10.

Format

isis cost { *cost* | **maximum** } [**level-1** | **level-2**]

undo isis cost [*cost* | **maximum**] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
cost	Specifies the link cost value of an interface.	The value is an integer that varies according to the cost style. - When the cost style is **narrow**, **narrow-compatible**, or **compatible**, the value ranges from 1 to 63. - When the cost style is **wide** or **wide-compatible**, the value ranges from 1 to 16777214. The default value is 10.
maximum	Sets the link cost of IS-IS interfaces to 16777215. **NOTE** You can configure this parameter only when the IS-IS cost style is wide or wide-compatible. After the interface cost is set to 16777215, the neighbor TLV generated on the link can only be used to transmit TE information but cannot be used for route calculation.	-
level-1	Specifies the link cost value of a Level-1 interface. If the interface level is not specified, link cost values of Level-1 and Level-2 interfaces are set.	-

Parameter	Description	Value
level-2	Specifies the link cost value of a Level-2 interface. If the interface level is not specified, link cost values of Level-1 and Level-2 interfaces are set.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On large networks, there may be multiple valid routes to the same destination. IS-IS uses the SPF algorithm to calculate an optimal route and transmits traffic over it, which brings the following problems:

- All traffic is transmitted over the optimal route, causing load imbalance.
- If the optimal route is faulty, traffic will get lost.

To solve the preceding problems, run the **isis cost** command to set a link cost for interfaces so that traffic can be transmitted over different physical links.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Configuration Impact

If the link cost of an interface is changed, routes will be re-calculated on the whole network, causing the changes in traffic forwarding paths.

Precautions

The priority of the **circuit-cost** command is lower than that of the **isis cost** command.

Example

Set the Level-2 link cost of VLANIF100 to 5.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis cost 5 level-2
```

Set the Level-2 link cost of GE0/0/1 to 5.

```
<HUAWEI> system-view
[HUAWEI] isis
```

```
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis cost 5 level-2
```

7.6.62 isis delay-peer

Function

The **isis delay-peer** command configures a delay for an interface so that the interface delays establishing neighbor relationships after the neighbor relationship with the last neighbor goes Down due to packet timeout.

The **undo isis delay-peer** command deletes the configured delay and restores the default configurations.

By default, if the neighbor relationship goes Down due to packet timeout, the interface re-establishes the neighbor relationship after it receives a new Hello packet.

Format

isis delay-peer track last-peer-expired [**delay-time** *delay-interval*]

undo isis delay-peer [**track last-peer-expired** [**delay-time** *delay-interval*]]

Parameters

Parameter	Description	Value
track	Tracks the mode of the neighbor relationship establishment delay.	-
last-peer-expired	Indicates that neighbor relationship establishment is delayed after the neighbor relationship with the last neighbor goes Down due to packet timeout.	-
delay-time *delay-interval*	Specifies the neighbor relationship establishment delay.	The value is an integer ranging from 1 to 3600, in seconds. The default value is 60 seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On IS-IS networks, devices at both ends of a link establish a neighbor relationship by exchanging Hello packets. After the neighbor relationship is established, both devices need to send Hello packets at a specified interval to maintain the neighbor relationship. If an IS-IS device does not receive any Hello packets from the neighbor at the other end within the specified period (Holddown time), the local device considers the neighbor Down and re-establishes the neighbor relationship after it receives a new Hello packet. If links are unstable or some Hello packets are lost or incorrect due to network transmission delay or poor transmission, neighbor relationships may alternate between Up and Down frequently, which causes a route flapping.

To address this issue, run the **isis delay-peer** command to configure a neighbor relationship establishment delay after the neighbor relationship goes Down.

Pre-configuration Tasks

IS-IS has been enabled using the **isis enable** command in the interface view.

Precautions

If a new *delay-interval* is configured and it is less than the remaining time of the ongoing delay, the new *delay-interval* takes effect immediately; if the new *delay-interval* is greater than the remaining time of the ongoing delay, the ongoing delay continues until the new *delay-interval* takes effect at the next delay.

Example

Set the delay to 100s on VLANIF100 so that the neighbor relationship establishment is delayed after the neighbor relationship with the last neighbor goes Down due to packet timeout.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis delay-peer track last-peer-expired delay-time 100
```

Set the delay to 100s on GE0/0/1 so that the neighbor relationship establishment is delayed after the neighbor relationship with the last neighbor goes Down due to packet timeout.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis delay-peer track last-peer-expired delay-time 100
```

7.6.63 isis dis-name

Function

The **isis dis-name** command configures a host name for the DIS.

The **undo isis dis-name** command deletes the host name configured for the DIS.

By default, no host name is configured for the DIS.

Format

isis dis-name *symbolic-name*

undo isis dis-name

Parameters

Parameter	Description	Value
symbolic-name	Specifies a host name for the DIS.	The value is a string of 1 to 64 characters without spaces. It is case sensitive. **NOTE** When double quotation marks are used around the string, spaces are allowed in the string.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

You can configure the name for the DIS on an interface only after you run the **isis enable** command to enable IS-IS on the interface. The DIS name is advertised in a pseudo-node LSP. In this manner, the configured DIS name is associated with the system ID of the DIS.

NOTE

This command takes effect only on the DIS in the broadcast network.

If the **isis circuit-type** command is run to emulate the interface as a P2P interface, the **isis dis-name** command becomes invalid on the interface; after the **undo isis circuit-type** command is run to restore the broadcast interface, the **isis dis-name** command becomes valid on the interface.

Example

Configure a host name for the DIS on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
```

```
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis dis-name LOCALAREA
```

Configure a host name for the DIS on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis dis-name LOCALAREA
```

7.6.64 isis dis-priority

Function

The **isis dis-priority** command sets the priority of the IS-IS interface that is a candidate for the DIS at a specified level.

The **undo isis dis-priority** command restores the default priority.

By default, the DIS priority of broadcast IS-IS interfaces at Level-1 and Level-2 is 64.

Format

isis dis-priority *priority* [**level-1** | **level-2**]

undo isis dis-priority [*priority*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
priority	Specifies the priority for DIS election.	The value is an integer that ranges from 0 to 127. The default value is 64. A larger value indicates a higher DIS priority.
level-1	Indicates the DIS priority of interfaces at Level 1. If the level is not specified, the same priority is set for Level-1 and Level-2 interfaces.	-
level-2	Indicates the DIS priority of interfaces at Level 2. If the level is not specified, the same priority is set for Level-1 and Level-2 interfaces.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The configuration is useful only for the broadcast network.

The DIS priority is advertised through Hello packets. The switch with the highest priority is elected as the DIS. In the case of the same priority, the switch with the largest MAC address is elected as the DIS.

NOTE

IS-IS has been enabled on the interface using the **isis enable** command.

If the **isis circuit-type** command is run to emulate the interface as a P2P interface, the **isis dis-priority** command becomes invalid on the interface; after the **undo isis circuit-type** command is run to restore the broadcast interface, the **isis dis-priority** command becomes valid on the interface.

Example

Set the Level-2 priority for electing the DIS to 127 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis dis-priority 127 level-2
```

Set the Level-2 priority for electing the DIS to 127 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis dis-priority 127 level-2
```

7.6.65 isis enable

Function

The **isis enable** command enables IS-IS on an interface and specifies the ID of the IS-IS process to be associated with the interface.

The **undo isis enable** command disables IS-IS on an interface and cancels the ID of the IS-IS process associated with the interface.

By default, IS-IS is disabled on an interface.

Format

isis enable [*process-id*]

undo isis enable

Parameters

Parameter	Description	Value
process-id	Specifies an IS-IS process ID.	The value is an integer that ranges from 1 to 65535. The default value is 1.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an IS-IS process is configured in the system view, to make the IS-IS protocol function normally, enable IS-IS on an interface to associate the interface with the IS-IS process.

Prerequisites

An IS-IS process has been enabled using the **isis** command in the system view.

Precautions

An interface can be associated with only one IS-IS process.

Example

Create IS-IS process 1 and activate the process on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
```

Create IS-IS process 1 and activate the process on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
```

7.6.66 isis lfa-backup

Function

The **isis lfa-backup** command enables an IS-IS interface to participate in loop-free alternate (LFA) calculation so that the interface can be a candidate for a backup interface.

The **undo isis lfa-backup** command disables an IS-IS interface from participating in LFA calculation.

By default, an IS-IS interface can participate in LFA calculation.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

isis lfa-backup [**level-1** | **level-2** | **level-1-2**]

undo isis lfa-backup [**level-1** | **level-2** | **level-1-2**]

Parameters

Parameter	Description	Value
level-1	Indicates that an interface can be a backup interface in Level-1 areas.	-
level-2	Indicates that an interface can be a backup interface in Level-2 areas.	-
level-1-2	Indicates that an interface can be a backup interface in both Level-1 and Level-2 areas.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

To facilitate traffic management and avoid the uncertainty in the traffic forwarding path in the case the primary link fails, run the **undo isis lfa-backup** command on some interfaces to disable them from participating in LFA calculation.

IS-IS has been enabled on the interface using the **isis enable** command.

Example

Disable VLANIF100 from becoming a backup interface for IS-IS Auto FRR.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] undo isis lfa-backup
```

Disable GE0/0/1 from becoming a backup interface for IS-IS Auto FRR.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] undo isis lfa-backup
```

7.6.67 isis lsp seq-overflow auto-recover disable

Function

The **isis lsp seq-overflow auto-recover disable** command prevents an IS-IS system from changing its system ID when it receives a locally generated LSP with the maximum sequence number (0xFFFFFFFF).

The **undo isis lsp seq-overflow auto-recover disable** command restores the default configuration.

By default, an IS-IS system changes its system ID when it receives a locally generated LSP with the maximum sequence number.

Format

isis lsp seq-overflow auto-recover disable

undo isis lsp seq-overflow auto-recover disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IS-IS network, if a device receives a locally generated LSP with the sequence number greater than that of the corresponding LSP stored locally, the device adds 1 to the sequence number of the received LSP and floods it. An attacker may send an IS-IS LSP with the maximum sequence number (0xFFFFFFFF) and the system ID of a target device. Upon receipt of the LSP, the target device considers it a locally generated LSP because it carries the local system ID and adds 1 to the sequence number because the sequence number is greater than that of the corresponding LSP stored locally. Consequently, the sequence number exceeds the maximum number, causing the target device to enter the hibernation state. The state can last 18 hours and 1 minute, affecting network operation. To prevent this problem, an IS-IS system changes its system ID when it receives a locally generated LSP with the sequence number of 0xFFFFFFFF. However, if the IS-IS system has changed its system ID for three times within 24 hours when it receives one more such an LSP, it directly enters the hibernation state.

The preceding function also applies to CSNPs and PSNPs.

By default, an IS-IS system changes its system ID when it receives a locally generated LSP with the maximum sequence number. To disable this function, run the **isis lsp seq-overflow auto-recover disable** command.

Example

Prevent an IS-IS system from changing its system ID when it receives a locally generated LSP with the maximum sequence number (0xFFFFFFFF).

```
<HUAWEI> system-view
[HUAWEI] isis lsp seq-overflow auto-recover disable
```

7.6.68 isis mesh-group

Function

The **isis mesh-group** command adds an IS-IS interface to a specified mesh group.

The **undo isis mesh-group** command deletes an IS-IS interface from a specified mesh group.

By default, an IS-IS interface does not belong to any mesh group and floods LSPs normally.

Format

isis mesh-group { *mesh-group-number* | **mesh-blocked** }

undo isis mesh-group

Parameters

Parameter	Description	Value
mesh-group-number	Specifies the mesh group number.	The value is an integer that ranges from 1 to 4294967295.

Parameter	Description	Value
mesh-blocked	Blocks an interface to prevent it from flooding received LSPs to other interfaces.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When receiving LSPs, the interface, not in the mesh group, floods the LSPs to other interfaces following the normal procedure. For the NBMA network that is with higher connectivity and several P2P links, this process causes repeated LSP flooding and wastes bandwidth.

After receiving LSPs, the interface that joins a mesh group only floods the LSPs to the interfaces that are not in the local mesh group.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

When adding interfaces to mesh groups or blocking interfaces, keep certain interfaces from being configured with the isis mesh-group command. This can prevent link faults from affecting the normal spreading of LSPs.

Example

Add VLANIF100 to mesh group 3.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis mesh-group 3
```

Add GE0/0/1 to mesh group 3.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis mesh-group 3
```

7.6.69 isis padding-hello

Function

The **isis padding-hello** command configures an IS-IS interface to send Hello packets with the padding field.

The **undo isis padding-hello** command restores the default setting.

By default, an IS-IS interface is not configured to send Hello packets with the padding field.

Format

isis padding-hello

undo isis padding-hello

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The **isis padding-hello** and **isis small-hello** commands are mutually exclusive and cannot be configured on the same interface simultaneously.

If an interface that is not configured with the two commands, it sends Hello packets based on the following rules:

- For a P2P interface
  - Before the P2P neighbor relationship is established, the P2P interface sends Hello packets with the padding field.
  - After the P2P neighbor relationship is established, the P2P interface sends Hello packets without the padding field.

  NOTE

  For a P2P interface, the length of the padding field is equal to the length of LSP packets generated by the local IS.
- For a broadcast interface

  It sends Hello packets with the padding field.

  NOTE

  For a broadcast interface, the length of padding field is equal to the length of MTU.

IS-IS has been enabled on the interface using the **isis enable** command.

Example

Configure VLANIF100 to send Hello packets with the padding field.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis padding-hello
```

Configure GE0/0/1 to send Hello packets with the padding field.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis padding-hello
```

7.6.70 isis peer-ip-ignore

Function

The **isis peer-ip-ignore** command configures IS-IS not to check the IP address of Hello packets received by an interface.

The **undo isis peer-ip-ignore** command restores the default setting.

By default, IS-IS checks the IP address of received Hello packets.

Format

isis peer-ip-ignore

undo isis peer-ip-ignore

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, IS-IS checks the IP address carried in the Hello packet. The neighbor relationship can be set up only when the local interface address and the interface address carried in the received packets belong to the same network segment. When the two interface IP addresses are not in the same network segment, if the **isis peer-ip-ignore** command is used, the check on the peer IP address is ignored, and the two IS-IS interfaces can set up normal neighbor relationship. Routes of this two network segments exist in the routing table, but cannot ping through each other.

Precautions

This command is valid for P2P interfaces, NBMA interfaces and the interface with the network type configured to P2P by using the **isis circuit-type p2p** command. The command takes effect only when the command is used on the two ends of the link.

NOTE

- For the broadcast interface, you can run the **isis peer-ip-ignore** command only after you run the **isis circuit-type p2p** command. The **isis circuit-type p2p** command is valid only for the broadcast interface.
- For the P2P and NBMA interfaces, you can run the **isis peer-ip-ignore** command without running the **isis circuit-type p2p** command.

Example

Configure VLANIF100 not to check the IP address of the Hello packets sent by the peer.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-type p2p
[HUAWEI-Vlanif100] isis peer-ip-ignore
```

Configure GE0/0/1 not to check the IP address of the Hello packets sent by the peer.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-type p2p
[HUAWEI-GigabitEthernet0/0/1] isis peer-ip-ignore
```

7.6.71 isis ppp-negotiation

Function

The **isis ppp-negotiation** command specifies the PPP negotiation mode for establishing neighbor relationships.

The **undo isis ppp-negotiation** command restores the default negotiation mode.

By default, the 3-way handshake mode is used.

Format

isis ppp-negotiation { **2-way** | **3-way** [**only**] }

undo isis ppp-negotiation

Parameters

Parameter	Description	Value
2-way	Establishes the neighbor relationship using the 2-way handshake negotiation mode.	-
3-way	Establishes the neighbor relationship using the 3-way handshake negotiation mode.	-
only	Establishes the neighbor relationship using the 3-way handshake negotiation mode that is not backward compatible.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The 3-way handshake negotiation mode is backward compatible. If the neighbor only supports 2-way handshake, use the 2-way handshake negotiation mode to establish a neighbor relationship.

The command is applicable only for P2P interfaces. It can be used on the broadcast interfaces only after the circuit type is set to P2P.

Example

Establish the neighbor relationship on VLANIF100 using the 2-way handshake negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-type p2p
[HUAWEI-Vlanif100] isis ppp-negotiation 2-way
```

Establish the neighbor relationship on GE0/0/1 using the 2-way handshake negotiation mode.

```
<HUAWEI> system-view
[HUAWEI] isis
```

```
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-type p2p
[HUAWEI-GigabitEthernet0/0/1] isis ppp-negotiation 2-way
```

7.6.72 isis ppp-osicp-check

Function

The **isis ppp-osicp-check** command enables OSICP negotiation check on a PPP interface. The negotiation status can affect IS-IS interface status.

The **undo isis ppp-osicp-check** command restores the default setting.

By default, IS-IS does not check OSICP status of PPP.

Format

isis ppp-osicp-check

undo isis ppp-osicp-check

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, OSCIP status of PPP does not affect IS-IS interface status.

After this command is configured, OSI network negotiation status of PPP can affect IS-IS interface status. When PPP senses that the OSI network fails, the link status of the IS-IS interface turns Down and the route to the network segment where the interface resides is not advertised through LSP.

Precautions

This command applies to only PPP interfaces. For other point-to-point interfaces, this command is invalid.

Example

Configure VLANIF100 to check OSICP status of PPP.

```
<HUAWEI> system-view
[HUAWEI] isis
```

```
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-type p2p
[HUAWEI-Vlanif100] isis ppp-osicp-check
```

Configure GE0/0/1 to check OSICP status of PPP.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-type p2p
[HUAWEI-GigabitEthernet0/0/1] isis ppp-osicp-check
```

7.6.73 isis purge-lsp auto-protect disable

Function

The **isis purge-lsp auto-protect disable** command disables IS-IS purge LSPs from triggering master/slave main control board switchovers.

The **undo isis purge-lsp auto-protect disable** command restores the default configuration.

By default, IS-IS purge LSPs trigger master/slave main control board switchovers.

Format

isis purge-lsp auto-protect disable

undo isis purge-lsp auto-protect disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When an IS-IS process on a device proactively sends a purge LSP, the device deletes the corresponding LSP and floods it to the network. In most cases, before the device sends a purge LSP, the end that generated the corresponding LSP sends an updated LSP. If the clock on the device runs fast, the device frequently floods purge LSPs to devices on the entire network, causing network flapping. If the device generates more than five purge LSPs for 80% or more non-pseudonode LSPs with a non-zero fragment number in the local LSDB within 6500s, a master/

slave main control board switchover is performed if the device has two main control boards, or the device is restarted if it has only one main control board. The switchover or restart prevents network flapping.

By default, IS-IS purge LSPs trigger master/slave main control board switchovers. To disable IS-IS purge LSPs from triggering master/slave main control board switchovers, run the **isis purge-lsp auto-protect disable** command.

Example

Disable IS-IS purge LSPs from triggering master/slave main control board switchovers.

```
<HUAWEI> system-view
[HUAWEI] isis purge-lsp auto-protect disable
```

7.6.74 isis silent

Function

The **isis silent** command configures an IS-IS interface as a silent interface. That is, the interface is suppressed from sending and receiving IS-IS packets, but routes of the network segment on which the interface resides can be advertised.

The **undo isis silent** command restores the default setting.

By default, no IS-IS interface is configured as a silent interface.

Format

isis silent [**advertise-zero-cost**]

undo isis silent

Parameters

Parameter	Description	Value
advertise-zero-cost	Specifies the route cost as 0. The default cost of IS-IS routes is 10.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an IS-IS network is connected to other ASs, it is required to enable IS-IS on the interfaces that connect the IS-IS network to other ASs so that the switch on the IS-IS network can learn the routes to other ASs. This interface, however, unnecessarily advertises IS-IS Hello packets on its network segment. In this case, you can run the **isis silent** command to suppress the IS-IS interface.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Example

Configure VLANIF100 as a silent interface.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis silent
```

Configure GE0/0/1 as a silent interface.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis silent
```

7.6.75 isis small-hello

Function

The **isis small-hello** command configures an IS-IS interface to send Hello packets without the padding field.

The **undo isis small-hello** command restores the default setting.

By default, an IS-IS interface is not configured to send Hello packets without the padding field.

Format

isis small-hello

undo isis small-hello

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The command can simplify the operations of sending and receiving Hello packets.

The **isis small-hello** and **isis padding-hello** commands are mutually exclusive and cannot be configured on the same interface simultaneously.

If an interface is not configured with the two commands, it sends Hello packets based on the following rules:

- P2P interface
  - Before the P2P neighbor relationship is established, the P2P interface sends Hello packets with the padding field.
  - After the P2P neighbor relationship is established, the P2P interface sends Hello packets without the padding field.

  NOTE

  For a P2P interface, the length of the padding field is equal to the length of LSP packets generated by the local IS.
- Broadcast interface

  The interface sends Hello packets with the padding field.

  NOTE

  For a broadcast interface, the length of padding field is equal to the length of MTU.

Before running this command on an interface, run the **isis enable** command on the interface to enable IS-IS.

Example

Configure VLANIF100 to send Hello packets without the padding field.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis small-hello
```

Configure GE0/0/1 to send Hello packets without the padding field.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis small-hello
```

7.6.76 isis suppress-flapping peer

Function

The **isis suppress-flapping peer** command configures detection parameters for IS-IS neighbor relationship flapping suppression.

The **undo isis suppress-flapping peer** command restores the default detection parameters.

By default, the detection interval of IS-IS neighbor relationship flapping suppression is 60s, the suppression threshold is 10, and the interval for exiting from suppression is 120s.

Format

isis suppress-flapping peer { **detecting-interval** *detecting-interval* | **threshold** *threshold* | **resume-interval** *resume-interval* } *

undo isis suppress-flapping peer { **detecting-interval** [*detecting-interval*] | **threshold** [*threshold*] | **resume-interval** [*resume-interval*] } *

Parameters

Parameter	Description	Value
detecting-interval *detecting-interval*	Specifies the detection interval of IS-IS neighbor relationship flapping suppression. Each IS-IS interface on which IS-IS neighbor relationship flapping suppression is enabled starts a flapping counter. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping_event is recorded, and the flapping_count is incremented by 1.	The value is an integer ranging from 1 to 300, in seconds. The default value is 60s.
threshold *threshold*	Specifies the threshold of IS-IS neighbor relationship flapping suppression. When the flapping-count reaches or exceeds *threshold*, flapping suppression takes effect.	The value is an integer ranging from 1 to 1000. The default value is 10.

Parameter	Description	Value
resume-interval *resume-interval*	- Specifies the interval for exiting from IS-IS neighbor relationship flapping suppression. If the interval between two successive neighbor status changes from Full to a non-Full state is longer than *resume-interval*, the flapping-count is reset. - If IS-IS neighbor relationship flapping suppression works in hold-max-cost mode, *resume-interval* indicates the duration of this mode. **NOTE** The value of *resume-interval* must be greater than that of *detecting-interval*.	The value is an integer ranging from 2 to 1000, in seconds. The default value is 120s.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure detection parameters for IS-IS neighbor relationship flapping suppression on an interface, run the **isis suppress-flapping peer** command. However, keeping the default configurations is recommended.

Prerequisites

IS-IS neighbor relationship flapping suppression must have been enabled globally before you configure detection parameters for it. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure the detection parameters.

Example

Set the detection interval of IS-IS neighbor relationship flapping suppression to 5s, the suppression threshold to 40, and the interval for exiting from suppression to 20s on VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis suppress-flapping peer detecting-interval 5 threshold 40 resume-interval 20
```

7.6.77 isis suppress-flapping peer disable

Function

The **isis suppress-flapping peer disable** command disables IS-IS neighbor relationship flapping suppression from an interface.

The **undo isis suppress-flapping peer disable** command enables IS-IS neighbor relationship flapping suppression on an interface.

By default, IS-IS neighbor relationship flapping suppression is enabled on all interfaces.

Format

isis suppress-flapping peer disable

undo isis suppress-flapping peer disable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, IS-IS neighbor relationship flapping suppression is enabled on all interfaces in the same IS-IS process. To disable the function from one of the interfaces, run the **isis suppress-flapping peer disable** command.

NOTE

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

Prerequisites

IS-IS neighbor relationship flapping suppression must have been enabled globally before you enable the function on an interface using the **undo isis suppress-flapping peer disable** command. By default, the function is enabled globally. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it first.

Example

Disable IS-IS neighbor relationship flapping suppression from VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis suppress-flapping peer disable
```

7.6.78 isis suppress-flapping peer hold-down

Function

The **isis suppress-flapping peer hold-down** command configures the Hold-down mode and sets duration for this mode.

The **undo isis suppress-flapping peer hold-down** command cancels the Hold-down mode.

By default, the Hold-down mode is disabled.

Format

isis suppress-flapping peer hold-down *interval*

undo isis suppress-flapping peer hold-down [*interval*]

Parameters

Parameter	Description	Value
interval	Specifies the duration of the Hold-down mode.	The value is an integer ranging from 1 to 600, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use the maximum value (16777214 for the wide mode and 63 for the narrow mode) as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set duration for this mode, run the **isis suppress-flapping peer hold-down** *interval* command.

Prerequisites

IS-IS neighbor relationship flapping suppression must have been enabled globally before you configure the Hold-down mode and set duration for this mode. By default, the function is enabled. If it is disabled, run the **undo suppress-flapping peer disable** command to enable it before you configure the Hold-down mode and set duration for this mode.

Example

Configure the Hold-down mode and set its duration to 200s on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis suppress-flapping peer hold-down 200
```

7.6.79 isis suppress-flapping peer hold-max-cost disable

Function

The **isis suppress-flapping peer hold-max-cost disable** command disables the Hold-max-cost mode.

The **undo isis suppress-flapping peer hold-max-cost disable** command enables the Hold-max-cost mode.

By default, the Hold-max-cost mode is enabled.

Format

isis suppress-flapping peer hold-max-cost disable

undo isis suppress-flapping peer hold-max-cost disable

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use the maximum value (16777214 for the wide mode and 63 for the narrow mode) as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link. If a device on a key path is isolated from the network due to IS-IS neighbor relationship flapping, the network is separated into two isolated parts. To prevent this problem, use the Hold-max-cost mode on the key path.

If the neighbor relationship does not go Down within successive **resume-interval**s, or the interval between two successive neighbor Down events is greater than or equal to **resume-interval**, the suppression in Hold-max-cost mode exits.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. To configure the Hold-down mode and set duration for this mode, run the **isis suppress-flapping peer hold-down** *interval* command.

Precautions

The Hold-max-cost mode takes effect only unidirectionally. If a remote device does not support IS-IS neighbor relationship flapping suppression, bidirectional traffic between the local and remote devices may travel along different paths.

Example

Disable the Hold-max-cost mode on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis suppress-flapping peer hold-max-cost disable
```

7.6.80 isis suppress-reachability

Function

The **isis suppress-reachability** command suppresses the advertisement of direct routes on an IS-IS interface in a specified topology.

The **undo isis suppress-reachability** command restores the default setting.

By default, direct routes on an IS-IS interface are advertised.

Format

isis suppress-reachability [**level-1** | **level-1-2** | **level-2**]

undo isis suppress-reachability

Parameters

Parameter	Description	Value
level-1	Indicates that the advertisement of IPv4 addresses is suppressed on Level-1 interfaces. If the level is not specified, the advertisement of IPv6 addresses on Level-1 and Level-2 interfaces is suppressed.	-
level-1-2	Indicates that the advertisement of IPv4 addresses is suppressed on Level-1 and Level-2 interfaces.	-
level-2	Indicates that the advertisement of IPv4 addresses is suppressed on Level-2 interfaces. If the level is not specified, the advertisement of IPv4 addresses is suppressed on Level-1 and Level-2 interfaces.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Before running this command on an interface, run the **isis enable** command on the interface to enable IS-IS.

Example

Suppress the advertisement of IPv4 addresses on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis suppress-reachability
```

Suppress the advertisement of IPv4 addresses on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis suppress-reachability
```

7.6.81 isis system-id auto-recover disable

Function

The **isis system-id auto-recover disable** command disables the system from automatically resolving IS-IS system ID conflicts.

The **undo isis system-id auto-recover disable** command enables the system to automatically resolve IS-IS system ID conflicts.

By default, if the system detects an IS-IS system ID conflict, it automatically changes the local system ID to resolve the conflict.

Format

isis system-id auto-recover disable

undo isis system-id auto-recover disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A system ID uniquely identifies an IS-IS device. If the same system ID is configured for more than one device on the network, a routing loop may occur. By default, if the system detects an IS-IS system ID conflict, it automatically changes the local system ID to resolve the conflict.

To disable the system from automatically resolving IS-IS system ID conflicts, run the **isis system-id auto-recover disable** command. After the command is run, IS-IS system ID conflicts need to be manually resolved.

NOTE

The first two bytes of the system ID automatically changed by the system are Fs, and the last four bytes are randomly generated. For example, FFFF:1234:5678 is such a system ID.

Precautions

If an IS-IS system ID conflict occurs between two directly connected devices, a neighbor relationship fails to be established only between the two devices, without affecting the entire network. As a result, the conflict is not automatically resolved in this case.

On broadcast networks, the system ID generated automatically is not recorded in the configuration file. If the device is restarted, the system restores this system ID to the originally configured one and then generates another one, which may be different from the one last generated automatically. If the conflict persists after the system automatically generates three system IDs, the system no longer resolves this conflict.

Example

Disable the system to automatically resolve IS-IS system ID conflicts.

```
<HUAWEI> system-view
[HUAWEI] isis system-id auto-recover disable
```

7.6.82 isis tag-value

Function

The **isis tag-value** command sets the administrative tag value of an IS-IS interface.

The **undo isis tag-value** command deletes the administrative tag value on an IS-IS interface.

By default, an IS-IS interface has no administrative tag value.

Format

isis tag-value *tag* [**level-1** | **level-2**]

undo isis tag-value [*tag*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
tag	Specifies the administrative tag of an IS-IS interface.	The value is an integer that ranges from 1 to 4294967295.
level-1	Indicates the administrative tag value of a Level-1 interface. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-
level-2	Indicates the administrative tag value of a Level-2 interface. If the interface level is not specified, the administrative tag value is set for Level-1 and Level-2 interfaces.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An administrative tag carries administrative information about IP address prefixes. The tag can be used to import routes of different levels and different areas. Administrative tags can advertise IP address prefixes in an IS-IS routing domain to control routes and simplify management.

Using the **isis tag-value** command, you can set the administrative tag value for all routes of a specified IS-IS process. The tag can be used as a filtering condition of a route-policy to filter routes.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

The advertised LSPs contain the administrative tag value only when the IS-IS cost style is wide, wide-compatible, or compatible.

The administrative tag value set using the **isis tag-value** command has a higher priority than the administrative tag value set using the **circuit default-tag** command.

Example

Set the administrative tag value of VLANIF100 to 77.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis tag-value 77
```

Set the administrative tag value of GE0/0/1 to 77.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis tag-value 77
```

7.6.83 isis timer csnp

Function

The **isis timer csnp** command sets the interval for sending CSNPs on a broadcast network.

The **undo isis timer csnp** command restores the default setting.

By default, the interval for sending CSNPs on a broadcast network is 10 seconds.

Format

isis timer csnp *csnp-interval* [**level-1** | **level-2**]

undo isis timer csnp [*csnp-interval*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
csnp-interval	Specifies the interval for sending CSNPs on a broadcast network.	The value is an integer that ranges from 1 to 65535, in seconds. The default value is 10 seconds.
level-1	Indicates the interval for sending Level-1 CSNPs. If no level is specified, the interval for the IS-IS process of the current level to send CSNP packets is set by default.	-
level-2	Indicates the interval for sending Level-2 CSNPs. If no level is specified, the interval for the IS-IS process of the current level to send CSNP packets is set by default.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a broadcast network, a DIS sends CSNPs periodically to enable all devices to synchronize LSDBs with one another. If a device finds that the local LSDB does not have a specific LSP or an existing LSPs is not the latest one after the device has received a CSNP, the device will send a PSNP to request the corresponding LSP. Only a DIS sends CSNPs periodically. Therefore, the **isis timer csnp** command will take effect only on a broadcast interface of the DIS. This command can be used to set an interval for sending CSNPs in an area at a specified level. A router may be elected as a DIS in both Level-1 and Level-2 areas. Therefore, you can set different intervals at which the DIS sends CSNPs in Level-1 and Level-2 areas.

Precautions

The IS-IS route convergence speed depends on the LSDB synchronization speed. Therefore, reducing the interval for sending CSNPs can speed up LSDB synchronization and IS-IS route convergence. If the interval is set too small, however, the DIS will send CSNPs frequently. This causes high CPU, memory, and network bandwidth usage and affects services.

NOTE

If the **isis circuit-type** command is run to emulate the interface as a P2P interface, the **isis timer csnp** command becomes invalid on the interface; after the **undo isis circuit-type** command is run to restore the broadcast interface, the interval for sending CSNPs is restored to the default setting.

Example

Set the interval for sending Level-2 CSNPs to 15 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer csnp 15 level-2
```

Set the interval for sending Level-2 CSNPs to 15 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer csnp 15 level-2
```

7.6.84 isis timer hello

Function

The **isis timer hello** command sets the interval for sending Hello packets on an IS-IS interface.

The **undo isis timer hello** command restores the default setting.

By default, the interval for sending Hello packets 10 seconds on an interface.

Format

isis timer hello *hello-interval* [**level-1** | **level-2**] [**conservative**]

undo isis timer hello [*hello-interval*] [**level-1** | **level-2**] [**conservative**]

Parameters

Parameter	Description	Value
hello-interval	Specifies the interval for sending Hello packets.	The value is an integer that ranges from 3 to 255, in seconds. The default value is 10 seconds.
level-1	Indicates the interval for sending Level-1 Hello packets. If the level is not specified, the interval for sending Level-1 and Level-2 Hello packets is set by default.	-
level-2	Indicates the interval for sending Level-2 Hello packets. If the level is not specified, the interval for sending Level-1 and Level-2 Hello packets is set by default. **NOTE** Parameters **level-1** and **level-2** are configured only on a broadcast interface that is enabled with IS-IS. Level-1 and Level-2 Hello packets are sent separately and their intervals must be set respectively. There is only one Hello packet on a point-to-point link. Therefore, level-1 and level-2 parameters are not used.	-
conservative	Indicates the conservative mode of the dead timer. If the conservative mode is configured, the value configured for the dead timer takes effect even when the value is less than 10s.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS maintains neighbor relationships between neighbors by sending and receiving Hello packets. If the local device does not receive Hello packets from its neighbor within a specified period, the device considers the neighbor Down.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

The shorter the interval, the more system resources used to send Hello packets. The interval should therefore be set according to the actual conditions.

If a broadcast interface is emulated as a P2P interface through the **isis circuit-type** command or then restored to the broadcast interface through the **undo isis circuit-type** command, the interval for sending IS-IS Hello packets is restored to the default value.

Example

Set the interval for sending Level-2 Hello packets to 20 seconds on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer hello 20 level-2
```

Set the interval for sending Level-2 Hello packets to 20 seconds on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer hello 20 level-2
```

7.6.85 isis timer holding-multiplier

Function

The **isis timer holding-multiplier** command sets the multiplier of the interval for sending Hello packets to change the holdtime of IS-IS neighbor relationship.

The **undo isis timer holding-multiplier** command restores the default setting.

By default, the multiplier of the interval for sending Hello packets is 3, that is, the neighbor holdtime is three times the interval for sending Hello packets.

Format

isis timer holding-multiplier *number* [**level-1** | **level-2**]

undo isis timer holding-multiplier [*number*] [**level-1** | **level-2**]

Parameters

Parameter	Description	Value
number	Indicates that the neighbor holdtime is a multiplier of the interval for sending Hello packets.	The value is an integer that ranges from 3 to 1000. The default value is 3.
level-1	Indicates the holdtime of Level-1 neighbors. If the level is not specified, the holdtime is set for both Level-1 and Level-2 neighbors.	-
level-2	Indicates the holdtime of Level-2 neighbors. If the level is not specified, the holdtime is set for both Level-1 and Level-2 neighbors. **NOTE** Parameters **level-1** and **level-2** are configured only on a broadcast interface that is enabled with IS-IS. Level-1 and Level-2 Hello packets are sent separately and their intervals must be set respectively. There is only one Hello packet on a point-to-point link. Therefore, level-1 and level-2 parameters are not used.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Devices at both ends of a link establish a neighbor relationship by sending Hello packets to each other. After the neighbor relationship is established, both devices need to send Hello packets at a specified interval to maintain the neighbor relationship. If a device does not receive any Hello packet from its neighbor within a specified period of time, the device considers the neighbor to be Down. The specified time period is known as the neighbor holdtime.

For example, run the **isis timer hello** command on a local device to set the interval for sending Hello packets to 20s. Then, run the **isis timer holding-multiplier** 4 command. The holdtime is 80s (four times the interval for sending Hello packets). If the interval for sending Hello packets is changed using the **isis timer hello** 20 command, the holdtime will be changed accordingly.

Prerequisites

IS-IS has been enabled on the interface using the **isis enable** command.

Precautions

If the *number* value is set too large, the local device needs to wait a long time before detecting that the remote device has gone Down. This slows down IS-IS route convergence. If the value of *number* is set too small, the neighbor relationship will alternate between **Up** and **Down** when some Hello packets are lost due to transmission delays and errors on the network. This causes route flapping on the IS-IS network. Therefore, exercise caution when setting the value of *number*. Set the same interval for sending Hello packets and the same neighbor holdtime for all devices on the IS-IS network is recommended. This is to ensure that all devices detect link failures at the same time and guarantee timely IS-IS route convergence.

If a broadcast interface is emulated as a P2P interface through the **isis circuit-type** command or then restored to the broadcast interface through the **undo isis circuit-type** command, the number of Hello packets that IS-IS does not receive from a neighbor before the neighbor is declared Down is restored to the default value.

Example

Set the number of Level-2 Hello packets that IS-IS does not receive from a neighbor before the neighbor is declared Down to 6 on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer holding-multiplier 6 level-2
```

Set the number of Level-2 Hello packets that IS-IS does not receive from a neighbor before the neighbor is declared Down to 6 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer holding-multiplier 6 level-2
```

7.6.86 isis timer lsp-retransmit

Function

The **isis timer lsp-retransmit** command sets the interval for retransmitting LSPs over a P2P link.

The **undo isis timer lsp-retransmit** command restores the default value.

By default, the interval for retransmitting LSPs over a P2P link is 5 seconds.

Format

isis timer lsp-retransmit *retransmit-interval*

undo isis timer lsp-retransmit

Parameters

Parameter	Description	Value
retransmit-interval	Specifies the interval for retransmitting LSPs.	The value is an integer that ranges from 1 to 300.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a point-to-point network, devices at both ends of a link synchronize LSDBs with each other by flooding LSPs. The device at one end of the link sends an LSP. If the device at the other end receives this LSP, it replies with a PSNP. If the device that has sent an LSP does not receive a PSNP from the other end in a period of time, the device will retransmit the LSP.

The **isis timer lsp-retransmit** command is used to set an interval for retransmitting LSPs. Only the devices on a point-to-point network send PSNPs. Therefore, the **isis timer lsp-retransmit** command will take effect only when it is run on point-to-point interfaces.

Precautions

After the **isis timer lsp-retransmit** command is run on a device, the device will wait *retransmit-interval* after having sent an LSP. If the device receives a PSNP from the other end, the device will not retransmit the LSP. Otherwise, the device will retransmit the LSP.

If the value of *retransmit-interval* is set too small, an LSP will be retransmitted even though it is not necessary, causing high CPU, memory, and network bandwidth usage.

NOTE

If a broadcast interface is emulated as a P2P interface through the **isis circuit-type** command or restored a P2P interface to the broadcast interface through the **undo isis circuit-type** command, the interval for retransmitting LSP packets on a P2P link is restored to the default value.

Example

Set the interval for retransmitting LSPs on VLANIF100 to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
```

```
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis circuit-type p2p
[HUAWEI-Vlanif100] isis timer lsp-retransmit 10
```

Set the interval for retransmitting LSPs on GE0/0/1 to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis circuit-type p2p
[HUAWEI-GigabitEthernet0/0/1] isis timer lsp-retransmit 10
```

7.6.87 isis timer lsp-throttle

Function

The **isis timer lsp-throttle** command sets the minimum interval for sending LSPs on an IS-IS interface and the maximum number of LSPs sent within the interval.

The **undo isis timer lsp-throttle** command restores the default setting.

By default, the minimum interval for sending LSPs on an IS-IS interface is 50 milliseconds and the maximum number of LSPs sent within the interval is 10.

Format

isis timer lsp-throttle *throttle-interval* [**count** *count*]

undo isis timer lsp-throttle

Parameters

Parameter	Description	Value
throttle-interval	Specifies the minimum interval for sending LSPs.	The value is an integer that ranges from 1 to 10000, in milliseconds.
count *count*	Specifies the maximum number of LSPs that are sent within the interval specified by *throttle-interval*.	The value is an integer that ranges from 1 to 1000.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The value specified by *throttle-interval* is the interval between two consecutive LSPs and is also the interval for sending multiple fragments of a CSNP.

Before running this command on an interface, run the **isis enable** command on the interface to enable IS-IS.

Example

Set the interval for retransmitting LSPs on VLANIF100 to 500 ms.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer lsp-throttle 500
```

Set the interval for retransmitting LSPs on GE0/0/1 to 500 ms.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] network-entity 01.0000.0000.0001.00
[HUAWEI-isis-1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer lsp-throttle 500
```

7.6.88 is-level

Function

The **is-level** command sets the level of an IS-IS switch.

The **undo is-level** command restores the default setting.

By default, the level of an IS-IS switch is Level-1-2.

Format

is-level { **level-1** | **level-1-2** | **level-2** }

undo is-level

Parameters

Parameter	Description	Value
level-1	Indicates that the level of the switch is Level-1. The switch calculates only intra-area routes and maintains the Level-1 LSDB.	-

Parameter	Description	Value
level-1-2	Indicates that the level of the switch is Level-1-2. The switch calculates Level-1 and Level-2 routes and maintains Level-1 and Level-2 LSDBs.	-
level-2	Indicates that the level of the switch is Level-2. The switch calculates only Level-2 routes, and maintains the Level-2 LSDB.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To support a network with a large number of routes, IS-IS uses a two-level structure in an IS-IS routing domain. IS-IS switches are classified into the following levels:

- Level-1 switch: A Level-1 switch manages intra-area routing. It establishes neighbor relationships with only Level-1 and Level-1-2 switches in the same area. Level-1 switches can be connected to other areas through Level-1-2 switches only.
- Level-2 switch: A Level-2 switch manages intra-area routing. It establishes neighbor relationships with Level-2 switches in the same area and Level-1-2 switches in other areas only. All Level-2 switches form the backbone network of the routing domain. They are responsible for communications between areas. The Level-2 switches in the routing domain must be reachable, and no switch of other levels is deployed between every two Level-2 switches.
- Level-1-2 switch: A Level-1-2 switch can establish Level-1 neighbor relationships with Level-1 switches and Level-1-2 switches in the same area. It can also establish Level-2 neighbor relationships with Level-2 switches and Level-1-2 switches in other areas.

In most cases, Level-1 switches are located within an area, Level-2 switches are located between areas, and Level-1-2 switches are located between Level-1 switches and Level-2 switches.

The level of an IS-IS switch and of an interface determine the level of a neighbor relationship. By default, neighbor relationships between two Level-1-2 switches are Level-1 and Level-2. To establish a Level-1 or Level-2 neighbor relationship, run the **isis circuit-level** command to modify the level of interfaces.

If only one area exists, setting the level of switches to Level-1 or Level-2 is recommended to prevent devices from maintaining two LSDBs that are the same. On an IP network, setting the level of all switches to Level-2 for future extension is recommended.

Precautions

- If the levels of IS-IS switches are changed during network operation, the IS-IS process will be restarted and IS-IS neighbor relationships will be disconnected. Setting the levels of switches when configuring IS-IS is recommended.
- If the **is-level** command is not configured for a switch, the switch works at Level-1-2. That is, the switch calculates Level-1 and Level-2 routes and maintains Level-1 and Level-2 LSDBs simultaneously.
- When both Level-1 and Level-2 switches have routes destined for the same destination address, the route on the Level-1 switch is preferred.

Example

Set the level of the current switch to Level-1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] is-level level-1
```

7.6.89 is-name

Function

The **is-name** command enables the capability of identifying the host name in an LSP and configures the dynamic host name for the IS-IS system of the local switch. The dynamic hostname is advertised in an LSP packet.

The **undo is-name** command deletes the dynamic host name configured for the IS-IS system of the local switch.

By default, the IS-IS system of the local switch has no dynamic host name.

Format

is-name *symbolic-name*

undo is-name [*symbolic-name*]

Parameters

Parameter	Description	Value
symbolic-name	Specifies a dynamic host name.	The value is a string of 1 to 64 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

In most cases, to check information about IS-IS neighbors and LSDBs on an IS-IS switch, you need to use a system ID of a 12-digit hexadecimal number, for example, aaaa.eeee.1234. This representation, however, is complicated and not easy to use. The dynamic host name mapping mechanism is introduced to facilitate maintenance and management of IS-IS networks. The **is-name** command is used to configure a simple host name for a local switch and enables the switch to advertise it in an LSP.

After the configuration is completed, you can run the **display isis name-table** command to check the configured hostname.

Example

Configure host name **RUTA** for the local IS-IS system.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] is-name RUTA
```

7.6.90 is-name map

Function

The **is-name map** command enables the local switch to identify the host name in LSPs, and sets a static host name for a remote IS-IS system on the local switch.

The **undo is-name map** command disables the local switch from identifying the host name in LSPs, and deletes the static host name for a remote IS-IS system set by the local switch.

By default, the local switch does not identify the host name in LSPs, and has no static host name of a remote IS-IS system.

Format

is-name map *system-id symbolic-name*

undo is-name map *system-id* [*symbolic-name*]

Parameters

Parameter	Description	Value
system-id	Specifies the ID of the remote mapped IS-IS system or pseudonode ID.	The format is XXXX.XXXX.XXXX[.XX].

Parameter	Description	Value
symbolic-name	Specifies the static host name of the remote mapped IS-IS system.	The value is a string of 1 to 64 characters without spaces. It is case sensitive. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When checking information about IS-IS neighbors and LSDBs on the switch that runs IS-IS, each switch in the IS-IS routing domain is represented by a system ID with a 12-bit hexadecimal number, for example, aaaa.eeee.1234. This representation is complicated and not easy to use. To manage and maintain IS-IS networks conveniently, IS-IS uses the dynamic host name exchange mechanism. The **is-name map** command can configure a host name for the remote switch and does not advertise the host name through an LSP.

After running the **is-name map** command to map the remote switch to the host name, you can find that the system ID of the remote switch is replaced by the host name configured using the **display isis name-table** command.

Precautions

This configuration is static configuration and takes effect only on the local device. Therefore, the configured host name *symbolic-name* is not advertised through an LSP. If dynamic host name mapping is configured on an IS-IS device, dynamic host name mapping takes precedence over static host name mapping.

Example

Configure static host name mapping for the IS-IS system on the remote switch as 0000.0000.0041.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] is-name map 0000.0000.0041 RUTB
```

7.6.91 log-peer-change

Function

The **log-peer-change** command enables the output of IS-IS adjacency changes.

The **undo log-peer-change** command disables the output of IS-IS adjacency changes.

By default, the output of IS-IS adjacency changes is disabled.

Format

log-peer-change [**topology**]

undo log-peer-change

Parameters

Parameter	Description	Value
topology	Enables the output of the IS-IS adjacency changes in an IPv6 topology.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IS-IS network, IS-IS adjacency changes pose a threat to network stability, causing frequent route convergence which consumes a lot of memory resources and possible traffic loss. Therefore, diagnose the fault immediately when the IS-IS adjacency changes.

To locate the fault, run the **log-peer-change** command to enable the output of IS-IS adjacency changes and record the changes in the log.

Precautions

IS-IS adjacency changes are recorded only when the **terminal monitor** and **log-peer-change** commands are run.

Example

Enable the output of IS-IS adjacency changes on the current switch.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] log-peer-change
```

7.6.92 loop-free-alternate

Function

The **loop-free-alternate** command enables IS-IS Auto FRR to calculate loop-free backup routes using the loop-free alternate (LFA) algorithm.

The **undo loop-free-alternate** command disables IS-IS Auto FRR from calculating loop-free backup routes using the LFA algorithm.

By default, IS-IS Auto FRR is disabled from calculating loop-free backup routes using the LFA algorithm.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported
S1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S6720S-S	Not supported

Format

loop-free-alternate [**level-1** | **level-2** | **level-1-2**]

undo loop-free-alternate [**level-1** | **level-2** | **level-1-2**]

Parameters

Parameter	Description	Value
level-1	Enables Level-1 IS-IS Auto FRR to generate loop-free backup routes. If the IS level is not specified, Level-1 and Level-2 IS-IS Auto FRR is enabled to generate backup routes.	-
level-2	Enables Level-2 IS-IS Auto FRR to generate loop-free backup routes. If the IS level is not specified, Level-1 and Level-2 IS-IS Auto FRR is enabled to generate backup routes.	-
level-1-2	Enables Level-1 and Level-2 IS-IS Auto FRR to generate loop-free backup routes.	-

Views

IS-IS FRR view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IS-IS Auto FRR pre-computes a backup link by using the Loop-Free Alternate (LFA) algorithm, and then adds the backup link and the primary link to the forwarding table. In the case of an IS-IS network failure, IS-IS Auto FRR can fast switch traffic to the backup link before routes on the control plane converge.

Precautions

To make IS-IS Auto FRR to take effect, enter the IS-IS FRR view and then run the **loop-free-alternate** command.

IS-IS can generate loop-free backup routes only when the IS-IS Auto FRR traffic protection inequality is met.

Example

Enable Level-2 IS-IS Auto FRR to generate loop-free backup routes.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] frr
[HUAWEI-isis-1-frr] loop-free-alternate level-2
```

7.6.93 lsp-fragments-extend

Function

The **lsp-fragments-extend** command enables LSP fragment extension on the IS-IS switch.

The **undo lsp-fragments-extend** command disables LSP fragment extension on the IS-IS switch.

By default, LSP fragment extension is disabled on the IS-IS switch.

Format

lsp-fragments-extend [[**level-1** | **level-2** | **level-1-2**] | [**mode-1** | **mode-2**]] *

undo lsp-fragments-extend [**mode-1** | **mode-2**] [**level-1** | **level-2** | **level-1-2**]

Parameters

Parameter	Description	Value
level-1	Enables LSP fragment extension on a Level-1 switch.	-
level-2	Enables LSP fragment extension on a Level-2 switch.	-

Parameter	Description	Value
level-1-2	Enables LSP fragment extension on a Level-1-2 switch.	-
mode-1	Indicates that the switch supporting LSP fragment extension is compatible with the switch with an earlier version that does not support LSP fragment extension.	-
mode-2	Requires that all the switches support LSP fragment extension. **NOTE** By default, **mode-1** and **level-1-2** are used.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

To enable the IS-IS switch to generate extended LSP fragments, run the **virtual-system** command to configure at least one virtual system ID.

After the **lsp-fragments-extend** command is run, run the **reset isis all** command to restart the IS-IS process to make LSP fragment extension take effect.

Example

Enable Level-2 LSP fragment extension in mode 1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] lsp-fragments-extend mode-1 level-2
```

7.6.94 lsp-length

Function

The **lsp-length** command sets the length of the LSP that is generated and received by the current IS-IS switch.

The **undo lsp-length** command restores the default setting.

By default, the IS-IS switch generates and receives 1497-byte LSPs.

Format

lsp-length { **originate** | **receive** } *max-size*

undo lsp-length { **originate** | **receive** }

Parameters

Parameter	Description	Value
originate	Indicates the maximum length of generated LSPs.	-
receive	Indicates the maximum length of received LSPs.	-
max-size	Specifies the maximum length of LSPs. The *max-size* of a generated LSP must be smaller than or equal to the *max-size* of a received LSP.	The value is an integer that ranges from 512 to 16384, in bytes. The default value is 1497. **NOTE** Because the maximum MTU supported by interfaces is 9600 bytes and the LSP header length is 3 bytes, the allowed maximum LSP length is 9597 (9600 – 3) bytes to ensure that two devices on both ends communicate properly.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By controlling the length of LSPs generated and received by IS-IS switches, you can adjust the LSDB synchronization speed and change the network convergence speed.

Precautions

The *max-size* set using the **lsp-length** command must meet the following requirements:

- The MTU of an Ethernet interface must be greater than or equal to the sum of the value of *max-size* and 3.
- The MTU of a P2P interface must be greater than or equal to the value of *max-size*.

Example

Set the maximum length of an LSP generated by the IS-IS switch to 1024 bytes.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] lsp-length originate 1024
```

7.6.95 maximum load-balancing (IS-IS)

Function

The **maximum load-balancing** command sets the maximum number of equal-cost routes for load balancing. You need to set the maximum value according to memory capacity.

The **undo maximum load-balancing** command restores the default maximum number of equal-cost routes for load balancing.

By default, the maximum number of equal-cost routes on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S6720S-S, and S5736-S is 8, and the maximum number of equal-cost routes on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S is 16.

Format

maximum load-balancing *number*

undo maximum load-balancing [*number*]

Parameters

Parameter	Description	Value
number	Specifies the maximum number of equal-cost routes for load balancing.	The value is an integer that ranges from 1 to 8 on the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S and S6720S-S. The value ranges from 1 to 16 on the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple routes are available on an IS-IS network, multiple equal-cost routes may exist. Use the load balancing method to allocate traffic evenly to each link. This method improves link efficiency on the network and reduces the congestion possibility caused by overloaded links.

Specify the *number* parameter to limit the number of equal-cost routes for load balancing.

Precautions

To cancel load balancing, set the *number* parameter to 1 or run the **nexthop** command to set the preferences of equal-cost routes.

Example

Set the maximum number of equal-cost routes for load balancing to 2.

```
<HUAWEI> system-view
[HUAWEI] isis 100
[HUAWEI-isis-100] maximum load-balancing 2
```

Restore the default value.

```
<HUAWEI> system-view
[HUAWEI] isis 100
[HUAWEI-isis-100] undo maximum load-balancing
```

7.6.96 network-entity

Function

The **network-entity** command configures a network entity title (NET) for an IS-IS process.

The **undo network-entity** command deletes the NET of an IS-IS process.

By default, no NET is configured for an IS-IS process.

Format

network-entity *net*

undo network-entity *net*

Parameters

Parameter	Description	Value
net	Specifies a NET.	The format is X...X.XXXX.XXXX.XXXX.00, in which X...X indicates an area address, the 12 Xs in the middle indicate the system ID of the switch, and the last 00 indicates the selector (SEL).

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

NET is the special form of the network service access point (NSAP). After the IS-IS view is displayed, IS-IS can start only when a NET is configured for an IS-IS process.

A NET consists of the following parts:

- Area ID: is 1 to 13 bytes in length.
- System ID: is 6 bytes in length.
- SEL: is 1 byte in length and fixed as 00.

Generally, you only need to configure one NET for an IS-IS process. When an area needs to be redefined, for example, the area needs to be merged with other areas or divided into sub-areas, configure multiple NETs to ensure route correctness.

Precautions

An area address uniquely identifies an area in a routing domain. All the switches in the same Level-1 area must have the same area address. The switches in a Level-2 area can have different area addresses.

The switches in an area or a backbone area must have the same system ID.

A maximum of three area addresses can be configured for an IS-IS process. Therefore, a maximum of three NETs can be configured for an IS-IS process. When configuring multiple NETs, ensure that their system IDs are the same.

Example

Set the NET to 10.0001.1010.1020.1030.00, in which the system ID is 1010.1020.1030 and the area ID is 10.0001.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] network-entity 10.0001.1010.1020.1030.00
```

7.6.97 nexthop (IS-IS)

Function

The **nexthop** command sets the preference of equal-cost routes.

The **undo nexthop** command cancels the preference of equal-cost routes.

By default, no preference is set for equal-cost routes.

Format

nexthop *ip-address* **weight** *value*

undo nexthop *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies a next-hop IP address.	The value is in dotted decimal notation.

Parameter	Description	Value
weight *value*	Specifies the next-hop weight.	The value is an integer that ranges from 1 to 254.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When there are multiple redundant links on an IS-IS network, there may be multiple equal-cost routes to the same destination network segment.

You can use this command to set the next-hop preference to determine the next hop when the interface cost remains unchanged. A smaller preference value indicates a higher preference.

Precautions

After this command is used, an IS-IS device does not load balance traffic when forwarding the traffic. Instead, the device forwards the traffic to the next hop with the highest preference.

Example

Set the preference of IS-IS equal-cost routes.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] nexthop 10.0.0.3 weight 1
```

7.6.98 optional-checksum enable

Function

The **optional-checksum enable** command enables IS-IS to configure Hello packets and SNP packets to carry optional checksum TLVs and to check received IS-IS packets and SNP packets.

The **undo optional-checksum enable** command restores IS-IS packets to default settings.

By default, Hello packets and SNPs do not carry checksum TLVs and the receiver does not check received packets.

Format

optional-checksum enable

undo optional-checksum enable

Parameters

None

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent the attack of malicious packets and to ensure packets are correctly received on an IS-IS network, you can configure the **optional-checksum enable** command to enable IS-IS routers to send SNP packets and Hello packets carrying optional checksum TLVs. After the peer device receives the packets, it checks whether the carried optional checksum TLVs are correct. If the TLVs are not correct, the peer device rejects the packets.

Prerequisites

You have run the **isis** command to create an IS-IS process and entered the IS-IS view.

Precautions

If MD5 authentication or Keychain authentication with valid MD5 authentication is configured on an IS-IS interface or area, IS-IS routers send Hello packets and SNP packets carrying no checksum TLVs and verify the checksum of the received packets.

Example

Configure IS-IS to add optional checksum TLVs to Hello packets and SNPs.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] optional-checksum enable
```

7.6.99 preference (IS-IS)

Function

The **preference** command sets the IS-IS preference.

The **undo preference** command restores the default IS-IS preference.

The default IS-IS preference is 15.

Format

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Parameters

Parameter	Description	Value
preference	Specifies the IS-IS preference. A smaller value indicates a higher preference.	The value is an integer that ranges from 1 to 255.
route-policy *route-policy-name*	Specifies the name of a route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device may run multiple dynamic routing protocols and there may be multiple routes of different routing protocols to the same destination. Therefore, routing protocols may share and select routing information. To solve this problem, the system sets a preference for each routing protocol. If different protocols discover routes to the same destination, the system selects the route with a higher protocol preference to forward traffic.

The **preference** command can set the preference of IS-IS routes to affect routing information sharing and selection:

- The **preference** *preference* command can set the preference for all IS-IS routes.
- The **preference** *preference* **route-policy** *route-policy-name* command can set different preferences for matched and unmatched routes.
- The **preference route-policy** *route-policy-name preference* command can set the preference for matched routes without affecting the preference of other IS-IS routes.

Precautions

You can use route-policies to set the preference for specified routes. If the **apply preference** clause is configured in the **route-policy** command, the route preference is as follows:

- The preference of matched routes is set using the **apply** clause.
- The preference of unmatched routes is set using the **preference** command.

As shown in the following example, the preference of the routes that pass route-policy **abc** is set to 50 and the preference of the routes that do not pass the route-policy is set to 30.

```
#
route-policy abc permit node 1
 if-match cost 20
 apply preference 50
#
isis 1
 preference 30 route-policy abc
```

If the **apply preference 50** clause is not configured in route-policy **abc**, the preference of all routes is set to 30.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, the configured priority applies to all IS-IS routes.

Example

Set the IPv4 IS-IS preference to 25.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] preference 25
```

7.6.100 prefix-priority (IS-IS)

Function

The **prefix-priority** command sets the convergence priority of IS-IS routes.

The **undo prefix-priority** command restores the default convergence priority of IS-IS routes.

By default, the convergence priority of IS-IS host routes and default routes is medium, and the convergence priority of other IS-IS routes is low.

Format

prefix-priority [**level-1** | **level-2**] { **critical** | **high** | **medium** } { **ip-prefix** *prefix-name* | **tag** *tag-value* }

undo prefix-priority [**level-1** | **level-2**] { **critical** | **high** | **medium** }

Parameters

Parameter	Description	Value
level-1	Specifies the convergence priority of Level-1 IS-IS routes.	-

Parameter	Description	Value
level-2	Specifies the convergence priority of Level-2 IS-IS routes.	-
critical	Sets the convergence priority of IS-IS routes to critical.	-
high	Sets the convergence priority of IS-IS routes to high.	-
medium	Sets the convergence priority of IS-IS routes to medium.	-
ip-prefix *prefix-name*	Sets the convergence priority of the IS-IS routes matching the specified IP prefix.	The value is a string of 1 to 169 case-sensitive characters without spaces.
tag *tag-value*	Sets the convergence priority of the IS-IS routes with the specified tag value. To use the tag value to filter the IPv4 routes for which convergence priorities need to be set, ensure that the IS-IS cost style of sent packets is not narrow and the routes carry the tag value.	The value is an integer that ranges from 1 to 4294967295.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a routing table has a large number of routing entries on an IS-IS device, the device needs to spend much time performing SPF calculation. To enable some key routes to be calculated first, run the **prefix-priority** command to set the convergence priority for these routes.

The convergence priorities of IS-IS routes are classified as critical, high, medium, and low in descending order.

The rules for applying convergence priorities to IS-IS routes are as follows:

- Existing IS-IS routes are converged based on the priorities set using the **prefix-priority** command.
- New IS-IS routes are converged based on the priorities set using the **prefix-priority** command.
- If an IS-IS route conforms to the matching rules of multiple convergence priorities, the highest convergence priority is used.
- If the route level is not specified, the **prefix-priority** command configuration takes effect for both Level-1 and Level-2 IS-IS routes.

Precautions

The **prefix-priority** command applies only to the public network.

After the **prefix-priority** command is run to set the convergence priority for IS-IS routes (including IS-IS host routes and default routes), the convergence priority of all the IS-IS routes that meet the matching rules is changed according to the command configuration, and the convergence priority of the IS-IS routes that do not meet the matching rules is changed to low.

Example

Set the convergence priority of Level-1 routes with tag value 3 to critical.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] prefix-priority level-1 critical tag 3
```

Set the convergence priority of the routes matching IP prefix **p1** to medium.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix p1 permit 192.168.0.1 24
[HUAWEI] isis 1
[HUAWEI-isis-1] prefix-priority medium ip-prefix p1
```

7.6.101 purge-originator-identification enable

Function

The **purge-originator-identification enable** command configures IS-IS to add purge-originator-identification (POI) TLV to Purge packets. If a dynamic hostname has been configured for the local device, the hostname TLV is also added to the Purge packets.

The **undo purge-originator-identification enable** command deletes POI TLV and hostname TLV from Purge packets.

By default, Purge packets do not carry POI TLV or hostname TLV.

Format

purge-originator-identification enable [**always**]

undo purge-originator-identification enable [**always**]

Parameters

Parameter	Description
always	

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When **Remaining Lifetime** of an LSP is 0, the LSP is invalid, and this invalid packet is a Purge packet. In most cases, a Purge packet does not carry any information about the router that generated the Purge packet. Without such information, troubleshooting is difficult if a network problem occurs.

To address this issue, you can run the **purge-originator-identification enable** command to configure IS-IS to add POI TLV to Purge packets. If a dynamic hostname has been configured for the local device, the hostname TLV is also added to the Purge packets, which facilitates troubleshooting.

- If the **purge-originator-identification enable** command is run and an authentication mode is configured, generated Purge LSPs do not carry the POI TLV or hostname TLV.
- If the **purge-originator-identification enable** command is run and no authentication is configured, generated Purge LSPs will carry the POI TLV or hostname TLV.
- If the **purge-originator-identification enable always** command is run, generated Purge LSPs carry the POI TLV and hostname TLV, regardless of whether authentication is configured.

Example

Configure IS-IS to add POI TLV to Purge packets.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] purge-originator-identification enable
```

7.6.102 reset isis all

Function

The **reset isis all** command restarts IS-IS processes.

Format

reset isis all [[*process-id* | **vpn-instance** *vpn-instance-name*] | **graceful-restart**] *

reset isis *process-id* **all** [**graceful-restart**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an IS-IS process to be restarted.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance. *vpn-instance-name* specifies the name of a VPN instance.	The value must be an existing VPN instance name.
graceful-restart	Restarts an IS-IS process in GR mode.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **reset isis all** command is used when LSPs need to be updated immediately. For example, after the **area-authentication-mode** and **domain-authentication-mode** commands are used, you can run the **reset isis all** command to clear old LSPs.

Precautions

NOTICE

Restarting IS-IS processes may interrupt services. Therefore, confirm the action before running the **reset isis all** command.

Example

Restart IS-IS processes.

```
<HUAWEI> reset isis all
Warning: The ISIS process(es) will be reset. Continue?[Y/N]y
```

7.6.103 reset isis peer

Function

The **reset isis peer** command resets a specified IS-IS neighbor relationship.

Format

reset isis peer *system-id* [*process-id* | **vpn-instance** *vpn-instance-name*]

reset isis *process-id* **peer** *system-id*

Parameters

Parameter	Description	Value
system-id	Specifies the system ID of an IS-IS neighbor.	The value is 6 bytes in length and in XXXX.XXXX.XXXX format.
process-id	Specifies the IS-IS process ID for which the neighbor relationship needs to be reset.	The value is an integer that ranges from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the IS-IS multi-instance process in a specified VPN instance. This parameter is optional for a default VPN instance.	The value must be an existing VPN instance name.

Views

User view

Default Level

3: Management level

Usage Guidelines

The **reset isis peer** command is used when a device needs to re-establish the neighbor relationship with a specified neighbor.

NOTICE

Exercise caution when using the **reset isis peer** command. This command will re-establish neighbor relationships with a specified neighbor, which may result in route flapping.

Example

Reset the IS-IS neighbor with system ID 0000.0c11.1111.

```
<HUAWEI> reset isis peer 0000.0c11.1111
```

7.6.104 reset isis suppress-flapping peer

Function

The **reset isis suppress-flapping peer** command forces an interface to exit from IS-IS neighbor relationship flapping suppression.

Format

reset isis *process-id* **suppress-flapping peer** [**interface** *interface-type interface-number*] [**notify-peer**]

Parameters

Parameter	Description	Value
process-id	Specifies the ID of an IS-IS process.	The value is an integer ranging from 1 to 65535.
interface *interface-type interface-number*	Specifies an interface type and number.	-
notify-peer	Instructs neighbors to exit from IS-IS neighbor relationship flapping suppression too.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Interfaces exit from flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding IS-IS process is reset.
- An IS-IS neighbor is reset using the **reset isis peer** command.
- IS-IS neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable (IS-IS)** command in the IS-IS view.
- The **reset isis suppress-flapping peer** command is run.
- Suppression is aborted forcibly using the **reset isis** *process-id* **suppress-flapping peer** [**interface** *interface-type interface-number*] **notify-peer** command on the remote device.

Example

Force interfaces to exit from IS-IS neighbor relationship flapping suppression.

```
<HUAWEI> reset isis 1 suppress-flapping peer
```

7.6.105 set-overload

Function

The **set-overload** command sets the overload bit for non-pseudonode LSPs.

The **undo set-overload** command removes the overload bit of non-pseudonode LSPs.

By default, no overload bit is set for non-pseudonode LSPs.

Format

set-overload [**on-startup** [*timeout1* | **start-from-nbr** *system-id* [*timeout1* [*timeout2*]] | **wait-for-bgp** [*timeout1*]] [**send-sa-bit** [*timeout3*]]] [**allow** { **interlevel** | **external** }*]

undo set-overload

Parameters

Parameter	Description	Value
on-startup	Indicates that the overload bit remains set within the specified period when the switch restarts or is faulty.	-
timeout1	Specifies the duration of the overload bit after the system starts.	The value is an integer that ranges from 5 to 86400, in seconds. The default value is 600 seconds.
start-from-nbr *system-id*	Specifies the duration of the system overload bit according to the status of a specified neighbor.	The value is in XXXX.XXXX.XXXX format.

Parameter	Description	Value
timeout1 [*timeout2*]	Specifies the period during which the overload bit remains set, which is related to the neighbor status.	- If the specified neighbor does not go Up before *timeout2* expires, the duration of the system overload bit is *timeout2*. *timeout2* ranges from 5 to 86400, in seconds. The default value is 1200 seconds (20 minutes). - If the specified neighbor goes Up before *timeout2* expires, the duration of the system overload bit is *timeout1*. *timeout1* ranges from 5 to 86400, in seconds. The default value is 600 seconds (10 minutes).
wait-for-bgp	Specifies the period during which the overload bit of the system remains set according to the BGP convergence status.	-
send-sa-bit	Specifies the overload bit remains in Hello packets after the device is started.	-
timeout3	Specifies the period during which the overload bit remains in Hello packets after the device is started.	The value is an integer ranging from 5 to 120, in seconds. The default value is 30 seconds.
allow	Allows advertising IP prefixes. By default, the system is prohibited from advertising IP prefixes when the system enters the overload state.	-
interlevel	Allows advertising the IP prefixes learned from IS-IS of different levels when **allow** is specified.	-
external	Allows advertising the IP prefixes learned from other protocols when **allow** is specified.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Although LSPs with the overload bit are flooded on the network, the LSPs are ignored in the calculation of the routes that pass through the switch in overload state. That is, after the overload bit is set on the switch, other switches ignore the switch when performing SPF calculation. Direct routes of the switch are not ignored during SPF calculation.

To prevent the local switch from being used by other switches to perform SPF calculation, run the **set-overload** command on the local switch without specifying the **on-startup** keyword. Then the system immediately sets the overload bit in the LSP to be sent. To remove the overload bit, run the **undo set-overload** command.

When the local switch restarts or is faulty, to prevent the local switch from being used by other switches to perform SPF calculation, run the **set-overload** command on the local switch and specify the **on-startup** keyword.

When the switch is experiencing memory shortage, the system automatically sets the overload bit in the sent LSPs regardless of whether the **set-overload** command is run.

You can set the overload bit to solve the problem of network traffic loss caused by the difference between the BGP convergence speed and IGP convergence speed.

Precautions

If a TE LSP uses the local device as a transit node before the **set-overload** command is run, the TE LSP is not torn down and re-established and still uses the local device as a transit node after the **set-overload** command is run; if the local device is restarted after the command is run and fast convergence is not configured on the ingress of the RSVP-LSP, TE LSP forwarding fails, and services are affected. Therefore, the **mpls te path-selection overload** command needs to be run on the ingress of the RSVP-LSP before the device is restarted.

Example

Set the overload bit for IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis
[HUAWEI-isis-1] set-overload
Warning: The IS-IS process overload state will be set. Continue?[Y/N]
```

7.6.106 spf-priority

Function

The **spf-priority** command sets the priority of SPF calculation.

The **undo spf-priority** command restores the default priority of SPF calculation.

By default, the priority of SPF calculation in a base topology is 64.

Format

spf-priority *priority-value*

undo spf-priority

Parameters

Parameter	Description	Value
priority-value	Specifies the priority of SPF calculation. A larger value indicates a higher priority.	The value is an integer that ranges from 1 to 127.

Views

IS-IS view
