State	Status of the MSDP session. ● Up: The connection is set up and is in the Up state. ● Listen: The local device acts as the server. The connection is not set up. ● Connect: The local device acts as the client. The connection is not set up. ● Shutdown: The MSDP peer is in Shutdown state. ● Down: The connection fails.
Up/down time	Time when the session becomes Up or Down. The time format is as follows: ● Time that is shorter than or equal to 24 hours: hour: minute: second. ● Time that is longer than 24 hours but shorter than or equal to one week: day: hour. ● Time that is longer than one week: week: day.
Resets	Resetting times.

Item	Description
Connection interface	Address of a connect-interface that is used to set up the TCP connection with the peer address. This parameter is configured using the **peer connect-interface (MSDP)** command.
Number of sent/ received messages	Number of MSDP messages received or sent through the connection.
Number of discarded output messages	Number of discarded messages.
Elapsed time since last connection or counters clear	Time that elapsed since the MSDP peer resetting count and control packet statistics were reset.
Information about (Source, Group)-based SA filtering policy	- Import policy: is used to receive the filtering list of the SA messages of a specified MSDP peer. You can configure the policy using the **peer sa-policy import** command. - Export policy: is used to forward the filtering list of the SA messages of a specified MSDP peer. You can configure the policy using the **peer sa-policy export** command. - Local Export policy: is used to send the policy of locally created SA messages tof a specified MSDP peer. You can configure the policy using the **peer sa-policy local-export** command. By default, a device accepts all SA messages from MSDP peers, sends all locally created SA messages to MSDP peers, and forwards all SA messages to MSDP peers.
Information about SA-Requests	- Policy to accept SA-Request messages: restricts the SA request messages received from an MSDP peer by the switch. By default, the switch receives all the SA Request messages sent by the MSDP peer. The item is expressed by none. You can set the policy using the **peer sa-request-policy** command. - Sending SA-Requests status: enables or disables the switch to send SA request messages to a specified MSDP peer when the switch receives a Join message. By default, when receiving a Join message, the switch does not send the SA Request message to its MSDP peers, but waits for the next SA message. You can configure the switch to send SA Request messages using the **peer request-sa-enable** command.

Item	Description
Minimum TTL to forward SA with encapsulated data	If the SA message received is encapsulated with the multicast data packet, the switch forwards the SA message to other peers only when the TTL of the packet is not smaller than the minimum TTL. You can configure the function using the **peer minimum-ttl** command.
SAs learned from this peer	SA messages that pass through the MSDP peer and the number of SA entries in the cache.
SA-cache maximum for the peer	Maximum number of (S, G) entries in the cache when the switch receives the SA message from an MSDP peer. You can configure the maximum number of (S, G) entries in the cache using the **peer sa-cache-maximum** command.
Input queue size	Length of the data in the input cache.
Output queue size	Length of the data in the output cache.
Counters for MSDP message	Number of MSDP messages. ● Count of RPF check failure: indicates the number of SA messages discarded because of the RPF check failure. ● Incoming/outgoing SA messages: indicates the number of sent or received SA messages. ● Incoming/outgoing SA requests: indicates the number of sent or received SA-Request messages. ● Incoming/outgoing SA responses: indicates the number of sent or received SA-Response messages. ● Incoming/outgoing data packets: indicates the number of sent or received SA messages that are encapsulated with multicast data packets.
Peer authentication	Whether MSDP authentication is configured.
Peer authentication type	MSDP authentication modes, including: ● none: indicates authentication is not configured. ● MD5: indicates MD5 authentication. This parameter is configured using the **peer password (MSDP)** command. ● Keychain: indicates Keychain authentication. This parameter is configured using the **peer keychain (MSDP)** command.

8.5.8 display msdp rpf-peer

Function

The **display msdp rpf-peer** command displays information about all RPF peers of a specific source RP address, including RPF peer selection rules and RPF route types.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **rpf-peer original-rp** *original-rp-address*

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Displays information about all the RPF peers of a specific source's RP address in all instances. If **vpn-instance** or **all-instance** is not specified, only the public network instance is displayed.	-
original-rp *original-rp-address*	Displays information about all the RPF peers of a specific source's RP address. *original-rp-address* specifies the source's RP address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To prevent looping of SA messages between MSDP peers, MSDP peers perform RPF checks on received SA messages and drop the SA messages that do not comply with RPF rules.

The **display msdp rpf-peer** command is used to check whether the forwarding path of SA messages works properly. Based on the RPF peer information in the command output, you can check every hop in the forwarding path. If the forwarding path is not working properly, this command helps you locate the faulty node.

Precautions

A device does not perform RPF checks on the SA messages received from an MSDP peer in the following situations:

- The address of the MSDP peer is the RP address of the source.
- The MSDP peer is a static RPF peer of the device.
- The MSDP peer is a unique MSDP peer of the device.
- The MSDP peer has joined a full-mesh group.

Before configuring this command, ensure that MSDP peers are configured. Only the MSDP peers with Up TCP connection can become RPF peers.

Example

Display information about RPF peers of the source RP 192.168.4.5.

```
<HUAWEI> display msdp rpf-peer original-rp 192.168.4.5
MSDP RPF peer information
 MSDP RPF peer information for Original RP: 192.168.4.5
 01. RPF peer: 10.6.6.6
  RPF selection rule: Peer is IGP next hop of best route
  RPF used topology: default
  RPF route type: multicast(static)
```

Table 8-78 Description of the **display msdp rpf-peer original-rp** command output

Item	Description
MSDP RPF peer information	information about the MSDP RPF peer.
MSDP RPF peer information for Original RP	Information about the MSDP RPF peer of a specific source's RP address.
01. RPF peer	RPF peer address.

Item	Description
RPF selection rule	RPF peer selection rule: ● Peer is IGP next hop of best route: RPF peer is a next hop of an IGP route. ● Peer is IGP advertiser of best route: RPF peer is a forwarder of an IGP route. ● Peer is in the AS-path to original RP: RPF peer is on an AS-path to the RP address of the source. ● Peer is BGP/MBGP next hop of best route: RPF peer is a next hop of a/an BGP/MBGP route. ● Peer is BGP/MBGP advertiser of best route: RPF peer is a forwarder of a/an BGP/MBGP route.
RPF used topology	RPF used topology: ● default: default topology. ● multicast: multicast topology. ● topology name (user-defined): unicast topology.
RPF route type	RPF route type: ● mbgp: MBGP route. ● unicast(bgp): BGP route ● multicast(static): static multicast route. ● unicast: IGP route (unicast route).

8.5.9 display msdp sa-cache

Function

The **display msdp sa-cache** command displays (S, G) entries in the SA cache.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **sa-cache** [*group-address* | *source-address* | [*as-number-plain* | *as-number-dot*]] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only statistics about the public network instance is displayed.	-
group-address	Specifies the group address of an (S, G) entry. It is used to display the corresponding (S, G) of the group in SA Cache.	The value is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
source-address	Specifies the source address of an (S, G) entry. It is used to display the corresponding the (S, G) of the source.	The value is in dotted decimal notation.
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the x.y format. Here, "x" and "y" are integers that range from 1 to 65535 and 0 to 65535 respectively.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If the SA cache function is enabled, the **display msdp sa-cache** command can be used to display the information about (S, G) entries learned from other MSDP peers in the SA cache. The information includes the source address, group address, address of the source's RP, routing protocol, AS number, and timeout period of entries.

Precautions

This command displays (S, G) entries in the SA cache only when SA cache is enabled (default setting).

Example

Display (S, G) entries in the SA cache.

```
<HUAWEI> display msdp sa-cache
MSDP Source-Active Cache Information
 MSDP Total Source-Active Cache - 2 entries
 MSDP matched 2 entries

(10.0.5.120, 225.0.0.1)
 Origin RP: 3.3.3.3
 Pro: ?, AS: ?
 Uptime: 00:01:01, Expires: 00:05:59

(10.0.5.120, 225.0.0.2)
 Origin RP: 3.3.3.3
 Pro: ?, AS: ?
 Uptime: 00:00:01, Expires: 00:05:59
```

Table 8-79 Description of the **display msdp sa-cache** command output

Item	Description
MSDP Source-Active Cache Information	MSDP SA cache.
MSDP Total Source-Active Cache - 2 entries	Two entries are cached by MSDP SA.
MSDP matched 2 entries	Two entries are matched by MSDP, such as the filtering policy and specified source/group address.
(10.0.5.120, 225.0.0.1)	(source address, group address) entry in the SA cache.
Origin RP	Source RP address that advertises the (S, G) entry.
Pro	Type of the protocol from which the AS number of the source RP is obtained. A question mark (?) indicates the protocol type if the AS number of the source RP cannot be obtained.
AS	AS number of the source RP. A question mark (?) indicates the protocol type if the AS number of the source RP cannot be obtained.
Uptime	Time when the (S, G) entry is created in the cache.

Item	Description
Expires	Time when the (S, G) entry in the cache times out.

8.5.10 display msdp sa-count

Function

The **display msdp sa-count** command displays statistics about the (S, G) entries in the SA cache.

Format

display msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **sa-count** [*as-number-plain* | *as-number-dot*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only statistics about the public network instance is displayed.	-
as-number-plain	Specifies the number of the AS, in integer format.	The value is an integer that ranges from 1 to 4294967295.
as-number-dot	Specifies the number of the AS, in dotted notation.	The value is in the x.y format. Here, "x" and "y" are integers that range from 1 to 65535 and 0 to 65535 respectively.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If the SA cache function is enabled, the **display msdp sa-count** command can be used to display the statistics about the (S, G) entries in the SA cache, including the addresses of the peers that send SA messages and the (S, G) entry statistics collected according to the AS numbers of sources' RPs.

Precautions

This command displays the number of (S, G) entries in the SA cache only when the MSDP peer has been enabled with SA cache (default setting).

Example

Display the number of (S, G) entries in the SA cache.

```
<HUAWEI> display msdp sa-count
MSDP Source-Active Count Information
  Number of cached Source-Active entries, counted by Peer
  Peer's Address     Number of SA
  10.10.10.10        5

  Number of source and group, counted by AS
  AS     Number of source    Number of group
  ?      3                   3

  Total 5 Source-Active entries matched
```

Table 8-80 Description of the **display msdp sa-count** command output

Item	Description
MSDP Source-Active Count Information	Number of MSDP SA messages.
Number of cached Source-Active entries, counted by Peer	Number of the (S, G) entries that are cached according to peers.
Peer's Address	Address of the peer that sends the SA message.
Number of SA	Number of the (S, G) entries received from the peer.
Number of source and group, counted by AS	Number of the (S, G) entries that is counted according to the AS to which the source RP belongs.
AS	AS number of the source RP. A question mark (?) indicates the protocol type if the AS number of the source RP cannot be obtained.

Item	Description
Number of source	Number of sources in the AS. **NOTE** If **0** is displayed in the **Number of source** and **Number of group** fields, the local device does not receive SA messages from its MSDP peer. Contact technical support personnel to troubleshoot faults.
Number of group	Number of groups in the AS.
Total 5 Source-Active entries matched	Number of (S, G) entries matching specified conditions in the cache.

8.5.11 encap-data-enable

Function

The **encap-data-enable** command enables the device to encapsulate a multicast data packet into an SA message.

The **undo encap-data-enable** command disables the device from encapsulating a multicast data packet into an SA message.

By default, no multicast data packet is encapsulated into an SA message.

Format

encap-data-enable

undo encap-data-enable

Parameters

None

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The source RP encapsulates information about all active sources into multiple SA messages to advertise it. Each SA message contains multiple (S, G) entries.

After the **encap-data-enable** command is configured on the source's RP, the RP encapsulates the multicast data carried in the Register message into an SA message, and then sends the SA message to the MSDP peer. Only one multicast data packet can be encapsulated into an SA message.

After the **encap-data-enable** command is configured on the MSDP peer, the switch can transmit the SA messages carrying a multicast data packet between PIM-SM domains.

Prerequisites

MSDP has been enabled using the **msdp** command.

Example

Encapsulate a multicast data packet into an SA message

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] encap-data-enable
```

8.5.12 import-source

Function

The **import-source** command prevents the information about active sources in a domain from being advertised when an SA message is created.

The **undo import-source** command restores the default configuration.

By default, the information about all active sources is advertised in a domain through SA messages.

Format

import-source [**acl** *acl-number*]

undo import-source

Parameters

Parameter	Description	Value
acl	Indicates the ACL that controls which source is to be advertised to a domain through an SA message and to which groups the SA message is to be advertised. If this parameter is not specified, multicast sources are not advertised.	-
acl-number	Specifies the number of the basic ACL or advanced ACL. ● Basic ACL: filters source addresses. ● Advanced ACL: filters source addresses and multicast group addresses.	The value is an integer that ranges from 2000 to 3999.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the **import-source** command is used to filter (S, G) forwarding entries to be advertised in SA messages based on source addresses. This configuration controls transmission of information about multicast sources.

You can also run the **peer sa-policy** command to filter the SA messages to be forwarded.

The **import-source** command takes effect for all peers. If both the **import-source** and **peer** *peer-address* **sa-policy local-export** commands are run, the parameters configured in the **peer** *peer-address* **sa-policy local-export** command take effect preferentially.

Prerequisites

MSDP has been enabled using the **msdp** command.

Precautions

The **import-source** and **acl** commands are used together.

- In the basic ACL view, set the source address range of advertised multicast packets using SA messages by specifying the **source** parameter in the **rule** command.
- In the advanced ACL view, set the source address range of advertised multicast packets using SA messages by specifying the **source** parameter in the **rule** command, and set the address range of advertised multicast groups using SA messages by specifying the **destination** parameter in the **rule** command.

Example

Configure an MSDP peer to advertise the information about a specified active source when creating SA messages. The multicast source is on 10.10.0.0/16 network segment, and the multicast group address is 225.1.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] acl number 3101
[HUAWEI-acl-adv-3101] rule permit ip source 10.10.0.0 0.0.255.255 destination 225.1.0.0 0.0.255.255
[HUAWEI-acl-adv-3101] quit
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] import-source acl 3101
```

8.5.13 msdp

Function

The **msdp** command enables MSDP and displays the MSDP view in the public network instance or the VPN instance.

The **undo msdp** command clears all configurations in the MSDP view, releases the resources occupied by MSDP, and restores the initial state.

By default, MSDP is disabled.

Format

msdp [**vpn-instance** *vpn-instance-name*]

undo msdp [**vpn-instance** *vpn-instance-name*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To configure MSDP, you can run the **msdp** command to enable MSDP and display the MSDP view. All the configurations related to MSDP peers must be done in the MSDP view.

Prerequisites

The multicast routing function has been enabled using the **multicast routing-enable** command.

Configuration Impact

Running the **undo msdp** command interrupts MSDP services. Therefore, use this command with caution.

Example

Enable MSDP and enter the MSDP view.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp]
```

8.5.14 originating-rp

Function

The **originating-rp** command configures an RP to replace the source RP address in the SA message with an IP address of a specified interface when the RP constructs an SA message. This interface is also called a logical RP.

The **undo originating-rp** command restores the default configuration.

By default, the source RP address in an SA message is the address of the RP that actually sends the SA message.

Format

originating-rp *interface-type interface-number*

undo originating-rp

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface that functions as a logical RP.	-

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You must run this command when configuring anycast RP in a PIM-SM domain.

An MSDP peer performs the RPF check on a received SA message and then discards the message if the addresses of the local RP and the remote RP are the same. In anycast RP, however, you need to configure RPs on two or more devices in a PIM-SM domain, assign the same IP address to these RPs, and set up MSDP peer relationships between these devices. You must configure an address that is different from the actual RP address for the logical RP so that the SA message can pass the RPF check.

Prerequisites

MSDP has been enabled using the **msdp** command.

Precautions

The interface functioning as a logical RP cannot be an actual RP interface. Commonly, the interfaces setting up an MSDP peer relationship can be specified as logical RP addresses.

Example

Configure VLANIF100 as the logical RP for the SA message.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] originating-rp vlanif 100
```

8.5.15 peer connect-interface (MSDP)

Function

The **peer connect-interface** command configures an MSDP peer.

The **undo peer** command removes the configured MSDP peer.

By default, no MSDP peer is configured.

Format

peer *peer-address* **connect-interface** *interface-type interface-number*

undo peer *peer-address*

Parameters

Parameter	Description	Value
peer-address	Specifies the address of a remote MSDP peer.	The address is in dotted decimal notation.
interface-type interface-number	Specifies the type and the number of the interface. The local switch uses the primary address of the interface as the source IP address to set up the TCP connection with the remote MSDP peer.	-

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MSDP peers are identified by addresses. You can run the **peer connect-interface** command on two devices to specify the peer addresses for each other and specify interfaces for establishing the TCP connection. In this way, an MSDP peer connection is established.

Prerequisites

MSDP has been enabled using the **msdp** command.

Configuration Impact

You can run the **peer** *peer-address* **connect-interface** *interface-type interface-number* command repeatedly to configure multiple MSDP peers for the local switch.

- You can specify the same *interface-type interface-number* for different *peer-address*. That is, you can specify the same local interface for different remote peers.
- You can specify different *interface-type interface-number* for different *peer-address*. That is, you can specify different local interfaces for different remote peers.

Precautions

Run the **peer connect-interface** command before running other peer commands. Otherwise, the system displays a message indicating that the peer does not exist.

When configuring a static RPF peer, you need to first run the **peer connect-interface** command to set the remote end as an MSDP peer and then the **static-rpf-peer** command to set the MSDP peer as a static RPF peer.

Example

Configure IP address 10.10.7.6 for the remote MSDP peer and specify VLANIF100 as the local interface.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
```

8.5.16 peer description (MSDP)

Function

The **peer description** command adds the description text for an MSDP peer.

The **undo peer description** command restores the default configuration.

By default, an MSDP peer does not have the description text.

Format

peer *peer-address* **description** *text*

undo peer *peer-address* **description**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.
text	Specifies the description text.	The description text is a string of 1 to 80 case-sensitive characters.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple MSDP peers are configured on the network, the MSDP peers cannot be easily distinguished only by IP addresses. The administrator can distinguish the MSDP peers by setting the descriptions for them.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Example

Add a description **ClientA** for the MSDP peer with the IP address being 10.10.7.6.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.10.7.6 description ClientA
```

8.5.17 peer keychain (MSDP)

Function

The **peer keychain** command configures keychain authentication for establishing a TCP connection between MSDP peers and transmitting MSDP message.

The **undo peer keychain** command removes keychain authentication between MSDP peers.

By default, MSDP keychain authentication is not configured.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

peer *peer-address* **keychain** *keychain-name*

undo peer *peer-address* **keychain**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The value is in dotted decimal notation.
keychain-name	Specifies the name of the keychain. This parameter is set using the **keychain** command.	The value is a string of 1 to 47 case-insensitive characters. Except the question mark (?) and space. However, when double quotation marks (") are used around the string, spaces are allowed in the string.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MSDP supports MD5 authentication and keychain authentication that improve security on TCP connections between MSDP peers. Keychain authentication supports multiple algorithms and is more suitable than MD5 authentication for networks that require high security.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

A keychain in accordance with the configured *keychain-name* has been enabled using the **keychain** command; otherwise, the TCP connection cannot be set up.

Precautions

You must configure keychain authentication on both MSDP peers. Note that encryption algorithms and passwords configured for keychain authentication on both peers must be the same; otherwise, the TCP connection cannot be set up between MSDP peers and MSDP messages cannot be transmitted.

MSDP MD5 authentication and MSDP keychain authentication are mutually exclusive.

Example

Configure MSDP keychain authentication between the local switch and the peer 10.1.1.2 and configure a keychain named **test**.

```
<HUAWEI> system-view
[HUAWEI] keychain test mode absolute
[HUAWEI-keychain-test] key-id 1
[HUAWEI-keychain-test-keyid-1] algorithm sha-256
[HUAWEI-keychain-test-keyid-1] key-string cipher Test@1234
[HUAWEI-keychain-test-keyid-1] quit
[HUAWEI-keychain-test] quit
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.1.1.2 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.1.1.2 keychain test
```

8.5.18 peer mesh-group

Function

The **peer mesh-group** command adds an MSDP peer to a mesh group.

The **undo peer mesh-group** command restores the default configuration.

By default, an MSDP peer does not belong to any mesh group.

Format

peer *peer-address* **mesh-group** *name*

undo peer *peer-address* **mesh-group**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer that is to be a member of a mesh group.	The address is in dotted decimal notation.
name	Specifies the name of a mesh group.	The name is a string of 1 to 32 case-sensitive characters.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If multiple MSDP peers exist on a network, SA messages may be flooded between peers. Especially when many MSDP peers are configured in the same PIM-SM domain, RPF rules cannot filter out useless SA messages effectively. The MSDP peer needs to perform an RPF check on each SA message received, which brings a heavy load to the system.

Configuring multiple MSDP peers to join the same mesh group can reduce the number of SA messages transmitted between these MSDP peers and reduce the load on the system.

Prerequisites

The device has established MSDP peer relationships with current mesh group members using the **peer connect-interface** command.

Configuration Impact

One MSDP peer can join only one mesh group. If an MSDP peer is added to different mesh groups several times, the latest configuration takes effect.

When a member of the mesh group receives an SA message, it checks the source of the SA message:

- If the SA message is sent by a certain MSDP peer outside the mesh group, the member performs the RPF check on the SA message. If the SA message passes the check, the member forwards it to other members of the mesh group.
- If the SA message is sent by a member of the mesh group, the member directly accepts the message without performing the RPF check. In addition, it does not forward the message to other members in the mesh group.

Precautions

The MSDP peer relationships must be established between the peers in a mesh group.

Commonly, the MSDP peers in the same AS join the same mesh group and EBGP routes need be configured between inter-AS MSDP peers.

Example

Add the MSDP peer with the address of 10.10.7.6 to the mesh group **Group1**

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.10.7.6 mesh-group Group1
```

8.5.19 peer minimum-ttl

Function

The **peer minimum-ttl** command sets a TTL threshold for the multicast data packet that can be encapsulated in an SA message and forwarded to a specified MSDP peer.

The **undo peer minimum-ttl** command restores the default value.

By default, the TTL threshold is 0.

Format

peer *peer-address* **minimum-ttl** *ttl*

undo peer *peer-address* **minimum-ttl**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.
ttl	Specifies the TTL threshold.	The value is an integer that ranges from 0 to 255.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MSDP peers transmit SA messages to each other over an established TCP connection. The **peer minimum-ttl** command limits the forwarding of SA messages with multicast data packets encapsulated.

After the TTL threshold is set for a specified peer, the switch checks the TTL values of multicast data packets before encapsulating them in SA messages. Only the multicast data packets with a TTL value greater than the threshold are encapsulated in an SA message and sent to the peer.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Example

Set the TTL threshold to 10. Only the multicast data packet with the TTL value being greater than 10 is encapsulated in the SA message and forwarded to MSDP peer 10.10.10.1.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.10.1 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.10.10.1 minimum-ttl 10
```

8.5.20 peer password (MSDP)

Function

The **peer password** command configures MD5 authentication for establishing a TCP connection between MSDP peers.

The **undo peer password** command removes the MD5 authentication between MSDP peers.

By default, the MSDP MD5 authentication is not configured.

Format

peer *peer-address* **password** { **cipher** *cipher-password* | **simple** *simple-password* }

undo peer *peer-address* **password**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.
cipher *cipher-password*	Specifies the password in the cipher text.	The value is a string of case sensitive characters without any space. A cipher password may contain 1 to 255 plain characters or 20 to 392 encrypted characters. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
simple *simple-password*	Specifies the password in the plain text. **NOTICE** If **simple** is selected, the password is saved in the configuration file in plain text. This brings high security risks. It is recommended that you select **cipher** to save the password in cipher text. To improve the device security, change the password periodically.	The value is a string of 1 to 255 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MSDP supports MD5 authentication and keychain authentication that improves security on TCP connections between MSDP peers.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Precautions

MD5 is not a secure authentication algorithm. For security purposes, you are advised to use the more secure Keychain algorithm for MSDP authentication.

MSDP peers must be configured with the same authentication password; otherwise, the TCP connections cannot be set up between MSDP peers and MSDP messages cannot be transmitted. The authentication password on peers can be in different formats, for example, the password on one end can be in the cipher text while the password on the peer can be in the plain text.

MSDP MD5 authentication and MSDP keychain authentication are mutually exclusive.

Example

Configure MSDP MD5 authentication between the local switch and the peer 10.1.1.1 and set the authentication password to **Test@1234** in the cipher text.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

```
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.1.1.1 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.1.1.1 password cipher Test@1234
```

8.5.21 peer request-sa-enable

Function

The **peer request-sa-enable** command enables the function of immediately sending the SA Request message to a specified MSDP peer.

The **undo peer request-sa-enable** command restores the default configuration.

By default, when receiving a new Join message for a group, the switch does not send an SA Request message to MSDP peer but waits to receive the next SA message.

Format

peer *peer-address* **request-sa-enable**

undo peer *peer-address* **request-sa-enable**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a new user joins multicast group G in a PIM-SM domain, a (*, G) entry is created on the RP. If no corresponding (S, G) information exists on the RP and SA cache is not enabled on the RP, multicast routes cannot be generated for this user. The RP then must wait for the next SA message from the remote MSDP peer to obtain valid (S, G) information.

Generally, the interval for an MSDP peer to send SA messages is set to a large value to reduce traffic load in the PIM-SM domain. This, however, will cause a delay in joining the source's SPT. To minimize the delay, enable the function of immediately sending SA Request messages on the local RP and enable the SA cache function on the remote MSDP peer. If a new Join message is received but the local entries and SA cache do not contain corresponding (S, G) information, the local RP immediately sends an SA Request message to the remote MSDP peer instead of waiting to receive the next SA message.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Precautions

Before configuring the **peer request-sa-enable** command on the local switch, disable SA cache on the local switch and enable SA cache on the peer of the specified *peer-address*. Therefore, when the local switch has new receiving requests, it can actively send SA Request messages to the peer and receive responses from the peer.

Example

Configure the switch to send SA Request messages to the MSDP peer 10.10.7.6 when receiving a new Join message.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.10.7.6 request-sa-enable
```

8.5.22 peer sa-cache-maximum

Function

The **peer sa-cache-maximum** command limits the maximum number of (S, G) entries that are learnt from MSDP peers and cached by the SA cache.

The **undo peer sa-cache-maximum** command restores the maximum number of (S, G) entries that are learnt from MSDP peers and cached by the SA cache to the default configuration.

By default, the maximum number of (S, G) entries in the SA cache is 8192.

Format

peer *peer-address* **sa-cache-maximum** *sa-limit*

undo peer *peer-address* **sa-cache-maximum**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.

Parameter	Description	Value
sa-limit	Specifies the maximum number of (S, G) entries that are allowed to cache.	The number is an integer that ranges from 1 to 4294967295.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You are recommended to perform this configuration on all MSDP peers on the network vulnerable to DoS attacks.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Configuration Impact

The total number of (S, G) entries that can be stored in SA-Cache is limited by the specification of the SA-Cache. At present, for an entire switch, the maximum number of (S, G) entries in SA-Cache is 8192.

For the (S, G) entries of a single peer:

- If the number of (S, G) entries is not set or exceeds 8192, the maximum number of (S, G) entries in the SA cache can be set to 8192.
- If the number of (S, G) entries is smaller than 8192, the maximum number of (S, G) entries in the SA cache is the configured value. The redundant (S, G) entries are not cached or advertised to PIM-SM but can be forwarded through SA messages.

Example

Set the maximum number of (S, G) entries that are learnt from MSDP peers and cached by the SA cache to 100 when the switch receives an SA message from MSDP peer 10.10.7.6.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] cache-sa-enable
[HUAWEI-msdp] peer 10.10.7.6 sa-cache-maximum 100
```

8.5.23 peer sa-policy

Function

The **peer sa-policy** command sets a filtering policy for SA messages received or forwarded.

The **undo peer sa-policy** command restores the default configuration.

By default, a device accepts all SA messages from MSDP peers, sends all locally created SA messages to MSDP peers, and forwards all SA messages to MSDP peers.

Format

peer *peer-address* **sa-policy** { **import** | **export** | **local-export** } [**acl** *advanced-acl-number*]

undo peer *peer-address* **sa-policy** { **import** | **export** | **local-export** }

Parameters

Parameter	Description	Value
peer-address	Specifies the address of a remote MSDP peer.	The address is in dotted decimal notation.
import	Receives the SA messages from a specified MSDP peer.	-
export	Forwards the SA messages to a specified MSDP peer.	-
local-export	Indicates that the locally created SA messages to be sent to the specified peer are filtered.	-
acl	Indicates the ACL that defines the import or export policy.	-
advanced-acl-number	Specifies the number of the advanced ACL.	The number is an integer that ranges from 3000 to 3999.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the **peer sa-policy** command is configured, MSDP can filter (S, G) forwarding entries carried in the SA message received from or forwarded to specified MSDP peers based on multicast source addresses, to control transmission of multicast source information.

- After the **peer** *peer-address* **sa-policy import** command is run, when an SA message reaches the local device from the specified peer, the local device filters the message using the import policy to determine whether to process the SA message.
  - If **acl** parameter is not configured, the device does not receive SA messages from any MSDP peer.
  - If **acl** parameter is configured, the device receives SA messages that carry the (S, G) entry only from a specified MSDP peer.
- After the **peer** *peer-address* **sa-policy export** command is run, the device filters an SA message using the export policy to determine whether to forward the SA message.
  - If **acl** parameter is not configured, the device does not forward SA messages from any MSDP peer.
  - If **acl** parameter is configured, the device forwards SA messages that carry the (S, G) entry only to a specified MSDP peer.
- After the **peer** *peer-address* **sa-policy local-export** command is run, the device filters the locally created SA messages to be sent to the peer specified by *peer-address*.
  - If **acl** parameter is not configured, no locally created SA messages that match the specified ACL to the specified MSDP peer.
  - If **acl** parameter is configured, the device sends only the locally created SA messages that match the specified ACL to the specified MSDP peer.

You can also run the **import-source** command on the peer nearest to a source to control the creation of SA messages.

The **import-source** command takes effect for all peers. If both the **import-source** and **peer** *peer-address* **sa-policy local-export** commands are run, the parameters configured in the **peer** *peer-address* **sa-policy local-export** command take effect preferentially.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Example

Configure the switch to forward only the SA messages that pass the ACL3100 filtering to peer 10.10.7.6.

```
<HUAWEI> system-view
[HUAWEI] acl number 3100
[HUAWEI-acl-adv-3100] rule permit ip source 10.15.0.0 0.0.255.255 destination 225.1.0.0 0.0.255.255
[HUAWEI-acl-adv-3100] quit
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.10.7.6 sa-policy export acl 3100
```

8.5.24 peer sa-request-policy

Function

The **peer sa-request-policy** command configures the filtering policy to respond to the SA Request messages sent by a specified MSDP peer. Once the SA Request message passes the filtering, the switch responds to the SA message immediately.

The **undo peer sa-request-policy** command restores the default configuration.

By default, the switch responds to all SA request messages sent by all MSDP peers.

Format

peer *peer-address* **sa-request-policy** [**acl** *basic-acl-number*]

undo peer *peer-address* **sa-request-policy**

Parameters

Parameter	Description	Value
peer-address	Specifies the address of MSDP peer that sends the SA Request message.	The address is in dotted decimal notation.
acl	Indicates an ACL. If the ACL is not specified, all SA Requests messages of the MSDP peer are ignored. If the ACL is specified, only the SA Request messages of the group that meets the requirements of the ACL are processed.	-
basic-acl-number	Indicates the number of the basic ACL.	The number is an integer that ranges from 2000 to 2999.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a local MSDP peer receives SA Request messages, the MSDP peer responds to all SA Request messages by default. To configure the switch to respond only to certain SA Request messages, configure the **peer sa-request-policy** command.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Precautions

The **peer sa-request-policy** and **acl** commands are used together.

- In the basic ACL view, you can set the multicast group address range of SA messages that are forwarded by the MSDP peer by specifying the **source** parameter in the **rule** command.

Example

Configure the ACL for filtering SA request messages sent by the MSDP peer 10.58.6.5: only SA request messages bound for the group whose address is 225.1.1.0/24 are received.

```
<HUAWEI> system-view
[HUAWEI] acl number 2001
[HUAWEI-acl-basic-2001] rule permit source 225.1.1.0 0.0.0.255
[HUAWEI-acl-basic-2001] quit
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.58.6.5 connect-interface vlanif 100
[HUAWEI-msdp] peer 10.58.6.5 sa-request-policy acl 2001
```

8.5.25 reset msdp control-message counters

Function

The **reset msdp control-message counters** command clears statistics about MSDP messages.

Format

reset msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **control-message counters** [**peer** *peer-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.

Parameter	Description	Value
all-instance	Indicates all instances, including the public network instance and all VPN instances. If **vpn-instance** or **all-instance** is not specified, only information about the public network instance is cleared.	-
peer *peer-address*	Specifies IP address of MSDP peer. If **peer** *peer-address* is specified, only statistics about the MSDP messages exchanged with a specified MSDP peer are cleared.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

This command clears statistics about the received, sent, and discarded MSDP messages.

Example

Clear statistics about the MSDP messages received, sent, and discarded on the peer 10.3.3.3.

```
<HUAWEI> reset msdp control-message counters peer 10.3.3.3
```

8.5.26 reset msdp peer

Function

The **reset msdp peer** command resets the TCP connection with a specified MSDP peer, and clears statistics about the specified MSDP peer.

Format

reset msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **peer** [*peer-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, the TCP connections set up between MSDP peers in the public network instance are reset and statistics about MSDP peers in the public network instance are cleared.	-
peer-address	Specifies the address of an MSDP peer. If the *peer-address* is not specified, all peers are reset.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To re-configure the TCP connection between MSDP peers and clear statistics about the specified MSDP peer, run the **reset msdp peer** command.

Use the **reset msdp statistics** command to clear the statistics about an MSDP peer without resetting the MSDP peer.

Configuration Impact

NOTICE

After you run this command, the TCP connection with the specified MSDP peer is torn down and a new TCP is set up again. During this process, MSDP services are interrupted, which may affect multicast services; for example, multicast data transmission may fail. Therefore, use this command with caution.

Example

Reset the TCP connection with MSDP peer 10.10.7.6 and clear the statistics about MSDP peer 10.10.7.6.

```
<HUAWEI> reset msdp peer 10.10.7.6
```

8.5.27 reset msdp sa-cache

Function

The **reset msdp sa-cache** command clears (S, G) entries in the SA cache.

Format

reset msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **sa-cache** [*group-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only the entries in the SA cache of the public network instance are cleared.	-
group-address	Specifies the group address carried in (S, G) information. If this parameter is not specified, all (S, G) information in the SA cache is cleared.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To clear (S, G) information from an SA cache, run the **reset msdp sa-cache** command.

Configuration Impact

NOTICE

(S, G) information in the SA cache cannot be restored after you clear it. Therefore, confirm the action before you use this command.

Example

Clear the (S, G) entries with the group address of 225.5.4.3 in the SA cache.

```
<HUAWEI> reset msdp sa-cache 225.5.4.3
```

8.5.28 reset msdp statistics

Function

The **reset msdp statistics** command clears statistics about one or more MSDP peers without resetting the MSDP peer (s).

Format

reset msdp [**vpn-instance** *vpn-instance-name* | **all-instance**] **statistics** [*peer-address*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances. If **vpn-instance** or **all-instance** is not specified, only information about the public network instance is cleared.	-
peer-address	Specifies the address of an MSDP peer. If the *peer-address* is not specified, the statistics about all MSDP peers are cleared.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

After the **reset msdp statistics** command is used, the statistics about the MSDP peer are cleared automatically. However, the TCP connections among peers are not closed, and MSDP services are not affected.

To clear the statistics about an MSDP peer and to rebuild the TCP connections among MSDP peers at the same time, use the **reset msdp peer** command.

Example

Clear the statistics of MSDP peer 10.10.7.6.

```
<HUAWEI> reset msdp statistics 10.10.7.6
```

8.5.29 shutdown (MSDP)

Function

The **shutdown** command terminates a specified MSDP peer.

The **undo shutdown** command restores the default configuration.

By default, the MSDP peers are not closed after the peer relationship is established.

Format

shutdown *peer-address*

undo shutdown *peer-address*

Parameters

Parameter	Description	Value
peer-address	Specifies the address of an MSDP peer.	The address is in dotted decimal notation.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **shutdown** command can be used to close the TCP connection between two MSDP peers while keeping the MSDP peer relationship.

Prerequisites

MSDP peers have been configured using the **peer connect-interface (MSDP)** command.

Configuration Impact

After the **shutdown** command is run on MSDP peers, the MSDP peers do not transmit SA messages or attempt to establish a connection. When the **display msdp brief** command or the **display msdp peer-status** command is used to check the status of MSDP peers, **State** in the command output is displayed as **Shutdown**.

Precautions

You only need to run the **undo shutdown** command to restore the configuration, and do not need to re-configure the MSDP peer using the **peer connect-interface (MSDP)** command.

Example

Close MSDP peer 10.10.7.6.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 10.10.7.6 connect-interface vlanif 100
[HUAWEI-msdp] shutdown 10.10.7.6
```

8.5.30 static-rpf-peer

Function

The **static-rpf-peer** command configures an MSDP peer as a static RPF peer. The SA messages sent by the static RPF peer do not require RPF checks.

The **undo static-rpf-peer** command restores the default configuration.

By default, no MSDP peer is configured as a static RPF peer.

Format

static-rpf-peer *peer-address* [**rp-policy** *ip-prefix-name*]

undo static-rpf-peer *peer-address*

Parameters

Parameter	Description	Value
peer-address	Specifies the address of a static RPF peer.	The value is in dotted decimal notation.

Parameter	Description	Value
rp-policy *ip-prefix-name*	Specifies the filtering policy that is used to filter SA messages based on RP addresses. **ip ip-prefix** specifies the name of the filtering policy.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To prevent SA messages from being circularly forwarded between MSDP peers, MSDP performs the RPF check on the received SA message. MSDP strictly controls the incoming SA messages. The SA messages that do not comply with the RPF rules are discarded.

To protect the SA messages transmitted between MSDP peers from being discarded in RPF checks and reduce redundant traffic, you can specify MSDP peers as static RPF peers. The SA messages received from a static RPF peer do not need to be checked according to RPF rules.

Prerequisites

The MSDP peer relationship has been established between the switch and a specified RPF peer using the **peer connect-interface (MSDP)** command.

Configuration Impact

You can specify multiple remote static RPF peers for the switch using the **static-rpf-peer** *peer-address* command repeatedly.

Precautions

When you specify multiple static RPF peers for the switch, pay attention to the following points:

- All the peers are configured with **rp-policy**

  When SA messages sent by a static RPF peer in the active state reaches the local switch, the local switch filters the SA messages according to specified **rp-policy** on the peers, and receives only the SA messages that pass the filter.
- None of the peers is configured with **rp-policy**

  The local switch receives all the SA messages from the static RPF peers in the active state.

Example

Configure 192.168.3.2 as a static RPF peer, with the source RP address range of 192.168.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix list-df permit 192.168.0.0 16 greater-equal 16 less-equal 32
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] peer 192.168.3.2 connect-interface vlanif 100
[HUAWEI-msdp] static-rpf-peer 192.168.3.2 rp-policy list-df
```

8.5.31 timer retry

Function

The **timer retry** command sets the interval for retrying to set up an MSDP peer relationship.

The **undo timer retry** command restores the default value.

By default, the interval for retrying to set up an MSDP peer relationship is 30 seconds.

Format

timer retry *interval*

undo timer retry

Parameters

Parameter	Description	Value
interval	Specifies the interval for retrying to set up an MSDP peer relationship.	The value is an integer that ranges from 1 to 60, in seconds.

Views

MSDP view of the public network instance or MSDP view of the VPN instance

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A TCP connection needs to be set up between two MSDP peers. The peer with a larger IP address listens to port 639, and the peer with a smaller IP address initiates a connection. If the connection setup fails, the peer retries connection setup after a specified interval.

A TCP connection needs to be established between MSDP peers in one of the following situations:

- An MSDP peer is created.
- A disconnected MSDP peer needs to be reconnected
- A faulty MSDP peer attempts to restore work.

You can run the **timer retry** command to adjust the interval for retrying to set up an MSDP peer relationship.

Prerequisites

MSDP has been enabled using the **msdp** command.

Example

Set the interval for retrying to set up an MSDP peer relationship to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] msdp
[HUAWEI-msdp] timer retry 60
```

8.6 Multicast VPN Configuration Commands

8.6.1 Command Support

Only the following switch models support Multicast VPN:

S5731-S, S5731-H, S5731S-H, S5732-H,, S6720-EI, S6720S-EI, S6730-S, S6730-H, and S6730S-H

8.6.2 auto-discovery

Function

The **auto-discovery** command configures the auto-discovery (A-D) mode for the multicast VPN, and associates an inbound multicast routing policy with the IPv4 address family of the current VPN instance.

The **undo auto-discovery** command deletes the A-D mode configuration for the multicast VPN and removes the association between the inbound multicast routing policy and the IPv4 address family of the current VPN instance.

By default, the A-D mode is not configured for the multicast VPN and the IPv4 address family of the current VPN instance is not associated with an inbound multicast routing policy.

Format

auto-discovery { **mdt** | **mvpn** } [**import route-policy** *route-policy-name*]

undo auto-discovery

Parameters

Parameter	Description	Value
mdt	Specifies the MDT-Subsequent Address Family Identifier (SAFI) A-D mode for the multicast VPN.	-
mvpn	Specifies the MCAST-VPN SAFI A-D mode for the multicast VPN.	-
route-policy *route-policy-name*	Specifies the inbound multicast routing policy that is to be associated with the IPv4 address family of the VPN instance.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Currently, the multicast VPN is implemented by establishing the PIM-SSM MDT on the public network to transmit multicast VPN services as all Provider Edges (PEs) on the network know information about the Rendezvous Point (RP). This mechanism, however, does not support the Share-Group address within the SSM address range. This is because PEs in the same VPN do not know the peer information of each other, therefore knowing nothing about the multicast source information. As a result, these PEs cannot directly send Join messages to the multicast source and establish the PIM-SSM MDT.

To solve this problem, in an autonomous system (AS), you can configure the BGP A-D mode to enable automatic discovery of the peer information about PEs in the same VPN. In this manner, multicast VPN services can be transmitted over the public network tunnel which is based on the PIM-SSM MDT.

At present, the multicast VPN supports two A-D modes:

- MDT-SAFI A-D mode: In this mode, a new address family is defined in the MDT-SAFI message advertised through BGP. After the multicast VPN is configured on a PE, the multicast VPN configurations, including the Route Distinguisher (RD) and the Share-Group address, can be advertised to all BGP peers. After a remote PE (a BGP peer) receives the MDT-SAFI message advertised through BGP, the remote PE compares the RD carried in the message with its local RD. If the RDs are the same, the remote PE is in the same VPN as the local PE. The remote PE then uses the MDT-SAFI message to establish the PIM-SSM MDT for transmitting multicast VPN services.

- MCAST-VPN SAFI A-D mode: In this mode, a new address family is defined in the MCAST-VPN-SAFI message advertised through BGP. Similar to the MDT-SAFI A-D mode, the MCAST-VPN SAFI A-D mode uses the MCAST-VPN-SAFI message advertised between BGP peers to transmit multicast VPN configurations, including the RD and Share-Group address. The difference is that the MCAST-VPN SAFI A-D mode has a broader definition, supports more extensions, and carries more multicast VPN attributes and information for establishing the public network tunnel. Therefore, the MCAST-VPN SAFI A-D mode applies to the next-generation multicast VPN.

Prerequisites

The **multicast routing-enable** command is configured in the public network instance view or the VPN instance view.

Precautions

- When configuring the A-D mode for the multicast VPN, you need to configure a matching A-D address family in the BGP view so that the BGP A-D mode can be used to implement the multicast VPN function. If the configured A-D mode is inconsistent with the A-D address family enabled in the BGP view, the A-D mode will not take effect.
- This command applies to the single-AS scenario, with no RP configured on the public network.
- In a VPN enabled with the IPv4 address family, only one A-D mode can be used. Different VPNs enabled with the IPv4 address family on a PE can use different A-D modes. Therefore, you need to enable two types of A-D address families in the BGP view, so that the VPNs can use different A-D modes to forward multicast data.
- The PEs enabled with the BGP A-D function must support the same PIM protocol and use the Share-Group address within the SSM address range.
- Running this command does not affect the original multicast VPN service flow. If the Share-Group address is in the Any-Source Multicast (ASM) address range, or if the PIM-DM protocol is used on the public network, multicast VPN traffic can still be transmitted over the public network tunnel for which PIM-SM or PIM-DM is configured.

Example

Configure the MDT-SAFI A-D mode for vpn1 enabled with the IPv4 address family, so that the multicast VPN services are transmitted over the public network tunnel based on the PIM-SSM MDT.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family mdt
[HUAWEI-bgp-af-mdt] peer 3.3.3.3 enable
[HUAWEI-bgp-af-mdt] quit
[HUAWEI-bgp] quit
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] vpn-target 100:1 both
[HUAWEI-vpn-instance-vpn1-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-vpn1-af-ipv4] multicast-domain share-group 232.2.2.0 binding mtunnel 0
[HUAWEI-vpn-instance-vpn1-af-ipv4] auto-discovery mdt
```

8.6.3 display default-parameter mvpn

Function

The **display default-parameter mvpn** command displays default configurations about the multicast VPN (MVPN).

Format

display default-parameter mvpn

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using this command displays only default configurations, regardless of whether the configurations about MVPN parameters are changed.

Example

Display default configurations about the MVPN.

```
<HUAWEI> display default-parameter mvpn
  MVPN Instance View Default Configurations:
  ------------------------------------------
  Multicast-domain switch-delay: 5 s
  Multicast-domain switch threshold: 0 kbps-preferred
  Multicast-domain holddown-time: 60 s
  Multicast-domain log switch-group-reuse: disabled
  Multicast-domain share-group: disabled
  Multicast-domain switch-group-pool: disabled
  Multicast-domain auto-discovery: disabled
  Multicast-domain switch-without-register: disabled
  Multicast extranet select-rpf rule: disabled
```

Table 8-81 Description of the **display default-parameter mvpn** command output

Item	Description
MVPN Instance View Default Configurations	Default configurations in the MVPN instance view.

Item	Description
Multicast-domain switch-delay	Delay in switching from the share-MDT to the switch-MDT. This parameter can be configured using the **multicast-domain switch-delay** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain switch threshold	Threshold of the multicast packet rate that can trigger the switch to the switch-MDT. This parameter can be configured using the **multicast-domain switch-group-pool** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain holddown-time	Delay in switching from the switch-MDT to the share-MDT. This parameter can be configured using the **multicast-domain holddown-time** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain log switch-group-reuse	Whether recording logs about switch-group address reuse is configured. This parameter can be configured using the **multicast-domain log switch-group-reuse** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain share-group	Whether the Share-Group address is configured and whether the MTI is bound to a VPN instance. This parameter can be configured using the **multicast-domain share-group binding** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain switch-group-pool	Whether the range of the switch-MDT switch-group-pool is configured. This parameter can be configured using the **multicast-domain switch-group-pool** command in the VPN instance view or VPN IPv4 address family view.
Multicast-domain auto-discovery	Whether the A-D mode is configured for the VPN. The switch does not support the A-D mode currently.

Item	Description
Multicast-domain switch-without-register	Whether the source PE sends the null Register message to the RP to establish the SPT on the public network before the Switch-Group address is used to encapsulate VPN data. This parameter can be configured using the **multicast-domain switch-without-register** command in the VPN instance view or VPN IPv4 address family view.
Multicast extranet select-rpf rule	Whether the multicast routing policy configured for a VPN is configured. The switch does not support the configuration of a multicast routing policy for a VPN currently.

8.6.4 display multicast-domain control-message counters

Function

The **display multicast-domain control-message counters** command displays statistics about sent and received MDT switch messages in a specified VPN instance or all VPN instances.

Format

display multicast-domain { **vpn-instance** *vpn-instance-name* | **all-instance** } **control-message counters**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about sent and received MDT switch messages in a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.
all-instance	Displays statistics about sent and received MDT switch messages in all VPN instances.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring a Switch-MDT, you can run the **display multicast-domain control-message counters** command to view statistics about sent and received MDT switch messages in a specified VPN instance or all VPN instances and check whether packets are normally sent and received on the current device.

You can run the **reset multicast-domain control-message counters** command to clear the statistics.

Example

Display statistics about sent and received MDT switch messages in VPN instance **red**.

```
<HUAWEI> display multicast-domain vpn-instance red control-message counters
VPN-Instance red:
 Message Type     Received         Sent            Invalid
 Switch           5000             0               5000
```

Table 8-82 Description of the **display multicast-domain vpn-instance red control-message counters** command output

Item	Description
VPN-Instance red	VPN instance in which statistics about sent and received MDT switch messages need to be displayed.
Message Type	Message type, that is MDT switch messages.
Received	Number of received messages.
Sent	Number of sent messages.
Invalid	Number of received invalid messages.

8.6.5 display multicast-domain invalid-packet

Function

The **display multicast-domain invalid-packet** command displays statistics about invalid MDT switch messages received by a device and details of these messages.

Format

display multicast-domain { **vpn-instance** *vpn-instance-name* | **all-instance** } **invalid-packet**

display multicast-domain invalid-packet [*packet-number*] **verbose**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays statistics about invalid MDT switch messages received in a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.
all-instance	Displays statistics about invalid MDT switch messages received in all VPN instances.	-
packet-number	Displays details of a specified number of invalid MDT switch messages recently received.	The value is an integer ranging from 1 to 100. By default, details of all the invalid MDT switch messages currently stored are displayed.
verbose	Displays details of invalid MDT switch messages.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display multicast-domain invalid-packet** command to view statistics and details of invalid MDT switch messages for fault location and rectification.

If an SPT fails to be set up in a VPN instance on a multicast network, you can run the **display multicast-domain invalid-packet** command first to check whether devices have received invalid MDT switch messages. If the command output contains statistics about invalid MDT switch messages, you need to run the **display multicast-domain invalid-packet** [*packet-number*] **verbose** command to view details of invalid MDT switch messages to locate the fault.

Example

Displays statistics about invalid MDT switch messages received in **vpn1**.

```
<HUAWEI> display multicast-domain vpn-instance vpn1 invalid-packet

             Statistics of invalid packets for vpn1:
-------------------------------------------------------------------
MDT Switch invalid packet:
Fault Length            : 0           Invalid Message Type    : 0
```

```
Invalid Multicast Source: 0          Invalid Multicast Group : 0
Invalid Switch Group    : 0
------------------------------------------------------------------
```

Table 8-83 Description of the **display multicast-domain vpn-instance vpn1 invalid-packet** command output

Item	Description
Statistics of invalid packets for vpn1	VPN instance in which statistics about MDT switch messages need to be displayed.
MDT Switch invalid packet	Invalid MDT switch messages.
Fault Length	Messages with invalid lengths.
Invalid Message Type	Messages with invalid message types.
Invalid Multicast Source	Messages with invalid multicast source addresses.
Invalid Multicast Group	Messages with invalid multicast group addresses.
Invalid Switch Group	Messages with invalid switch group addresses.

Display details of one invalid MDT switch message recently received in the public network instance.

```
<HUAWEI> display multicast-domain invalid-packet 1 verbose
      Detailed information of invalid packets
----------------------------------------------------
Packet information (Index 1):
----------------------------------------------------
Interface           :  10.44.44.44
Time                :  2010-6-9 10:50:08 UTC-08:00
Message Length      :  16
Invalid Type        :  Invalid Switch Group
0000: 01 00 10 00 64 64 64 64 e8 00 00 00 0a 00 00 00
----------------------------------------------------
```

Table 8-84 Description of the **display multicast-domain invalid-packet 1 verbose** command output

Item	Description
Detailed information of invalid packets	Details of the invalid MDT switch message.
Packet information (Index 1)	Sequence number of the invalid MDT switch message (numbered in the opposite order that the message is received, for example, the index of the last received message is 1, the index of the last but one message is 2, and so on).

Item	Description
Interface	IP address of interface receiving the invalid MDT switch message
Time	Time when the invalid MDT switch message is received, in any of the following formats: ● YYYY-MM-DD HH:MM:SS ● YYYY-MM-DD HH:MM:SS UTC±HH:MM DST ● YYYY-MM-DD HH:MM:SS UTC±HH:MM ● YYYY-MM-DD HH:MM:SS DST UTC±HH:MM indicates that a time zone is configured through the **clock timezone** command; DST indicates that the daylight saving time is configured through **clock daylight-saving-time** command.
Message Length	Length of the invalid MDT switch message.
Invalid Type	Type of the invalid MDT switch message.
0000: 01 00 10 00 64 64 64 64 e8 00 00 00 0a 00 00 00	Contents of the invalid MDT switch message.

8.6.6 display multicast-domain vpn-instance share-group

Function

The **display multicast-domain vpn-instance share-group** command displays information about the Share-Group address configured for a specified VPN instance.

Format

display multicast-domain vpn-instance *vpn-instance-name* **share-group** [**local** | **remote**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays information about the Share-Group of a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.

Parameter	Description	Value
local	Indicates the locally configured Share-Group address.	-
remote	Indicates the Share-Group address configured on remote PE and learned through BGP Update packets.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display multicast-domain vpn-instance share-group** command displays information about the Share-Group, peer IP address, and tunnel type, which allows you to determine whether the multicast tunnel is correctly established to forward multicast services.

Example

Display the Share-Group information of VPN instance **BLUE** in an MD.

```
<HUAWEI> display multicast-domain vpn-instance BLUE share-group
MD local share-group information for VPN-Instance: BLUE
  Share-group: 239.2.2.0
  MTunnel address: 3.3.3.3
```

Table 8-85 Description of the **display multicast-domain vpn-instance share-group** command output

Item	Description
MD local share-group information for VPN-Instance	VPN instance to which local Share-Group information in the multicast domain belongs.
Share-group	Share-MDT group address configured on the local switch. This parameter can be configured using the **multicast-domain share-group binding** command in the VPN instance view or VPN IPv4 address family view.

Item	Description
MTunnel address	Configured IP address of the MTI bound to the Share-Group on the local switch. The source interface whose IP address is referenced by the MTI can be configured using the **multicast-domain source-interface** command in the VPN IPv4 address family view. In this way, the IP address of the MTI is obtained. You can also directly configure an IP address for an MTI in the MTI interface view.

8.6.7 display multicast-domain vpn-instance switch-group receive

Function

The **display multicast-domain vpn-instance switch-group receive** command displays the Switch-Group information received by a specified VPN instance.

Format

display multicast-domain vpn-instance *vpn-instance-name* **switch-group receive brief**

display multicast-domain vpn-instance *vpn-instance-name* **switch-group receive** [**active** | **sender** *source-address* | **group** *group-address* | *vpn-source-address* [**mask** { *source-mask-length* | *source-mask* }] | *vpn-group-address* [**mask** { *group-mask-length* | *group-mask* }]] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays the Switch-Group information received by a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.
active	Displays the received Switch-Group that joins the Switch-MDT.	-
brief	Displays brief information about the received Switch-Group.	-

Parameter	Description	Value
group *group-address*	Displays the Switch-Group related to a multicast group specified by *group-address* of the public network. *group-address* specifies the address of the multicast group.	The value is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
sender *source-address*	Displays the Switch-Group information related to the specified multicast source *source-address* of the public network. The *source-address* indicates the multicast.	The value is in dotted decimal notation.
vpn-source-address	Displays the Switch-Group information related to a VPN multicast source specified by *vpn-source-address*.	The value is in dotted decimal notation.
mask	Indicates the mask of the VPN multicast group or source address.	-
source-mask-length	Specifies the mask length of the VPN multicast source address.	The value is an integer that ranges from 0 to 32.
source-mask	Specifies the mask of the VPN multicast source address.	The value is in dotted decimal notation.
vpn-group-address	Displays the Switch-Group information related to a VPN multicast group specified by *vpn-group-address*.	The value is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
group-mask-length	Specifies the mask length of the VPN multicast group address.	The value is an integer that ranges from 4 to 32.
group-mask	Specifies the mask of the VPN multicast group address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display multicast-domain vpn-instance switch-group receive** command to display the Switch-Group information received by the local router:

- Each VPN instance corresponds to an MD. *vpn-instance-name* specifies a VPN instance. Use the command to display the information about the Switch-Group of a specified MD.

- If **brief** is specified, brief information about all Switch-Groups is displayed in ascending order of the Switch-Group address.
- If **active** is specified, only information about the Switch-Groups that have joined the Switch-MDT is displayed, in ascending order of the VPN (S, G).

Example

Display Switch-Group information received by VPN instance **VPN1** in an MD.

```
<HUAWEI> display multicast-domain vpn-instance VPN1 switch-group receive
MD switch-group information received by VPN-Instance: VPN1
Switch group:  226.1.1.0 ref count: 8, active count: 8
  Sender:  172.16.1.1 active count: 8
    (192.168.1.5, 239.1.1.1)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.5, 239.1.1.158)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.5, 239.1.2.12)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.5, 239.1.2.197)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.5, 239.1.3.62)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.2, 225.1.1.109)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.2, 225.1.4.80)
    Up time: 01:20:20  expire time: 00:03:10  active
    (192.168.1.2, 225.1.4.173)
    Up time: 01:20:20  expire time: 00:03:10  active
```

Display brief Switch-Group information received by VPN instance **VPN1** in an MD.

```
<HUAWEI> display multicast-domain vpn-instance VPN1 switch-group receive brief
MD switch-group information received by VPN-Instance: VPN1
switch group:  226.1.1.0 ref count: 8, active count: 0
switch group:  226.1.1.1 ref count: 4, active count: 0
switch group:  226.1.1.2 ref count: 8, active count: 0
switch group:  226.1.1.3 ref count: 4, active count: 0
switch group:  226.1.1.4 ref count: 8, active count: 0
```

Table 8-86 Description of the **display multicast-domain vpn-instance switch-group receive** command output

Item	Description
MD switch-group information received by VPN-Instance	VPN instance to which MD Switch-Group information belongs.
switch group	Address of the received Switch-Group.
ref count	Number of VPN multicast groups referenced by the Switch-Group.
active count	Number of active VPN multicast groups (where receivers exist) referenced by the Switch-Group.
sender	BGP peer IP address of the PE that sends Switch-Group information.

Item	Description
Up time	Creation time of switching messages in which the VPN multicast (S, G) entry is referenced by the Switch-group
expire time	Timeout period of the VPN multicast (S, G) entry referenced by the Switch-Group.

8.6.8 display multicast-domain vpn-instance switch-group send

Function

The **display multicast-domain vpn-instance switch-group send** command displays the Switch-Group information sent by the specified VPN instance in an MD.

Format

display multicast-domain vpn-instance *vpn-instance-name* **switch-group send** [**reuse** *interval* | *vpn-source-address* [**mask** { *source-mask-length* | *source-mask* }] | *vpn-group-address* [**mask** { *group-mask-length* | *group-mask* }] | **group** *group-address*] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Displays the Switch-Group information sent by a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.
group *group-address*	Displays the Switch-Group information related to a multicast group G. The parameter *group-address* indicates multicast group address.	The value is in dotted decimal notation format. The address ranges from 224.0.1.0 to 239.255.255.255.
reuse *interval*	Displays Switch-Group information that is reused by an MD in the specified period. The parameter *interval* indicates the specified period.	The value of the interval is an integer that ranges from 1 to 2147483647 seconds.

Parameter	Description	Value
vpn-source-address	Displays the Switch-Group information related to the specified VPN multicast source.	The value is in dotted decimal notation format.
mask	Indicates the mask of the VPN multicast group or source address.	-
source-mask-length	Specifies the mask length of the VPN multicast source address.	The value is an integer that ranges from 0 to 32.
source-mask	Specifies the mask of the VPN multicast source address.	The value is in dotted decimal notation.
vpn-group-address	Displays the Switch-Group information related to the specified VPN multicast group G.	The value is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
group-mask-length	Specifies the mask length of the VPN multicast group address.	The value is an integer that ranges from 4 to 32.
group-mask	Specifies the mask of the VPN multicast group address.	The value is in dotted decimal notation.

1: Monitoring level

Usage Guidelines

Use the **display multicast-domain vpn-instance switch-group send** command to display the Switch-Group information sent by the local switch:

- Each VPN instance corresponds to an MD. *vpn-instance-name* specifies a VPN instance. The command is only used to display the Switch-Group information related to the specified MD.
- The Switch-Group information is displayed in ascending order of VPN (S, G) entry.
- If **reuse** *interval* is specified, the group information that is reused in a specified interval is displayed in ascending order of Switch-Group address.

Example

Display the Switch-Group information sent by VPN instance **VPN1** in an MD.

```
<HUAWEI> display multicast-domain vpn-instance VPN1 switch-group send
MD switch-group information sent by VPN-Instance: VPN1
  226.1.1.0 reference_count: 3
    (1.1.1.1, 239.1.1.1)                switch time: 00:00:21
    (1.1.1.1, 239.1.1.158)              switch time: 00:00:21
```

```
   (1.1.1.1, 239.1.2.50)              switch time: 00:00:05
 226.1.1.1 reference_count: 3
   (1.1.1.1, 225.1.1.1)               switch time: 00:00:21
   (1.1.1.1, 225.1.2.50)              switch time: 00:00:05
   (1.1.1.1, 239.1.1.159)             switch time: 00:00:21
```

Display information about the Switch-Group reuse sent by VPN instance **VPN1** in an MD within the latest 30s.

```
<HUAWEI> display multicast-domain vpn-instance VPN1 switch-group send reuse 30
MD switch-group information sent by VPN-Instance: VPN1
  226.1.1.0 reuse_count: 1
  226.1.1.1 reuse_count: 1
  226.1.1.2 reuse_count: 1
```

Table 8-87 Description of the **display multicast-domain vpn-instance switch-group send** command output

Item	Description
MD switch-group information sent by VPN-Instance	VPN instance to which MD Switch-Group information belongs.
226.1.1.0 reference_count	Number of VPN multicast groups referenced by the Switch-Group.
switch time	Switching time of the VPN multicast (S, G) entry referenced by the Switch-Group.
226.1.1.0 reuse_count	Number of times of reusing the Switch-Group sent in the specified period.

8.6.9 interface mtunnel

Function

The **interface mtunnel** command displays the MTI view.

Format

interface mtunnel *interface-number*

Parameters

Parameter	Description	Value
interface-number	Specifies an MTI number.	The value is an integer that ranges from 0 to 1023.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An MTI is the inbound/outbound interface of a multicast tunnel and also functions as the inbound/outbound interfaces of the MD. A local PE sends VPN data through the MTI, and the remote PE receives data from the MTI. The MTI is the tunnel for data exchange between the public network instance and the VPN instance on the PE. A PE connects to the MT through the MTI. The VPN instances on PEs in the MD establish PIM neighbor relationships with each other on the MTI.

When you run the **multicast-domain share-group binding** command, the MTI is automatically created. You can run the **interface mtunnel** command to enter the MTI view and configure MTI parameters

Prerequisites

The MIT has been automatically created after the **multicast-domain share-group binding** command is executed to configure a Share-Group for a VPN instance and bind the Share-Group to the MTI.

Example

Enter the view of MTunnel interface 10, which has been automatically created.

```
<HUAWEI> system-view
[HUAWEI] interface mtunnel 10
[HUAWEI-MTunnel10]
```

8.6.10 mtu (MTI view)

Function

The **mtu** command sets the MTU for a multicast tunnel interface (MTI).

The **undo mtu** command restores the default MTU of an MTI.

By default, the MTU of an MTI is 1472 bytes.

Format

mtu *mtu*

undo mtu

Parameters

Parameter	Description	Value
mtu	Specifies the MTU value of an MTI.	The value is an integer that ranges from 46 to 1500, in bytes.

Views

MTI view

Usage Guidelines

Usage Scenario

If the length of a VPN multicast packet is equal or close to the MTU of the outbound interface of the public network instance, the length of the GRE-encapsulated public network multicast data packet is larger than the MTU of the outbound interface of the public network instance. In this case, the local PE must fragment the encapsulated packet and sends it through the outbound interface of the public network instance. Upon receiving the packet, the remote PE reassembles the packet.

You can set the MTU of the MTI to a smaller value so that VPN multicast packets can be fragmented before being encapsulated using the GRE. The remote PE does not need to reassemble the packets, improving efficiency.

Precautions

If the MTU is set too small and the size of packets is large, packets are broken into a great number of fragments, and may be discarded by QoS queues.

Example

Set the MTU of MTunnel 10 to 1400.

```
<HUAWEI> system-view
[HUAWEI] interface mtunnel 10
[HUAWEI-MTunnel10] mtu 1400
```

8.6.11 multicast-domain holddown-time

Function

The **multicast-domain holddown-time** command sets the delay for the switching from the Switch-MDT to the Share-MDT.

The **undo multicast-domain holddown-time** command restores the default value of the interval.

By default, the delay for the switching from the Switch-MDT to the Share-MDT is 60 seconds.

Format

multicast-domain holddown-time *interval*

undo multicast-domain holddown-time

Parameters

Parameter	Description	Value
interval	Specifies the delay for the switching from the Switch-MDT to the Share-MDT.	The value of the delay ranges from 0 to 512, in seconds.

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During the Switch-MDT configuration, the forwarding rate of VPN multicast data may fluctuate above and below the switchover threshold due to network instability. To prevent multicast data traffic from being frequently switched between the Switch-MDT and Share-MDT, the system does not perform the switchover immediately after it finds that the forwarding rate is smaller than the switching threshold. Instead, the system starts the hold-down timer and performs the switchover after the hold-down timer expires.

Prerequisites

A Share-Group has been configured using the **multicast-domain share-group binding** command.

Precautions

During a switchover, there is a delay about 1 to 30 seconds from the time when the forwarding rate ranges to the time when the system starts the Switch-Delay timer. The delay is not included in the hold-down time. Consequently, the total delay from the time when the forwarding rate changes to the time when the system completes the switchover is 1-30 seconds longer than the hold-down time.

When *interval* is set to 0, the system triggers a switchover from the Switch-MDT to the Share-MDT immediately after it finds that the forwarding rate is below the threshold.

If a VPN instance has many multicast forwarding entries, the time taken to collect multicast traffic statistics will exceed the default hold-down time. In this case, increase the hold-down time to prevent frequent switchovers between the Switch-MDT and Share-MDT. Table 8-88 lists the recommended hold-down time values in various conditions.

Table 8-88 Recommended hold-down time values

Number of Multicast Forwarding Entries in a VPN Instance	Recommended Hold-down Time Value (Seconds)
1024	60
2048	128
4094	256

Example

Set the delay for the switching from the Switch-MDT to the Share-MDT to 80 seconds.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain holddown-time 80
```

8.6.12 multicast-domain log switch-group-reuse

Function

The **multicast-domain log switch-group-reuse** command enables the output of log information about reusing group address in Switch-Group-Pool.

The **undo multicast-domain log** command disables the output of log information about reusing group address in Switch-Group-Pool.

By default, the output of log information about reusing Switch-Group is disabled.

Format

multicast-domain log switch-group-reuse

undo multicast-domain log

Parameters

None

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the VPN instance that the source PE is bound to, if the Switch-Group-Pool cannot provide enough addresses for VPN multicast data packets whose transmission path needs to be switched to the Switch-MDT, the multicast group addresses can be reused. To record information about reusing Switch-Group, enable the output of log information about reusing Switch-Group addresses.

Prerequisites

A Share-Group has been configured using the **multicast-domain share-group binding** command.

Example

Enable the output of log information about reusing Switch-Group addresses in VPN **mytest**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain log switch-group-reuse
```

8.6.13 multicast-domain share-group binding

Function

The **multicast-domain share-group binding** command specifies the Share-MDT group and binds the Multicast Tunnel Interface (MTI) to a VPN instance.

The **undo multicast-domain share-group** command restores the default configuration.

By default, the group address of Share-MDT is not specified.

Format

multicast-domain share-group *group-address* **binding mtunnel** *number*

undo multicast-domain share-group

Parameters

Parameter	Description	Value
group-address	Specifies the multicast group address. **NOTE** Do not enter an IP address in the SSM address range (232.*.*.*); otherwise, the multicast VPN cannot be established.	The value is in the dotted decimal notation. The address ranges from 224.0.1.0 to 239.255.255.255.
mtunnel *number*	Specifies the MTI number.	The value is an integer that ranges from 0 to 1023.

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you run the **multicast-domain share-group binding** command, the device automatically creates the MTI and establishes a Share-MDT with the *group-address* value as the multicast group address for forwarding VPN multicast packets.

Prerequisites

The multicast routing function has been enabled using the **multicast routing-enable** command in the VPN instance.

Follow-up Procedure

Manually configure an IP address for the MTI in the MTI view or run the **multicast-domain source-interface** command in the VPN IPv4 address family view to configure the MTI to automatically obtain an IP address.

Precautions

You cannot configure the same Share-Group address for different VPN instances on a PE. The Share-Group address cannot be the same as the Switch-Group address. The *number* value must be set different from the MTI number.

You cannot repeatedly run the **multicast-domain share-group binding** command in the same VPN instance view. You can configure a new Share-MDT group address and MTI only after deleting the existing ones.

After the **undo multicast-domain share-group** command is executed, configurations about the MTI and Switch-MDT are deleted.

Some multicast protocol packets (such as Register and Graft packets) are sent in unicast mode. These packets are transmitted over unicast VPN tunnels but not multicast VPN tunnels (Mtunnels) on the public network.

Example

Specify the Share-Group of VPN instance **mytest** as 224.1.1.1 and bind MTI0.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
```

8.6.14 multicast-domain source-interface

Function

The **multicast-domain source-interface** command allows an MTI to use an IP address of a default interface.

The **undo multicast-domain source-interface** command restores the default setting.

By default, an MTI does not use an IP address of a default interface.

Format

multicast-domain source-interface *interface-type interface-number*

undo multicast-domain source-interface

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. **NOTE** To avoid frequent protocol changes caused by interface flapping, use the loopback interface address as the MTI address.	-

Views

System view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a PE encapsulates VPN multicast packets, the MTI address is used as the multicast source address of the encapsulated public network multicast data packets. You can run the **multicast-domain source-interface** command to configure the source interface whose address is referenced by the MTI. This keeps the MTI address consistent with the IP address of the interface on which IBGP neighbor relationships are established, which ensures that VPN multicast packets pass the RPF check.

Prerequisites

The multicast routing function has been enabled using the **multicast routing-enable** command in the VPN instance.

Precautions

If the **multicast-domain source-interface** command is run in the system view, the setting takes effect globally. The command run in the VPN IPv4 address family view takes precedence over that run in the system view. If the command is configured in the system view rather than the VPN IPv4 address family view, the setting in the system view takes effect.

A manually configured IP address on an MTI takes precedence over a default interface address specified using the **multicast-domain source-interface** command.

The source interface whose address is referenced by the MTI must be the interface on which public network IBGP neighbor relationships are established on the PE; otherwise, VPN multicast packets cannot pass the RPF check.

Example

Configure the MTI to use the IP address of the default interface named **loopback 1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain source-interface loopback 1
```

8.6.15 multicast-domain switch-delay

Function

The **multicast-domain switch-delay** command specifies the delay for the switchover from the Share-MDT to Switch-MDT in a specified VPN instance.

The **undo multicast-domain switch-delay** command restores the default value of the delay.

By default, the delay for the switchover from the Share-MDT to Switch-MDT is 5 seconds.

Format

multicast-domain switch-delay *switch-delay*

undo multicast-domain switch-delay

Parameters

Parameter	Description	Value
switch-delay	Specifies the delay for the switchover from the Share-MDT to Switch-MDT.	The value of the delay is an integer that ranges from 3 to 60, in seconds.

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some cases, the forwarding rate of VPN multicast data packets fluctuates above and below the switchover threshold. To prevent frequent switchovers between the Share-MDT and Switch-MDT, configure a delay for the switchover from the Share-MDT to Switch-MDT. When detecting that the forwarding rate is higher than the switchover threshold, the system does not immediately perform the switchover but starts the Switch-Delay timer. Before the Switch-Delay timer expires, the system continues to detect the data forwarding rate. If the rate remains higher than the switchover threshold throughout the duration of the Switch-Delay timer, the transmission path of data packets is switched to the Switch-MDT; otherwise, the packets are still forwarded along the Share-MDT.

Prerequisites

The Share-Group has been configured using the **multicast-domain share-group binding** command in the VPN instance.

Precautions

During a switchover, there is a delay about 1 to 30 seconds from the time when the forwarding rate ranges to the time when the system starts the Switch-Delay timer. The delay is not included in the value of the Switch-Delay. Consequently, the total delay from the time when the forwarding rate of the data changes to the time when the system completes the switchover is 1-30 seconds longer than the Switch-Delay.

Example

Specify the delay for the switching to Switch-MDT to 20 seconds in VPN instance **mytest**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain switch-delay 20
```

8.6.16 multicast-domain switch-group-pool

Function

The **multicast-domain switch-group-pool** command specifies the conditions for the switchover from the Share-MDT to Switch-MDT and configures the Switch-Group-Pool in a specified VPN instance.

The **undo multicast-domain switch-group-pool** command restores the default configuration.

By default, the Switch-Group-Pool is not specified, and the switchover to the Switch-MDT is not performed.

Format

multicast-domain switch-group-pool *switch-group-pool* { *network-mask* | *network-mask-length* } [**threshold** *threshold-value* | **acl** *advanced-acl-number*] *

undo multicast-domain switch-group-pool

Parameters

Parameter	Description	Value
switch-group-pool	Specifies the start address of the Switch-Group-Pool.	The value is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
network-mask	Specifies the mask of a Switch-Group-Pool address.	The value is in dotted decimal notation and ranges from 255.255.255.0 to 255.255.255.255.
network-mask-length	Specifies the mask length of a Switch-Group-Pool address.	The value is an integer that ranges from 24 to 32; that is, the range of the group address in the Switch-MDT Switch-Group-Pool is from 0 to 255.
threshold *threshold-value*	Specifies the switchover threshold.	The value is an integer that ranges from 0 to 4194304, in kbit/s. By default, it is 0.
acl *advanced-acl-number*	Specifies the (S, G) entry which the Switch-Group-Pool takes effect on. *advanced-acl-number* indicates the advanced ACL number. If the ACL is not specified, the Switch-Group-Pool takes effect on all (S, G) entries.	The value is an integer that ranges from 3000 to 3999.

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Between the PE connected to the VPN receivers and the PE connected to the VPN multicast source, a special Switch-MDT is set up for the high-speed VPN multicast data packets flowing into the public network. The multicast data flow can be switched from the Share-MDT to the Switch-MDT. Therefore, on-demand multicast can be realized. This prevents data from be flooded in the public network when the Share-MDT is used to transmit VPN multicast data packets.

Prerequisites

A Share-Group has been configured using the **multicast-domain share-group binding** command.

Follow-up Procedure

In some cases, the forwarding rate of VPN multicast data packets fluctuates above and below the switchover threshold. Configure a delay for the switchover from the Share-MDT to Switch-MDT using the **multicast-domain switch-delay** command. If the rate remains higher than the switchover threshold throughout the duration of the Switch-Delay timer, the transmission path of data packets is switched to the Switch-MDT; otherwise, the packets are still forwarded along the Share-MDT.

Precautions

On a PE, the address ranges defined by the Switch-Group-Pool cannot overlap for VPN instances.

From the time when data forwarding rate changes to the time when the system starts the switch-delay timer, there is a delay of 1 to 30 seconds because of necessary traffic calculation and protocol processing. In actual switchover, the delay is longer than the switch-delay period by 1 to 30 seconds.

Example

Configure the Switch-Group-Pool of VPN instance named **mytest** to range from 225.2.2.1 to 225.2.2.15.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain switch-group-pool 225.2.2.1 28
```

8.6.17 multicast-domain switch-without-register

Function

The **multicast-domain switch-without-register** command disables the source PE from sending null Register messages to the RP to establish the SPT on the public network before the Switch-Group address is used to encapsulate VPN data.

The **undo multicast-domain switch-without-register** command restores the default setting.

By default, before the Switch-Group address is used to encapsulate VPN data, the source PE sends null Register messages to the RP and establishes the SPT on the public network.

Format

multicast-domain switch-without-register

undo multicast-domain switch-without-register

Parameters

None

Views

VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In previous implementation, if the Switch-Group address is in the ASM address range, when the SPT switchover occurs on the multicast tunnel of the public network, the source PE sends the switchover message to all receiver PEs. After receiving the switchover message, these receiver PEs send the (*, G) Join messages to the RP of the public network to establish the RPT. When the Switch-Group address is used in the VPN to encapsulate multicast data, the public network side of the source PE receives the data forwarded from the VPN based on the Switch-Group address. Then the forwarding entries are created on the source PE, and the source PE encapsulates the data in the Register messages which are sent to the RP of the public network. Then, the RP decapsulates the Register messages, and sends the data to the receiver PEs. Finally, the receiver PEs trigger the SPT switchover towards the source PE. In this manner, the SPT is established on the public network.

When there are many entries involved in SPT switchovers, the speed of sending Register messages is reduced. As a result, sending the first Register message to the RP takes a long time for certain entries, and establishing the SPT on the public network is delayed. In addition, in the process of establishing the SPT on the public network, multicast services are interrupted and certain VPN data may also be discarded, leading to the service interruption on the user end.

To address the preceding problems, disable the source PE from sending the null Register message to the RP and establishing a public network SPT before the Switch-Group address is used to encapsulate VPN data.

Prerequisites

A Share-Group has been configured using the **multicast-domain share-group binding** command.

Configuration Impact

After the VPN data traffic exceeds the upper limit, the source PE uses the Switch-Group address to encapsulate data and sends the switchover message to the receiver PEs. If the Switch-Group address is allocated for the first time, when sending the switchover message, the source PE sends the Register message that is encapsulated with the VPN Hello message to the RP, and the RP forwards the Register message to the receiver PEs. Based on the received messages, the receiver PEs and the RP directly send the (S, G) Join messages to the source PE and establish the SPT on the public network in advance. In this manner, when the public network tunnel is switched from the RPT to the SPT, the number of discarded multicast messages is reduced and the impact on multicast services is minimized.

Example

When the Switch-Group address is not used to encapsulate VPN data for mytest, configure the source PE to send the null Register message to the RP to establish the SPT on the public network.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance mytest
[HUAWEI-vpn-instance-mytest] route-distinguisher 11:11
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast routing-enable
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain share-group 224.1.1.1 binding mtunnel 0
[HUAWEI-vpn-instance-mytest-af-ipv4] multicast-domain switch-without-register
```

8.6.18 reset multicast-domain control-message counters

Function

The **reset multicast-domain control-message counters** command clears statistics about sent and received MDT switch messages in a specified VPN instance or all VPN instances.

Format

reset multicast-domain { **vpn-instance** *vpn-instance-name* | **all-instance** } **control-message counters**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Clears statistics about sent and received MDT switch messages in a specified VPN instance. The parameter *vpn-instance-name* specifies the name of an existing VPN instance on the device.	The value must be an existing VPN instance name.
all-instance	Clears statistics about sent and received MDT switch messages in all VPN instances.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

If a fault occurs on a multicast VPN network, you need to check whether MDT switch messages are properly sent and received. If the current device already records a large number of statistics about MDT switch messages, you can run the **reset multicast-domain control-message counters** command to clear statistics about sent and received messages in a specified VPN instance or all VPN instances and then run the **display multicast-domain control-message counters** command to check whether the count of MDT switch messages increases, which helps fault location.

Precautions

Running the **reset multicast-domain control-message counters** command will clear all statistics about MDT switch messages. Therefore, exercise caution before using this command.

Example

Clear statistics about sent and received MDT switch messages in VPN instance **red**.

```
<HUAWEI> reset multicast-domain vpn-instance red control-message counters
```

8.6.19 service type (Eth-trunk interface view)

Function

The **service type multicast-tunnel** command configures an Eth-trunk interface as a multicast loopback interface.

The **undo service type multicast-tunnel** command cancels the configuration.

By default, an Eth-trunk interface is not configured as a multicast loopback interface.

Format

service type multicast-tunnel

undo service type multicast-tunnel

Parameters

None

Views

Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The switch can receive the VPN multicast packets and use GRE to encapsulate them only after a multicast loopback interface has been configured.

Follow-up Procedure

Configure member interfaces of the multicast loopback interface using the **trunkport** command.

Precautions

- After you configure an interface as a multicast loopback interface, the switch automatically disables STP on this interface. The interface then does not support STP configuration commands. After the multicast loopback interface configuration is cancelled, the switch automatically enables STP on the interface.
- On the switch, only one Eth-Trunk interface can function as the multicast loopback interface. All VPN multicast packets are encapsulated on this interface into public network multicast data packets.
- The configurations allowed on an Eth-Trunk to be configured as a loopback interface include **description**, **enable snmp trap updown**, **jumboframe enable**, **mixed-rate link enable**, **qos phb marking enable**, **set flow-stat interval**, **shutdown**, **local-preference enable**, **traffic-policy (interface view)**, and **trust**. If other configurations exist on the Eth-Trunk, the Eth-Trunk cannot be configured as a loopback interface.
- After an Eth-Trunk is configured as a loopback interface, the Eth-Trunk supports only the following configurations: **authentication open ucl-policy enable**, **description**, **enable snmp trap updown**, **jumboframe enable**, **mixed-rate link enable**, **qos phb marking enable**, **set flow-stat interval**, **shutdown**, **local-preference enable**, **statistic enable (interface view)**, **traffic-policy (interface view)**, **vcmp disable**, and **trust**.

- Before disabling an Eth-Trunk interface from working as the multicast loopback interface, delete all member interfaces of the Eth-Trunk interface.
- If "Warning: ACL resources are insufficient when the physical interface is added to the multicast loopback interface, so the multicast VPN function may be abnormal." is displayed when you add a physical interface to a multicast loopback interface, resources on the multicast loopback interface are occupied by other services. To ensure normal running of services, delete this physical interface from the multicast loopback interface or delete unnecessary configurations, for example, unnecessary traffic policies.
- If an Eth-Trunk has been configured as a multicast VPN loopback interface, do not use the MIB to perform other service configuration on the Eth-Trunk. Otherwise, the multicast VPN loopback interface will become invalid or the service configuration issued by the MIB may not take effect.

Example

Configure Eth-Trunk 1 as a multicast loopback interface.

```
<HUAWEI> system-view
[HUAWEI] interface Eth-Trunk 1
[HUAWEI-Eth-Trunk1] service type multicast-tunnel
```

8.6.20 set multicast tunnel enhanced

Function

The **set multicast tunnel enhanced** command allows an Eth-Trunk that works as a multicast VPN loopback interface to have member interfaces from different cards.

The **undo set multicast tunnel enhanced** command forbids an Eth-Trunk that works as a multicast VPN loopback interface to have member interfaces from different cards.

By default, an Eth-Trunk that works as a multicast VPN loopback interface cannot have member interfaces from different cards.

Format

set multicast tunnel enhanced

undo set multicast tunnel enhanced

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an Eth-Trunk that works as a multicast VPN loopback interface have member interfaces from different member switches in a stack system, multicast VPN services can function properly if the switch where a member interface is located fails. This improves device reliability.

Follow-up Procedure

Run the **service type multicast-tunnel** command to configure an Eth-Trunk as a multicast VPN loopback interface.

Configuration Impact

After the **set multicast tunnel enhanced** command is executed, the number of ACLs for multicast VPN will increase if the Eth-Trunk that functions as a multicast VPN loopback interface contains more than one member interface from a device. The number of ACLs equals to the number of interfaces on a device configured as the member interfaces of an Eth-Trunk functioning as a multicast VPN loopback interface multiplied by the number of Mtunnel outbound interfaces for accessing the public network. For example, if two interfaces on a device are configured as member interfaces of the Eth-Trunk functioning as a multicast VPN loopback interface, and if the device is configured with four Mtunnel outbound interfaces for accessing the public network, a total of eight (2*4) ACLs will be used by multicast VPN services. If there are insufficient ACL resources, multicast VPN services cannot run properly.

Precautions

A multicast VPN loopback interface cannot be configured together with the **set multicast tunnel enhanced** and **undo set multicast tunnel enhanced** commands.

Example

Configure the Eth-Trunk that works as a multicast VPN loopback interface to allow member ports from different cards.

```
<HUAWEI> system-view
[HUAWEI] set multicast tunnel enhanced
```

8.7 IPv4 Multicast Route Management Commands

8.7.1 Command Support

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.

Product	Support
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.
S6700	Supported.

NOTE

Only S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the multicast multi-instance feature.

8.7.2 display default-parameter mrm

Function

The **display default-parameter mrm** command displays the default configurations for multicast routing management (MRM).

Format

display default-parameter mrm

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays only the default configurations, regardless of whether MRM parameters are changed. Therefore, you can use this command to check which parameters have been modified.

Example

Display default configurations for MRM.

```
<HUAWEI> display default-parameter mrm
 System View Default Configurations:
 ----------------------------------
 Load splitting rule: disabled
 Load-splitting-timer: 1800 s
 Route selection rule: preference-preferred
```

```
Multi-topology: disabled

Interface View Default Configurations:
--------------------------------------
Minimum TTL: 1
Reject inbound data: disabled
Reject outbound data: disabled
Multicast load-splitting weight: 1
```

Table 8-89 Description of the **display default-parameter mrm** command output

Item	Description
System View Default Configurations	Default configurations for multicast routing management (MRM) in the system view.
Load splitting rule	Whether multicast load splitting is configured. By default, multicast load splitting is not configured. To configure multicast load splitting, run the **multicast load-splitting** command.
Load-splitting-timer	Default value of the multicast load splitting balancing timer. By default, the value is 1800s. You can run the **multicast load-splitting-timer** command to set the value of the multicast load splitting balancing timer.
Route selection rule	RPF route selection rule. By default, RPF route selection is based on the preference of the routing protocol.
Interface View Default Configurations	Default configurations for multicast routing management (MRM) in the interface view.
Minimum TTL	Minimum TTL value for multicast packet forwarding.
Reject inbound data	Whether the interface is disabled from receiving multicast packets.
Reject outbound data	Whether the interface is disabled from forwarding multicast packets.
Multicast load-splitting weight	Multicast load splitting weight of the interface. By default, the multicast load splitting weight of an interface is 1. You can run the **multicast load-splitting weight** command to set the value of the multicast load splitting weight.

8.7.3 display migp routing-table

Function

The **display migp routing-table** command displays brief information about the MIGP routing table.

Format

display migp routing-table [*ip-address* [*mask-length* | *mask*]] [**verbose**]

Parameters

Parameter	Description	Value
ip-address	Specifies a destination IP address.	The address is in dotted decimal notation.
mask	Indicates a mask.	The mask is in dotted decimal notation.
mask-length	Specifies the length of the mask.	The value is a decimal integer ranging from 0 to 32.
verbose	Displays detailed information about active routes and inactive routes. If the parameter is not specified, only brief information about active routes is displayed.	-

1: Monitoring level

Usage Guidelines

This command displays the MIGP routing table. You can specify parameters in the command to view specified routes.

Example

Display brief information about the MIGP routing table.

```
<HUAWEI> display migp routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
```

```
Routing Tables: MIGP
         Destinations : 4        Routes : 4

Destination/Mask    Proto  Pre  Cost     Flags NextHop         Interface

10.4.4.4/32        OSPF   10   3             10.0.1.1        Vlanif100
10.5.5.5/32        OSPF   10   4             10.0.1.1        Vlanif100
10.0.3.0/24        OSPF   10   3             10.0.1.1        Vlanif100
192.168.3.0/24      OSPF   10   4             10.0.1.1        Vlanif100
```

Table 8-90 Description of the **display migp routing-table** command output

Item	Description
Route Flags	Flag of a route: ● R: indicates that the route is a recursive route. ● D: indicates that the route is delivered to the FIB table. ● T: indicates a route whose next hop belongs to a VPN instance.
Routing Tables: MIGP	MIGP routing table.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination/Mask	Address and mask length of the destination network or host.
Proto	Routing protocol that learns a route.
Pre	Route preference.
Cost	Route cost.
Flags	Route flags in the header of the routing table.
NextHop	Next hop of a route.
Interface	Outbound interface to a reachable next hop.

Display detailed information about the MIGP routing table.

```
<HUAWEI> display migp routing-table verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Table : MIGP
         Destinations : 5        Routes : 5

Destination: 10.4.4.4/32
     Protocol: ISIS            Process ID: 1
   Preference: 15                    Cost: 20
      NextHop: 10.0.1.1          Interface: Vlanif100
```

```
        State: Active Adv             Age: 00h34m26s

Destination: 10.5.5.5/32
     Protocol: ISIS            Process ID: 1
   Preference: 15                    Cost: 30
      NextHop: 10.0.1.1         Interface: Vlanif100
        State: Active Adv             Age: 00h34m26s

Destination: 10.0.2.0/24
     Protocol: ISIS            Process ID: 1
   Preference: 15                    Cost: 20

   Preference: 15                    Cost: 40
      NextHop: 10.0.1.1         Interface: Vlanif100
        State: Active Adv             Age: 00h34m28s
```

Table 8-91 Description of the **display migp routing-table** verbose command output

Item	Description
Destination	Address and mask length of the destination network or host.
Protocol	Routing protocol that learns a route.
Process ID	Process ID of the routing protocol.
Preference	Preference of a route.
Cost	Indicates the route cost.
NextHop	Next hop of a route.
Interface	Outbound interface of a route.

Item	Description
State:	Status of routes, which can be: ● Active: indicates routes in the Active state. ● Invalid: indicates invalid routes. ● Inactive: indicates routes in the Inactive state. ● NoAdv: indicates routes that cannot be advertised. ● Adv: indicates routes that can be advertised. ● Del: indicates routes to be deleted. ● GotQ: indicates routes that are relayed successfully. ● WaitQ: indicates routes that are not relayed successfully yet. ● Stale: indicates routes with the Stale flag. The routes are used in GR.
Age	Time that elapsed since a route is generated.

8.7.4 display migp routing-table statistics

Function

The **display migp routing-table statistics** command displays the statistics about the MIGP routing table.

Format

display migp routing-table statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Integrated route statistics contain the total number of routes added or deleted through protocols and the total number of active or inactive routes with deletion flags but are not deleted.

Example

Display the statistics about routes in the MIGP routing table.

```
<HUAWEI> display migp routing-table statistics
Proto     total      active      added        deleted      freed
         routes     routes      routes       routes       routes
OSPF      0           0           0            0            0
IS-IS     5           5           45           40           40
Total     5           5           45           40           40
```

Table 8-92 Description of the **display migp routing-table statistics** command output

Item	Description
Proto	Routing protocol.
total routes	Total number of routes in the current routing table.
active routes	Number of active routes in the routing table.
added routes	Number of routes (active and inactive) added to the routing table.
deleted routes	Number of routes deleted from the routing table.
freed routes	Number of released routes that are deleted permanently from the routing table.

8.7.5 display mrt routing-table

Function

The **display mrt routing-table** command displays MRT routes.

Format

display mrt routing-table [**vpn-instance** *vpn-instance-name*] [*ip-address* [*mask* | *mask-length*]] [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
ip-address	Specifies a destination IP address.	The address is in dotted decimal notation.
mask	Specifies mask.	The mask is in dotted decimal notation.
mask-length	Specifies mask length.	It is an integer ranging from 0 to 32.
verbose	Displays detailed information about active and inactive routes. If the parameter **verbose** is not specified, detailed information about active routes is displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view specific routing information.

Example

Display information about all MRT routes.

```
<HUAWEI> display mrt routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Tables: MRT
         Destinations : 1        Routes : 1

Destination/Mask  Proto  Pre  Cost  Flags  NextHop  Interface

  10.5.5.1/32     MSR    255     0     R   10.1.1.1  Vlanif100
```

Table 8-93 Description of the **display mrt routing-table** command output

Item	Description
Route Flags	Flag of a route: - R: indicates that the route is a recursive route. - D: indicates that the route is delivered to the FIB table. - T: indicates a route whose next hop belongs to a VPN instance.
Routing Tables: MRT	IMRT routing table.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination/Mask	Address and mask length of the destination network or host.
Proto	Protocol that learns a route.
Pre	Route preference.
Cost	Route cost.
Flags	Route flags in the header of the routing table.
NextHop	Next hop of a route.
Interface	Outbound interface to a reachable next hop.

Display the detailed information of the specified routes.

```
<HUAWEI> display mrt routing-table 10.12.12.12 verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance
------------------------------------------------------------------------------
Routing Table : MRT
Summary Count : 1

Destination: 10.12.12.12/32
     Protocol: MSR            Process ID: 0
   Preference: 1                    Cost: 0
      NextHop: 10.11.11.12     Neighbour: 0.0.0.0
        State: Active Adv Relied     Age: 00h04m49s
          Tag: 0                Priority: low
        Label: NULL              QoSInfo: 0x0
   IndirectID: 0x80000002
 RelayNextHop: 0.0.0.0         Interface: Vlanif100
     TunnelID: 0x0                 Flags: R
```

Table 8-94 Description of the **display mrt routing-table verbose** command output

Item	Description
Routing Table: MRT	MRT routing table.

Item	Description
Summary Count	Number of the destination network and host.
Destination	Address and mask length of the destination network or host.
Protocol	Routing protocol that learns a route.
Process ID	Process ID of the routing protocol.
Preference	Route preference.
Cost	Route cost.
NextHop	Next hop of a route.
Neighbour	Address of the neighbor.
State	Status of routes: ● Active: indicates active routes. ● Invalid: indicates invalid routes. ● Inactive: indicates inactive routes. ● NoAdv: indicates the routes that cannot be advertised. ● Adv: indicates the routes that can be advertised. ● Del: indicates the routes to be deleted. ● Relied: indicates the route that finds the next hop and outbound interface or the route that finds the tunnel during packet forwarding. ● WaitQ: indicates the route that does not find the next hop or outbound interface or the route that does not find the tunnel. ● Stale: indicates the routes with the stale flag. The routes are used in GR.
Age	Time that elapsed since a route is generated.
Tag	Administrative tag for routes.
Priority	Priority of a route.
Label	MPLS label allocated to a route.
QoSInfo	QoS information.
IndirectID	ID of the indirect next hop.
RelayNextHop	Relay next hop.
Interface	Outbound interface through which the next hop is reachable.
TunnelID	Tunnel ID.

Item	Description
Flags	Route flags in the header of the routing table.

8.7.6 display mrt routing-table statistics

Function

The **display mrt routing-table statistics** command displays statistics about the MRT routes.

Format

display mrt routing-table [**vpn-instance** *vpn-instance-name*] **statistics**

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Route statistics include:

- Total number of routes that are added or deleted by the protocol
- Number of active or inactive routes that are tagged for deletion but not deleted

Example

Display statistics about routes in the MRT routing table.

```
<HUAWEI> display mrt routing-table statistics
Proto     total      active      added       deleted      freed
          routes     routes      routes      routes       routes
MSTATIC   1          0           1           0            0
```

Table 8-95 Description of the **display mrt routing-table statistics** command output

Item	Description
Proto	Routing protocol.
total routes	Total number of routes in the routing table.
active routes	Number of active routes in the routing table.
added routes	Number of active and inactive routes added in the routing table.
deleted routes	Number of routes to be deleted from the routing table.
freed routes	Number of routes that are permanently deleted from the routing table.

8.7.7 display mrt routing-table vpn-instance

Function

The **display mrt routing-table vpn-instance** command displays the MRT routing table of a VPN instance.

Format

display mrt routing-table vpn-instance *vpn-instance-name* [*ip-address* [*mask* | *mask-length*] [**longer-match**]] [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
ip-address	Specifies a destination IP address.	The address is in dotted decimal notation.
mask	Specifies mask.	The mask is in dotted decimal notation.
mask-length	Specifies mask length.	The value is a decimal integer that ranges from 0 to 32.
longer-match	Displays only routes that match the specified network or mask.	-
verbose	Displays detailed information about active and inactive routes.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can specify different parameters to view the specific routing information.

Example

Display the MRT routing table of the IPv4 VPN instance named vpn1.

```
<HUAWEI> display mrt routing-table vpn-instance vpn1
Route Flags: R - relay, D - download to fib
------------------------------------------------------------------------------
Routing Tables: MSR
        Destinations : 1        Routes : 1

Destination/Mask  Proto  Pre  Cost  Flags  NextHop  Interface

  10.5.5.1/32     MSR    255    0     R    10.1.1.1    Vlanif100
```

Table 8-96 Description of the **display mrt routing-table vpn-instance** command output

Item	Description
Route Flags	Route flag that identifies the attribute of a route. ● R: indicates an iterated route. ● D: indicates that the route is downloaded to the FIB table.
Routing Tables: MSR	MRT routing table.
Destinations	Total number of destination networks or hosts.
Routes	Total number of routes.
Destination/Mask	Address and mask length of the destination network or host.
Proto	Protocol through which routes are learned.
Pre	Route preference.
Cost	Route cost.
Flags	Route flags in the header of the routing table.
NextHop	Next hop of a route.
Interface	Outbound interface to a reachable next hop.

8.7.8 display mtrace statistics

Function

The **display mtrace statistics** command displays statistics about multicast trace (Mtrace) packets.

Format

display mtrace statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To collect statistics about Mtrace traffic generated in a certain period, clear the original statistics.

Example

Display statistics about the current Mtrace traffic.

```
<HUAWEI> display mtrace statistics
Mtrace statistics:
 Type         Send        Receive        Invalid
 Query         10          5              0
 Request        20          4              0
 Response      3           7              1
```

Table 8-97 Description of the **display mtrace statistics** command output

Item	Description
Type	Indicates the types of Mtrace packets. The types are as follows: ● Query: IGMP-Tracert-Query packets. ● Request: IGMP-Tracert-Request packets. ● Response: IGMP-Tracert-Response packets.
Send	Indicates the number of sent packets.
Receive	Indicates the number of received packets.
Invalid	Indicates the number of invalid packets.

8.7.9 display multicast boundary

Function

The **display multicast boundary** command displays the multicast boundary configured on an interface.

Format

display multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **boundary** [*group-address* [*mask* | *mask-length*]] [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
group-address	Specifies a multicast group address.	The address is in dotted decimal notation. The value ranges from 224.0.1.0 to 239.255.255.255.
mask	Specifies the mask of the multicast group address.	The mask is in dotted decimal notation.
mask-length	Specifies the mask length of the multicast group address.	The value is a decimal integer that ranges from 4 to 32.
interface *interface-type interface-number*	Specifies the type and the number of an interface. The parameter is used to specify an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command enables you to check the boundary of a PIM-SM network. When some hosts cannot receive multicast data, you can use this command to check whether the problem is caused by multicast boundary configuration.

Example

Display the boundaries configured on all the interfaces.

```
<HUAWEI> display multicast boundary
Multicast boundary information
Total 1 Multicast IPv4 boundary
 Interface           Boundary
 Vlanif100            225.1.1.0/24
```

Table 8-98 Description of the **display multicast boundary** command output

Item	Description
Multicast boundary information of	multicast boundary information.
Total 1 Multicast IPv4 boundary	Total number of multicast boundaries configured on a switch.
Interface	Interface configured with a multicast boundary.
Boundary	Information about the multicast boundary address.

8.7.10 display multicast forwarding-table

Function

The **display multicast forwarding-table** command displays the multicast forwarding table.

Format

display multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **forwarding-table** [*group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **register** | **none** } | { **statistics** | **verbose** }] *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
group-address	Specifies a multicast group address.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Specifies the mask of a multicast address or source address.	-
group-mask	Specifies the mask of the multicast group address.	The mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of the multicast group address.	The value is a decimal integer that ranges from 4 to 32.
source-address	Specifies the mask of the multicast source address.	The mask is in dotted decimal notation.
source-mask	Specifies the mask of the multicast source address.	The mask is in dotted decimal notation.
source-mask-length	Specifies the mask length of the multicast source address.	The value is a decimal integer that ranges from 0 to 32.
incoming-interface	Indicates the inbound interface of a multicast forwarding entry.	-
interface-type interface-number	Specifies the type and the number of an interface.	-
register	Indicates the register interface of PIM-SM.	-
outgoing-interface	Indicates the outbound interface of a multicast forwarding entry.	-

Parameter	Description	Value
include	Displays the (S, G) entry list that contains the specified downstream interface.	-
exclude	Displays the (S, G) entry list that does not contain the specified downstream interface.	-
match	Displays the (S, G) entry list that matches the specified interface and the (S, G) entries have only one specified interface.	-
none	Indicates that the downstream interface list is null.	-
verbose	Displays the detailed information about the multicast forwarding table.	-
statistics	Displays the statistics about the multicast forwarding table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

During multicast routing and forwarding, routing information generated by multicast routing protocols is saved in a multicast routing table. The switch selects the optimal multicast routes from the routing table according to multicast routing and forwarding policies, and then delivers the selected multicast routes to the multicast forwarding table to guide multicast data forwarding.

You can use the **display multicast forwarding-table** command to check whether multicast forwarding entries have been generated and whether multicast data can be forwarded normally.

Example

Display the multicast forwarding table.

```
<HUAWEI> display multicast forwarding-table
Multicast Forwarding Table of VPN-Instance: public net
```

```
Total 1 entry, 1 matched

00001. (10.10.10.2, 225.0.0.1)
     MID: 0, Flags: ACT
     Uptime: 00:08:32, Timeout in: 00:03:26
     Incoming interface: Vlanif10
     List of 1 outgoing interfaces:
       1:  Vlanif20
           Activetime: 00:23:15
     Matched 154 packets(15378 bytes), Wrong If 0 packets
     Forwarded 154 packets(15378 bytes)
```

Table 8-99 Description of the **display multicast forwarding-table** command output

Item	Description
Multicast Forwarding Table of VPN-Instance: public net	VPN instance to which the multicast forwarding table corresponds. **public net** indicates the public network instance.
Total 1 entry, 1 matched	Total number of forwarding entries and number of eligible forwarding entries.
00001	Sequence number of the (S, G) entry.
(10.10.10.2, 225.0.0.1)	(S, G) entry in the multicast forwarding table.
MID	Uniquely identifies the multicast forwarding entry in the MFIB table. MID is used to rapidly search the multicast forwarding table.

Item	Description
Flags	Indicates the status flag of the (S, G) entry. ● ACT: indicates that an active event is triggered. ● DUM: indicates a dummy entry. ● MISS: indicates that the nocache time needs to be reported. ● DROP: indicates packet dropping. ● LTH: indicates that the traffic volume is below the threshold. ● DEL: indicates a deleted entry. ● RST: indicates that registration of the known timer is started. ● 2SYNC: indicates that the entry is contained in the MFIB table but it does not exist on the device. ● 2ADD: indicates that the entry existing on the device has not been added to the MFIB table. ● CLR: indicates that the MFIB table is resetting. ● L2FWD: indicates that the device forwards Layer 2 traffic in multicast mode. ● 2ACK: indicates that the VPN instance is waiting for the ACK message from the slave main control board. ● 2RSED: indicates that the entry is waiting for retransmission. ● BKCLR: indicates that the MFIB table on the slave main control board is resetting. ● 2DEL: indicates that the entry deleted from the device has not been removed from the MFIB table. ● PDEL: indicates that the entry does not exist on the device. ● A denotes addition; D denotes deletion; I denotes upstream update; R denotes RP update; P denotes PMBR; F denotes flag. ● S denotes SPT; E denotes encapsulation group update; US denotes status update; CS denotes status clearing.
Uptime	Period duration of the (S, G) entry.
Timeout in	Remaining time of the (S, G) entry.
Incoming interface	Upstream interface of the (S, G) entry.
List of 1 outgoing interfaces	Downstream interface list. The contents of the downstream interface list are as follows: ● Name and number of the outbound interface ● The existing time of outbound interface

Item	Description
Matched 154 packets(15378 bytes)	Number of multicast packets and bytes matching the (S, G) entry. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.
Wrong If 0 packets	Number of multicast packets matching the (S, G) entry but are not forwarded. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.
Forwarded 154 packets(15378 bytes)	Number of packets and bytes forwarded by the (S, G) entry. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.

8.7.11 display multicast forwarding-table optimization-mode configuration

Function

The **display multicast forwarding-table optimization-mode configuration** command displays the configuration of the optimization mode in which Layer 3 multicast forwarding entries are stored.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support this command.

Format

display multicast forwarding-table optimization-mode configuration [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	*slot-id* specifies the slot that uses the multicast optimization mode. If no slot ID is specified, configurations of all slots are displayed.	The value is an integer and must be the slot ID of a running slot.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to display the configuration of the optimization mode in which Layer 3 multicast forwarding entries are stored. The configuration helps you select a slot based on your storage requirement.

Example

Display the configuration of the optimization modes.

```
<HUAWEI> display multicast forwarding-table optimization-mode configuration
Multicast forwarding-table optimization mode :
Slot      Mode
-------------------------
2         Normal mode
4         Normal mode
5         Rich MCast mode
```

Table 8-100 Description of the **display multicast forwarding-table optimization-mode configuration** command output

Item	Description
Multicast forwarding-table optimization mode	When the multicast optimization mode is enabled.
slot	Slot ID.
mode	Storage Mode. The following storage modes are available: ● Normal: The ARP cache table or ND cache table and multicast forwarding table share hardware resources, without affecting hardware resources allocated to the routing table. ● Rich MCast mode: also known as multicast optimization mode. The system allocates hardware resources preferentially to the multicast forwarding table. The ARP/ND cache table and routing table share hardware resources.

8.7.12 display multicast routing-table

Function

The **display multicast routing-table** command displays information about a multicast routing table.

Format

display multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table** [*group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **register** | **none** }] * [**outgoing-interface-number** [*number*]]

display multicast routing-table [*group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **include** | **exclude** | **match** } { *interface-type interface-number* | **vpn-instance** *vpn-instance-name* | **register** | **none** }] * [**outgoing-interface-number** [*number*]]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Specifies all the instances.	-
group-address	Indicates the multicast group address.	The address is in dotted decimal notation. The value ranges from 224.0.1.0 to 239.255.255.255.
mask { *group-mask* | *group-mask-length* }	Indicates the mask of the multicast group address.	● *group-mask*: The address is in dotted decimal notation. The value ranges from 240.0.0.0 to 255.255.255.255. ● *group-mask-length*: The value is an integer that ranges from 4 to 32
source-address	Indicates the multicast source address.	The address is in dotted decimal notation.

Parameter	Description	Value
mask { *source-mask* | *source-mask-length* }	Indicates the mask of the specified source address.	● *source-mask*: The address is in dotted decimal notation. The value ranges from 0.0.0.0 to 255.255.255.255. ● *source-mask-length*: The value is an integer that ranges from 0 to 32
incoming-interface	Indicates the upstream interface of a multicast routing entry.	-
interface-type interface-number	Indicates the type and the number of an interface.	-
register	Indicates the register interface of a multicast routing entry.	-
outgoing-interface	Indicates the downstream interface of a multicast routing entry.	-
include	Indicates the (S, G) entries whose downstream interface list contains specified downstream interfaces.	-
exclude	Indicates the (S, G) entries whose downstream interface list does not contain specified downstream interfaces.	-
match	Indicates (S, G) entries whose the downstream interface list contains only one interface that is the same as a specified downstream interface.	-
none	Indicates that the downstream interface list is null.	-

Parameter	Description	Value
outgoing-interface-number	Indicates the number of downstream interfaces of multicast routing entries.	-
number	Specifies the number of downstream interfaces.	The value is an integer that ranges from 0 to 2048.

Usage Guidelines

The **display multicast routing-table** command is used to display the information of a multicast routing table.

Example

Display the corresponding routing entry of a multicast group in the multicast routing table.

```
<HUAWEI> display multicast routing-table
Multicast routing table of VPN-Instance: public net
 Total 1 entry
 00001. (192.168.0.2, 227.0.0.1)
       Uptime: 00:00:28
       Upstream Interface: Vlanif10
       List of 2 downstream interfaces
           1:  Vlanif20
           2:  Vlanif30
```

Table 8-101 Description of the **display multicast routing-table** command output

Item	Description
Multicast routing table of VPN-Instance	VPN instance to which the multicast routing information corresponds. **public net** indicates the public network instance.
Total 1 entry	Number of eligible routing entries.
00001	Sequence number of the (S, G) entry.
(192.168.0.2, 227.0.0.1)	(S, G) entry in the multicast routing table.
Uptime	Time that elapsed since the (S, G) entry was generated.

Item	Description
Upstream Interface	Upstream interface of the (S, G) entry.
List of 2 downstream interfaces	Downstream interface list.

Display the number of downstream interfaces of the multicast routing entries.

```
<HUAWEI> display multicast routing-table outgoing-interface-number
Multicast routing table
 Total 2 entries

 00001. (10.1.1.22, 232.1.1.1)
       Uptime: 00:00:07
       Upstream Interface: Vlanif10
       List of 20 downstream interfaces

 00002. (10.1.1.22, 232.1.2.1)
       Uptime: 00:00:07
       Upstream Interface: Vlanif20
       List of 20 downstream interfaces
```

Table 8-102 Description of the display multicast routing-table outgoing-interface-number command output

Item	Description
List of 20 downstream interfaces	Number of downstream interfaces in multicast routing entries.

8.7.13 display multicast routing-table static

Function

The **display multicast routing-table static** command displays the multicast static routes.

Format

display multicast routing-table [**vpn-instance** *vpn-instance-name*] **static** [**config**] [*source-address* { *mask* | *mask-length* }]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
config	Displays the configuration of the multicast static routes.	-

Parameter	Description	Value
source-address	Specifies a multicast source address.	The address is in dotted decimal notation.
mask	Specifies the mask of the multicast source address.	The mask is in dotted decimal notation.
mask-length	Specifies the mask length of the multicast source address.	The value is an integer that ranges from 0 to 32.

1: Monitoring level

Usage Guidelines

To check whether multicast RPF static routes are configured successfully, run the **display multicast routing-table static** command.

If the multicast static route configured on the local switch cannot be displayed, use the **ip rpf-route-static** command to configure multicast static routes.

Example

Display all multicast static routes on the switch.

```
<HUAWEI> display multicast routing-table static
Multicast Routing Table
Routes : 1

 Mroute 10.1.0.0/24
         Interface = Vlanif100       RPF Neighbor = 10.1.2.2
         Matched routing protocol = ospf, process-id = 100, Route-policy = none
         Preference = 1, Order = 1
 Running Configuration = ip rpf-route-static 10.1.0.0 24 ospf 100 10.1.2.2 order 1
```

Table 8-103 Description of the **display multicast routing-table static** command output

Item	Description
Multicast Routing Table	Multicast routing table.
Routes	Number of routes.
Mroute	Source address and mask length of a multicast route.
Interface	Outbound interface of the reachable multicast source.
RPF Neighbor	Neighbor IP address through which the source address is reachable.

Item	Description
Matched routing protocol	Matching unicast route type, which can be: ● IS-IS ● RIP ● OSPF ● BGP ● Unicast static route
process-id	Process ID of a routing protocol.
Route-policy	Routing policy. The source address of a route must match the routing policy.
Preference	Preference of a route.
Order	Order of a route.
Running Configuration	Command line for configuring a static route.

8.7.14 display multicast rpf-info

Function

The **display multicast rpf-info** command displays the Reverse Path Forwarding (RPF) routes of a specified IPv4 multicast source or source/group.

Format

display multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **rpf-info** *source-address* [*group-address*] [**rpt** | **spt**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
source-address	Specifies the address of a multicast source, used to display the information of RPF routing corresponding to the source.	The address is in dotted decimal notation.

Parameter	Description	Value
group-address	Specifies the multicast group address, used to display the information of RPF routing corresponding to the source/group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
rpt	Displays the RPF routing information corresponding to a specified source or source/group on the shared RP-tree.	-
spt	Displays the RPF routing information corresponding to a specified source or source/group on the shortest path tree.	-

1: Monitoring level

Usage Guidelines

The RPF route with the *source-address* as the destination address is an optimal route selected from unicast routes, multicast static routes, MBGP routes, and MIGP routes. You can use the **display multicast rpf-info** command to check the RPF route to the specified source or source-group.

Example

Display all RPF routes to the source address 192.168.0.1.

```
<HUAWEI> display multicast rpf-info 192.168.0.1
 VPN-Instance: public net
 RPF information about source: 192.168.0.1
     RPF interface: Vlanif100, RPF neighbor: 10.1.5.2
     Referenced route/mask: 192.168.0.0/24
     Referenced route type: unicast
     Route selection rule: preference-preferred
     Load splitting rule: disable
```

Table 8-104 Description of the **display multicast rpf-info** command output

Item	Description
RPF information about source	Multicast source to which the multicast RPF path belongs.
RPF interface	RPF interface.
RPF neighbor	RPF neighbor.
Referenced route/mask	Referenced route and its mask.

Item	Description
Referenced route type	Referenced route types: - unicast: unicast routes - MBGP: MBGP routes - mstatic: multicast static routes - MIGP: MIGP routes
Route selection rule	RPF route selection rules: - preference-preferred: selecting routes based on the preference of the routing protocols - longest-match: selecting routes based on the longest matching rule
Load splitting rule	Load splitting rules: - disable: load splitting disabled. - balance-preferred: load balancing preferred. - stable-preferred: stable-preferred load splitting. - source: load splitting based on source addresses. - group: load splitting based on group addresses. - source-group: load splitting based source and group addresses.

8.7.15 ip rpf-route-static

Function

The **ip rpf-route-static** command configures a multicast static route.

The **undo ip rpf-route-static** command deletes a multicast static route.

By default, no multicast static route is configured.

Format

ip rpf-route-static [**vpn-instance** *vpn-instance-name*] *source-address* { *mask* | *mask-length* } [**isis** *process-id* | **ospf** *process-id* | **rip** *process-id* | **bgp** | **static**] [**route-policy** *route-policy-name*] { *interface-type interface-number* | *gateway-address* } [**preference** *preference*] [**order** *order-number*]

undo ip rpf-route-static [**vpn-instance** *vpn-instance-name*] { *source-address* { *mask* | *mask-length* } [**isis** *process-id* | **ospf** *process-id* | **rip** *process-id* | **bgp** | **static**] [**route-policy** *route-policy-name*] | **all** }

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* specifies the name of the VPN instance.	The value must be an existing VPN instance name.
source-address	Specifies the address of a multicast source.	The address is in dotted decimal notation.
mask	Indicates the address mask of the multicast source.	The address mask is in dotted decimal notation.
mask-length	Specifies the mask length of the multicast source address.	The value is a decimal integer that ranges from 0 to 32.
isis *process-id*	Specifies that matched routes must be generated by the IS-IS protocol. *process-id* indicates the IS-IS process ID.	The value is a decimal integer that ranges from 1 to 65535.
ospf *process-id*	Specifies that matched routes must be generated by the OSPF protocol. *process-id* indicates the OSPF process ID.	The value is a decimal integer that ranges from 1 to 65535.
rip *process-id*	Specifies that matched routes must be generated by the RIP protocol. *process-id* indicates the RIP process ID.	The value is a decimal integer that ranges from 1 to 65535.
bgp	Specifies that matched routes must be generated by the BGP protocol.	-
static	Specifies that matched routes must be static routes.	-
route-policy *route-policy-name*	Indicates the matching rule of multicast static routes. *route-policy-name* specifies the name of a route matching rule.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of an interface, used to specify an interface.	-
gateway-address	Specifies the address of the gateway.	-
order *order-number*	Indicates the configuration order of routes in the same network segment.	The value is a decimal integer that ranges from 1 to 100.
preference *preference*	Indicates the preference of routes. The greater the value is, the lower the preference is.	The value is a decimal integer that ranges from 1 to 255. By default, it is 1.
all	Indicates all multicast static routes in the multicast static routing table.	-

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast static route specifies an RPF interface or RPF neighbor for multicast packets from a specified multicast source. You can configure a multicast static route to:

- Change an RPF route.

  If you want an interface to receive multicast data packets from a specified multicast source but the interface is not the RPF interface for the multicast source, configure a multicast static route to specify this interface as the RPF interface for the multicast source. When the switch receives multicast data packets from the multicast source, it performs an RPF check using the configured RPF route. Packets sent from the source to the switch through other interfaces fail the RPF check.

- Connect RPF routes.

  If the unicast route on a network segment is incomplete, multicast packets cannot be forwarded due to the lack of an RPF route. For example, when two adjacent devices run different routing protocols and the routing protocols do not import routes from each other, packets cannot be forwarded between the two devices. In this case, you can configure RPF static routes on the devices. The devices can perform RPF checks using the specified RPF interfaces so that multicast packets can be forwarded successfully.

Precautions

- If you specify a protocol type in the **ip rpf-route-static** command, the switch compares the configured multicast static route with the unicast routes of the specified protocol. If protocol types of the optimal unicast route and the multicast static route are different, the switch selects the optimal unicast route as the RPF route.
- A multicast static route is identified by three elements: *source-address* { *mask* | *mask-length* }, protocol type, and *route-policy-name*. Two multicast static routes are considered different as long as one element has different values in the two routes. A maximum of eight multicast static routes can be configured on a network segment.
- If the next-hop interface of a multicast static route is a P2P interface, you can specify the next-hop interface in the command. If the next-hop interface is not a P2P interface, you must specify the next-hop address.
- A multicast static route may not take effect after you configure it using the **ip rpf-route-static**, because the specified interface is Down. After configuring a multicast static route, you are advised to run the **display multicast routing-table static** command to check whether the route is configured successfully and takes effect.

Example

Configure a multicast static route.

```
<HUAWEI> system-view
[HUAWEI] ip rpf-route-static 10.0.0.0 255.0.0.0 rip 1 route-policy map1 10.10.0.1
```

8.7.16 mtrace

Function

The **mtrace** command detects the multicast path or RPF path from a multicast source to the querier or to a destination host. The querier indicates the switch on which the **mtrace** command is executed.

Format

mtrace -gw *last-hop-router* **-r** *receiver* [**-g** *group*] [[**-mr** | **-ur** *resp-dest*] | **-a** *source-ip-address* | **-l** [[*stat-times*] [**-st** *stat-int*]] | **-m** *max-ttl* | **-q** *nqueries* | **-ts** *ttl* | **-tr** *ttl* | **-v** | **-w** *timeout* | **-vpn-instance** *vpn-instance-name*] * **source** *source-address*

mtrace -b -r *receiver* **-g** *group* [[**-mr** | **-ur** *resp-dest*] | **-a** *source-ip-address* | **-l** [[*stat-times*] [**-st** *stat-int*]] | **-m** *max-ttl* | **-q** *nqueries* | **-ts** *ttl* | **-tr** *ttl* | **-v** | **-w** *timeout* | **-vpn-instance** *vpn-instance-name*] * **source** *source-address*

mtrace -d -r *receiver* [**-g** *group*] [[**-mr** | **-ur** *resp-dest*] | **-a** *source-ip-address* | **-l** [[*stat-times*] [**-st** *stat-int*]] | **-m** *max-ttl* | **-q** *nqueries* | **-ts** *ttl* | **-tr** *ttl* | **-v** | **-w** *timeout* | **-vpn-instance** *vpn-instance-name*] * **source** *source-address*

mtrace -r *receiver* [**-g** *group*] [[**-mr** | **-ur** *resp-dest*] | **-l** [[*stat-times*] [**-st** *stat-int*]] | **-m** *max-ttl* | **-q** *nqueries* | **-ts** *ttl* | **-tr** *ttl* | **-v** | **-w** *timeout* | **-vpn-instance** *vpn-instance-name*] * **source** *source-address*

mtrace [**-g** *group*] [[**-mr** | **-ur** *resp-dest*] | **-l** [[*stat-times*] [**-st** *stat-int*]] | **-m** *max-ttl* | **-q** *nqueries* | **-ts** *ttl* | **-tr** *ttl* | **-v** | **-w** *timeout* | **-vpn-instance** *vpn-instance-name*] * **source** *source-address*

Parameters

Parameter	Description	Value
-l	Performs Mtrace tracking for multiple times, collects traffic statistics and rate, uses detailed display mode, and ignores the configuration of **-v**.	If **-l** is not specified, Mtrace tracking is performed once.
stat-times	Indicates the number of times for Mtrace tracking.	The value is an integer that ranges from 2 to 65535. If **-l** is specified while *stat-times* is not specified, Mtrace tracking stops after it is performed 65535 times.
-st *stat-int*	Sets the interval at which the rate is calculated during cyclic query.	The value is an integer that ranges from 10 to 60, in seconds. The default value is 10. To configure **-st**, configure **-l** first. In addition, the cyclic count must be greater than or equal to 2.
-m *max-ttl*	Specifies the maximum number of hops to be traced.	The value is an integer that ranges from 1 to 255. The default value is 255.
-mr	Indicates that the response address is specified as the traced multicast group address.	The **-mr** is applicable only when the querier resides in a multicast distribution tree.
-q *nqueries*	Sets the number of retry times of mtrace.	The value is an integer that ranges from 1 to 65535. The default value is 3.

Parameter	Description	Value
-tr *ttl*	Specifies the TTL value of the IGMP Tracert Response messages sent in multicast mode.	The value is an integer that ranges from 1 to 255. The default value is 30.
-ts *ttl*	Sets the maximum number of hops to be traced in hop-by-hop mode.	The value is an integer that ranges from 1 to 255. The default value is 30. When Mtrace in max-hop mode fails, Mtrace automatically enters the hop-by-hop mode. The number of hops increases by one each time a new hop is traced.
-ur *resp-dest*	Specifies the response address as a unicast address. The value of *resp-dest* must be a local interface address. **NOTE** If neither **-mr** nor **-ur** *resp-dest* is specified, multicast address 224.0.1.32 is used as the response address.	-
-v	Sets the detailed mode and exports time and statistics.	-
-vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
-w *timeout*	Specifies the timeout period to wait for an IGMP Tracert Response message.	The value is an integer that ranges from 1 to 60, in seconds. The default value is 3.
-g *group*	Specifies the multicast group address to be traced.	The address cannot be a reserved group address.
-gw *last-hop-router*	Specifies the last-hop switch address, which ensures that unicast packets can be transmitted between the querier and the last-hop switch. After this parameter is specified, the initiating mode of Mtrace is specified as last-hop.	-

Parameter	Description	Value
-d	Indicates that unicast packets can be transmitted between the querier and the destination host. After this parameter is specified, the initiating mode of Mtrace is specified as destination.	-
-r *receiver*	Specifies the destination host address.	The value is in dotted decimal notation.
-a *source-ip-address*	Specifies the source address of an IGMP Tracert Query message. The value of *source-ip-address* must be a local interface address. **NOTE** When you need to detect the multicast path or the RPF path from the multicast source to the querier, **-a** is not supported.	The value is in dotted decimal notation.
-b	Indicates that the querier is directly connected to the destination host, but whether the querier is the last-hop switch is unknown. After this parameter is specified, the initiating mode of Mtrace is specified as all-router. **NOTE** After a VPN or RPF is specified, the initiating mode of Mtrace cannot be specified as all-router.	-
source *source-address*	Specifies the multicast source address.	The value is in dotted decimal notation.

Usage Guidelines

Usage Scenario

During multicast troubleshooting and routine maintenance, you can run the **mtrace** command to collect traffic information for locating faulty nodes, which helps reduce configuration errors, perform cyclic tracert, and collect statistics on multicast flow rates.

The **mtrace** command format varies according to the types of paths.

- **mtrace source** *source-address*: detects the RPF path from the multicast source to the querier.
- **mtrace -g** *group* **source** *source-address*: detects the multicast path from the multicast source to the querier.

  The corresponding (S, G) entry must exist on the querier.
- **mtrace** [**-gw** *last-hop-router* | **-d**] **-r** *receiver* **source** *source-address*: detects the RPF path from the multicast source to the destination host.
  - The querier is directly connected to the destination host, or the querier can ping the last-hop switch or detonation host in unicast mode.
  - When multiple switches are connected to the specified host, RPF paths from different switches can be different. You can specify the last-hop switch using **-gw** *last-hop-router* to uniquely define an RPF path.
- **mtrace** [**-b** | **-gw** *last-hop-router* | **-d**] **-r** *receiver* **-g** *group* **source** *source-address*: detects the multicast path from the multicast source to the destination host.

  The corresponding (S, G) entry must exist on the querier. In addition, one of the following conditions must be met:
  - The querier is directly connected to the destination host.
  - The querier can ping the last-hop switch or the destination host in unicast mode.
  - The querier resides in the multicast path from the multicast source to the destination host. For example, the querier is the first hop switch.

When running the **mtrace** [**-b** | **-gw** *last-hop-router* | **-d**] **-r** *receiver* **-g** *group* **source** *source-address* command to detect the multicast path from a multicast source to a destination host, specify **-gw** *last-hop-router*, **-b** or **-d**, which helps implement tracking quickly and accurately.

- **-b**: indicates that the querier is directly connected to the destination host.
- **-gw** *last-hop-router*: specifies the last-hop switch address. Unicast packets can be transmitted between the querier and the last-hop switch.
- **-d**: indicates that unicast packets can be transmitted between the querier and the destination host.
- If none of the preceding three parameters are specified, Mtrace fails unless the querier resides in the multicast path from the multicast source to the destination host.

Precautions

- According to draft-fenner-traceroute-ipm-01, the Router Alert option needs to be carried in the IGMP Tracert Query messages that are sent to the destination address in unicast mode and in the IGMP Tracert Response messages that sent in response in multicast mode. However, manufacturers have not reached an agreement on this issue. Packets sent from a Huawei switch carry the Router Alert option. If Huawei switches need to communicate with devices that do not support the Router Alert option, use **-gw** to specify the last-hop address and **-ur** to specify the unicast response address.

- The parameter **vpn-instance** is used on the PE to initiate a multicast VPN probe.
- If the destination address of an IGMP Tracert Response message is a multicast address, the device sends the message to all PIM-enabled interfaces (except the interface that receives the message). The message is then looped back on the ring network until the TTL value becomes 0, upon which time the message is discarded.

Example

- Detect the RPF path from a multicast source to the querier.

Detect the RPF path from the multicast source 10.1.0.1 to the querier 10.1.5.1.

```
<HUAWEI> mtrace source 10.1.0.1
 Press Ctrl+C to break multicast traceroute facility
 From the receiver(10.1.5.1), trace reverse path to source (10.1.0.1) according to RPF rules

 Num  Reverse-Path    FwdTTL Protocol
  0   10.1.5.1
 -1   10.1.5.1        1      PIM
 -2   10.1.2.1        1      PIM
  In maximum-hop mode, received the response message, and multicast traceroute finished.
```

Detect the RPF path from the multicast source 10.1.0.1 to the querier 10.1.5.1. The unicast response address is 10.1.5.1, and the maximum number of hops to be traced in hop-by-hop mode is 2.

```
<HUAWEI>mtrace -ur 10.1.5.1 -ts 2 source 10.1.0.1
 Press Ctrl+C to break multicast traceroute facility
 From the receiver(10.1.5.1), trace reverse path to source (10.1.0.1) accordin
g to RPF rules *  *  *
 Switch from max hop mode to hop-by-hop mode
 In hop-by-hop mode, current probe hops is: 1
 Num  Reverse-Path    FwdTTL Protocol
  0   10.1.5.1
 -1   10.1.5.1        1      PIM
 In hop-by-hop mode, current probe hops is: 2
 Num  Reverse-Path    FwdTTL Protocol
  0   10.1.5.1
 -1   10.1.5.1        1      PIM
 -2   10.1.2.1        1      PIM
  In hop-by-hop mode, the current trace hops is equal to the specified max hops,
 hops is 2,and multicast traceroute finished.
```

- Detect the multicast path from a multicast source to the querier.

Detect the multicast path from the multicast source 10.1.0.1 to the querier 10.1.5.1. The group address is 225.0.0.1, the cyclic count is 2, and the interval at which the rate is calculated is 10s.

```
<HUAWEI> mtrace -g 225.0.0.1 -l 2 -st 10 source 10.1.0.1
 Press Ctrl+C to break multicast traceroute facility
 From the receiver(10.1.5.1), trace (10.1.0.1, 225.0.0.1)'s reverse path according to multicast routing-table
 In calculating-rate mode, current statistic times is: 1

 -1 10.1.5.1
   Incoming Interface Address: 10.1.5.1 Input packets rate: 0
   Outgoing Interface Address: 0.0.0.0 Output packets rate: 0xffffffff
   Forwarding Cache (10.1.0.1, 225.0.0.1) Forwarding packets rate: 0

 -2 10.1.2.1
   Incoming Interface Address: 10.1.2.1 Input packets rate: 0

Table 8-105 Description of the **mtrace** command output

Item	Description
Press Ctrl+C to break multicast traceroute facility	The ongoing Mtrace test is terminated after you press **Ctrl+C**.
From the receiver (10.1.6.4), trace reverse path to source (10.1.0.1) according to RPF rules	The RPF path from destination host 10.1.6.4 to multicast source 10.1.0.1 is detected.
From the receiver (10.1.6.4), trace (10.1.0.1, 225.0.0.1)'s reverse path according to multicast routing-table	The transmission path of multicast data (10.1.0.1, 225.0.0.1) from the destination host 10.1.6.4 to the source is tested.
Num	Number of traced hops.
Reverse-Path	Reverse path of multicast traffic.
FwdTTL	Minimum TTL value for multicast packet forwarding.
Protocol	Multicast routing protocol used on the switch.
-1 10.1.5.1 1 PIM	The address of the last hop is 10.1.5.1, the minimum TTL value for multicast forwarding is 1, and the multicast routing protocol used on the switch is PIM.
In calculating-rate mode, current statistic times is: 1	The rate is calculated for the first time in the calculating rate mode.

Item	Description
-1 10.1.5.1	Last hop with the address as 10.1.5.1 in calculating rate mode.
Incoming Interface Address: 10.1.5.1 Input packets rate: 0	Multicast inbound interface address and the inbound packet rate on the inbound interface in calculating rate mode.
Outgoing Interface Address: 0.0.0.0 Output packets rate: 0xffffffff	Multicast outbound interface address and the outbound packet rate on the outbound interface in calculating rate mode.
Forwarding Cache (10.1.0.1, 225.0.0.1) Forwarding packets rate: 0	Rate for a switch to forward multicast packets of the (S, G) entry in calculating rate mode.
In maximum-hop mode, received the response message, and multicast traceroute finished.	IGMP Tracert Response messages are received in maximum hop tracking mode.
In calculating-rate mode, reach the demanded number of statistic, and multicast traceroute finished.	Mtrace is complete in calculating rate mode when the required number of calculating times is reached.

8.7.17 mtrace query-policy

Function

The **mtrace query-policy** command enables a device to filter IGMP-Tracert-Query packets in unicast mode based on the source address of these packets.

The **undo mtrace query-policy** command cancels the filtering of IGMP-Tracert-Query packets.

By default, the switch does not filter IGMP-Tracert-Query packets.

Format

mtrace query-policy [*basic-acl-number*]

undo mtrace query-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of the basic ACL. This ACL defines the address range of a trusted querier. According to this ACL, the last hop switch rejects the IGMP-Tracert-Query packets sent by an invalid querier.	The value is an integer ranging from 2000 to 2999.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The source address of IGMP-Tracert-Query packets in unicast mode is the local interface address. Before you create an ACL rule, create an ACL.

Run this command on the switch that is connected to the host.

- This command takes effect only on the last hop switch, which is not the querier.
- This command filters only the IGMP-Tracert-Query packets encapsulated in unicast IP packets.
- This command is not applicable to the tracking initiated from the querier.

When you run the **mtrace query-policy** command on the last hop switch, note the following points:

- If *basic-acl-number* is not specified, the last hop switch does not reject IGMP-Tracert-Query packets in unicast mode.
- If *basic-acl-number* is specified but the ACL is not defined on the switch, the last hop switch rejects any IGMP-Tracert-Query packet in unicast mode.
- If *basic-acl-number* is specified and this ACL is defined on the switch, only the IGMP-Tracert-Query packets allowed by the ACL can be received.

Example

Apply the querier filtering rules to the last hop switch.

```
<HUAWEI> system-view
[HUAWEI] mtrace query-policy 2000
```

8.7.18 multicast boundary

Function

The **multicast boundary** command configures a multicast boundary for a single administrative range.

The **undo multicast boundary** command deletes the configured multicast boundary.

By default, no multicast boundary is configured on an interface.

Format

multicast boundary *group-address* { *mask* | *mask-length* }

undo multicast boundary { *group-address* { *mask* | *mask-length* } | **all** }

Parameters

Parameter	Description	Value
group-address	Specifies the address of a multicast group, used to specify a multicast group and configure the forwarding range of the multicast packets for the group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Indicates the mask of a specified group address.	The mask is in dotted decimal notation.
mask-length	Indicates the mask length of a specified group address.	The value is an integer that ranges from 4 to 32.
all	Deletes all the multicast boundaries configured on an interface.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view, tunnel interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Data of some multicast groups needs to be forwarded within a specified range. For example, each BSR administrative domain serves a specific group address range, and data packets sent from multicast sources to these groups need to be forwarded within the matching administrative domain. After a multicast boundary is configured for specified multicast groups on an interface, multicast packets sent to these groups cannot be forwarded through the interface. This restricts multicast forwarding within a range.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

To configure the boundary for different multicast groups, you can repeat the command on the same interface.

A and B are the forwarding boundary sets of the multicast group range to be configured, and B is a subset of A. If A is first configured on an interface, B cannot be configured. If you configure A on the interface that has been configured with B, B is replaced by A.

Example

Configure VLANIF100 as the boundary of group 239.2.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] multicast boundary 239.2.0.0 16
```

Configure GE0/0/1 as the boundary of group 239.2.0.0/16.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] multicast boundary 239.2.0.0 16
```

8.7.19 multicast cpu-forward disable

Function

The **multicast cpu-forward disable** command disables software forwarding for multicast packets.

The **undo multicast cpu-forward disable** command restores the default configuration.

By default, software forwarding for multicast packets is enabled.

Format

multicast cpu-forward disable

undo multicast cpu-forward disable

Parameters

None.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In most cases, the switch forwards packets based on software before the hardware forwarding is completed. Then, the switch forwards packets based on hardware. Soft forwarding for multicast packets must be disabled on the switch to prevent packet loss and disorder caused by the low forwarding speed and first packet cache mechanism of soft forwarding.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Example

Disable software forwarding for multicast packets.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast cpu-forward disable
```

8.7.20 multicast forwarding-table downstream-limit

Function

The **multicast forwarding-table downstream-limit** command sets the maximum number of downstream nodes of an entry in the multicast forwarding table.

The **undo multicast forwarding-table downstream-limit** command restores the default setting.

By default, the maximum number of downstream nodes of an entry is 128.

Format

multicast forwarding-table downstream-limit *limit*

undo multicast forwarding-table downstream-limit

Parameters

Parameter	Description	Value
limit	Indicates the maximum number of downstream nodes of an entry in the forwarding table.	The value of ranges from 0 to 128.

Views

System view, VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch receives a multicast packet, it copies the packet for each downstream node in the matching multicast forwarding entry. If the switch has a large number of multicast forwarding entries or each entry has many downstream nodes, many system resources are consumed. To reduce the load on the switch, limit the maximum number of downstream nodes in each multicast forwarding entry.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

If the configured number is smaller than the current number, the excessive downstream nodes are not deleted immediately, and must be deleted by the multicast routing protocol. In addition, no new downstream node can be added to the entry in the forwarding table.

Example

Set the maximum number of downstream nodes of an entry in the forwarding table to 32.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast forwarding-table downstream-limit 32
```

8.7.21 multicast forwarding-table route-limit

Function

The **multicast forwarding-table route-limit** command sets the limit on the number of entries in the multicast forwarding table.

The **undo multicast forwarding-table route-limit** command restores the default value of the limit.

The following lists the maximum number of entries allowed in the multicast forwarding table of each model by default:

- S5720-LI, S5720S-LI: 1022
- S5731-S, S5731S-S, S5720I-SI: 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5735S-H, S5736-S, S6720S-S: 1536
- S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, S6730S-S: 4096

Format

multicast forwarding-table route-limit *limit*

undo multicast forwarding-table route-limit

Parameters

Parameter	Description	Value
limit	Specifies the limit on the number of entries in the multicast forwarding table.	The value is an integer that ranges from 0 to *The maximum number of entries allowed in the multicast forwarding table by default.* **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

System view, VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Excessive multicast forwarding entries will exhaust the memory of the switch. To prevent this problem, use the **multicast forwarding-table route-limit** command to limit the number of entries in the multicast forwarding table.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

NOTICE

If you set the limit on the number of entries in the multicast forwarding table after multicast services are deployed on a switch, ensure that the limit is greater than or equal to the number of current forwarding entries. Otherwise, faults may occur.

It is recommended that you set this limit based on the actual network environment before deploying multicast services on the switch.

If the configured limit is smaller than the number of existing entries, the excessive entries are not deleted immediately. The configured limit takes effect in the following cases:

- Entries are added to the multicast forwarding table after the existing entries age out.
- The **reset multicast forwarding-table all** command is run.

Example

Set the limit on the number of the entries in the forwarding table to 60.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast forwarding-table route-limit 60
```

8.7.22 multicast invalid-packet

Function

The **multicast invalid-packet** command sets the maximum number of invalid multicast protocol packets that can be stored on the switch.

The **undo multicast invalid-packet** command deletes the set maximum number of invalid multicast protocol packets that can be stored on the switch.

By default, the switch can save a maximum of 10 invalid packets for each specific multicast protocol.

Format

multicast invalid-packet { **igmp** | **mdt** | **msdp** | **pim** } **max-count** *max-number*

undo multicast invalid-packet { **igmp** | **mdt** | **msdp** | **pim** }

Parameters

Parameter	Description	Value
igmp	Sets the maximum number of invalid IGMP messages.	-
mdt	Sets the maximum number of invalid multicast VPN messages.	-
msdp	Sets the maximum number of invalid MSDP messages.	-
pim	Sets the maximum number of invalid PIM messages.	-
max-count *max-number*	Sets the maximum number of invalid multicast protocol packets that can be stored on a device.	The value is an integer ranging from 1 to 100.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If multicast entries fail to be generated or peer relationships fail to be set up, you can enable the switch to store invalid multicast protocol packets and view statistics and details of the invalid multicast protocol packets. Based on the command output, you can locate and rectify faults.

Example

Set the maximum number of invalid IGMP messages that can be stored on the switch to 20.

```
<HUAWEI> system-view
[HUAWEI] multicast invalid-packet igmp max-count 20
```

8.7.23 multicast load-splitting

Function

The **multicast load-splitting** command enables load splitting among multicast routes.

The **undo multicast load-splitting** command restores the default configuration.

By default, load splitting among multicast routes is disabled.

Format

multicast load-splitting { **balance-preferred** | **stable-preferred** | **group** | **source** | **source-group** }

undo multicast load-splitting

Parameters

Parameter	Description	Value
balance-preferred	Indicates balance-preferred load splitting. This policy is applicable to the scenario where hosts frequently join or leave groups, which requires automatic load adjustment.	-
stable-preferred	Indicates stable-preferred load splitting. This policy is applicable to stable multicast networking.	-

Parameter	Description	Value
group	Indicates group address-based load splitting. This policy is applicable to the scenario of one source to multiple groups.	-
source	Indicates source address-based load splitting. This policy is applicable to the scenario of multiple sources to one group.	-
source-group	Indicates source and group addresses-based load splitting. This policy is applicable to the scenario of multiple sources to multiple groups.	-

Views

System view, VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if there are multiple equal-cost routes to a multicast source, the switch applies the following route selection rules during RPF check:

- If the equal-cost routes are in the same routing table, for example, a unicast routing table, multicast static routing table, or MBGP routing table, the switch selects the route with the largest next-hop address as the RPF route.
- If the equal-cost routes are in different routing tables, the switch selects the route with the highest preference. If the routes have the same preference, the switch selects the route with the longest mask length. If the routes have the same preference and mask length, the switch uses certain algorithm to select a route as the RPF route.

No matter which rule is used, the switch selects only one route as the RPF route. To enable multicast data to be forwarded through multiple paths, run the **multicast load-splitting** command to configure multicast load splitting. After multicast load splitting is configured, the switch uses the specified load splitting policy to distribute multicast data among multiple paths. This function improves quality of multicast forwarding.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Follow-up Procedure

Because the forwarding capabilities of equal-cost routes are different from the actual load distribution situation on the equal-cost routes, even load splitting cannot meet network requirements in some scenarios. Then, you can run the

multicast load-splitting weight command to configure the multicast load splitting weight on the interface to realize unbalanced load splitting.

Precautions

The five load splitting policies are mutually exclusive. It is recommended that you use a fixed load splitting policy based on the actual situation on your network. The **balance-preferred** or **stable-preferred** policy is preferred.

If PIM-DM is enabled in the current public network instance, the **balance-preferred** or **stable-preferred** policy cannot be used.

Example

Configure group address-based load splitting.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast load-splitting group
```

8.7.24 multicast load-splitting weight

Function

The **multicast load-splitting weight** command sets the multicast load splitting weight for an interface.

The **undo multicast load-splitting weight** command restores the default setting.

By default, the multicast load splitting weight of an interface is 1.

Format

multicast load-splitting weight *weight-value*

undo multicast load-splitting weight

Parameters

Parameter	Description	Value
weight-value	Specifies the multicast load splitting weight of an interface.	The value is an integer that ranges from 0 to 32.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view, VBDIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a stable-preferred or balance-preferred multicast splitting policy is configured, you can run this command to set load splitting weights for interfaces to realize unbalanced load splitting. The larger weight value an interface has, the more multicast routing entries have it as the upstream interface.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Precautions

This command is applicable only when the multicast load splitting policy is set to stable-preferred or balance-preferred.

When the multicast load splitting weight on an interface is 0, the routes that have this interface as the upstream interface do not take part in load splitting.

Example

Set the multicast load splitting weight on VLANIF100 to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] multicast load-splitting weight 10
```

Set the multicast load splitting weight on GE0/0/1 to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] multicast load-splitting weight 10
```

8.7.25 multicast load-splitting-timer

Function

The **multicast load-splitting-timer** command sets a load splitting timer.

The **undo multicast load-splitting-timer** command restores the default setting.

By default, the value of a load splitting timer is 1800 seconds.

Format

multicast load-splitting-timer *interval*

undo multicast load-splitting-timer

Parameters

Parameter	Description	Value
interval	Specifies the value of the load splitting timer.	The value is an integer ranging from 10 to 1800, in seconds.

Views

System view, VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In stable-preferred load splitting or balance-preferred load splitting mode, entries may not be well-balanced among paths because of the addition or deletion of entries, change of load splitting weights of the paths, or change of equal-cost routes. In such a case, the device will balance entries after a certain waiting time to reduce the impact of frequent changes on the system.

Currently, setting a load splitting timer to change the waiting time before balancing entries is supported.

- If the network is stable, for example, when entries are not deleted or added frequently or equal-cost routes are not changed frequently, set the load splitting timer value to a smaller value so that entries can be balanced rapidly. The recommended value is 300 to 600 seconds.
- If the network is not stable, for example, when entries are deleted or added frequently or equal-cost routes are changed frequently, set the load splitting timer value to a larger value to reduce the impact of frequent entry changes on the system and network stability. The recommended value is 1200 to 1800 seconds.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Example

Set a load splitting timer to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast load-splitting-timer 100
```

8.7.26 multicast longest-match

Function

The **multicast longest-match** command configures the switch to select the RPF route based on the longest matching rule.

The **undo multicast longest-match** command restores the default configuration.

By default, the switch selects the route with the highest preference as the RPF route.

Format

multicast longest-match

undo multicast longest-match

Parameters

None

Views

System view, VPN instance view, VPN IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch selects the RPF route based on route preference. This command changes the route selection policy used by the switch during RPF check. After you run this command, the switch selects the RPF route with the longest mask. If multiple routes have the same mask length, the switch selects the route with the highest preference.

Prerequisites

IP multicast routing has been enabled using the **multicast routing-enable** command.

Example

Select routes according to the longest match on the switch.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
[HUAWEI] multicast longest-match
```

8.7.27 multicast routing-enable

Function

The **multicast routing-enable** command enables the multicast routing function.

The **undo multicast routing-enable** command restores the default configuration.

By default, the multicast routing function is disabled.

Format

multicast routing-enable

undo multicast routing-enable

Parameters

None

Views

System view, VPN instance view, VPN IPv4 address family view

NOTE

Only the following models support the VPN instance view and VPN IPv4 address family view: S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S, S6720-EI, S6735-S and S6720S-EI

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before configuring Layer 3 multicast, you must enable the multicast routing function globally. Layer 3 multicast protocols (such as PIM and IGMP) and other Layer 3 multicast functions can be configured only after multicast routing is enabled.

Precautions

Multicast functions (Layer 2 and Layer 3 multicast) and the flow control function (configured using the **flow-control** command) are mutually exclusive on the following models: S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-S, S5735-S-I

NOTICE

The **undo multicast routing-enable** command deletes all multicast configurations of the public network instance or VPN instance. After this command is run, multicast services that are running on the instance will be interrupted. To restore the multicast services, you must run the deleted multicast commands again.

Example

Enable multicast routing globally.

```
<HUAWEI> system-view
[HUAWEI] multicast routing-enable
```

8.7.28 multicast ttl-check disable

Function

The **multicast ttl-check disable** command disables a switch from checking the TTL value of multicast packets.

The **undo multicast ttl-check disable** command enables a switch to check the TTL value of multicast packets again.

By default, a switch checks the TTL value of multicast packets.

NOTE

This command is supported only on the following models: S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Format

multicast ttl-check disable

undo multicast ttl-check disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

In V200R019C10 and later versions, when multicast packets between a multicast source and receiver are forwarded across VLANs, the multicast packets with a TTL value less than or equal to 1 will be discarded by default.

In versions earlier than V200R019C10, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not discard multicast packets whose TTL value is less than or equal to 1. After the switch software version is upgraded to V200R019C10 or later, however, if you want a switch not to discard multicast packets whose TTL value is less than or equal to 1, run the **multicast ttl-check disable** command to disable the switch from checking the TTL value of multicast packets.

The **multicast ttl-check disable** command does not apply to the following scenarios:

- This command is not applicable to multicast packets on a VPN. A switch always discards multicast packets on a VPN if their TTL value is less than or equal to 1.
- This command does not apply when a multicast source and receiver are in the same VLAN, in which case, the switch does not check the TTL value of multicast packets between them.
- When the forwarding mode of multicast packets is changed to MAC address-based forwarding, the switch does not check the TTL value of multicast packets.

Example

Disable a switch from checking the TTL value of multicast packets.

```
<HUAWEI> system-view
[HUAWEI] multicast ttl-check disable
```

8.7.29 ping multicast

Function

The **ping multicast** command enables a device to detect the reserved members in the network segment, simulates the common group traffic, triggers the establishment of a distribution tree, and checks whether the network can normally bear multicast services.

Format

ping multicast [**-c** *count* | **-h** *ttl-value* | **-i** *interface-type interface-number* | **-m** *time* | **-p** *pattern* | **-q** | **-s** *packetsize* | **-t** *timeout* | **-tos** *tos-value* | **-v**] * *host*

Parameters

Parameter	Description	Value
-c *count*	Specifies the number of times for sending ICMP Echo Request messages.	The value is an integer that ranges from 1 to 65535. The default value is 5.
-h *ttl-value*	Sets the TTL value of an ICMP Echo Request message.	The value is an integer that ranges from 1 to 255. The default value is 255.
-i *interface-type interface-number*	Sets the outgoing interface that sends ICMP Echo Request messages. • When the MPing destination group address is a reserved multicast group address, **-i** must be specified. • When the MPing destination group address is a common multicast group address, **-i** cannot be specified.	-
-m *time*	Specifies the time to wait before sending the next ICMP Echo Request message. Each time the source sends an ICMP Echo Request message using the **ping multicast** command, the source waits a period of time (2000 ms by default) before sending the next ICMP Echo Request message. You can set the time to wait before sending the next ICMP Echo Request message using the parameter *time*. In the case of poor network condition, the value should be equal to or larger than 2000, in milliseconds.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 2000.
-p *pattern*	Specifies the padding byte of ICMP Echo Request messages. After the padding byte of the ICMP Echo Request message is set, the destination host can identify a certain ICMP Echo Reply message.	The value ranges from 0 to FFFFFFFF, in the hexadecimal format. By default, the padding starts from 0x01, and continues in ascending order.

Parameter	Description	Value
-q	Indicates that only statistics are displayed. When **-q** is specified in the **ping multicast** command, only the number of sent and received packets, packet loss rate, and the minimum, average, and maximum RTTs are displayed.	By default, all information is displayed.
-s *packetsize*	Sets the length of an ICMP Echo Request message, excluding the IP or ICMP header.	The value is an integer that ranges from 20 to 8100, in bytes. The default value is 56.
-t *timeout*	Specifies the timeout period to wait for an ICMP Echo Reply message after an ICMP Echo Request message is sent. After the **ping multicast** command is run, the source sends an ICMP Echo Request message to a destination and waits for an ICMP Echo Reply message. If the destination, after receiving the ICMP Echo Request message, returns an ICMP Echo Reply message to the source within the period specified by the parameter *timeout*, the destination is reachable. If the destination does not return an ICMP Echo Reply message within the specified period, the source displays a message indicating that the message times out. Normally, the source receives an ICMP Echo Reply message within 1 to 10 seconds after sending an ICMP Echo Request message. If the transmission speed is low, properly prolong the timeout period.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 2000.
-tos *tos-value*	Specifies the ToS value of the sent ICMP Echo Request messages.	The value is an integer that ranges from 0 to 255. The default value is 196.

Parameter	Description	Value
-v	Displays all received ICMP Echo Reply messages. - If **-v** is not specified, the system displays the received ICMP Echo Reply messages of the user. - If **-v** is specified, the system displays all received ICMP Echo Reply messages.	By default, only ICMP Echo Reply messages of the user are displayed.
host	Specifies the destination address of an ICMP Echo Request message, also called the MPing destination group address.	It includes reserved group addresses and common group addresses.

Usage Guidelines

Usage Scenario

The **ping multicast** command is used to check a multicast network in the following scenarios:

Scenario 1: When configuring the destination group address *host* as a reserved group address, you can run the **ping multicast** command to check which reserved multicast members reside on the network segment of the outbound interface. In this scenario, the TTL of an ICMP Echo Request message cannot be set.

The reserved multicast group identifies a group of network devices (reserved multicast members) that match certain conditions. When the reserved multicast members receive ICMP Echo Request messages with the destination addresses as the reserved group addresses, they return ICMP Echo Reply messages. Common reserved group addresses are as follows:

- 224.0.0.1: indicates all systems in the subnet.
- 224.0.0.2: indicates all routers in the subnet.
- 224.0.0.5: indicates OSPF IGP routers.
- 224.0.0.13: indicates PIM routers.

NOTE

In this scenario, **-i** must be specified in the **ping multicast** command.

Scenario 2: When setting the destination group address *host* as a common group address, you can run the **ping multicast** command to implement the following functions:

- Simulates the multicast traffic and triggers a series of protocol processes. By viewing the multicast routing information on the switch, check whether the protocol running status is normal and whether the multicast distribution tree is correctly established.
- Check multicast members in the network and calculate the TTL value and the RTT from the MPing initiator to multicast members. This function requires that the host support MPing and is implemented by calculating the number of ICMP Echo Reply messages sent by the destination host. MPing is performed continuously at a certain interval to calculate the network delay and route jitter.

NOTE

In this scenario, **-i** cannot be specified in the **ping multicast** command.

You can specify different parameters in **ping multicast** command for different scenarios:

- On an unstable network, you can run the **ping multicast -c** *count* **-t** *timeout host* command to check the quality of the multicast network. By analyzing the packet loss rate and average delay in the command output, you can evaluate the network quality. If the network is unreliable, set the packet transmission count (**-c**) and timeout (**-t**) to the upper limits. This makes the test result accurate.
- You can run the **ping multicast -s** *packetsize host* to set the size of a multicast probe packet. In this way, you can check the quality of the multicast network by simulating real service datagrams. The path MTU is then obtained through multiple probes.

Prerequisites

Before running the **ping multicast** command, ensure that the ICMP module is working properly.

Configuration Impact

If an intermediate device is disabled from responding to ICMP messages, detection on this node fails.

Precautions

If a fault occurs in the MPing process, you can press **Ctrl+C** to terminate the MPing operation.

Example

Perform MPing, specify the reserved multicast group address as 224.0.0.5 and the outbound interface as VLANIF 100, and detect the OSPF IGP router in the network segment.

```
<HUAWEI> ping multicast -i vlanif 100 224.0.0.5
MULTICAST PING 224.0.0.5 : 56 data bytes, press Ctrl+C to break
Reply from 10.1.1.5 : bytes=56 Sequence=1 TTL =255 time=30ms
Reply from 10.1.1.5 : bytes=56 Sequence=2 TTL =255 time=10ms
Reply from 10.1.1.5 : bytes=56 Sequence=3 TTL =255 time=10ms
Reply from 10.1.1.5 : bytes=56 Sequence=4 TTL =255 time=20ms
```

```
Reply from 10.1.1.5 : bytes=56 Sequence=5 TTL =255 time=10ms
Destination multicast address 224.0.0.5
--- Multicast ping statistics ---
5 Request packet(s) transmitted
5 Reply packet(s) received
0.00% packet loss
Round-trip min/avg/max = 10/16/40 ms
```

Specify the padding field of **-p**.

```
<HUAWEI> ping multicast -i vlanif 100 -p 12345678 224.0.0.5
MULTICAST PING 224.0.0.5 : 56 data bytes, press Ctrl+C to break
The padding string: 12345678
Reply from 10.1.1.5 : bytes=56 Sequence=1 TTL =255 time=30ms
Reply from 10.1.1.5 : bytes=56 Sequence=2 TTL =255 time=10ms
Reply from 10.1.1.5 : bytes=56 Sequence=3 TTL =255 time=10ms
Reply from 10.1.1.5 : bytes=56 Sequence=4 TTL =255 time=20ms
Reply from 10.1.1.5 : bytes=56 Sequence=5 TTL =255 time=10ms
Destination multicast address 224.0.0.5
--- Multicast ping statistics ---
5 Request packet(s) transmitted
5 Reply packet(s) received
0.00% packet loss
Round-trip min/avg/max = 10/16/40 ms
```

Table 8-106 Description of the ping multicast command output

Item	Description
MULTICAST PING 224.0.0.5	The destination group address of MPing is 224.0.0.5.
56 data bytes	The length of the sent ICMP Echo Request message is 56 bytes.
press Ctrl+C to break	The ongoing MPing test can be terminated by pressing **Ctrl+C**.
The padding string: 12345678	The padding string is 12345678. If **-p** is not specified, the padding character string is not displayed.
Reply from 10.1.1.5: bytes=56 Sequence=1 TTL=255 time=30ms	The ICMP Echo Reply message sent from 10.1.1.5 is received. The message carries the following information: ● bytes=56: indicates the length of the ICMP Echo Reply message. ● Sequence=1: indicates the sequence number of the ICMP Echo Reply message. ● TTL=255: indicates the TTL value of the ICMP Echo Reply message. ● time=30ms: indicates the RTT, in milliseconds. If no ICMP Echo Reply message is received after the timeout period, "Request time out" is displayed.
Destination multicast address 224.0.0.5	The destination group address is 224.0.0.5.

Item	Description
--- Multicast ping statistics --- 5 Request packet(s) transmitted 5 Reply packet(s) received 0.00% packet loss Round-trip min/avg/max = 10/16/40 ms	Statistics collected after the Ping test on the destination host. The statistics are as follows: ● Number of sent ICMP Echo Request messages: 5 ● Number of received ICMP Echo Reply messages: 5 ● Percentage of non-Reply messages against total sent messages: 0.00% ● The minimum RTT is 10 ms, the average RTT is 16 ms, and the maximum RTT is 40 ms.

8.7.30 reset mtrace statistics

Function

The **reset mtrace statistics** command clears statistics about Mtrace packets.

Format

reset mtrace statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

To collect statistics about Mtrace traffic generated in a certain period, reset the original statistics.

Example

Clear statistics about the current Mtrace traffic.

```
<HUAWEI> reset mtrace statistics
```

8.7.31 reset multicast forwarding-table

Function

The **reset multicast forwarding-table** command clears the entries of the multicast forwarding table.

Format

reset multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **forwarding-table all**

reset multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **forwarding-table** { *group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }] | **incoming-interface** { *interface-type interface-number* | **register** } } *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* indicates the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
all	Indicates all forwarding entries of multicast forwarding tables.	-
group-address	Specifies the address of a multicast group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Specifies the mask of a multicast group address or source address.	-
group-mask	Specifies the address mask of a multicast group.	The address mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies the address of a multicast source.	The address is in dotted decimal notation.
source-mask	Specifies the address mask of a multicast source.	The address mask is in dotted decimal notation.
source-mask-length	Specifies the mask length of the multicast source address.	The value is an integer that ranges from 0 to 32.
incoming-interface	Indicates the upstream interface of the forwarding entry.	-

Parameter	Description	Value
interface-type interface-number	Specifies the type and the number of an interface, used to specify an interface.	-
register	Indicates the register interface in PIM-SM.	-

Views

User view

3: Management level

Usage Guidelines

NOTICE

After you run this command to delete information from the multicast forwarding table, multicast data will be interrupted for a period. Confirm the action before you use the command.

The time interval before you run the **reset multicast forwarding-table** command again must be longer than 30 seconds.

Example

Delete the multicast forwarding entries of the group 225.5.4.3 from the forwarding table.

```
<HUAWEI> reset multicast forwarding-table 225.5.4.3
```

8.7.32 reset multicast routing-table

Function

The **reset multicast routing-table** command clears the entries in the multicast routing table. The corresponding forwarding entries in the forwarding table are deleted at the same time.

Format

reset multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table all**

reset multicast [**vpn-instance** *vpn-instance-name* | **all-instance**] **routing-table** { *group-address* [**mask** { *group-mask* | *group-mask-length* }] | *source-address* [**mask** { *source-mask* | *source-mask-length* }] | **incoming-interface** { *interface-type interface-number* | **register** } } *

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies a VPN instance. *vpn-instance-name* indicates the name of the VPN instance.	The value must be an existing VPN instance name.
all-instance	Indicates all the instances.	-
all	Indicates all entries in the multicast routing table.	-
group-address	Specifies the address of the specified group.	The address is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.
mask	Indicates the address mask of a multicast group or source.	-
group-mask	Specifies the address mask of a multicast group.	The address mask is in dotted decimal notation.
group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies the address of a specified source.	The address is in dotted decimal notation.
source-mask	Specifies the address mask of a multicast source, in dotted decimal notation.	The address mask is in dotted decimal notation.
source-mask-length	Specifies the mask length of the multicast source address.	The value is an integer that ranges from 0 to 32.
incoming-interface	Specifies the incoming interface of a multicast entry.	-
interface-type interface-number	Specifies the type and the number of an interface, used to specify an interface.	-
register	Indicates the register interface of PIM-SM.	-

Views

User view

3: Management level

Usage Guidelines

NOTICE

After you run this command to delete information from the multicast routing table, the matching entries in the multicast forwarding table are also deleted. As a result, multicast forwarding will be interrupted for a period. Confirm the action before you use the command.

Example

Delete the entries of the group 225.5.4.3 from the multicast routing table.

```
<HUAWEI> reset multicast routing-table 225.5.4.3
```

8.7.33 set multicast forwarding-table enhance-mode

Function

The **set multicast forwarding-table enhance-mode** command sets the multicast forwarding mode to enhanced forwarding. In this forwarding mode, the device generates dummy entries (Layer 3 multicast dummy forwarding entries) for multicast packets that fail RPF check, even if Layer 2 multicast is disabled on the device.

The **undo set multicast forwarding-table enhance-mode** command disables enhanced forwarding for multicast traffic on the device. After this command is run, the device no longer generates dummy entries (Layer 3 multicast dummy forwarding entries) for multicast packets that fail RPF check, if Layer 2 multicast is disabled on the device.

By default, a device forwards multicast traffic in enhanced mode.

Format

set multicast forwarding-table enhance-mode

undo set multicast forwarding-table enhance-mode

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If Layer 2 multicast is not enabled on a device using the **igmp-snooping enable (VLAN view)** command, the device cannot generate dummy entries for multicast packets that fail the RPF check, so such packets cannot match any multicast entries. As a result, a large number of unknown multicast packets will be continuously sent to the CPU, causing high CPU usage. To prevent such a problem, you can run the **set multicast forwarding-table enhance-mode** command to set the multicast forwarding mode to enhanced forwarding. In this forwarding mode, the device generates dummy entries for multicast packets that fail RPF check, even if Layer 2 multicast is disabled on the device. The dummy entries guide Layer 3 multicast traffic forwarding, preventing high CPU usage caused by continuous sending of unknown multicast traffic.

Precautions

This command takes effect only for multicast packets in a VLAN.

Example

Set multicast forwarding mode to enhanced forwarding.

```
<HUAWEI> system-view
[HUAWEI] set multicast forwarding-table enhance-mode
```

8.7.34 set multicast forwarding-table optimization-mode

Function

The **set multicast forwarding-table optimization-mode** command configures the multicast optimization mode in which the Layer 3 forwarding entries are stored on a switch.

The **undo set multicast forwarding-table optimization-mode** command restores the default storage mode.

By default, a switch uses the normal storage mode.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support this command.

Format

set multicast forwarding-table optimization-mode [**slot** *slot-id*]

undo set multicast forwarding-table optimization-mode [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	*slot-id* specifies the slot that uses the multicast optimization mode. If no slot ID is specified, storage modes of all slots are configured to be the multicast optimization mode.	The value is an integer and must be the slot ID of a running slot.

Views

System view

Default Level

3: Management level

Usage Guidelines

Applicable Environment

In most cases, the Layer 3 forwarding entries are stored in normal mode. The ARP cache table, ND cache table, and multicast forwarding table share hardware resources, without affecting hardware resources allocated to the routing table.

This command optimizes storage resources of Layer 3 forwarding entries through preferential allocation of hardware resources preferentially to the multicast forwarding table. The ARP cache table, ND cache table, and routing table share hardware resources. Run this command if either of the following situations occurs:

- A large number of ARP prefix entries and multicast forwarding entries exist in the system at the same time.
- A large number of ND prefix entries and multicast forwarding entries exist in the system at the same time.

Precautions

Note the following points when running this command:

- If the multicast optimization modes on a switch are configured or deleted, the system prompts the user to save the configurations and then restart the device. If the device configuration is not saved, the new storage mode does not take effect after the restart.
- This function can be implemented on an IPv6 network only when a switch with an extended entry register is available. In addition, the storage mode of the register must be set to IPv6 mode. For details on how to configure the extended entry register, see **assign resource-mode** in "Device Management Commands > Hardware Configuration Commands".

NOTICE

When the user configures this mode or restores the default mode, the system will prompt the user to restart the device or a specified slot. If the system receives no response, the configuration times out, and the system view is displayed. The system does not restart. The restart can cause the network to crash for a short period. In most cases, this command is not recommended.

Example

Configure the storage mode to be the multicast optimization mode for a switch.

```
<HUAWEI> system-view
[HUAWEI] set multicast forwarding-table optimization-mode
```

8.7.35 set multicast forwarding-table super-mode

Function

The **set multicast forwarding-table super-mode** command configures the high specification mode for multicast forwarding. In the high specification mode, the number of multicast entries can reach the maximum value supported by the switch, which is much more than the default limit.

The **undo set multicast forwarding-table super-mode** command restores the default configuration.

By default, the common specification mode is used for multicast forwarding after Layer 3 multicast is configured. In this mode, the number of multicast entries cannot exceed the default limit defined on the switch.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support this command.

Format

set multicast forwarding-table super-mode

undo set multicast forwarding-table super-mode

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After Layer 3 multicast is enabled, the common specification mode is used for multicast forwarding by default. This mode can meet requirements of most multicast service scenarios. In some large-scale multicast applications, a network has a large number of multicast sources to provide many channels for multicast users. In these applications, the number of multicast entries may exceed the default limit defined on a multicast device. When this occurs, some multicast entries cannot be generated. As a result, some users cannot receive the multicast data they request.

The **set multicast forwarding-table super-mode** command configures the high specification mode to increase the number of entries used for multicast forwarding. In high specification mode, the number of multicast entries supported by the switch is much larger than the default limit on the number of multicast entries. This mode maximizes a device's capability to support large-scale multicast applications.

Precautions

After you run this command:

- This command can only increase the number of Layer 3 multicast forwarding entries, but cannot increase the number of Layer 2 multicast forwarding entries. In scenarios when both Layer 2 and Layer 3 multicast services are configured, the number of Layer 3 multicast forwarding entries is limited by the number of Layer 2 multicast forwarding entries. Therefore, this command cannot increase the number of multicast forwarding entries if both Layer 2 and Layer 3 multicast services are configured.
- Restart the switch for the configuration to take effect.
- The default value of the IGMP general query interval changes from 60s to 120s. You can set the IGMP general query interval using the **igmp timer query** or **timer query (IGMP view)** command.
- The default value of the IGMP robustness variable changes from 2 to 3. You can set the robustness variable using the **igmp robust-count** or **robust-count (IGMP view)** command.
- The default value of the other querier present interval changes from 125s to 245s. You can set the other querier present interval using the **igmp timer other-querier-present** or **timer other-querier-present (IGMP view)** command.
- The default value of the MLD robustness variable changes from 2 to 3. You can set the robustness variable using the **mld robust-count** or **robust-count (MLD view)** command.
- The default interval for sending PIM-DM State-Refresh messages changes from 60s to 255s. On an IPv4 multicast network, run the **state-refresh-interval (IPv4)** command to set the interval for sending PIM-DM State-Refresh messages. On an IPv6 network, run the **state-refresh-interval (IPv6)** command to set the interval for sending PIM-DM State-Refresh messages.
- The default interval for sending PIM Join-Prune messages changes from 210s to 300s. On an IPv4 multicast network, run the **holdtime join-prune (IPv4)** or **pim holdtime join-prune** command to set the interval for sending PIM

Join-Prune messages. On an IPv6 network, run the **holdtime join-prune (IPv6)** or **pim ipv6 holdtime join-prune** command to set the interval for sending PIM Join-Prune messages.

- Run the **car** command to change the rate limit for IGMP/MLD messages sent to the CPU according to the actual situations of multicast services.
- More system resources are consumed in the high specification mode. If the number of multicast protocol packets sent to the switch increases sharply in a short time, the CPU usage of the switch becomes high.
- It is recommended that you set the same general query interval on all the IGMP/MLD-enabled interfaces of a switch. For an IGMP-enabled interface, run the **igmp timer query** command in the interface view to set the general query interval. For an MLD-enabled interface, run the **mld timer query** command in the interface view to set the general query interval. This configuration prevents IGMP/MLD-enabled interfaces from sending Query messages at the same time, so that the switch does not have to process a large number of Report messages in a short time, which could cause a high CPU usage.
- In a stack, if member interfaces of an Eth-trunk interface are located on member switches that support different numbers of multicast forwarding entries, the maximum number of multicast forwarding entries supported by the Eth-Trunk interface depends on the member switch that supports the fewest multicast forwarding entries. Multicast forwarding entries supported by an Eth-Trunk interface meet either of the following conditions:
  - The outbound interface of the multicast forwarding entries is the Eth-Trunk interface that has been switched to the Layer 3 mode using the **undo portswitch** command.
  - The Eth-Trunk interface belongs to the VLANs corresponding to the VLANIF interfaces of the multicast forwarding entries.

Example

Configure the high specification mode for multicast forwarding.

```
<HUAWEI> system-view
[HUAWEI] set multicast forwarding-table super-mode
Warning: This command will modify some default multicast settings and has limitations
in a few special scenarios. Use the command according to product manual.Continue? [Y/N]:y
```

8.7.36 set multicast-hash-mode

Function

The **set multicast-hash-mode** command specifies a hash algorithm for multicast forwarding.

The **undo multicast-hash-mode** command restores the default hash algorithm for multicast forwarding.

By default, the crc-32-lower algorithm is used.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support support this command.

Format

set multicast-hash-mode { **crc-32-upper** | **crc-32-lower** | **lsb** | **crc-16-upper** | **crc-16-lower** }

undo set multicast-hash-mode { **crc-32-upper** | **crc-32-lower** | **lsb** | **crc-16-upper** | **crc-16-lower** }

Parameters

Parameter	Description
crc-32-upper	
crc-32-lower	
lsb	
crc-16-upper	
crc-16-lower	

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve multicast forwarding performance, the switch uses a hash algorithm to learn multicast addresses. If multiple addresses match a key value, a hash conflict occurs. A large number of hash conflicts will cause failures to learn some multicast addresses. When such a problem occurs, use an appropriate hash algorithm to reduce hash conflicts.

Precautions

- An appropriate hash algorithm can reduce but not eliminate hash conflicts.
- MAC addresses are distributed on a network randomly, so the system cannot determine the best hash algorithm. The default hash algorithm is the best algorithm in most cases, so changing the hash algorithm is not recommended.
- After changing the hash algorithm, restart the switch for the configuration to take effect.

Example

Set the hash algorithm for multicast forwarding to crc-32-upper.

```
<HUAWEI> system-view
[HUAWEI] set multicast-hash-mode crc-32-upper
```

8.8 IPv6 Multicast Route Management Commands

8.8.1 Command Support

Product	Support
S1700	Not supported.
S300	Supported.
S500	Supported.
S2700	Supported.
S5700	Supported except S5731-L and S5731S-L.
S6700	Supported.

8.8.2 display multicast ipv6 boundary

Function

The **display multicast ipv6 boundary** command displays the multicast boundary configured on an interface.

Format

display multicast ipv6 boundary [*ipv6-group-address ipv6-group-mask-length* | **scope** *scope-id*] [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies an IPv6 multicast group address to display the corresponding multicast routing table.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of the IPv6 multicast group address.	The value is an integer that ranges from 8 to 128.

Parameter	Description	Value
scope *scope-id*	Specifies a scope ID.	The value is an integer that ranges from 3 to 15.
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command enables you to check the boundary of a PIM-SM (IPv6) network. When some hosts cannot receive multicast data, you can use this command to check whether the problem is caused by multicast boundary configuration.

Example

Display the boundaries configured on all the interfaces.

```
<HUAWEI> display multicast ipv6 boundary
IPv6 multicast boundary information
Total 1 Multicast IPv6 boundary
 Interface           Boundary
 Vlanif100            FF02::/64
```

Table 8-107 Description of the display multicast ipv6 boundary command output

Item	Description
IPv6 multicast boundary information	IPv6 multicast boundary.
Total 1 Multicast IPv6 boundary	Total number of IPv6 multicast boundaries.
Interface	Name of the interface configured with multicast boundary.
Boundary	Multicast group with the interface as the boundary.

8.8.3 display multicast ipv6 forwarding-table

Function

The **display multicast ipv6 forwarding-table** command displays the IPv6 multicast forwarding table.

Format

display multicast ipv6 forwarding-table [*ipv6-source-address* [*ipv6-source-mask-length*] | *ipv6-group-address* [*ipv6-group-mask-length*] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { { **exclude** | **include** | **match** } { *interface-type interface-number* | **register** | **none** } } | { **statistics** | **verbose** }] *

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-source-mask-length	Specifies the mask length of the multicast source address.	The value is an integer that ranges from 0 to 128.
ipv6-group-address	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 8 to 128.
incoming-interface	Indicates the incoming interface of an IPv6 multicast forwarding entry.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Indicates the register interface of PIM-SM.	-
outgoing-interface	Indicates the outgoing interface of an IPv6 multicast forwarding entry.	-
exclude	Indicates that the downstream interface list does not contain the route forwarding entries of a specified interface.	-

Parameter	Description	Value
include	Indicates that the downstream interface list contains the route forwarding entries of a specified interface.	-
match	Indicates that the downstream interface list matches the route forwarding entries of a specified interface.	The downstream interface list contains only one eligible interface. After **match** is configured, the route forwarding entries of a null downstream interface list are displayed if the outgoing interface is not specified.
none	Displays the (S, G) entry without a downstream interface.	-
statistics	Displays the statistics of the multicast forwarding table.	-
verbose	Displays the detailed information about the multicast forwarding table.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

During IPv6 multicast routing and forwarding, routing information generated by IPv6 multicast routing protocols is saved in an IPv6 multicast routing table. The switch selects the optimal multicast routes from the routing table according to multicast routing and forwarding policies, and then delivers the selected multicast routes to the IPv6 multicast forwarding table to guide multicast data forwarding.

You can use the **display multicast ipv6 forwarding-table** command to check whether IPv6 multicast forwarding entries have been generated and whether multicast data can be forwarded normally.

Example

Display the IPv6 multicast forwarding table.

```
<HUAWEI> display multicast ipv6 forwarding-table
IPv6 Multicast Forwarding Table
Total 2 entries, 2 matched

00001. (FC00:AA::123, FF33::)
     MID: 0, Flags: ACT
     Uptime: 00:01:03, Timeout in: 00:02:27
     Incoming interface: Vlanif10
     List of 1 outgoing interfaces:
       1: LoopBack0
         Activetime: 00:23:15
     Matched 0 packets(0 bytes), Wrong If 0 packets
     Forwarded 0 packets(0 bytes)

00002. (FC00:AA::123, FF34::)
     MID: 1, Flags: ACT
     Uptime: 00:00:03, Timeout in: 00:03:27
     Incoming interface: Vlanif20
     List of 1 outgoing interfaces:
       1: LoopBack0
         Activetime: 00:23:15
     Matched 0 packets(0 bytes), Wrong If 0 packets
     Forwarded 0 packets(0 bytes)
```

Table 8-108 Description of the **display multicast ipv6 forwarding-table** command output

Item	Description
IPv6 Multicast Forwarding Table	IPv6 multicast forwarding table.
Total 2 entries, 2 matched	Total forwarding entries and total eligible forwarding entries.
00001	Number of the (S, G) entry.
(FC00:AA::123, FF33::)	(S, G) entry in the multicast routing table.
MID	Unique multicast forwarding entry in the MFIB table. MID is used to rapidly search the multicast forwarding table.

Item	Description
Flags	Status flag of the (S, G) entry. - ACT: indicates that an active event is triggered. - DUM: indicates a dummy entry. - MISS: indicates that the nocache time needs to be reported. - DROP: indicates packet dropping. - LTH: indicates that the traffic volume is below the threshold. - DEL: indicates a deleted entry. - RST: indicates that registration of the known timer is started. - 2IODEL: indicates that an entry is deleted from the MFIB table, and the update needs to be synchronized to the IO board. - 2PDEL: indicates that an entry is deleted from the device, and the update needs to be synchronized to the IO board. - 2SYNC: indicates that the entry is contained in the MFIB table but it does not exist on the device. - 2ADD: indicates that the entry existing on the device has not been added to the MFIB table. - CLR: indicates that the MFIB table is resetting. - L2FWD: indicates that the device forwards Layer 2 traffic in multicast mode. - NORPF: indicates that the device does not perform RPF check. - 2ACK: indicates that the VPN instance is waiting for the ACK message from the slave main control board. - 2RSED: indicates that the entry is waiting for retransmission. - IOACK: indicates that the VPN instance has received the ACK message from the device. - SACK: indicates that the VPN instance has received the ACK message forwarded by software.

Item	Description
	- BKCLR: indicates that the MFIB table on the slave main control board is resetting. - EXTR: indicates an extranet entry. - 2DEL: indicates that the entry deleted from the device has not been removed from the MFIB table. - PDEL: indicates that the entry does not exist on the device. - A denotes addition; D denotes deletion; I denotes upstream update; R denotes RP update; P denotes PMBR; F denotes flag. - S denotes SPT; E denotes encapsulation group update; US denotes status update; CS denotes status clearing.
Uptime	Period during which the (S, G) entry exists.
Timeout in	Remaining time of the (S, G) entry.
Incoming interface	Incoming interface of the (S, G) entry.
List of 1 outgoing interfaces: 1: LoopBack0	Outgoing interface list, including the outgoing interface number and name.
Activetime	Existing time of the outgoing interface of the (S, G) entry.
Matched 0 packets(0 bytes)	Bytes of multicast packets matching the (S, G) entry. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.
Wrong If 0 packets	Number of multicast packets matching the (S, G) entry but are not forwarded. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.

Item	Description
Forwarded 0 packets(0 bytes)	Number of packets and bytes forwarded by the (S, G) entry. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S can provide the accurate counter values.

8.8.4 display multicast forwarding-table optimization-mode configuration

Function

The **display multicast forwarding-table optimization-mode configuration** command displays the configuration of the optimization mode in which Layer 3 multicast forwarding entries are stored.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support this command.

Format

display multicast forwarding-table optimization-mode configuration [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	*slot-id* specifies the slot that uses the multicast optimization mode. If no slot ID is specified, configurations of all slots are displayed.	The value is an integer and must be the slot ID of a running slot.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command is used to display the configuration of the optimization mode in which Layer 3 multicast forwarding entries are stored. The configuration helps you select a slot based on your storage requirement.

Example

Display the configuration of the optimization modes.

```
<HUAWEI> display multicast forwarding-table optimization-mode configuration
Multicast forwarding-table optimization mode :
Slot      Mode
-------------------------
2         Normal mode
4         Normal mode
5         Rich MCast mode
```

Table 8-109 Description of the **display multicast forwarding-table optimization-mode configuration** command output

Item	Description
Multicast forwarding-table optimization mode	When the multicast optimization mode is enabled.
slot	Slot ID.
mode	Storage Mode. The following storage modes are available: ● Normal: The ARP cache table or ND cache table and multicast forwarding table share hardware resources, without affecting hardware resources allocated to the routing table. ● Rich MCast mode: also known as multicast optimization mode. The system allocates hardware resources preferentially to the multicast forwarding table. The ARP/ND cache table and routing table share hardware resources.

8.8.5 display multicast ipv6 routing-table

Function

The **display multicast ipv6 routing-table** command displays information about an IPv6 multicast routing table.

Format

display multicast ipv6 routing-table [*ipv6-source-address* [*ipv6-source-mask-length*] | *ipv6-group-address* [*ipv6-group-mask-length*] | **incoming-interface** { *interface-type interface-number* | **register** } | **outgoing-interface** { **exclude** | **include** | **match** } { *interface-type interface-number* | **register** | **none** }] * [**outgoing-interface-number** [*number*]]

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 128.
ipv6-group-address	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of an IPv6 multicast group address.	The value is an integer that ranges from 8 to 128.
incoming-interface	Indicates the incoming interface of a multicast forwarding entry.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Indicates the register interface of IPv6 PIM-SM.	-
outgoing-interface	Indicates the outgoing interface of a multicast forwarding entry.	-
include	Displays the (S, G) entries whose downstream interface list contains specified outgoing interfaces.	-
exclude	Displays the (S, G) entries whose downstream interface list does not contain specified outgoing interfaces.	-
match	Displays (S, G) entries whose the downstream interface list contains only one interface that is the same as a specified outgoing interface.	If no interface is specified, the (S, G) entry with the null downstream interface list is displayed.
none	Displays the routing entry without a downstream interface.	-
outgoing-interface-number	Displays the number of the outgoing interfaces of multicast routing entries.	-
number	Specifies the number of outgoing interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display multicast ipv6 routing-table** command to view the IPv6 multicast routing table, including the multicast source address, multicast group address, upstream interface, and downstream interface list.

Example

Display the corresponding routing entry of a multicast group in the IPv6 multicast routing table.

```
<HUAWEI> display multicast ipv6 routing-table
IPv6 multicast routing table
 Total 1 entry

 00001. (FC00::2, FFE3::1)
       Uptime: 00:00:14
       Upstream Interface: Vlanif10
       List of 1 downstream interface
           1:  Vlanif20
```

Table 8-110 Description of the display multicast ipv6 routing-table command output

Item	Description
IPv6 multicast routing table	IPv6 multicast routing table.
Total 1 entry	Number of routing entries that meet the query condition.
00001	Sequence number of the (S, G) entry.
(FC00::2, FFE3::1)	(S, G) entry in the IPv6 multicast routing table.
Uptime	Period during which the (S, G) entry exists.
Upstream Interface	Upstream interface of the (S, G) entry.
List of 1 downstream interface	Downstream interface list.

Display the number of downstream interfaces of the IPv6 multicast routing entries.

```
<HUAWEI> display multicast ipv6 routing-table outgoing-interface-number
IPv6 multicast routing table
 Total 2 entries

 00001. (FC00::55, FF33::1)
       Uptime: 00:00:05
```

```
     Upstream Interface: Vlanif10
     List of 2 downstream interfaces

00002. (FC00::55, FF33::2)
     Uptime: 00:00:05
     Upstream Interface: Vlanif20
     List of 2 downstream interfaces
```

Table 8-111 Description of the display multicast ipv6 routing-table outgoing-interface-number command output

Item	Description
List of 2 downstream interfaces	Number of the outgoing interfaces of IPv6 multicast routing entries.

8.8.6 display multicast ipv6 rpf-info

Function

The **display multicast ipv6 rpf-info** command displays the Reverse Path Forwarding (RPF) routes of a specified IPv6 multicast source or source/group.

Format

display multicast ipv6 rpf-info *ipv6-source-address* [*ipv6-group-address*] [**rpt** | **spt**]

Parameters

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source, used to display the information of RPF routing corresponding to the source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-group-address	Specifies the IPv6 address of a multicast group, used to display the information of RPF routing corresponding to the group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
rpt	Displays the RPF routing information corresponding to a specified source or group on the RPT.	-
spt	Displays the RPF routing information corresponding to a specified source or group on the SPT.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The RPF route with the *ipv6-source-address* as the destination address is an optimal route selected from IPv6 unicast routes. You can use the **display multicast ipv6 rpf-info** command to check the RPF route to the specified source or source-group.

Example

Display all RPF routes to the source address FC00::101.

```
<HUAWEI> display multicast ipv6 rpf-info fc00::101
 VPN-Instance: public net
 RPF information about source: FC00::101
     RPF interface: Vlanif100
     Referenced route/mask: FC00::/64
     Referenced route type: unicast
     Load splitting rule: disabled
```

Table 8-112 Description of the display multicast ipv6 rpf-info command output

Item	Description
RPF information about source	Indicates the multicast source to which RPF information belongs.
RPF interface	Indicates the RPF interface.
Referenced route/mask	Indicates the referenced route and its mask.
Referenced route type	Indicates the referenced route type.
Load splitting rule	Load splitting rules: ● disable: load splitting disabled. ● balance-preferred: load balancing preferred. ● stable-preferred: stable-preferred load splitting. ● source: source address-based load splitting. ● group: group address-based load splitting. ● source-group: source and group addresses-based load splitting.

8.8.7 multicast ipv6 boundary

Function

The **multicast ipv6 boundary** command configures a multicast boundary on an interface.

The **undo multicast ipv6 boundary** command deletes the configured multicast boundary.

By default, no multicast boundary is configured on an interface.

Format

multicast ipv6 boundary { *ipv6-group-address ipv6-group-mask-length* | **scope** *scope-id* }

undo multicast ipv6 boundary { *ipv6-group-address ipv6-group-mask-length* | **all** | **scope** }

Parameters

Parameter	Description	Value
ipv6-group-address	Specifies a multicast group address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of an IPv6 multicast group address.	The value is an integer that ranges from 8 to 128.
scope *scope-id*	Specifies a scope ID.	The value is an integer that ranges from 3 to 15.
all	Deletes all the multicast boundaries configured on an interface.	-

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Data of some multicast groups needs to be forwarded within a specified range. For example, each BSR administrative domain serves a specific group address range, and data packets sent from multicast sources to these groups need to be forwarded within the matching administrative domain. After a multicast boundary is configured for specified multicast groups on an interface, multicast packets sent to these groups cannot be forwarded through the interface. This restricts multicast forwarding within a range.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

To configure the boundary for different multicast groups, you can repeat the command on the same interface.

A and B are the forwarding boundary sets of the multicast group range to be configured, and B is a subset of A. If A is first configured on an interface, B cannot be configured. If you configure A on the interface that has been configured with B, B is replaced by A.

Example

Configure VLANIF100 as the boundary of group FF02::101/16.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] multicast ipv6 boundary FF02::101 16
```

Configure GE0/0/1 as the boundary of group FF02::101/16.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] multicast ipv6 boundary FF02::101 16
```

8.8.8 multicast ipv6 cpu-forward disable

Function

The **multicast ipv6 cpu-forward disable** command disables software forwarding for IPv6 multicast packets.

The **undo multicast ipv6 cpu-forward disable** command restores the default configuration.

By default, software forwarding for IPv6 multicast packets is enabled.

Format

multicast ipv6 cpu-forward disable

undo multicast ipv6 cpu-forward disable

Parameters

None.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In most cases, the switch forwards packets based on software before the hardware forwarding is completed. Then, the switch forwards packets based on hardware. Soft forwarding for multicast packets must be disabled on the switch to prevent packet loss and disorder caused by the low forwarding speed and first packet cache mechanism of soft forwarding.

Prerequisites

IPv6 multicast routing has been enabled using the **multicast ipv6 routing-enable** command in the system view.

Example

Disable software forwarding for IPv6 multicast packets.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] multicast ipv6 cpu-forward disable
```

8.8.9 multicast ipv6 forwarding-table downstream-limit

Function

The **multicast ipv6 forwarding-table downstream-limit** command sets the maximum number of downstream nodes of an entry in the IPv6 multicast forwarding table.

The **undo multicast ipv6 forwarding-table downstream-limit** command restores the default setting.

By default, the maximum number of downstream nodes of an entry is 128.

Format

multicast ipv6 forwarding-table downstream-limit *limit*

undo multicast ipv6 forwarding-table downstream-limit

Parameters

Parameter	Description	Value
limit	Indicates the maximum number of downstream nodes of an entry in the forwarding table.	The value is an integer that ranges from 0 to 128.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the switch receives a multicast packet, it copies the packet for each downstream node in the matching IPv6 multicast forwarding entry. If the switch has a large number of IPv6 multicast forwarding entries or each entry has many downstream nodes, many system resources are consumed. To reduce the load on the switch, limit the maximum number of downstream nodes in each IPv6 multicast forwarding entry.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

If the configured number is smaller than the current number, the excessive downstream nodes are not deleted immediately, and must be deleted by the IPv6 multicast routing protocol. In addition, no new downstream node can be added to the entry in the forwarding table.

Example

In the system view, set the maximum number of downstream nodes of an entry in the IPv6 multicast forwarding table to 32.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] multicast ipv6 forwarding-table downstream-limit 32
```

8.8.10 multicast ipv6 forwarding-table route-limit

Function

The **multicast ipv6 forwarding-table route-limit** command sets the limits on the number of entries in the IPv6 multicast forwarding table.

The **undo multicast ipv6 forwarding-table route-limit** command restores the default value of the limit.

The following lists the maximum number of entries allowed in the IPv6 multicast forwarding table of each model by default:

- S5720-LI, S5720S-LI: 496
- S5735S-H, S5736-S, S6720S-S: 512
- S5731-S, S5731S-S, S5720I-SI 1024
- S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735S-S, S5735-S-I: 1500
- S5732-H, S6730-H, S6730S-H: 2048
- S6730-S, S6730S-S, S5731-H, S5731S-H, S6735-S, S6720-EI, S6720S-EI: 4096

Format

multicast ipv6 forwarding-table route-limit *limit*

undo multicast ipv6 forwarding-table route-limit

Parameters

Parameter	Description	Value
limit	Specifies the limit on the number of entries in the IPv6 multicast forwarding table.	The value is an integer that ranges from 0 to *The maximum number of entries allowed in the multicast forwarding table by default.* **NOTE** The value range of S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H are expanded after the high specification mode is configured for multicast forwarding using the **set multicast forwarding-table super-mode** command. The actual value range depends on the specification of the device.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Excessive IPv6 multicast forwarding entries will exhaust the memory of the switch. To prevent this problem, use the **multicast ipv6 forwarding-table route-limit** command to limit the number of entries in the IPv6 multicast forwarding table.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

NOTICE

If the limit on the number of entries in the IPv6 multicast forwarding table is set after multicast services are deployed on a switch, ensure that this limit is greater than or equal to the number of existing forwarding entries. Otherwise, faults may occur.

It is recommended that you set the limit based on the actual network environment before deploying multicast services on the switch.

If the newly-configured limit on the number of entries is smaller than the number of existing entries, the excessive entries are not deleted immediately. The configured limit takes effect in the following cases:

- Entries are added to the IPv6 multicast forwarding table after the existing entries age out.
- The **reset multicast ipv6 forwarding-table all** command is executed.

Example

Set the limit on the number of the entries in the IPv6 forwarding table to 1024.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] multicast ipv6 forwarding-table route-limit 1024
```

8.8.11 multicast ipv6 invalid-packet

Function

The **multicast ipv6 invalid-packet** command sets the maximum number of invalid IPv6 multicast protocol packets that can be stored on the switch.

The **undo multicast ipv6 invalid-packet** command deletes the set maximum number of invalid IPv6 multicast protocol packets that can be stored on the switch.

By default, the switch can save a maximum of 10 invalid packets for each specific IPv6 multicast protocol.

Format

multicast ipv6 invalid-packet { **mld** | **pim** } **max-count** *max-number*

undo multicast ipv6 invalid-packet { **mld** | **pim** }

Parameters

Parameter	Description	Value
mld	Sets the maximum number of invalid MLD messages.	-
pim	Sets the maximum number of invalid PIM (IPv6) messages.	-
max-count *max-number*	Sets the maximum number of invalid IPv6 multicast protocol packets that can be stored on a device.	The value is an integer that ranges from 1 to 100.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

If IPv6 multicast entries fail to be generated or peer relationships fail to be set up, you can enable the switch to store invalid IPv6 multicast protocol packets and view statistics and details of the invalid IPv6 multicast protocol packets. Based on the command output, you can locate and rectify faults.

Example

Set the maximum number of invalid MLD messages that can be stored on the switch to 20.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 invalid-packet mld max-count 20
```

8.8.12 multicast ipv6 load-splitting

Function

The **multicast ipv6 load-splitting** command enables load splitting among IPv6 multicast routes.

The **undo multicast ipv6 load-splitting** command restores the default configuration.

By default, load splitting among IPv6 multicast routes is disabled.

Format

multicast ipv6 load-splitting { **balance-preferred** | **stable-preferred** | **group** | **source** | **source-group** }

undo multicast ipv6 load-splitting

Parameters

Parameter	Description	Value
balance-preferred	Indicates balance-preferred load splitting. This policy is applicable to the scenario where hosts frequently join or leave groups, which requires automatic load adjustment.	-
group	Indicates group address-based load splitting. This policy is applicable to the scenario of one source to multiple groups.	-
source	Indicates source address-based load splitting. This policy is applicable to the scenario of multiple sources to one group.	-
source-group	Indicates source and group addresses-based load splitting. This policy is applicable to the scenario of multiple sources to multiple groups.	-
stable-preferred	Indicates stable-preferred load splitting. This policy is applicable to stable multicast networking.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, if there are multiple equal-cost routes to a multicast source, the device selects the route with the largest next-hop address as the RPF route. To enable multicast data to be forwarded through multiple paths, run this command to configure multicast load splitting. After multicast load splitting is configured, the device uses the specified load splitting policy to distribute multicast data among multiple paths. This function improves quality of multicast forwarding.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Follow-up Procedure

Because the forwarding capabilities of equal-cost routes are different from the actual load distribution situation on the equal-cost routes, even load splitting cannot meet network requirements in some scenarios. In this case, you can run the **multicast ipv6 load-splitting weight** command to configure the IPv6 multicast load splitting weight on the interface to realize unbalanced load splitting.

Precautions

The five load splitting policies are mutually exclusive. It is recommended that you use a fixed load splitting policy based on the actual situation on your network. The **balance-preferred** or **stable-preferred** policy is preferred.

If PIM-DM (IPv6) is enabled on the switch, the **balance-preferred** or **stable-preferred** policy cannot be used.

Example

Configure stable-preferred load splitting in the system view.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] multicast ipv6 load-splitting stable-preferred
```

8.8.13 multicast ipv6 load-splitting weight

Function

The **multicast ipv6 load-splitting weight** command sets the IPv6 multicast load splitting weight for an interface.

The **undo multicast ipv6 load-splitting weight** command restores the default setting.

By default, the IPv6 multicast load splitting weight of an interface is 1.

Format

multicast ipv6 load-splitting weight *weight-value*

undo multicast ipv6 load-splitting weight

Parameters

Parameter	Description	Value
weight-value	Specifies the IPv6 multicast load splitting weight of an interface.	The value is an integer that ranges from 0 to 32.

Views

GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-Trunk interface view, VLANIF interface view, loopback interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a stable-preferred or balance-preferred multicast splitting policy is configured, you can run this command to set load splitting weights for interfaces to realize unbalanced load splitting. The larger weight value an interface has, the more IPv6 multicast routing entries have it as the upstream interface.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Precautions

This command is applicable only when the IPv6 multicast load splitting policy is set to stable-preferred or balance-preferred.

When the IPv6 multicast load splitting weight on an interface is 0, the routes with this interface as the upstream interface do not take part in load splitting.

Example

Set the IPv6 multicast load splitting weight on VLANIF100 to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ipv6 enable
[HUAWEI-Vlanif100] multicast ipv6 load-splitting weight 10
```

Set the IPv6 multicast load splitting weight on GE0/0/1 to 10.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ipv6 enable
[HUAWEI-GigabitEthernet0/0/1] multicast ipv6 load-splitting weight 10
```

8.8.14 multicast ipv6 load-splitting-timer

Function

The **multicast ipv6 load-splitting-timer** command sets an IPv6 multicast load splitting timer.

The **undo multicast ipv6 load-splitting-timer** command restores the default setting.

By default, the value of the IPv6 multicast load splitting timer is 1800 seconds.

Format

multicast ipv6 load-splitting-timer *interval*

undo multicast ipv6 load-splitting-timer

Parameters

Parameter	Description	Value
interval	Specifies the value of the IPv6 multicast load splitting timer.	The value is an integer that ranges from 10 to 1800, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In stable-preferred load splitting or balance-preferred load splitting mode, entries may not be well-balanced among paths because of the addition or deletion of entries, change of load splitting weights of the paths, or change of equal-cost routes. In such a case, the device will balance entries after a certain waiting time to reduce the impact of frequent changes on the system.

Currently, setting a load splitting timer to change the waiting time before balancing entries is supported.

- If the network is stable, for example, when entries are not deleted or added frequently or equal-cost routes are not changed frequently, set the load splitting timer value to a smaller value so that entries can be balanced rapidly. The recommended value is 300 to 600 seconds.
- If the network is not stable, for example, when entries are deleted or added frequently or equal-cost routes are changed frequently, set the load splitting timer value to a larger value to reduce the impact of frequent entry changes on the system and network stability. The recommended value is 1200 to 1800 seconds.

Prerequisites

IPv6 multicast routing has been enabled globally using the **multicast ipv6 routing-enable** command in the system view.

Example

Set the IPv6 multicast load splitting timer to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
[HUAWEI] multicast ipv6 load-splitting-timer 100
```

8.8.15 multicast ipv6 routing-enable

Function

The **multicast ipv6 routing-enable** command enables the IPv6 multicast routing function.

The **undo multicast ipv6 routing-enable** command restores the default configuration.

By default, the IPv6 multicast routing function is disabled.

Format

multicast ipv6 routing-enable

undo multicast ipv6 routing-enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before configuring Layer 3 IPv6 multicast, you must enable the IPv6 multicast routing function globally. Layer 3 IPv6 multicast protocols (such as PIM (IPv6) and MLD) and other Layer 3 IPv6 multicast functions can be configured only after IPv6 multicast routing is enabled.

Precautions

Multicast functions (Layer 2 and Layer 3 multicast) and the flow control function (configured using the **flow-control** command) are mutually exclusive on the following models: S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-S, S5735-S-I

NOTICE

The **undo multicast ipv6 routing-enable** command deletes all IPv6 multicast configurations of the device. If IPv6 multicast services are running on the device, the IPv6 multicast services are interrupted when this command is executed. To restore IPv6 multicast services on the instance, you must re-configure the corresponding commands.

Example

Enable IPv6 multicast routing globally.

```
<HUAWEI> system-view
[HUAWEI] multicast ipv6 routing-enable
```

8.8.16 multicast ttl-check disable

Function

The **multicast ttl-check disable** command disables a switch from checking the TTL value of multicast packets.

The **undo multicast ttl-check disable** command enables a switch to check the TTL value of multicast packets again.

By default, a switch checks the TTL value of multicast packets.

NOTE

This command is supported only on the following models: S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S.

Format

multicast ttl-check disable

undo multicast ttl-check disable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

In V200R019C10 and later versions, when multicast packets between a multicast source and receiver are forwarded across VLANs, the multicast packets with a TTL value less than or equal to 1 will be discarded by default.

In versions earlier than V200R019C10, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S do not discard multicast packets whose TTL value is less than or equal to 1. After the switch software version is upgraded to V200R019C10 or later, however, if you want a switch not to discard multicast packets whose TTL value is less than or equal to 1, run the **multicast ttl-check disable** command to disable the switch from checking the TTL value of multicast packets.

The **multicast ttl-check disable** command does not apply to the following scenarios:

- This command is not applicable to multicast packets on a VPN. A switch always discards multicast packets on a VPN if their TTL value is less than or equal to 1.
- This command does not apply when a multicast source and receiver are in the same VLAN, in which case, the switch does not check the TTL value of multicast packets between them.
- When the forwarding mode of multicast packets is changed to MAC address-based forwarding, the switch does not check the TTL value of multicast packets.

Example

Disable a switch from checking the TTL value of multicast packets.

```
<HUAWEI> system-view
[HUAWEI] multicast ttl-check disable
```

8.8.17 reset multicast ipv6 forwarding-table

Function

The **reset multicast ipv6 forwarding-table** command clears the entries of the IPv6 multicast forwarding table.

Format

reset multicast ipv6 forwarding-table all

reset multicast ipv6 forwarding-table { *ipv6-group-address* [*ipv6-group-mask-length*] | *ipv6-source-address* [*ipv6-source-mask-length*] | **incoming-interface** { *interface-type interface-number* | **register** } } *

Parameters

Parameter	Description	Value
all	Resets all the multicast forwarding caches (MFCs) in the multicast forwarding table.	-
ipv6-group-address	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of a multicast group address.	The value is an integer that ranges from 8 to 128.

Parameter	Description	Value
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 128.
incoming-interface	Indicates the incoming interface of a forwarding entry.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Indicates the register interface of IPv6 PIM.	-

Usage Guidelines

NOTICE

After you run this command to delete information from the IPv6 multicast forwarding table, multicast data will be interrupted for a period. Confirm the action before you use the command.

Example

Delete all the IPv6 multicast forwarding entries.

```
<HUAWEI> reset multicast ipv6 forwarding-table all
```

8.8.18 reset multicast ipv6 routing-table

Function

The **reset multicast ipv6 routing-table** command clears the entries in the IPv6 multicast routing table. The corresponding forwarding entries in the forwarding table are deleted at the same time.

Format

reset multicast ipv6 routing-table all

reset multicast ipv6 routing-table { *ipv6-group-address* [*ipv6-group-mask-length*] | *ipv6-source-address* [*ipv6-source-mask-length*] | **incoming-interface** { *interface-type interface-number* | **register** } } *

Parameters

Parameter	Description	Value
all	Resets all routing entries in the multicast core routing table.	-
ipv6-group-address	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
ipv6-group-mask-length	Specifies the mask length of an IPv6 multicast group address.	The value is an integer that ranges from 8 to 128.
ipv6-source-address	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
ipv6-source-mask-length	Specifies the mask length of a multicast source address.	The value is an integer that ranges from 0 to 128.
incoming-interface	Indicates the incoming interface of a routing entry.	-
interface-type interface-number	Specifies the type and number of an interface.	-
register	Indicate the register interface of IPv6 PIM.	-

Views

User view

Usage Guidelines

NOTICE

After you run this command to delete information from the IPv6 multicast routing table, the matching entries in the IPv6 multicast forwarding table are also deleted. As a result, multicast forwarding will be interrupted for a period. Confirm the action before you use the command.

Example

Delete the entries of the group FF02::101 from the IPv6 multicast routing table.

```
<HUAWEI> reset multicast ipv6 routing-table FF02::101
```

8.8.19 set multicast forwarding-table optimization-mode

Function

The **set multicast forwarding-table optimization-mode** command configures the multicast optimization mode in which the Layer 3 forwarding entries are stored on a switch.

The **undo set multicast forwarding-table optimization-mode** command restores the default storage mode.

By default, a switch uses the normal storage mode.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support this command.

Format

set multicast forwarding-table optimization-mode [**slot** *slot-id*]

undo set multicast forwarding-table optimization-mode [**slot** *slot-id*]

Parameters

Parameter	Description	Value
slot *slot-id*	*slot-id* specifies the slot that uses the multicast optimization mode. If no slot ID is specified, storage modes of all slots are configured to be the multicast optimization mode.	The value is an integer and must be the slot ID of a running slot.

Views

System view

Default Level

3: Management level

Usage Guidelines

Applicable Environment

In most cases, the Layer 3 forwarding entries are stored in normal mode. The ARP cache table, ND cache table, and multicast forwarding table share hardware resources, without affecting hardware resources allocated to the routing table.

This command optimizes storage resources of Layer 3 forwarding entries through preferential allocation of hardware resources preferentially to the multicast forwarding table. The ARP cache table, ND cache table, and routing table share hardware resources. Run this command if either of the following situations occurs:

- A large number of ARP prefix entries and multicast forwarding entries exist in the system at the same time.
- A large number of ND prefix entries and multicast forwarding entries exist in the system at the same time.

Precautions

Note the following points when running this command:

- If the multicast optimization modes on a switch are configured or deleted, the system prompts the user to save the configurations and then restart the device. If the device configuration is not saved, the new storage mode does not take effect after the restart.
- This function can be implemented on an IPv6 network only when a switch with an extended entry register is available. In addition, the storage mode of the register must be set to IPv6 mode. For details on how to configure the extended entry register, see **assign resource-mode** in "Device Management Commands > Hardware Configuration Commands".

NOTICE

When the user configures this mode or restores the default mode, the system will prompt the user to restart the device or a specified slot. If the system receives no response, the configuration times out, and the system view is displayed. The system does not restart. The restart can cause the network to crash for a short period. In most cases, this command is not recommended.

Example

Configure the storage mode to be the multicast optimization mode for a switch.

```
<HUAWEI> system-view
[HUAWEI] set multicast forwarding-table optimization-mode
```

8.8.20 set multicast forwarding-table super-mode

Function

The **set multicast forwarding-table super-mode** command configures the high specification mode for multicast forwarding. In the high specification mode, the number of multicast entries can reach the maximum value supported by the switch, which is much more than the default limit.

The **undo set multicast forwarding-table super-mode** command restores the default configuration.

By default, the common specification mode is used for multicast forwarding after Layer 3 multicast is configured. In this mode, the number of multicast entries cannot exceed the default limit defined on the switch.

NOTE

Only the S5731-H, S5731S-H, S5732-H, S6730S-H, and S6730-H support this command.

Format

set multicast forwarding-table super-mode

undo set multicast forwarding-table super-mode

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After Layer 3 multicast is enabled, the common specification mode is used for multicast forwarding by default. This mode can meet requirements of most multicast service scenarios. In some large-scale multicast applications, a network has a large number of multicast sources to provide many channels for multicast users. In these applications, the number of multicast entries may exceed the default limit defined on a multicast device. When this occurs, some multicast entries cannot be generated. As a result, some users cannot receive the multicast data they request.

The **set multicast forwarding-table super-mode** command configures the high specification mode to increase the number of entries used for multicast forwarding. In high specification mode, the number of multicast entries supported by the switch is much larger than the default limit on the number of multicast entries. This mode maximizes a device's capability to support large-scale multicast applications.

Precautions

After you run this command:

- This command can only increase the number of Layer 3 multicast forwarding entries, but cannot increase the number of Layer 2 multicast forwarding entries. In scenarios when both Layer 2 and Layer 3 multicast services are configured, the number of Layer 3 multicast forwarding entries is limited by the number of Layer 2 multicast forwarding entries. Therefore, this command cannot increase the number of multicast forwarding entries if both Layer 2 and Layer 3 multicast services are configured.
- Restart the switch for the configuration to take effect.

- The default value of the IGMP general query interval changes from 60s to 120s. You can set the IGMP general query interval using the **igmp timer query** or **timer query (IGMP view)** command.
- The default value of the IGMP robustness variable changes from 2 to 3. You can set the robustness variable using the **igmp robust-count** or **robust-count (IGMP view)** command.
- The default value of the other querier present interval changes from 125s to 245s. You can set the other querier present interval using the **igmp timer other-querier-present** or **timer other-querier-present (IGMP view)** command.
- The default value of the MLD robustness variable changes from 2 to 3. You can set the robustness variable using the **mld robust-count** or **robust-count (MLD view)** command.
- The default interval for sending PIM-DM State-Refresh messages changes from 60s to 255s. On an IPv4 multicast network, run the **state-refresh-interval (IPv4)** command to set the interval for sending PIM-DM State-Refresh messages. On an IPv6 network, run the **state-refresh-interval (IPv6)** command to set the interval for sending PIM-DM State-Refresh messages.
- The default interval for sending PIM Join-Prune messages changes from 210s to 300s. On an IPv4 multicast network, run the **holdtime join-prune (IPv4)** or **pim holdtime join-prune** command to set the interval for sending PIM Join-Prune messages. On an IPv6 network, run the **holdtime join-prune (IPv6)** or **pim ipv6 holdtime join-prune** command to set the interval for sending PIM Join-Prune messages.
- Run the **car** command to change the rate limit for IGMP/MLD messages sent to the CPU according to the actual situations of multicast services.
- More system resources are consumed in the high specification mode. If the number of multicast protocol packets sent to the switch increases sharply in a short time, the CPU usage of the switch becomes high.
- It is recommended that you set the same general query interval on all the IGMP/MLD-enabled interfaces of a switch. For an IGMP-enabled interface, run the **igmp timer query** command in the interface view to set the general query interval. For an MLD-enabled interface, run the **mld timer query** command in the interface view to set the general query interval. This configuration prevents IGMP/MLD-enabled interfaces from sending Query messages at the same time, so that the switch does not have to process a large number of Report messages in a short time, which could cause a high CPU usage.
- In a stack, if member interfaces of an Eth-trunk interface are located on member switches that support different numbers of multicast forwarding entries, the maximum number of multicast forwarding entries supported by the Eth-Trunk interface depends on the member switch that supports the fewest multicast forwarding entries. Multicast forwarding entries supported by an Eth-Trunk interface meet either of the following conditions:
  - The outbound interface of the multicast forwarding entries is the Eth-Trunk interface that has been switched to the Layer 3 mode using the **undo portswitch** command.
  - The Eth-Trunk interface belongs to the VLANs corresponding to the VLANIF interfaces of the multicast forwarding entries.

Example

Configure the high specification mode for multicast forwarding.

```
<HUAWEI> system-view
[HUAWEI] set multicast forwarding-table super-mode
Warning: This command will modify some default multicast settings and has limitations
in a few special scenarios. Use the command according to product manual.Continue? [Y/N]:y
```

8.8.21 set multicast-hash-mode

Function

The **set multicast-hash-mode** command specifies a hash algorithm for multicast forwarding.

The **undo multicast-hash-mode** command restores the default hash algorithm for multicast forwarding.

By default, the crc-32-lower algorithm is used.

NOTE

Only the S6720-EI, S6735-S and S6720S-EI support support this command.

Format

set multicast-hash-mode { **crc-32-upper** | **crc-32-lower** | **lsb** | **crc-16-upper** | **crc-16-lower** }

undo set multicast-hash-mode { **crc-32-upper** | **crc-32-lower** | **lsb** | **crc-16-upper** | **crc-16-lower** }

Parameters

Parameter	Description
crc-32-upper	
crc-32-lower	
lsb	
crc-16-upper	
crc-16-lower	

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve multicast forwarding performance, the switch uses a hash algorithm to learn multicast addresses. If multiple addresses match a key value, a hash conflict occurs. A large number of hash conflicts will cause failures to learn some multicast addresses. When such a problem occurs, use an appropriate hash algorithm to reduce hash conflicts.

Precautions

- An appropriate hash algorithm can reduce but not eliminate hash conflicts.
- MAC addresses are distributed on a network randomly, so the system cannot determine the best hash algorithm. The default hash algorithm is the best algorithm in most cases, so changing the hash algorithm is not recommended.
- After changing the hash algorithm, restart the switch for the configuration to take effect.

Example

Set the hash algorithm for multicast forwarding to crc-32-upper.

```
<HUAWEI> system-view
[HUAWEI] set multicast-hash-mode crc-32-upper
```

8.9 VLAN-based IGMP Snooping Configuration Commands

8.9.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.9.2 dhcp-snooping user-offline remove igmp-snooping

Function

The **dhcp-snooping user-offline remove igmp-snooping** command enables the switch to delete the IGMP snooping entries of DHCP snooping users immediately after the users go offline.

The **undo dhcp-snooping user-offline remove igmp-snooping** command restores the default configuration.

By default, the switch does not delete the IGMP snooping entries of DHCP snooping users immediately after the users go offline.

Format

dhcp-snooping user-offline remove igmp-snooping

undo dhcp-snooping user-offline remove igmp-snooping

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, when IGMP snooping is enabled for DHCP snooping users, the switch does not delete the IGMP snooping entry of a user immediately after the user goes offline. The multicast flow requested by the user is still transmitted until the IGMP snooping entry of the user is aged out.

The **dhcp-snooping user-offline remove igmp-snooping** command enables the switch to delete the IGMP snooping entry of a DHCP snooping user immediately after the user goes offline, terminating the multicast flow requested by the user.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Example

Enable the system to delete IGMP snooping entries of DHCP snooping users immediately after the users go offline.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] dhcp-snooping user-offline remove igmp-snooping
```

8.9.3 display igmp-snooping

Function

The **display igmp-snooping** command displays the IGMP snooping running parameters.

Format

display igmp-snooping [**vlan** [*vlan-id*]]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays the IGMP snooping running parameters in a specified VLAN. If this parameter is not specified, the system displays the IGMP running parameters in all VLANs with IGMP snooping configured.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use this command to view the IGMP snooping running parameters.

To view the IGMP snooping configuration, run the **display igmp-snooping configuration** command.

Precautions

This command can display the IGMP snooping running parameters in a VLAN only when at least one interface in the VLAN is in Up state and IGMP snooping enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.

Example

Display the IGMP snooping running parameters.

```
<HUAWEI> display igmp-snooping
 IGMP Snooping Information for VLAN 3
    IGMP Snooping is Enabled
    IGMP Version is Set to default 2
    IGMP Query Interval is Set to default 125s
    IGMP Max Response Interval is Set to default 10s
    IGMP Robustness is Set to default 2
    IGMP Last Member Query Interval is Set to default 1s
    IGMP Router Port Aging Interval is Set to 180s or holdtime in hello
    IGMP Filter Group-Policy is not set
    IGMP Prompt Leave Disable
    IGMP Host-based Prompt Leave Disable
    IGMP Router Alert is Not Required
    IGMP Send Router Alert Enable
```

```
  IGMP Proxy Disable
  IGMP Report Suppress Disable
  IGMP Suppress Time is set to default 10 seconds
  IGMP Querier Disable
  IGMP Router Port Learning Enable
  IGMP SSM-Mapping Disable
  IGMP Limit Action Disable
  IGMP Suppress-dynamic-join Disable
IGMP Snooping Information for VLAN 4
  IGMP Snooping is Enabled
  IGMP Version is 3
  IGMP snooping version 3 uses ASM-SSM mode
  IGMP Query Interval is Set to default 125s
  IGMP Max Response Interval is Set to default 10s
  IGMP Robustness is Set to default 2
  IGMP Last Member Query Interval is Set to default 1s
  IGMP Router Port Aging Interval is Set to 180s or holdtime in hello
  IGMP Filter Group-Policy is not set
  IGMP Prompt Leave Disable
  IGMP Host-based Prompt Leave Disable
  IGMP Router Alert is Not Required
  IGMP Send Router Alert Enable
  IGMP Proxy Disable
  IGMP Report Suppress Disable
  IGMP Suppress Time is set to default 10 seconds
  IGMP Querier Disable
  IGMP Router Port Learning Enable
  IGMP SSM-Mapping Disable
  IGMP Limit Action Disable
  IGMP Suppress-dynamic-join Disable
```

Table 8-113 Description of the **display igmp-snooping** command output

Item	Description
IGMP Snooping Information for VLAN 3	The following information displayed is the IGMP snooping running parameters in VLAN 3.
IGMP Snooping is Enabled	IGMP snooping is enabled in the VLAN. By default, IGMP snooping is disabled in a VLAN. IGMP snooping can be enabled in a VLAN using the **igmp-snooping enable (VLAN view)** command.
IGMP Version is Set to default 2 IGMP Version is 3	Version of IGMP messages that can be processed in the VLAN. The default version is 2, indicating that both IGMPv1 and IGMPv2 messages can be processed. This parameter is configured using the **igmp-snooping version** command.
IGMP snooping version 3 uses ASM-SSM mode	The ASM-SSM model is used for IGMPv3. This parameter is configured using the **igmp-snooping version** command.
IGMP Query Interval is Set to default 125s	Interval at which IGMP General Query messages are sent. In this example, the default value (125 seconds) is displayed. This parameter is configured using the **igmp-snooping query-interval** command.

Item	Description
IGMP Max Response Interval is Set to default 10s	Maximum response time for IGMP General Query messages. In this example, the default value (10 seconds) is displayed. This parameter is configured using the **igmp-snooping max-response-time** command.
IGMP Robustness is Set to default 2	IGMP robustness variable. In this example, the default value 2 is displayed. This parameter is configured using the **igmp-snooping robust-count** command.
IGMP Last Member Query Interval is Set to default 1s	Interval at which IGMP Group-Specific Query messages are sent. In this example, the default value (1 second) is displayed. This parameter is configured using the **igmp-snooping lastmember-queryinterval** command.
IGMP Router Port Aging Interval is Set to 180s or holdtime in hello	Aging time of a router port. In this example, the default value (180 seconds or the holdtime value contained in PIM Hello messages) is displayed. This parameter is configured using the **igmp-snooping router-aging-time** command.
IGMP Filter Group-Policy is not set	Multicast group policy. In this example, the default configuration is displayed. That is, no policy is configured. A multicast group policy is configured using the **igmp-snooping group-policy** command.
IGMP Prompt Leave Disable	The fast leave function is disabled for interfaces in the VLAN (default configuration). The fast leave function can be enabled using the **igmp-snooping prompt-leave** command.
IGMP Host-based Prompt Leave Disable	The host-based fast leave function is disabled (default configuration). The host-based fast leave function can be enabled using the **igmp-snooping host-based prompt-leave** command.
IGMP Router Alert is Not Required	The switch does not require that the IGMP messages received from the VLAN contain the Router-Alert option in the IP header (default configuration). The switch can be configured to discard IGMP messages without the Router-Alert option using the **igmp-snooping require-router-alert** command.

Item	Description
IGMP Send Router Alert Enable	The switch sends the IGMP messages with the Router-Alert option to the VLAN (default configuration). The switch can be configured to send IGMP messages with the Router-Alert option using the **igmp-snooping send-router-alert** command.
IGMP Router Port Learning Enable	Router port learning is enabled (default configuration). Router port learning can be enabled using the **igmp-snooping router-learning** command.
IGMP Proxy Disable	IGMP snooping proxy is disabled (default configuration). IGMP snooping proxy can be enabled using the **igmp-snooping proxy** command.
IGMP Report Suppress Disable	IGMP message suppression is disabled (default configuration). IGMP message suppression can be enabled using the **igmp-snooping report-suppress** command.
IGMP Suppress Time is set to default 10 seconds	IGMP message suppression time. In this example, the default value (10 seconds) is displayed. This parameter is configured using the **igmp-snooping suppress-time** command.
IGMP Querier Disable	IGMP snooping querier is disabled (default configuration). IGMP snooping querier can be enabled using the **igmp-snooping querier enable** command.
IGMP SSM-Mapping Disable	IGMP snooping SSM mapping is disabled (default configuration). IGMP snooping SSM mapping can be enabled using the **igmp-snooping ssm-mapping enable** command.
IGMP Limit Action Disable	Layer 2 multicast entry overwriting is disabled (default configuration). Layer 2 multicast entry overwriting can be enabled using the **igmp-snooping limit-action** command.
IGMP Suppress-dynamic-join Disable	Report and Leave messages received in the VLAN can be forwarded to the upstream multicast device with static multicast groups configured (default configuration). This function can be disabled using the **igmp-snooping static-group suppress-dynamic-join** command.

8.9.4 display igmp-snooping configuration

Function

The **display igmp-snooping configuration** command displays the IGMP snooping configuration.

Format

display igmp-snooping [**vlan** [*vlan-id*]] **configuration**

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays the IGMP snooping configuration in a specified VLAN. If this parameter is not specified, the system displays the IGMP snooping configuration in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command displays only the IGMP snooping configuration so that you can check whether the IGMP snooping configuration made in the system is proper.

To check all IGMP snooping running parameters, run the **display igmp-snooping** command.

Prerequisites

The IGMP snooping configuration in a VLAN can be displayed as long as IGMP snooping parameters have been configured in the VLAN, no matter whether the VLAN contains interfaces in Up state.

Global IGMP snooping must be enabled using the **igmp-snooping enable (system view)** command before any IGMP snooping configuration is performed.

Example

Display the IGMP snooping configuration in all VLANs.

```
<HUAWEI> display igmp-snooping configuration
 IGMP Snooping Configuration for VLAN 7
    igmp-snooping enable
    igmp-snooping version 3
    igmp-snooping ssm-mapping enable
    igmp-snooping ssm-policy 2000
    igmp-snooping ssm-mapping 232.1.1.0 255.255.255.0 10.1.2.1
```

8.9.5 display igmp-snooping port-info

Function

The **display igmp-snooping port-info** command displays information about multicast group member ports.

Format

display igmp-snooping port-info [**vlan** *vlan-id* [**group-address** *group-address*]] [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays information about multicast group member ports in a specified VLAN. If this parameter is not specified, the system displays multicast group member ports in all VLANs.	The value is an integer ranging from 1 to 4094.
group-address *group-address*	Displays information about member ports of a specified multicast group. If this parameter is not specified, the system displays member ports of all multicast groups.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
verbose	Displays detailed information about multicast group member ports. If this parameter is not specified, the system displays the summary of multicast group member ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When the switch with IGMP snooping enabled receives IGMP messages exchanged between hosts and a Layer 3 device, the switch maintains a Layer 2 multicast forwarding table based on information in the messages. The **display igmp-snooping port-info** command shows member ports in the Layer 2 multicast forwarding table. According to the command output, you can know which downlink ports of the switch have multicast users connected, and control multicast services conveniently.

Precautions

This command can display information about multicast group member ports in a VLAN only when IGMP snooping has been enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command, and at least one interface in the VLAN is in Up state. If interfaces in the VLAN are dynamic group member ports, the command can display information about these member ports only after they receive IGMP Report messages and before their aging time expires.

Example

Display information about multicast group member ports in VLAN 7.

```
<HUAWEI> display igmp-snooping port-info vlan 7
-------------------------------------------------------------------------------
                       (Source, Group)  Port                      Flag
             Flag: S:Static    D:Dynamic    M: Ssm-mapping
-------------------------------------------------------------------------------
 VLAN 7, 2 Entry(s)
                        (*, 225.0.0.1)  GE0/0/1                   -D-
                                               1 port(s) include
                  (1.1.1.1, 225.0.0.1)  GE0/0/1                   -D-
                                               1 port(s) exclude
-------------------------------------------------------------------------------
```

Table 8-114 Description of the **display igmp-snooping port-info** command output

Item	Description
(Source, Group)	(S, G) entry, specifying the multicast source and multicast group. Multicast data is sent from multicast source S to group G. If S is displayed as *, multicast data may be sent from any multicast source. If S is displayed as an IP address, multicast data is sent from this IP address.
Port	Member port. **include** and **exclude** indicate the multicast source filtering mode.
Flag	Type of a member port, which can be: ● S: static member port, which is configured using the **l2-multicast static-group** command ● D: dynamic member port learned through IGMP snooping ● M: member port established through SSM mapping
VLAN *x*, *x* Entry(s)	VLAN ID and the number of entries in the VLAN.

Display detailed information about all multicast group member ports.

```
<HUAWEI> display igmp-snooping port-info verbose

The port information of Group 225.0.0.1 on VLAN
100:
   Time of this group has been up : 00:00:55

  The port information of (0.0.0.0, 225.0.0.1):
   Time of this source has been up : 00:00:55
   Port Table on this source(0.0.0.0):
   List of ports in include mode:
     No.1
       Port name : GE0/0/1
       Time of this port has been up as a host-port : 00:00:55
       Remain time of port expire as dynamic host-port :
00:03:33
       Host-port flags : Dynamic
   There are 1 port(s) in include mode.

  The port information of (1.1.1.1, 225.0.0.1):
   Time of this source has been up : 00:00:55
   Port Table on this source(1.1.1.1):
   List of ports in exclude mode:
     No.1
       Port name : GE0/0/1
       Time of this port has been up as a host-port : 00:00:55
       Remain time of port expire as dynamic host-port :
00:03:33
       Host-port flags : Dynamic
   There are 1 port(s) in exclude mode.
```

Table 8-115 Description of the display igmp-snooping port-info verbose command output

Item	Description
The port information of Group *xxx*	Information about member ports of multicast group in VLAN.
Time of this group has been up	Time that elapsed since the multicast group was set up.
The port information of *xxx*	Information about member ports of a specified (S, G).
Time of this source has been up	Time that elapsed since the multicast source was set up.
Port Table on this source	List of member ports of the specified multicast source.
List of ports in include mode	Information about member ports that join a multicast group in INCLUDE mode.
List of ports in exclude mode	Information about member ports that join a multicast group in EXCLUDE mode.
No.1	First member port.
Port name	Type and number of the first member port.
Time of this port has been up as a host-port	Time that elapsed since the first member port was bound to a source or (S, G).
Remain time of port expire as dynamic host-port	Remaining aging time of the first member port. This field displays "NA" for a static member port. The aging time of a dynamic member port is calculated using the following formula: Aging time = Robustness variable x General query interval + Maximum response time for General Query messages. The robustness variable is configured using the **igmp-snooping robust-count** command. The general query interval is configured using the **igmp-snooping query-interval** command. The maximum response time for General Query messages is configured using the **igmp-snooping max-response-time** command.
Version2-host-present-timer-expiry	Aging time of the IGMPv2 host.
Version1-host-present-timer-expiry	Aging time of the IGMPv1 host.

Item	Description
Host-port flags	Type of a member port, which can be: - Static: static member - Dynamic: dynamic member port learned through IGMP snooping - Mapping: member port established through SSM mapping
There are *x* port(s) in include mode	Number of member ports that join a multicast group in INCLUDE mode.
There are *x* port(s) in exclude mode	Number of member ports that join a multicast group in EXCLUDE mode.

8.9.6 display igmp-snooping host-tracking

Function

The **display igmp-snooping host-tracking** command displays information about group member hosts.

Format

display igmp-snooping host-tracking [**vlan** *vlan-id* [**group-address** *group-address*]] [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays information about group member hosts in a specified VLAN. If this parameter is not specified, the command displays information about group member hosts in all VLANs.	The value is an integer that ranges from 1 to 4094.
group-address *group-address*	Displays information about member hosts of a specified multicast group. If this parameter is not specified, the command displays information about member hosts of all multicast groups.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about group member hosts on a specified interface. If this parameter is not specified, the command displays information about group member hosts on all interfaces. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

IGMP snooping creates and maintains a Layer 2 multicast forwarding table by listening to IGMP messages exchanged between hosts and an upstream Layer 3 device. You can use this command to view information about member hosts in the Layer 2 multicast forwarding table. The command output shows which hosts under group member ports are using multicast services, helping you manage multicast services.

Precautions

If no forwarding entry is available for a member host, the command does not display information about this host.

Example

Display information about group member hosts.

```
<HUAWEI> display igmp-snooping host-tracking
-------------------------------------------------------------------------------------------------
VLAN                    (Source, Group)       Interface         Reporter         Mode
-------------------------------------------------------------------------------------------------
100                    (*, 225.0.0.2)       GE0/0/1          192.51.100.1      Include
100               (192.1.1.1,225.0.0.1)       GE0/0/1          10.10.5.2        Exclude
-------------------------------------------------------------------------------------------------
```

Table 8-116 Description of the **display igmp-snooping host-tracking** command output

Item	Description
VLAN	VLAN ID.
(Source, Group)	(S, G) entry, indicating that data is sent from multicast source S to group G. If Source is displayed as *, multicast data may be sent from any multicast source. If Source is displayed as an IP address, multicast data is sent from this IP address.
Interface	Group member interface.
Reporter	Host IP address.
Mode	Mode in which an interface filters multicast traffic specified by (S,G) entries. ● Include: The interface receives multicast traffic specified by (S,G) entries. ● Exclude: The interface does not receive multicast traffic specified by (S,G) entries.

8.9.7 display igmp-snooping qinq-port-info

Function

The **display igmp-snooping qinq-port-info** command displays multicast group membership on a QinQ or dot1q termination sub-interface.

Format

display igmp-snooping qinq-port-info interface *interface-type interface-number* [**group-address** *group-address*]

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays multicast group membership of a specified interface.	-

Parameter	Description	Value
group-address *group-address*	Displays group membership of a specified multicast group. If this parameter is not specified, the command displays group membership of all multicast groups on the specified interface.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.

Usage Guidelines

Usage Scenario

This command is used to check group membership on a QinQ or dot1q termination sub-interface.

Example

Display group membership of all multicast groups on QinQ termination sub-interface GE0/0/18.1.

```
<HUAWEI> display igmp-snooping qinq-port-info interface GigabitEthernet 0/0/18.1
Interface GigabitEthernet0/0/18.1, 1 Group(s)
 (Source,Group)                    PE-VID/CE-VID LiveTime          Flag
 -------------------------------------------------------------------------------
 (*,225.0.0.1)                    1001/0        --                S-
 (*,225.0.0.2)                    1001/0        00:00:23          -D-
```

Table 8-117 Description of the **display igmp-snooping qinq-port-info** command output

Item	Description
Interface GigabitEthernet0/0/18.1, 1 Group(s)	Group membership on a termination sub-interface.
(Source, Group)	(S, G) entry. If S is displayed as *, multicast data may be sent from any multicast source. If S is displayed as an IP address, multicast data is sent from this IP address.

Item	Description
PE-VID/CE-VID	Outer VLAN ID and inner VLAN ID.
LiveTime	Time elapsed since the group is discovered, in any of the following formats: ● If the time is shorter than or equal to 24 hours, the format is hh:mm:ss. ● If the time is longer than 24 hours but shorter than or equal to one week, the format is day:hour. ● If the time is longer than one week, the format is week:day. -- indicates that the group Up time is not obtained.
Flag	Type of a member port, which can be: ● S: static member port, which is configured using the **igmp static-group** command ● D: dynamic member port learned through IGMP snooping ● M: member port established through SSM mapping

8.9.8 display igmp-snooping querier

Function

The **display igmp-snooping querier** command displays whether the IGMP snooping querier function is enabled in a VLAN.

Format

display igmp-snooping querier vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays whether the IGMP snooping querier function is enabled in a specified VLAN. If *vlan-id* is not specified, the system displays status of the IGMP snooping querier function in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can configure an IGMP snooping querier on the switch to send IGMP Query messages in place of the upstream Layer 3 device in the following situations:

- The Layer 3 device cannot send IGMP messages for some reasons, for example, IGMP is not enabled on the Layer 3 device.
- The Layer 3 device uses static multicast forwarding entries and does not need to learn multicast forwarding entries.

You can use the **display igmp-snooping querier** command to check in which VLANs the IGMP snooping querier function is enabled.

Precautions

The querier function is disabled in a VLAN by default after IGMP snooping is enabled in the VLAN. To enable the querier function, run the **igmp-snooping querier enable** command.

Example

Display the status of the IGMP snooping querier function in all VLANs.

```
<HUAWEI> display igmp-snooping querier vlan
 VLAN              Querier-state
------------------------------------------------
 10                Enable
 20                Disable
 30                Disable
------------------------------------------------
 total entry 3
```

Table 8-118 Description of the **display igmp-snooping querier vlan** command output

Item	Description
VLAN	VLAN ID.
Querier-state	Querier status in a VLAN. ● Disable: The IGMP snooping querier function is disabled in the VLAN. ● Enable: The IGMP snooping querier function is enabled in the VLAN.
total entry 3	Number of VLANs in which the querier status is displayed.

8.9.9 display igmp-snooping router-port

Function

The **display igmp-snooping router-port** command displays information about the router ports in a specified VLAN, including static and dynamic router ports.

Format

display igmp-snooping router-port vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays information about the router ports in a specified VLAN. If *vlan-id* is not specified, the command displays router ports in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A router port connects the switch to an upstream Layer 3 multicast device. The router port can be statically configured or dynamically generated after the interface receives an IGMP Query message or a PIM Hello message.

You can run the **display igmp-snooping router-port** command to view the type, name, lifetime, and aging time of a router port.

Precautions

This command can display information about router ports in a VLAN only when IGMP snooping has been enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command, and at least one interface in the VLAN is in Up state.

Example

Display information about router ports in VLAN 2.

```
<HUAWEI> display igmp-snooping router-port vlan 2
Port Name              UpTime      Expires     Flags
```

```
-------------------------------------------------------------
VLAN 2, 2 router-port(s)
GE0/0/1                03:28:16    00:01:20    DYNAMIC
GE0/0/2                2d:10h      --          STATIC
```

Table 8-119 Description of the display igmp-snooping router-port command output

Item	Description
Port Name	Type and number of a router port.
UpTime	Time that elapsed since the interface became a router port.
Expires	Aging time of the router port. ● The aging time is displayed for a dynamic router port. This parameter is configured using the **igmp-snooping router-aging-time** command. ● For a static router port, "--" is displayed, indicating that the static router does not age.
Flags	Type of the router port, which can be: ● STATIC: static router port configured using the **igmp-snooping static-router-port** command. ● DYNAMIC: dynamic router port

8.9.10 display igmp-snooping statistics

Function

The **display igmp-snooping statistics** command displays IGMP snooping statistics.

Format

display igmp-snooping statistics vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays IGMP snooping statistics in a specified VLAN. - If *vlan-id* is not specified, the system displays IGMP snooping statistics in all VLANs. - If *vlan-id* is specified, the system displays statistics about IGMP messages in the specified VLAN, but does not display the counts of IGMP snooping events that occur in the VLAN.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing IGMP snooping configuration, you can use the **display igmp-snooping statistics** command to view IGMP snooping statistics, including the number of IGMP messages sent, number of IGMP messages received, number of PIM Hello messages received in each VLAN, and number of Layer 2 events that have occurred in all VLANs. Layer 2 events include changes in interface status, changes in VLAN status, changes in VLAN member interfaces (interfaces join or leave VLANs), and MSTP events. When a multicast fault occurs, the IGMP snooping statistics help you identify the cause of the fault.

Precautions

This command displays IGMP snooping statistics only when IGMP snooping has been enabled globally using the **igmp-snooping enable (VLAN view)** command.

Example

Display IGMP snooping statistics in all VLANs.

```
<HUAWEI> display igmp-snooping statistics vlan
 IGMP Snooping Events Counter
```

```
    Recv VLAN Up Event Times      3
    Recv VLAN Down Event Times    0
    Recv VLAN Del Event Times     0
    Recv Port Up Event Times      2
    Recv Port Down Event Times    0
    Recv Port Del Event Times     0
    Recv Port Inc Event Times     0
    Recv Port Exc Event Times     0
    Recv MSTP Block Event Times   0
    Recv MSTP Forward Event Times 0
    Recv LINK Change Event Times  0
 IGMP Snooping Packets Counter
  Statistics for VLAN 10
    Recv V1 Report          0
    Recv V2 Report          0
    Recv V3 Report          0
    Recv V1 Query           0
    Recv V2 Query           0
    Recv V3 Query           0
    Recv General Query      0
    Recv Leave              0
    Recv Pim Hello          0
    Send Query(S=0)         0
    Send Query(S!=0)        0
    Suppress Report         0
    Suppress Leave          0
    Proxy Send General Query              0
    Proxy Send Group-Specific Query       0
    Proxy Send Group-Source-Specific Query 0
```

Display IGMP snooping statistics in VLAN 10.

```
<HUAWEI> display igmp-snooping statistics vlan 10
 IGMP Snooping Packets Counter
  Statistics for VLAN 10
    Recv V1 Report  16
    Recv V2 Report  8768
    Recv V3 Report  0
    Recv V1 Query   0
    Recv V2 Query   2243
    Recv V3 Query   0
    Recv Leave      215
    Recv Pim Hello  0
    Send Query(S=0) 0
    Send Query(S!=0)529
    Suppress Report         0
    Suppress Leave          0
    Proxy Send General Query              0
    Proxy Send Group-Specific Query       0
    Proxy Send Group-Source-Specific Query 0
```

Table 8-120 Description of the display igmp-snooping statistics command output

Item	Description
IGMP Snooping Events Counter	Statistics on IGMP snooping events, including changes in interface status, changes in VLAN status, interfaces joining or leaving VLANs, and MSTP events.
Recv VLAN Up Event Times	Number of VLAN Up events.
Recv VLAN Down Event Times	Number of VLAN Down events.
Recv VLAN Del Event Times	Number of VLAN deletion events.

Item	Description
Recv Port Up Event Times	Number of interface Up events.
Recv Port Down Event Times	Number of interface Down events.
Recv Port Del Event Times	Number of interface deletion events.
Recv Port Inc Event Times	Number of times interfaces join VLANs.
Recv Port Exc Event Times	Number of times interfaces leave VLANs.
Recv MSTP Block Event Times	Number of times static groups fail to be created on interfaces that are blocked by MSTP and cannot forward multicast packets.
Recv MSTP Forward Event Times	Number of times static groups are successfully created on interfaces that are in MSTP forwarding state and can forward multicast packets normally.
Recv LINK Change Event Times	Number of link status change events.
IGMP Snooping Packets Counter	Statistics on IGMP Snooping packets.
Statistics for VLAN 10	Packet statistics in VLAN 10.
Recv V1 Report	Number of IGMPv1 Report messages received.
Recv V2 Report	Number of IGMPv2 Report messages received.
Recv V3 Report	Number of IGMPv3 Report messages received.
Recv V1 Query	Number of IGMPv1 Query messages received.
Recv V2 Query	Number of IGMPv2 Query messages received.
Recv V3 Query	Number of IGMPv3 Query messages received.
Recv General Query	Interval for sending IGMP General Query messages.
Recv Leave	Number of IGMP Leave messages received.
Recv Pim Hello	Number of PIM Hello messages received.
Send Query(S=0)	Number of IGMP Query messages sent with the source address 0.0.0.0.
Send Query(S!=0)	Number of IGMP Query messages sent with source addresses other than 0.0.0.0.
Suppress Report	Number of duplicate IGMP Report messages dropped.
Suppress Leave	Number of duplicate IGMP Leave messages dropped.

Item	Description
Proxy Send General Query	Number of General Query messages sent by the IGMP snooping proxy.
Proxy Send Group-Specific Query	Number of Group-Specific Query messages sent by the IGMP snooping proxy.
Proxy Send Group-Source-Specific Query	Number of Group-Source-Specific Query messages sent by the IGMP snooping proxy.

8.9.11 display l2-multicast forwarding-mode

Function

The **display l2-multicast forwarding-mode** command displays the Layer 2 multicast forwarding mode in VLANs.

Format

display l2-multicast forwarding-mode vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays the Layer 2 multicast forwarding mode in a specified VLAN. If *vlan-id* is not specified, the system displays the Layer 2 multicast forwarding mode in all VLANs.	The value is an integer ranging from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After Layer 2 multicast is enabled on the switch, the switch maintains a Layer 2 multicast forwarding table. When receiving a multicast packet, the switch searches the Layer 2 multicast forwarding table for the outbound interface based on the multicast address of the packet. The switch determines the outbound interface based on the IP multicast address or IP multicast MAC address, depending on the configured Layer 2 multicast forwarding mode.

To check which Layer 2 multicast forwarding mode is used, run the **display l2-multicast forwarding-mode** command.

Precautions

You can change the forwarding mode using the **l2-multicast forwarding-mode** command.

Example

Display the Layer 2 multicast forwarding mode in all VLANs.

```
<HUAWEI> display l2-multicast forwarding-mode vlan
VLAN                 Forwarding-mode        Router-discard
-------------------------------------------------------------
1                    IP                     disable
2                    IP                     disable
3                    MAC                       disable
```

Table 8-121 Description of the **display l2-multicast forwarding-mode vlan** command output

Item	Description
VLAN	VLAN ID.
Forwarding-mode	Forwarding mode used in a VLAN, which can be: ● MAC address-based forwarding ● IP address-based forwarding This parameter can be configured using the **l2-multicast forwarding-mode** { **ip** | **mac** } command.
Router-discard	Whether the switch is configured not to forward multicast data packets to router ports in a VLAN. ● enable: The switch does not forward multicast data packets to router ports in the VLAN. ● disable: The switch forwards multicast data packets to router ports in the VLAN. This function is configured using the **l2-multicast router-port-discard** command.

8.9.12 display l2-multicast forwarding-table vlan

Function

The **display l2-multicast forwarding-table vlan** command displays the Layer 2 multicast forwarding table in VLANs.

Format

display l2-multicast forwarding-table vlan [*vlan-id* [[**source-address** *source-address*] **group-address** { *group-address* | **router-group** }]]

Parameters

Parameter	Description	Value
vlan-id	Displays Layer 2 multicast forwarding entries in a specified VLAN. If *vlan-id* is not specified, the command displays Layer 2 multicast forwarding entries in all VLANs.	The value is an integer that ranges from 1 to 4094.
source-address *source-address*	Displays the forwarding entries of a specified Layer 2 multicast source.	The value is in dotted decimal notation.
group-address *group-address*	Displays multicast forwarding entries of a specified Layer 2 multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.
router-group	Displays Layer 2 multicast forwarding entries of all router ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing IGMP snooping configuration, you can use the **display l2-multicast forwarding-table** command to view the Layer 2 multicast forwarding table. This command displays statically configured and dynamically learned multicast forwarding entries.

Each entry contains the multicast source, multicast group, list of outbound interfaces, and VLAN ID of multicast data packets. When the IGMP snooping version is set to v3 in a VLAN or when the IGMP snooping version is set to v2 or v1 but SSM mapping is configured, the **display l2-multicast forwarding-table** command displays (S, G) entries.

Precautions

This command displays Layer multicast forwarding entries in a VLAN only when the VLAN is in Up state (At least one interface in the VLAN is in Up state. If interfaces in the VLAN are dynamic group member ports, the interfaces must have received IGMP Report messages and have not been aged out.)

Example

Display multicast forwarding entries in VLAN 10.

```
<HUAWEI> display l2-multicast forwarding-table vlan 10
VLAN ID : 10, Forwarding Mode : IP
Total Group(s): 2
-------------------------------------------------------------------------------
             (Source, Group)     Interface                Out-Vlan
-------------------------------------------------------------------------------
                 Router-port    GigabitEthernet0/0/1           10
               (*, 225.1.1.6)    GigabitEthernet0/0/1           10
                                GigabitEthernet0/0/2           10
            (*, 235.80.68.83)    GigabitEthernet0/0/1           10
                                GigabitEthernet0/0/2           10
-------------------------------------------------------------------------------
```

Table 8-122 Description of the **display l2-multicast forwarding-table** command output

Item	Description
VLAN ID	VLAN ID of the forwarding entries.
Forwarding Mode	Multicast forwarding mode in the VLAN, which can be: ● IP ● MAC The multicast forwarding mode is configured using the **l2-multicast forwarding-mode** command.
(Source, Group)	(S, G) entry, specifying the multicast source and multicast group. The Router-port field indicates a router port.
Interface	Outbound interface. The value **Stream** indicates an unknown flow entry.
Out-Vlan	VLAN ID of packets.
Total Group(s)	Total number of multicast forwarding entries.

8.9.13 display l2-multicast forwarding-table statistics

Function

The **display l2-multicast forwarding-table statistics** command displays statistics about Layer 2 multicast forwarding entries.

Format

display l2-multicast forwarding-table statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After configuring IGMP snooping, you can use this command to view statistics about Layer 2 multicast forwarding entries.

Example

Display statistics about Layer 2 multicast forwarding entries. (The actual output information may differ from the following information.)

```
<HUAWEI> display l2-multicast forwarding-table statistics
---------------------------------------------------------------------
0 Stream entries are calculated in statistics
1 IP entries are calculated in statistics
0 MAC entries are calculated in statistics
1 VLAN entries are calculated in statistics
0 VPLS entries are calculated in statistics
0 VXLAN entries are calculated in statistics
---------------------------------------------------------------------
```

Table 8-123 Description of the **display l2-multicast forwarding-table statistics** command output

Item	Description
Stream entries are calculated in statistics	Number of unknown stream entries in a VLAN.
IP entries are calculated in statistics	Number of entries for IP address-based forwarding in a VLAN.
MAC entries are calculated in statistics	Number of entries for MAC address-based forwarding in a VLAN.
VLAN entries are calculated in statistics	Number of entries for IP address-based and MAC address-based forwarding in a VLAN.
VPLS entries are calculated in statistics	Number of entries for MAC address-based forwarding on a VPLS network.

Item	Description
VXLAN entries are calculated in statistics	Number of entries for MAC address-based forwarding on a VXLAN network.

8.9.14 igmp-snooping enable (system view)

Function

The **igmp-snooping enable** command enables IGMP snooping globally or in specified VLANs.

The **undo igmp-snooping enable** command disables IGMP snooping globally or in specified VLANs.

By default, IGMP snooping is disabled globally and in a VLAN.

Format

igmp-snooping enable [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo igmp-snooping enable [**vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }]

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Enables IGMP snooping in a VLAN or in multiple VLANs. *vlan-id1* and *vlan-id2* identify a range of VLAN IDs. If VLAN IDs are specified, IGMP snooping is enabled in the specified VLANs. If no VLAN ID is specified, IGMP snooping is enabled globally.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094.
all	Disables IGMP snooping in all VLANs.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGMP snooping runs on a Layer 2 device between a Layer 3 multicast device and hosts. By listening on the multicast protocol packets exchanged between the Layer 3 device and hosts, IGMP snooping maintains a multicast forwarding table to control Layer 2 multicast forwarding.

Before configuring IGMP snooping parameters, run the **igmp-snooping enable** command in the system view to enable IGMP snooping globally. Other IGMP snooping configuration commands can be used only after IGMP snooping is enabled globally.

You can enable IGMP snooping in multiple VLANs by using the **igmp-snooping enable** command in the system view.

Prerequisites

To enable IGMP snooping in multiple VLANs, ensure that IGMP snooping has been enabled globally.

Precautions

If you run the **igmp-snooping enable vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command multiple times, all the configurations take effect.

When you run the **undo igmp-snooping enable** command in the system view, the system displays a message, asking you whether to disable IGMP snooping globally. When you disable IGMP snooping globally, all the IGMP snooping configurations are deleted. When you run the **igmp-snooping enable** command to enable IGMP snooping globally again, the switch uses the default IGMP snooping configuration.

Multicast functions (Layer 2 and Layer 3 multicast) and the flow control function (configured using the **flow-control** command) are mutually exclusive on the following models: S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-S, S5735-S-I

The **igmp snooping enable** command in a VLAN and the **igmp on-demand** configuration of the VLANIF interface are mutually exclusive.

After global IGMP snooping is enabled on a switch, the switch sends all the IGMP messages received from a VLAN to the CPU for processing. If the multicast service is not configured in a VLAN and you want the switch to directly forward the IGMP messages of this VLAN without sending them to the CPU, run the **protocol-transparent** command in the VLAN view to enable transparent transmission of protocol packets.

Example

Enable IGMP snooping globally.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
```

Enable IGMP snooping in multiple VLANs.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan batch 2 to 10
[HUAWEI] igmp-snooping enable vlan 2 to 10
```

8.9.15 igmp-snooping enable (VLAN view)

Function

The **igmp-snooping enable** command enables IGMP snooping in a VLAN.

The **undo igmp-snooping enable** command disables IGMP snooping in a VLAN.

By default, IGMP snooping is disabled in a VLAN.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, IGMP snooping is not enabled in a VLAN after being enabled in the system view. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable** command in the VLAN view.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Configuration Impact

After IGMP snooping is enabled in a VLAN, this function takes effect only on interfaces in this VLAN.

After IGMP snooping is enabled globally, it is recommended that you enable IGMP snooping in all other VLANs. This prevents IGMP messages in this VLAN from being broadcast to access switches in the other VLANs.

Precautions

The **igmp snooping enable** command in a VLAN and the **igmp on-demand** configuration of the VLANIF interface are mutually exclusive.

If Layer 2 and Layer 3 multicast are both configured in a VLAN, you must delete the Layer 2 multicast configuration before you can modify or delete the Layer 3 multicast configuration. This means that you must disable IGMP snooping in the VLAN first, then modify or disable the IGMP and PIM (IPv4) configuration in the VLANIF interface view, and finally enable IGMP snooping in the VLAN. Otherwise, the Layer 3 multicast configuration cannot be modified or deleted on the corresponding VLANIF interface.

Example

Enable IGMP snooping in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
```

8.9.16 igmp-snooping fast-switch enable

Function

The **igmp-snooping fast-switch enable** command enables fast multicast forwarding path switching upon STP topology changes.

The **undo igmp-snooping fast-switch enable** command disables fast multicast forwarding path switching upon STP topology changes.

By default, fast multicast forwarding path switching upon STP topology changes is disabled.

Format

igmp-snooping fast-switch enable

undo igmp-snooping fast-switch enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the Layer 2 network topology changes, multicast forwarding paths may change. You can configure the switch to send Query messages upon topology changes using the **igmp-snooping send-query enable** command. In this way, multicast data flows can be switched to new forwarding paths quickly after the Layer 2 network topology changes. However, the downstream device may not receive the Query message immediately after convergence of the Layer 2 network, because the Query message is sent after a certain interval (60s by default). As a result, multicast traffic cannot be quickly switched to the new forwarding paths.

If the Layer 2 network is running the Spanning Tree Protocol (STP), you can enable fast multicast forwarding path switching upon STP topology changes. When the STP topology changes, this function quickly changes the ports in Forwarding state into router ports to direct multicast data flows to the new forwarding paths.

Prerequisite

Global IGMP snooping has been enabled using the **igmp-snooping enable (system view)** command.

Precautions

- This function takes effect only when STP is used as the loop prevention protocol on a Layer 2 network and the STP operation mode is MSTP, RSTP, or STP.
- With this function configured, the switch sets all ports in Forwarding state as router ports when the STP topology changes. In this case, multicast data flows are forwarded to all the router ports before the router ports are aged. This will cause increase in multicast traffic on the network.

Example

Enable fast multicast forwarding path switching upon STP topology changes.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping fast-switch enable
```

8.9.17 igmp-snooping fast-send report enable

Function

The **igmp-snooping fast-send report enable** command configures a device to send IGMP Report messages to the upstream device through the active interface in a Smart Link group when the other Smart Link member interface experiences a change of state.

The **undo igmp-snooping fast-send report enable** command disables a device from proactively sending IGMP Report messages to the upstream device when a member interface in a Smart Link group experiences a change of state.

By default, a device does not proactively send IGMP Report messages to the upstream device through the active interface in a Smart Link group when the other Smart Link member interface experiences a change of state.

Format

igmp-snooping fast-send report enable

undo igmp-snooping fast-send report enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the status of a Smart Link member interface on a device changes, the active interface in the Smart Link group can forward IGMP Report messages to the upstream device only after receiving the next IGMP General Query message. In this way, multicast data can be switched to the new forwarding path. To enable a device to proactively send IGMP Report messages to the upstream device through the active interface in a Smart Link group when the status of the other Smart Link member interface changes, run the **igmp-snooping fast-send report enable** command. In this way, multicast data can be quickly switched to the new forwarding path.

Prerequisites

IGMP snooping has been enabled globally by running the **igmp-snooping enable** command in the system view.

Precautions

Use this command only on networks configured with Smart Link.

Example

Configure a device to send IGMP Report messages when a member interface of a Smart Link group experiences a change of state.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping fast-send report enable
```

8.9.18 igmp-snooping fast-send robust-count interval

Function

The **igmp-snooping fast-send robust-count interval** command configures the robustness variable and interval for sending Report messages through the active interface in a Smart Link group when the other Smart Link member interface experiences a change of state.

The **undo igmp-snooping fast-send robust-count interval** command restores the default robustness variable and interval for sending Report messages through the active interface in a Smart Link group when the other Smart Link member interface experiences a change of state.

By default, the robustness variable is 3 and the interval is 10s.

Format

igmp-snooping fast-send robust-count *robust-count* **interval** *interval*

undo igmp-snooping fast-send robust-count *robust-count* **interval** *interval*

Parameters

Parameter	Description	Value
robust-count *robust-count*	Specifies the robustness variable for sending Report messages.	The value is an integer in the range from 1 to 10.
interval *interval*	Specifies the interval for sending Report messages.	The value is an integer ranging from 1 to 60, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable a device to proactively send IGMP Report messages to the upstream device through the active interface in a Smart Link group when the status of the other Smart Link member interface changes, run the **igmp-snooping fast-send report enable** command. In this way, multicast data can be quickly switched to the new forwarding path. Then, you can run the **igmp-snooping fast-send robust-count interval** command to adjust IGMP parameters to optimize multicast services.

- The robustness variable for sending Report messages refers to the number of times Report messages are sent through the active interface of a Smart Link group when the status of the other Smart Link member interface changes. The robustness variable helps prevent packet loss.
- The interval parameter configures a device to periodically send IGMP Report messages to the upstream device through the active interface of the Smart Link group when the status of the other Smart Link member interface changes. On a network with a small number of multicast receivers, a smaller interval enables multicast data to be switched to the new forwarding path more rapidly.

Maximum total time for sending Report messages = Robustness variable for sending Report messages x Interval for sending Report messages

Prerequisites

IGMP snooping has been enabled globally by running the **igmp-snooping enable** command in the system view.

Precautions

Use this command only after the **igmp-snooping fast-send report enable** command is run.

When receiving a Query message, a device stops sending IGMP Report messages to the upstream device through the active interface of a Smart Link group.

When a device sends IGMP Report messages, the transmitting interval is the maximum response time. It is recommended that you set the interval to a value greater than the suppression time, thereby preventing messages from being suppressed.

Example

Set the robustness variable and interval for sending Report messages through the active interface in a Smart Link group to 5 and 20s, respectively.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping fast-send robust-count 5 interval 20
```

8.9.19 igmp-snooping group-limit

Function

The **igmp-snooping group-limit** command sets the maximum number of multicast entries that an interface can learn.

The **undo igmp-snooping group-limit** command cancels the limit on the number of multicast entries that an interface can learn.

By default, the number of multicast entries that an interface can learn is not limited.

Format

igmp-snooping group-limit *group-limit* **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo igmp-snooping group-limit *group-limit* **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo igmp-snooping group-limit vlan { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Parameters

Parameter	Description	Value
group-limit	Specifies the maximum number of multicast groups that an interface can learn.	The value is an integer and the value range depends on the product model: - SS1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5731-S, S5731S-S, and S5720I-SI: 1 to 1024 - S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S, S5735-S-I, and S5735S-S: 1 to 1500 - S5735S-H, S5736-S, and S6720S-S: 1 to 1536 - S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S: 1 to 4096
vlan *vlan-id1* [**to** *vlan-id2*]	Specifies the ID of a VLAN. *vlan-id1* and *vlan-id2* identify a range of VLAN IDs.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094.
all	Cancels the limit on the number of multicast groups that interfaces in all VLANs can learn.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can use the **igmp-snooping group-limit** command to limit the number of multicast programs that a user can request. This configuration limits the multicast data traffic volume on the interface.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Configuration Impact

During the configuration, if the number of multicast entries on the interface already exceeds the configured threshold, the number of multicast entries on the interface does not change and the interface cannot learn new multicast entries.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.

Example

Configure GE0/0/1 to learn a maximum of 10 IGMP snooping entries in VLAN 10, and IGMP snooping is enabled globally and in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-limit 10 vlan 10
```

Configure GE0/0/1 to learn a maximum of 50 IGMP snooping entries in VLANs 20 to 30, and IGMP snooping is enabled globally and in these VLANs.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-limit 50 vlan 20 to 30
```

8.9.20 igmp-snooping group-policy (interface view)

Function

The **igmp-snooping group-policy** command configures a multicast group policy on an interface.

The **undo igmp-snooping group-policy** command deletes a multicast group policy from an interface.

By default, no multicast group policy is available on an interface, and hosts connected to the interface can join any multicast group.

Format

igmp-snooping group-policy *acl-number* [**version** *version-number*] **vlan** *vlan-id1* [**to** *vlan-id2*]

undo igmp-snooping group-policy *acl-number* **vlan** *vlan-id1* [**to** *vlan-id2*]

undo igmp-snooping group-policy *acl-number* **version** *version-number* **vlan** *vlan-id1* [**to** *vlan-id2*]

undo igmp-snooping group-policy vlan { *vlan-id1* [**to** *vlan-id2*] | **all** }

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the ACL that limits the multicast groups that hosts in a VLAN can join.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
version *version-number*	Applies the multicast group policy only to the IGMP messages of the specified version. If this parameter is not specified, the multicast group policy applies to all IGMP messages.	The value is an integer ranging from 1 to 3. ● 1: IGMPv1 ● 2: IGMPv2 ● 3: IGMPv3
vlan *vlan-id1* [**to** *vlan-id2*]	Applies the multicast group policy to the specified VLANs on the interface.	*vlan-id1* and *vlan-id2* are integers that range 1 from 4094.
all	Deletes multicast groups policies in all VLANs from the interface.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group policy controls the multicast programs that users can order on a device with IGMP snooping enabled. When a user orders a multicast program, the user host sends a Report message to the device, requesting to join the multicast group. The device checks whether the multicast group matches the ACL in the multicast group policy applied to the interface. If so, the device allows the user to join the multicast group. If not, the device drops the message and prohibits the user from joining the multicast group.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect when IGMP snooping is enabled in the specified VLANs using the **igmp-snooping enable (VLAN view)** command.
- Before running the **igmp-snooping group-policy (interface view)** command, run the **acl** command to configure the ACL that you want to apply to the group policy to limit the range of multicast groups that hosts connected to the interface can join.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that an interface can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that an interface can join.

  After the **igmp-snooping group-policy (interface view)** command is executed on an interface:
  - The interface filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The interface discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.
- A multicast group policy can also be configured in the VLAN view to control the multicast groups that users in the VLAN can join. A multicast group policy configured in the interface view controls the multicast groups that users in one or more VLANs on the interface can join. If you configure multicast group policies for the same VLAN in the interface view and VLAN view, the system first uses the policy configured in the interface view and then the policy configured in the VLAN view to determine the groups that user hosts can join.

Example

Prevent users in VLANs 20 to 30 from joining multicast group 225.1.1.123 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan batch 20 to 30
[HUAWEI] igmp-snooping enable vlan 20 to 30
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
```

```
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 20 to 30
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-policy 2000 vlan 20 to 30
```

Allow hosts belonging to VLANs 20 to 30 on GE0/0/1 to join group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan batch 20 to 30
[HUAWEI] igmp-snooping enable vlan 20 to 30
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 20 to 30
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-policy 2000 vlan 20 to 30
```

8.9.21 igmp-snooping group-policy (VLAN view)

Function

The **igmp-snooping group-policy** command configures a multicast group policy in a VLAN.

The **undo igmp-snooping group-policy** command deletes the multicast group policy from a VLAN.

By default, no multicast group policy is available in a VLAN, and hosts in the VLAN can join any multicast group.

Format

igmp-snooping group-policy *acl-number* [**version** *version-number*]

undo igmp-snooping group-policy

Parameters

Parameter	Description	Value
acl-number	Specifies the number of an ACL used to restrict the range of groups users can join.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
version *version-number*	Applies the multicast group policy only to the IGMP messages of the specified version. If this parameter is not specified, the multicast group policy applies to all IGMP messages.	The value is an integer that ranges from 1 to 3. ● 1: IGMPv1 ● 2: IGMPv2 ● 3: IGMPv3

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group policy controls the multicast programs that users can order on a switch with IGMP snooping enabled. When a user orders a multicast program, the user host sends a Report message, requesting to join the multicast group. After the switch receives the message, it checks whether the multicast group matches the multicast group policy applied to the VLAN. If the messages match the ACL, the switch allows user hosts in the VLAN to join the group and accepts the Report messages. If the messages do not match the ACL, the switch prevents the user hosts in the VLAN from joining the group.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect when IGMP snooping is enabled in the specified VLANs using the **igmp-snooping enable (VLAN view)** command.
- Before running the **igmp-snooping group-policy (VLAN view)** command, run the **acl** command to configure the ACL that you want to apply to the group policy to limit the range of multicast groups that hosts connected to the VLAN can join.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that a VLAN can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that a VLAN can join.

  After the **igmp-snooping group-policy (VLAN view)** command is executed on an interface:
  - The VLAN filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The VLAN discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.
- A multicast group policy can also be configured in the interface view to control the multicast groups that users in one or more VLANs on the interface

can join. A multicast group policy configured in the VLAN view controls the multicast groups that users in the VLAN can join. If you configure multicast group policies for the same VLAN in the interface view and VLAN view, the system first uses the policy configured in the interface view and then the policy configured in the VLAN view to determine the groups that user hosts can join.

Example

Prevent hosts in VLAN 2 from joining group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping group-policy 2000
```

Allow hosts in VLAN 2 to join group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping group-policy 2000
```

8.9.22 igmp-snooping lastmember-queryinterval

Function

The **igmp-snooping lastmember-queryinterval** command sets the last member query interval in a VLAN, that is, the interval at which Group-Specific Query messages are sent in the VLAN.

The **undo igmp-snooping lastmember-queryinterval** command restores the default last member query interval in a VLAN.

By default, Group-Specific Query messages are sent in a VLAN at intervals of 1 second.

Format

igmp-snooping lastmember-queryinterval *lastmember-queryinterval*

undo igmp-snooping lastmember-queryinterval

Parameters

Parameter	Description	Value
lastmember-queryinterval	Specifies the interval at which IGMP Group-Specific Query messages are sent.	The value is an integer that ranges from 1 to 5, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the last member query interval, you can:

- Configure the switch to send IGMP Group-Specific Query messages at intervals when the querier function is enabled.
- Change the aging time of multicast group member ports.

  When the switch receives an IGMP Leave message from a host, the switch starts the aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = Last member query interval x Last member query count. The **igmp-snooping lastmember-queryinterval** command sets the last member query interval. The last member query count is set by the **igmp-snooping robust-count** command.

  If the switch (querier) receives Report messages from other hosts within the aging time, it continues to maintain memberships of the multicast group. If the switch does not receive any Report messages within the aging time, it stops maintaining memberships of the multicast group.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The switch sets the maximum response time field in the Group-Specific Query message to the configured last member query interval. Therefore, the maximum response time for Group-Specific Query messages is the same as the interval at which Group-Specific Query messages are sent.

The configuration takes effect only when all the following conditions are met:

- IGMP snooping is enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command.
- The IGMP message version is set to v2 or v3 messages in the VLAN. (Hosts running IGMPv1 do not send Leave messages when they leave a multicast group.)

Example

Set the last member query interval in VLAN 3 to 4 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping lastmember-queryinterval 4
```

8.9.23 igmp-snooping learning

Function

The **igmp-snooping learning** command enables learning of multicast group memberships on an interface.

The **undo igmp-snooping learning** command disables learning of multicast group memberships on an interface.

By default, learning of multicast group memberships is enabled on an interface.

Format

igmp-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

undo igmp-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] }	Enables learning of multicast group memberships in specified VLANs. The interface must have been added to the specified VLAN. *vlan-id1* [**to** *vlan-id2*] specifies the range of VLAN IDs. ● *vlan-id1*: specifies the first VLAN ID. ● **to** *vlan-id2*: specifies the last VLAN ID. If **to** *vlan-id2* is not specified, learning of multicast group memberships is enabled only in the VLAN specified by *vlan-id1*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. The value of *vlan-id2* must be greater than the value of *vlan-id1*. The *vlan-id1* and *vlan-id2* parameters identify a range of VLANs.
all	Enables learning of multicast group memberships in all VLANs that an interface has joined.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A group member port is a user-side interface that connects to multicast group members. Group memberships can be learned dynamically or configured statically. After IGMP snooping is enabled in a VLAN, all interfaces in the VLAN are enabled to learn forwarding entries from multicast packets. An interface is identified as a dynamic group member port when it receives an IGMP Report message.

If users connected to an interface need to receive data of a fixed multicast group, the interface can be statically bound to the multicast group. In this case, run the **undo igmp-snooping learning** command on the interface to disable learning of group memberships. This reduces the system resources used for protocol packet exchange.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The configuration takes effect only when all the following conditions are met:

- IGMP snooping is enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command.
- The interface belongs to the specified VLANs.

If you run the **undo igmp-snooping learning** command multiple times, all the configurations take effect.

Example

Disable learning of group memberships in VLAN 3 and VLAN 4 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] quit
[HUAWEI] vlan 4
[HUAWEI-vlan4] igmp-snooping enable
[HUAWEI-vlan4] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 3 to 4
[HUAWEI-GigabitEthernet0/0/1] undo igmp-snooping learning vlan 3 to 4
```

8.9.24 igmp-snooping limit-action

Function

The **igmp-snooping limit-action** command enables multicast entry overwriting on interfaces in a VLAN.

The **undo igmp-snooping limit-action** command disables multicast entry overwriting on interfaces in a VLAN.

By default, multicast entry overwriting is disabled on an interface. When the number of multicast entries on an interface reaches the limit, the switch does not process subsequent Report messages or replace the existing entries on the interface.

Format

igmp-snooping limit-action

undo igmp-snooping limit-action

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of multicast groups on an interface or the switch reaches the limit, users connected to the interface or switch cannot join new multicast groups. To allow users to join new multicast groups in this case, enable multicast entry overwriting on interfaces in a VLAN.

After the configuration is complete, the switch records information about multicast users. When a user requests to join a new multicast group but the number of multicast groups on the interface or switch has reached the limit, the switch checks all the programs that the user has ordered. If a program is watched only by this user, the switch replaces the entry of this program with the entry of the new program.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

To make the multicast entry overwriting configuration take effect, perform the following operations:

- Run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- Run the **igmp-snooping group-limit** command to set the maximum number of multicast entries that an interface can learn.

The multicast entry overwriting function has the following limitations:

- When an interface is statically bound to a multicast group, the Layer 2 multicast entry overwriting function becomes invalid on the interface.
- The new multicast entry cannot replace the old one when the old multicast group has multiple multicast users or is a static multicast group.
- A new (S, G) entry can replace only an old (S, G), and a new (*, G) entry can replace only an old (*, G) entry.

Example

Enable multicast entry overwriting on interfaces in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping limit-action
```

8.9.25 igmp-snooping max-response-time

Function

The **igmp-snooping max-response-time** command sets the maximum response time for IGMP General Query messages in a VLAN.

The **undo igmp-snooping max-response-time** command restores the default maximum response time for IGMP General Query messages in a VLAN.

By default, the maximum response time for IGMP General messages in a VLAN is 10 seconds.

Format

igmp-snooping max-response-time *max-response-time*

undo igmp-snooping max-response-time

Parameters

Parameter	Description	Value
max-response-time	Specifies the maximum response time for IGMP General Query messages.	The value is an integer that ranges from 1 to 25, in seconds. The default value is 10.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting IGMP snooping parameters helps improve the multicast forwarding performance. By setting the maximum response time for IGMP General Query messages, you can:

- Control the deadline for a host to send an IGMP Report message. When hosts are required to respond to IGMP General Query messages quickly, set a short maximum response time. To avoid congestion caused by a large number of IGMP messages sent by hosts, set a long maximum response time.
- Adjust the aging time of member ports. When the switch receives a Report message, it starts the aging timer for the member port. The aging time is calculated using the following formula: Aging time = General query count x General query interval + Maximum response time for General Query messages. The **igmp-snooping max-response-time** command sets the maximum response time. The General query count is set by the **igmp-snooping robust-count** command, and the general query interval is set by the **igmp-snooping query-interval** command.

The switch sets the maximum response time field in General Query messages to the value set by the **igmp-snooping max-response-time** command.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

Perform the following operations to improve multicast performance:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.

The maximum response time for General Query messages must be shorter than the interval at which General Query messages are sent. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the maximum response time for IGMP Query messages in VLAN 3 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping max-response-time 20
```

8.9.26 igmp-snooping prompt-leave

Function

The **igmp-snooping prompt-leave** command enables the fast leave function in a VLAN so that member ports in the VLAN can fast leave multicast groups.

The **undo igmp-snooping prompt-leave** command disables the fast leave function in a VLAN.

By default, the fast leave function is disabled in a VLAN.

Format

igmp-snooping prompt-leave [**group-policy** *acl-number*]

undo igmp-snooping prompt-leave

Parameters

Parameter	Description	Value
group-policy	Specifies a multicast group policy that allows member ports to fast leave some multicast groups. Before using this parameter, create an ACL and configure filter rules in the ACL.	-
acl-number	Specifies the number of an ACL that defines a range of multicast groups. A basic or advanced ACL can be used.	The value is an integer that ranges from 2000 to 3999.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The fast leave function enables the switch to delete the multicast forwarding entry of a multicast group from an interface immediately after the interface receives an IGMP Leave message for the group. This function saves bandwidth and system resources because the switch does not need to wait until the aging timer of the interface expires.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

When an interface has more than one receiver connected, enabling the fast leave function interrupts multicast traffic of the other receivers in the multicast group. It is recommended that you enable this function only on interfaces with one receiver.

The configuration takes effect only when all the following conditions are met:

- IGMP snooping is enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command.
- IGMPv2 or IGMPv3 messages can be processed in the VLAN.
- If you do not specify **group-policy** when configuring the fast leave function, this function takes effect for all groups. To specify a group policy in the command, create an ACL and configure rules for the ACL before running the command.

Example

Allow member ports in VLAN 2 to fast leave all groups.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping prompt-leave
```

Allow member ports in VLAN 3 to fast leave group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping prompt-leave group-policy 2000
```

Prevent member ports in VLAN 3 from fast leaving group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
```

```
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping prompt-leave group-policy 2000
```

8.9.27 igmp-snooping host-based prompt-leave

Function

The **igmp-snooping host-based prompt-leave** command enables host-based fast leave in a VLAN.

The **undo igmp-snooping host-based prompt-leave** command disables host-based fast leave in a VLAN.

By default, host-based fast leave is disabled.

Format

igmp-snooping host-based prompt-leave

undo igmp-snooping host-based prompt-leave

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The host-based fast leave function enables a switch to delete a host from the host list of a group immediately after receiving an IGMP Leave message from the host. If the deleted host is the last receiver host connected to the member port, the switch deletes the forwarding entry of the group from the port, without waiting the aging timer of the port to expire. This conserves bandwidth and system resources.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command, then IGMP snooping has been enabled in the VLAN using the **igmp-snooping enable (VLAN view)** command.

Precautions

If a group member port is connected to multiple receiver hosts, the forwarding entry of the multicast group will be deleted without waiting for aging of the port only when the last receiver host leaves the group.

The configuration takes effect only when the switch can process IGMPv2 or IGMPv3 packets in the VLAN.

Example

Enable host-based fast leave in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping host-based prompt-leave
```

8.9.28 igmp-snooping proxy

Function

The **igmp-snooping proxy** command enables IGMP snooping proxy in a VLAN.

The **undo igmp-snooping proxy** command disables IGMP snooping proxy in a VLAN.

By default, IGMP snooping proxy is disabled in a VLAN.

Format

igmp-snooping proxy

undo igmp-snooping proxy

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After IGMP snooping is enabled on a switch, the switch forwards Query messages from the upstream IGMP querier and Report/Leave messages from downstream hosts without changing the messages. When there are a large number of hosts on a network, redundant IGMP messages overload the upstream device. Enabling the IGMP snooping proxy function on the switch can solve this problem. This function allows the switch to send IGMP Query messages in place of the upstream Layer 3 device and send Report/Leave messages in place of downstream hosts, conserving link bandwidth between the Layer 3 device and switch. The switch sends IGMP Report/Leave messages to the upstream Layer 3 device only in the following situations:

- When the first member joins a multicast group or a host sends a Report message in response to an IGMP Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device can create or maintain the matching forwarding entry based on the Report message.
- When the last member of a multicast group leaves the group, the Layer 2 device forwards a Leave message to the upstream device. The upstream device then deletes the matching forwarding entry.

An upstream Layer 3 device does not send Query messages as a querier when IGMP is not enabled, for example, the Layer 3 device has only static multicast groups. In this case, the switch cannot create or maintain group memberships even though IGMP snooping is enabled. The IGMP snooping proxy function enables the switch to send Query messages to downstream hosts. For the hosts, the switch is a querier.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Configuration Impact

If IGMP is enabled on the upstream Layer 3 device, enabling the IGMP snooping proxy function on the switch may affect the querier election result, because the General Query messages sent by the switch have a smaller source IP address than the General Query messages sent by the Layer 3 device. To solve this problem, run the **igmp-snooping proxy-uplink-port** command to prevent the switch from sending Query messages to the uplink interface connected to the upstream device. Alternatively, run the **igmp-snooping send-query source-address** command to set a large source IP address for Query messages.

Precautions

- The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- IGMP snooping proxy cannot be enabled in a VLAN if the corresponding VLANIF interface has Layer 3 multicast function (such as IGMP and PIM) enabled.
- After enabling IGMP snooping proxy in a VLAN, do not enable IGMP snooping querier or IGMP message suppression in the VLAN because these functions conflict.
- If multicast VLAN replication is configured on the switch, the IGMP snooping proxy function cannot be enabled in user VLANs.

Example

Enable IGMP snooping proxy in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] igmp-snooping enable
[HUAWEI-vlan100] igmp-snooping proxy
```

8.9.29 igmp-snooping proxy-uplink-port

Function

The **igmp-snooping proxy-uplink-port** command configures an IGMP snooping proxy uplink interface. No IGMP Query message can be sent to this interface.

The **undo igmp-snooping proxy-uplink-port** command deletes an IGMP snooping proxy uplink interface.

By default, no IGMP snooping proxy uplink interface exists in a VLAN.

Format

igmp-snooping proxy-uplink-port vlan *vlan-id*

undo igmp-snooping proxy-uplink-port vlan *vlan-id*

Parameters

Parameter	Description	Value
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After IGMP snooping proxy or IGMP snooping querier is enabled in a VLAN, the switch periodically broadcasts IGMP Query messages to all interfaces in the VLAN, including router ports in the VLAN. This may result in IGMP querier reelection. To prevent IGMP querier reelection, run the **igmp-snooping proxy-uplink-port** command on the router port to disable the switch from sending IGMP Query messages to the router port.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

Only one IGMP snooping proxy uplink interface can be configured in a VLAN.

The **igmp-snooping proxy-uplink-port** command is used only on an uplink interface. Therefore, the specified VLAN cannot be a user VLAN mapping the multicast VLAN.

Example

Configure GE0/0/1 in VLAN 10 as an IGMP snooping proxy uplink interface.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping proxy-uplink-port vlan 10
```

8.9.30 igmp-snooping querier enable

Function

The **igmp-snooping querier enable** command enables the IGMP snooping querier function in a VLAN.

The **undo igmp-snooping querier enable** command disables the IGMP snooping querier function in a VLAN.

By default, the IGMP snooping querier function is disabled in a VLAN.

Format

igmp-snooping querier enable

undo igmp-snooping querier enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IGMP-capable network, a Layer 3 multicast device functions as a querier to send IGMP Query messages and maintain group memberships on the local network segment. If the Layer 3 multicast device does not run IGMP or it uses only static multicast forwarding entries, it cannot function as a querier. In this case, you can enable IGMP snooping querier on the downstream Layer 2 device so that it acts as a querier to send IGMP Query messages.

On a Layer 2 network that has no Layer 3 devices, multicast sources are connected to Layer 2 devices. IGMP snooping querier needs to be enabled on the Layer 2 devices so that they can maintain multicast group memberships.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

Perform the following operations as required on your network:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.
- Run the **igmp-snooping robust-count** command to set the number of times Query messages are sent.

Configuration Impact

The IGMP snooping querier does not participate in IGMP querier election. However, the IGMP snooping querier on an IGMP-capable multicast network may affect the election result, because the Query messages sent by the IGMP snooping querier may have a smaller source IP address than the Query messages sent by other devices. Therefore, the IGMP snooping querier function is not recommended on an IGMP-capable multicast network.

Precautions

- The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- The IGMP snooping querier function cannot be enabled in a VLAN if the corresponding Layer 3 VLANIF interface has Layer 3 multicast functions (such as IGMP and PIM) enabled.
- The IGMP snooping proxy and IGMP snooping querier functions cannot be enabled in the same VLAN.
- If multicast VLAN replication is configured on the switch, the IGMP snooping querier function cannot be enabled in user VLANs.

Example

Enable the querier function in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping querier enable
Warning: Please confirm that no other querier is configured on the network, otherwise this command may
cause querier re-election, continue? [Y/N]:y
```

8.9.31 igmp-snooping query-interval

Function

The **igmp-snooping query-interval** command sets the general query interval in a VLAN, that is, the interval at which IGMP General Query messages are sent in the VLAN.

The **undo igmp-snooping query-interval** command restores the default general query interval in a VLAN.

By default, the general query interval is 125 seconds.

Format

igmp-snooping query-interval *query-interval*

undo igmp-snooping query-interval

Parameters

Parameter	Description	Value
query-interval	Specifies the interval at which IGMP General Query messages are sent.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the general query interval, you can:

- Configure the switch to send IGMP General Query messages at intervals to maintain memberships of interfaces. When a shorter interval is configured, the switch is more sensitive to multicast membership changes, but more bandwidth and system resources are consumed.
- Change the aging time of multicast member ports.

  When receiving an IGMP Report message from a host, the switch starts the aging timer for the multicast member port. The aging time is calculated using the following formula: Aging time = IGMP robustness variable x General query interval + Maximum response time for General Query messages. The **igmp-snooping query-interval** command sets the general query interval. The general query count is set by the **igmp-snooping robust-count** command, and the maximum response time for General Query messages is set by the **igmp-snooping max-response-time** command.

The general query interval affects the aging time of group member ports. A shorter general query interval results in a shorter aging time of group member ports and therefore a faster update speed of Layer 2 multicast entries. However, when there are many downstream users connected to a device, a short general query interval can cause flapping of multicast entries, leading to a high CPU usage on the device. Therefore, the default general query interval is recommended. If you need to change the interval to suit service deployment, set the value according to the following table.

Number of IGMP Messages Sent from Downstream Users Within Maximum Response Time	Minimum General Query Interval Reference Value (Seconds)
1 to 1024	10
1024 to 2048	20
2048 to 5120	40

NOTE

The default general query interval defined in RFC documents is 125 seconds, but some vendors define their own default general query intervals. It is recommended that all devices on a multicast network use the same general query intervals (including IGMP and IGMP snooping general query intervals). On Huawei fixed switches, the default value of the IGMP general query interval is 60 seconds, and the default value of the IGMP snooping general query interval is 125 seconds.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- The interval at which General Query messages are sent must be longer than the maximum response time for General Query messages. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the general query interval in VLAN 3 to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping query-interval 100
```

8.9.32 igmp-snooping report-suppress

Function

The **igmp-snooping report-suppress** command enables suppression of IGMP Report and Leave messages in a VLAN.

The **undo igmp-snooping report-suppress** command disables suppression of IGMP Report and Leave messages in a VLAN.

By default, IGMP Report and Leave message suppression is disabled in a VLAN.

Format

igmp-snooping report-suppress

undo igmp-snooping report-suppress

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Layer 2 device receives an IGMP Membership Report message (Report or Leave message) from a group member, the Layer 2 device forwards the message to the directly connected Layer 3 device. A group member host sends a Membership Report message in the following situations:

- When joining a multicast group, a host sends a Report message. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Report messages from the member hosts.
- When receiving an IGMP General Query message, a host sends a Report message. Hosts use a timer to suppress duplicate Report messages on the same network segment. However, if the timer values on hosts are the same, the Layer 3 device can still receive duplicate Report messages.
- A host running IGMPv2 or IGMPv3 sends a Leave message when leaving a multicast group. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Leave messages from the member hosts.

After Report message suppression is enabled on a Layer 2 device, the device forwards only one IGMP Membership Report message to the upstream device in the following scenarios:

- When the first member joins a multicast group or a host sends a Report message in response to an IGMP Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device can create or maintain the matching forwarding entry based on the Report message.
- When the last member of a multicast group leaves the group, the Layer 2 device forwards a Leave message to the upstream device. The upstream device then deletes the matching forwarding entry.

This reduces the number of IGMP messages on the network.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Configuration Impact

- The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- When receiving a Leave message from a group member, the device sends Group-Specific Query messages to check whether the group has other members on the network segment.
- IGMP message suppression cannot be configured in a VLAN if the corresponding VLANIF interface has Layer 3 multicast function (such as IGMP and PIM) enabled.
- The functions of IGMP snooping proxy and IGMP message suppression cannot be configured in the same VLAN.
- If multicast VLAN replication is configured on the switch, the IGMP message suppression function cannot be enabled in user VLANs.
- The device can suppress duplicate Report messages even when IGMP message suppression is disabled. The default suppression time is 10 seconds. To change the suppression time, run the **igmp-snooping suppress-time** *suppress-time* command. If the *suppress-time* is set to 0, all the membership packets are forwarded immediately.
- This function cannot suppress IGMPv3 packets.

Example

Enable suppression of Report and Leave messages in VLAN 2.

```
<HUAWEI> system view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping report-suppress
```

8.9.33 igmp-snooping require-router-alert

Function

The **igmp-snooping require-router-alert** command configures the switch to drop the IGMP messages without the Router-Alert option in the IP header received from a VLAN.

The **undo igmp-snooping require-router-alert** command restores the default configuration.

By default, the switch does not check the Router-Alert option of IGMP messages and processes all the received IGMP messages, regardless of whether they carry the Router-Alert option in the IP header.

Format

igmp-snooping require-router-alert

undo igmp-snooping require-router-alert

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch does not check whether IGMP messages contain the Router-Alert option and sends all the IGMP messages to the upper-layer routing protocol. After the **igmp-snooping require-router-alert** command is executed, the switch checks each IGMP message for the Router-Alert option and discards those IGMP messages without this option. This improves device performance, reduces cost, and enhances security of the upper-layer routing protocol

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.

Example

Configure the switch to forward only the IGMP messages with the Router-Alert option in the IP header received from VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
```

```
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping require-router-alert
```

8.9.34 igmp-snooping robust-count

Function

The **igmp-snooping robust-count** command sets the IGMP robustness variable in a VLAN, which specifies how many times IGMP Query messages are sent.

The **undo igmp-snooping robust-count** command restores the default IGMP robustness variable in a VLAN.

By default, the robustness variable in a VLAN is 2.

Format

igmp-snooping robust-count *robust-count*

undo igmp-snooping robust-count

Parameters

Parameter	Description	Value
robust-count	Specifies the IGMP robustness variable in a VLAN.	The value is an integer that ranges from 2 to 5.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting IGMP snooping parameters helps improve the multicast forwarding performance. By setting the IGMP robustness variable, you can:

- Specify the number of times the querier sends a Group-Specific Query message, which prevents packet loss on the network.

  When receiving an IGMP Leave message for a multicast group, the switch sends a Group-Specific Query message a certain number of times (specified by the IGMP robustness variable) to check whether this group has any other members. If the quality of transmission links is low, increase the IGMP robustness variable.
- Change the aging time of multicast group member ports.

When receiving an IGMP Report message from a host, the switch starts the aging timer for the member port. The aging time is calculated using the following formula: Aging time = IGMP robustness variable x General query interval + Maximum response time for General Query messages. The **igmp-snooping robust-count** command sets the general query count.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

Perform the following operations to optimize multicast service performance:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping max-response-time** command to set the maximum response time for General Query messages.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.

Example

Set the IGMP robustness variable to 5 in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping robust-count 5
```

8.9.35 igmp-snooping router-aging-time

Function

The **igmp-snooping router-aging-time** command sets the aging time of dynamic router ports in a VLAN.

The **undo igmp-snooping router-aging-time** command restores the default aging time of dynamic router ports in a VLAN.

By default, the aging time of dynamic router ports in a VLAN is 180 seconds or equal to the holdtime value contained in PIM Hello messages.

Format

igmp-snooping router-aging-time *router-aging-time*

undo igmp-snooping router-aging-time

Parameters

Parameter	Description	Value
router-aging-time	Specifies the aging time of dynamic router ports in a VLAN.	The value is an integer that ranges from 1 to 1000, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a short-term congestion occurs on the network, it takes a longer time to transmit Query messages from the IGMP querier to the switch. If a router port on the switch ages in this period, the switch does not send Report or Leave messages to router ports. As a result, multicast data forwarding may be interrupted. Therefore, set a long aging time for the router port if the network is unstable.

When a dynamic router port on the switch receives an IGMP Query message or a PIM Hello message, the switch resets the aging time of the router port.

- If the router port receives an IGMP Query message, the switch sets the remaining aging time of the interface to the configured value.
- If the router port receives a PIM Hello message, the switch sets the aging time of the interface to the holdtime value.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.

If the aging time of a router port is too short, the router port ages frequently, degrading system performance.

Example

Set the aging time of router ports in VLAN 3 to 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
```

```
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping router-aging-time 300
```

8.9.36 igmp-snooping router-learning (interface view)

Function

The **igmp-snooping router-learning** command enables router port learning on an interface.

The **undo igmp-snooping router-learning** command disables router port learning on an interface.

By default, router port learning is enabled on an interface.

Format

igmp-snooping router-learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

undo igmp-snooping router-learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Enables an interface to function as a router port in the specified VLANs.	*vlan-id1* and *vlan-id2* are integers that range from 1 to 4094.
all	Enables an interface to function as a router port in all the VLANs.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A router port is located on a Layer 2 device and connects to an upstream Layer 3 device (a multicast router or Layer 3 switch). A switch running IGMP snooping considers an interface as a dynamic router port when the interface receives an IGMP General Query message with any source IP address except 0.0.0.0 or a PIM Hello message. If the switch does not need to receive Query messages or PIM

Hello messages from a VLAN, disable router port learning in the VLAN. A router port provides the following functions:

- Receives multicast data from the upstream device.
- Forwards IGMP Report/Leave messages. IGMP Report/Leave messages received in a VLAN are forwarded only to router ports in the VLAN.

By default, router port learning is enabled on an interface. To prevent an interface from becoming a router port, disable router port learning on the interface.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

After router port learning is disabled on an interface, the interface no longer listens on IGMP Query or PIM Hello messages. Run the **igmp-snooping static-router-port** command to configure a static router port.

Precautions

- This command takes effect only when the interface has been added to the specified VLANs and IGMP snooping has been enabled in these VLANs using the **igmp-snooping enable (VLAN view)** command.
- You can also disable router port learning by running the **undo igmp-snooping router-learning (VLAN view)** command. The **undo igmp-snooping router-learning (VLAN view)** command is the same as the **undo igmp-snooping router-learning (interface view)** command only except for the scopes they take effect. The command used in the VLAN view disables router port learning on all interfaces in a VLAN, whereas the command used in the interface view disables router port learning on a specific interface in a VLAN.
- If the specified VLAN is bound to a BD, this command takes effect only in the VLAN, but not in the BD bound to the VLAN.

Example

Disable router port learning on GE0/0/1 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo igmp-snooping router-learning vlan 10
```

8.9.37 igmp-snooping router-learning (VLAN view)

Function

The **igmp-snooping router-learning** command enables router port learning in a VLAN.

The **undo igmp-snooping router-learning** command disables router port learning in a VLAN.

By default, router port learning is enabled in a VLAN.

Format

igmp-snooping router-learning

undo igmp-snooping router-learning

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A router port is located on a Layer 2 device and connects to an upstream Layer 3 device (a multicast router or Layer 3 switch). A switch running IGMP snooping considers an interface as a dynamic router port when the interface receives an IGMP General Query message with any source IP address except 0.0.0.0 or a PIM Hello message. If the switch does not need to receive Query messages or PIM Hello messages from a VLAN, disable router port learning in the VLAN. A router port provides the following functions:

- Receives multicast data from the upstream device.
- Forwards IGMP Report/Leave messages. IGMP Report/Leave messages received in a VLAN are forwarded only to router ports in the VLAN.

By default, router port learning is enabled on an interface. To prevent interfaces in a VLAN from becoming a router port, disable router port learning in the VLAN.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

The switch does not listen on IGMP Query or PIM Hello messages in a VLAN after router port learning is disabled in the VLAN. To ensure normal multicast forwarding in the VLAN, run the **igmp-snooping static-router-port** command to configure a static router port.

Precautions

If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.

You can also disable router port learning by running the **undo igmp-snooping router-learning (interface view)** command. The **undo igmp-snooping router-learning (interface view)** command is the same as the **undo igmp-snooping router-learning (VLAN view)** command only except for the scope they take effect. The command used in the VLAN view disables router port learning on all interfaces in a VLAN, whereas the command used in the interface view disables router port learning on a specific interface in a VLAN.

When inter-VLAN multicast replication is enabled on the switch, enable router port learning in user VLANs.

Example

Disable router port learning in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] undo igmp-snooping router-learning
```

8.9.38 igmp-snooping send-query enable

Function

The **igmp-snooping send-query enable** command enables the switch to send IGMP General Query messages to non-router ports when receiving topology change events.

The **undo igmp-snooping send-query enable** command disables the switch from sending IGMP General Query messages to non-router ports.

By default, the switch does not send IGMP General Query messages to non-router ports when receiving topology change events.

Format

igmp-snooping send-query enable

undo igmp-snooping send-query enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network topology changes, the switch receives a topology change event. By default, the switch does not send IGMP General Query messages in this case. A network topology change triggers recalculation of the ring network protocol used (such as STP, MSTP, RRPP, SEP, and Smart Link), but multicast data packets cannot be switched to the new path immediately. To enable multicast data flows to be switched to the new forwarding path immediately after a network topology change, configure the switch to send IGMP General Query messages upon topology changes.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

This command is used on a ring network. When the ring network topology changes, the switch sends IGMP General Query messages with source IP address 192.168.0.1. When this address has been occupied by another device on the network, run the **igmp-snooping send-query source-address** command to change the source IP address.

Precautions

Use this command only when a ring network protocol is enabled on the switch.

Example

Configure the switch to send IGMP General Query messages upon topology changes.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping send-query enable
```

8.9.39 igmp-snooping send-query source-address

Function

The **igmp-snooping send-query source-address** command sets the source IP address of IGMP Query messages.

The **undo igmp-snooping send-query source-address** command restores the default source IP address of IGMP Query messages.

By default, the source IP address of IGMP Query messages is 192.168.0.1.

Format

igmp-snooping send-query source-address *ip-address*

undo igmp-snooping send-query source-address

Parameters

Parameter	Description	Value
ip-address	Specifies the source IP address of IGMP Query messages.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGMP Query messages include General Query messages, Group-Specific Query messages, and Group-and-Source-Specific Query messages. A Layer 2 device sends two types of IGMP General Query messages:

- IGMP General Query messages sent by the querier when the querier function is enabled using the **igmp-snooping proxy** or **igmp-snooping querier enable** command.
- IGMP General Query messages that the Layer 2 device sends after receiving Layer 2 topology change events (configured using the **igmp-snooping send-query enable** command).

By default, IGMP Query messages sent from a Layer 2 device use the source IP address 192.168.0.1. When this IP address is used by another device on the network, run the **igmp-snooping send-query source-address** command to change the source IP address of IGMP Query messages.

When multiple Layer 2 devices exist on a shared network, you can set source IP addresses of IGMP Query messages to identify the devices. For example, when multiple devices with different performance need to participate in querier election, you must configure a different source IP address of IGMP Query messages for each device.

When the IGMP proxy function is enabled on a device using the **igmp-snooping proxy** command or the function of suppressing Report and Leave messages is enabled in a VLAN using the **igmp-snooping report-suppress** command, the device sends IGMP Report and IGMP Leave messages on behalf of downstream users, with the default source IP address of the IGMP Report and IGMP Leave messages being 192.168.0.1. You can run this command to change the source IP address of IGMP Report and IGMP Leave messages.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Example

Set the source IP address of IGMP Query messages sent by the switch to 192.168.0.2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping send-query source-address 192.168.0.2
```

8.9.40 igmp-snooping send-router-alert

Function

The **igmp-snooping send-router-alert** command configures the switch to send IGMP messages with the Router-Alert option in the IP header to a VLAN.

The **undo igmp-snooping send-router-alert** command configures the switch to send IGMP messages without the Router-Alert option in the IP header to a VLAN.

By default, the switch sends IGMP messages with the Router-Alert option in the IP header.

Format

igmp-snooping send-router-alert

undo igmp-snooping send-router-alert

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch sends IGMP messages with the Router-Alert option. If some devices in the same VLAN as the switch can process only the IGMP messages without the Router-Alert option, use the **undo igmp-snooping send-router-alert** command to configure the switch to send IGMP messages without the Router-Alert option.

The switch adds the Router-Alert option only to locally originated IGMP messages and does not add this option to IGMP messages received from other devices.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.

Example

Configure the switch to send IGMP messages that do not contain the Router-Alert option in the IP header to VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] undo igmp-snooping send-router-alert
```

8.9.41 igmp-snooping ssm-mapping

Function

The **igmp-snooping ssm-mapping** command configures the mapping between a multicast group and a multicast source in a VLAN.

The **undo igmp-snooping ssm-mapping** command deletes the mapping between a multicast group and a multicast source in a VLAN.

By default, no mappings between multicast groups and multicast sources exist in a VLAN.

Format

igmp-snooping ssm-mapping *group-address* { *group-mask* | *mask-length* } *source-address*

undo igmp-snooping ssm-mapping *group-address* { *group-mask* | *mask-length* } *source-address*

Parameters

Parameter	Description	Value
group-address	Specifies the IP address of a multicast group.	The value is in dotted decimal notation, and the value range is specified by the **igmp-snooping ssm-policy** command.
group-mask	Specifies the mask of the multicast group address.	The value is in dotted decimal notation.

Parameter	Description	Value
mask-length	Specifies the mask length of the multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies the IP address of the multicast source mapped to a multicast group.	The value is in dotted decimal notation.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SSM mapping mechanism converts IGMPv1 and IGMPv2 Report messages into messages with (S, G) information. This mechanism enables hosts that do not support IGMPv3 to work with SSM. To use this mechanism, enable SSM mapping and configure mappings between a multicast group G and multicast sources such as S1, S2 on the Layer 2 device connected to user hosts. When the Layer 2 device receives IGMPv1 and IGMPv2 Report messages for a multicast group, it checks the group address of the messages. If the group address is in the SSM group range, the Layer 2 device converts the messages into one or more IGMPv3 IS_IN (S1, S2...) messages with the group address G.

Prerequisites

- IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

Before configuring the mapping between a multicast group and a multicast source:

- IGMP snooping has been enabled in the specified VLAN using the **igmp-snooping enable (VLAN view)** command.
- The IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the VLAN.
- SSM mapping has been enabled using the **igmp-snooping ssm-mapping enable** command.
- An SSM group policy has been configured using the **igmp-snooping ssm-policy** command in the VLAN to add the multicast group address to the SSM group range. This prerequisite is required when the multicast group address is an any-source multicast (ASM) address.

Example

Map multicast groups 238.1.1.1 through 238.1.1.255 to multicast source 10.1.1.1 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] igmp-snooping version 3
[HUAWEI-vlan10] igmp-snooping ssm-mapping enable
[HUAWEI-vlan10] igmp-snooping ssm-mapping 238.1.1.0 24 10.1.1.1
```

8.9.42 igmp-snooping ssm-mapping enable

Function

The **igmp-snooping ssm-mapping enable** command enables Source-Specific Multicast (SSM) mapping in a VLAN.

The **undo igmp-snooping ssm-mapping enable** command disables SSM mapping in a VLAN.

By default, SSM mapping is disabled in a VLAN.

Format

igmp-snooping ssm-mapping enable

undo igmp-snooping ssm-mapping enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an SSM network, hosts running IGMPv1 or IGMPv2 cannot select multicast sources when they join a multicast group. To provide SSM services for these hosts, enable SSM mapping on the Layer 2 devices connected to the hosts.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

Run the **igmp-snooping ssm-mapping** command to configure group-source mappings.

Precautions

- If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.
- SSM mapping is applicable only to the VLANs where IGMP snooping can process IGMPv3 messages. To set the IGMP message version to v3, use the **igmp-snooping version** command in the VLAN.
- If the multicast group address is an Any-Source Multicast (ASM) address, configure an SSM group policy to add the multicast group address to the SSM group range using the **igmp-snooping ssm-policy** command in the VLAN view.
- If the inter-VLAN multicast replication function is configured, you only need to configure SSM mapping in the multicast VLAN.

Example

Enable SSM mapping in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] igmp-snooping version 3
[HUAWEI-vlan10] igmp-snooping ssm-mapping enable
```

8.9.43 igmp-snooping ssm-policy

Function

The **igmp-snooping ssm-policy** command configures an SSM group policy in a VLAN to specify the range of SSM groups.

The **undo igmp-snooping ssm-policy** command deletes the SSM group policy from a VLAN.

By default, no SSM group policy is available in a VLAN.

Format

igmp-snooping ssm-policy *basic-acl-number*

undo igmp-snooping ssm-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of a basic ACL that defines the range of SSM groups.	The value is an integer that ranges from 2000 to 2999.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

SSM allows multicast group addresses in the range of 232.0.0.0 to 232.255.255.255. If hosts need to join multicast groups out of this range or they are allowed to join only some of multicast groups in the range, configure an SSM group range for the hosts.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The **igmp-snooping ssm-policy** command takes effect only when the following configurations are complete:

- IGMP snooping has been enabled in the specified VLAN using the **igmp-snooping enable (VLAN view)** command.
- SSM mapping has been enabled in the specified VLAN using the **igmp-snooping ssm-mapping enable** command.
- If IGMPv1 or IGMPv2 packets are sent by user hosts, the IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the VLAN.
- The ACL has been created and configured rules for the ACL. By default, the ACL applied to an SSM group policy denies all multicast groups. Therefore, to exclude specific group addresses from the SSM group address range, use a **rule permit source any** rule with **deny** rules in the ACL. For details about ACL configuration commands, see **14.1 ACL Configuration Commands**.

Example

Specify multicast group 225.1.1.123 as an SSM group in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] igmp-snooping enable
[HUAWEI-vlan3] igmp-snooping ssm-mapping enable
[HUAWEI-vlan3] igmp-snooping ssm-policy 2000
```

8.9.44 igmp-snooping static-group suppress-dynamic-join

Function

The **igmp-snooping static-group suppress-dynamic-join** command disables a device from forwarding IGMP Report and Leave messages that are received from a VLAN and contain a static group address to upstream Layer 3 devices configured with the static group address.

The **undo igmp-snooping static-group suppress-dynamic-join** command enables a device to forward IGMP Report and Leave messages that are received from a VLAN and contain a static group address to upstream Layer 3 devices configured with the static group address.

By default, a device forwards IGMP Report and Leave messages that are received from a VLAN and contain a static group address to upstream Layer 3 devices configured with the static group address.

Format

igmp-snooping static-group suppress-dynamic-join

undo igmp-snooping static-group suppress-dynamic-join

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the upstream Layer 3 multicast device is a non-Huawei device and a static group is configured on its interface connected to the device, users cannot dynamically join or leave the multicast group. You must disable the device from sending Report and Leave messages that contain static group addresses to the Layer 3 multicast device.

This function takes effect only for IGMPv1 and IGMPv2 message and is invalid for IGMPv3 messages.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.

Example

Disable a device from forwarding IGMP Report and Leave messages that are received from VLAN 10 and contain a static group address to upstream Layer 3 devices configured with the static group address.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] igmp-snooping static-group suppress-dynamic-join
```

8.9.45 igmp-snooping static-router-port

Function

The **igmp-snooping static-router-port** command configures an interface as a static router port in specified VLANs.

The **undo igmp-snooping static-router-port** command cancels the router port configuration in specified VLANs.

By default, an interface is not a static router port.

Format

igmp-snooping static-router-port vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo igmp-snooping static-router-port vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Specifies VLAN IDs. This parameter specifies in which VLANs the current interface functions as a router port. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. If **to** *vlan-id2* is not specified, the interface functions as a router port only in the VLAN specified by *vlan-id1*.	The value is an integer that ranges from 1 to 4094. The value of vlan-id2 must be greater than the value of vlan-id1. The vlan-id1 and vlan-id2 parameters identify a range of VLANs.

Parameter	Description	Value
all	Cancels the static router port configuration in all VLANs on the interface.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an interface needs to keep forwarding IGMP Report/Leave messages for a long time, configure the interface as a static router port.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

This command takes effect only when the interface is added to the specified VLANs.

If you run the **igmp-snooping static-router-port** command multiple times, all the configurations take effect.

Example

Configure GE0/0/1 as a static router port in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping static-router-port vlan 2
```

8.9.46 igmp-snooping suppress-time

Function

The **igmp-snooping suppress-time** command sets the IGMP message suppression time in a VLAN.

The **undo igmp-snooping suppress-time** command restores the default IGMP message suppression time in a VLAN.

By default, the IGMP message suppression time is 10 seconds.

Format

igmp-snooping suppress-time *suppress-time*

undo igmp-snooping suppress-time

Parameters

Parameter	Description	Value
suppress-time	Specifies the IGMP message suppression time in a VLAN.	The value is an integer that ranges from 0 to 300, in seconds. The value 0 indicates that IGMP messages are not suppressed.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To reduce the IGMP messages sent from a Layer 2 device to the upstream Layer 3 device and protect the Layer 3 device from attacks, enable the Layer 2 device to suppress IGMP Report and IGMP Leave messages sent by hosts in a VLAN. After this function is enabled, the Layer 2 device processes IGMP Report and IGMP Leave messages as follows:

- After receiving an IGMP Report/Leave message and forwarding the message, the Layer 2 device does not forward the same type of messages to the router port within the suppression time.
- If the Layer 2 device receives an IGMP General Query message or Group-Specific message, it does not suppress the first IGMP Report message that responds to the General Query message. In addition, the Layer 2 device resets the suppression timer when it receives the first IGMP Report message.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Follow-up Procedure

Run the **igmp-snooping max-response-time** command to set the maximum response time for General Query messages. It is recommended that the suppression time be the same as the maximum response time for IGMP Query messages in a VLAN.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.

The configured suppression time is invalid for IGMPv3 messages.

Example

Set the IGMP message suppression time in VLAN 2 to 15 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping suppress-time 15
```

8.9.47 igmp-snooping version

Function

The **igmp-snooping version** command configures the version of IGMP messages that IGMP snooping can process in a VLAN.

The **undo igmp-snooping version** command restores the default IGMP message version.

By default, the IGMP snooping version is 2, indicating that IGMP snooping can process IGMPv1 and IGMPv2 messages.

Format

igmp-snooping version { **1** | **2** | **3** [**mode asm-ssm**] }

undo igmp-snooping version

Parameters

Parameter	Description	Value
1	Indicates that IGMP snooping only processes IGMPv1 messages.	-
2	Indicates that IGMP snooping processes both IGMPv1 and IGMPv2 messages.	-
3	Indicates that IGMP snooping processes IGMPv1, IGMPv2, and IGMPv3 messages.	-

Parameter	Description	Value
mode asm-ssm	Indicates that when IGMPv3 is configured, the ASM-SSM model is used.	If this parameter is not specified, the SSM model is used when IGMPv3 is configured.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The IGMP protocol maintains group memberships between Layer 3 multicast devices and hosts. IGMP has three versions: v1, v2, and v3. This command specifies the version of IGMP messages that IGMP snooping can process. Generally, configure the same version on the Layer 2 device as that on the upstream Layer 3 multicast device. If IGMP is not enabled on the Layer 3 multicast device, configure the IGMP message version on the Layer 2 device to be later than or equal to the version running on downstream hosts.

When hosts in a VLAN run different IGMP versions, run the **igmp-snooping version** command to enable the Layer 2 device to process IGMP messages sent from all the hosts.

Table 8-124 compares how Report messages are processed in the ASM and ASM-SSM models when IGMPv3 is configured.

Table 8-124 Difference in Report message processing in SSM and ASM-SSM models

Multicast Address in a Report Message	Filtering Action	Processing Mode in the SSM Model	Processing Mode in the ASM-SSM Model
SSM group address, for example, 232.1.1.1	INCLUDE	The message is processed normally and the (S, G) entry is generated.	The message is processed normally and the (S, G) entry is generated.
SSM group address, for example, 232.1.1.1	EXCLUDE	The message is considered invalid and discarded.	The message is considered invalid and discarded.

Multicast Address in a Report Message	Filtering Action	Processing Mode in the SSM Model	Processing Mode in the ASM-SSM Model
ASM group address, for example, 225.1.1.1	INCLUDE	The message is considered invalid and discarded.	The message is processed normally and the (S, G) entry is generated.
ASM group address, for example, 225.1.1.1	EXCLUDE (None)	The message is processed normally and the (*, G) entry is generated.	The message is processed normally and the (*, G) entry is generated.
ASM group address, for example, 225.1.1.1	EXCLUDE (Source)	The message is processed, and the (*, G) entry is generated. However, the expected result cannot be achieved.	The message is processed normally, and the INCLUDE (*, G) and EXCLUDE (S, G) entries are generated, which are consistent with the expected result.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- If IGMP snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until IGMP snooping is enabled in the VLAN. To enable IGMP snooping in a VLAN, run the **igmp-snooping enable (VLAN view)** command.
- When the IGMP snooping version is set to IGMPv3:
  - The switch can use only the default Layer 2 multicast forwarding mode.
  - The S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, and S6720S-S forward multicast data by looking up the forwarding table according to the VLAN ID and group address.
- This command cannot be used in user VLANs of a multicast VLAN.
- If the IGMP message version is changed from IGMPv3 to IGMPv2, the system deletes all the dynamic IGMP snooping entries when the aging time expires and processes static IGMP snooping entries as follows:
  - Does not delete static entries that have only multicast groups and no multicast sources.
  - Deletes the static entries that have both multicast groups and multicast sources. When the IGMP message version is restored to IGMPv3, the system restores these entries.

- Before modifying the service model used when IGMP snooping v3 is configured, run the **undo igmp-snooping enable** command in the VLAN view to disable IGMP snooping in the VLAN.
- After the **igmp-snooping version 3 mode asm-ssm** command is configured in a VLAN, no (S, G) entry can be generated if the **l2-multicast static-group** command is run to add an interface to a specified multicast group with a non-SSM multicast address to receive multicast packets from a multicast source. For example, when the **igmp-snooping version 3 mode asm-ssm** command is configured in VLAN 10 and the **l2-multicast static-group source-address 2.1.1.1 group-address 225.0.0.1 vlan 10** command is configured on an interface, the (2.1.1.1, 225.0.0.1) entry cannot be generated.

Example

Set the version of the IGMP messages that can be processed by IGMP snooping to IGMPv1 in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] igmp-snooping version 1
```

8.9.48 l2-multicast forwarding-mode

Function

The **l2-multicast forwarding-mode** command configures the forwarding mode of multicast data in a VLAN.

The **undo l2-multicast forwarding-mode** command restores the default forwarding mode of multicast data.

By default, multicast data is forwarded in a VLAN based on IP addresses.

Format

l2-multicast forwarding-mode { **ip** | **mac** }

undo l2-multicast forwarding-mode mac

Parameters

Parameter	Description	Value
ip	Forwards multicast data based on IP addresses.	-
mac	Forwards multicast data based on MAC addresses.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After Layer 2 multicast is enabled on a Layer 2 device, the Layer 2 device maintains a Layer 2 multicast forwarding table. When receiving a multicast packet, the Layer 2 device searches the Layer 2 multicast forwarding table for the outbound interface based on the multicast address of the packet. The Layer 2 device determines the outbound interface based on the IP multicast address or IP multicast MAC address, depending on the configured Layer 2 multicast forwarding mode.

Multiple multicast IP addresses may be mapped to one MAC address. If multicast data is forwarded based on MAC addresses, multicast data may be sent to the users who do not require the multicast data. To prevent this problem, use the IP address-based forwarding mode on devices with Layer 3 functions.

Configuration Impact

To set the IGMP snooping version to IGMPv3 or the MLD snooping version to MLDv2, do not change the default forwarding mode using this command.

After the multicast data forwarding mode is set to MAC address-based forwarding in a VLAN using this command, the VLAN cannot be configured as a multicast VLAN.

Precautions

- This command can only be used in VLANs with Layer 2 multicast snooping disabled. After running this command in a VLAN, enable Layer 2 multicast snooping in the VLAN for the configuration to take effect.
  - On an IPv4 network, run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
  - On an IPv6 network, run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

Example

After IGMP snooping is enabled globally, configure the switch to forward multicast data in VLAN 100 based on MAC addresses.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] l2-multicast forwarding-mode mac
[HUAWEI-vlan100] igmp-snooping enable
```

After MLD snooping is enabled globally, configure the switch to forward multicast data in VLAN 100 based on MAC addresses.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] l2-multicast forwarding-mode mac
[HUAWEI-vlan100] mld-snooping enable
```

8.9.49 l2-multicast router-port-discard

Function

The **l2-multicast router-port-discard** command disables the switch from sending multicast data to routed ports in a VLAN.

The **undo l2-multicast router-port-discard** command restores the default configuration.

By default, multicast data can be forwarded to routed ports in a VLAN.

Format

l2-multicast router-port-discard

undo l2-multicast router-port-discard

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some scenarios, multicast data does not need to be forwarded to routed ports in a VLAN. For example, when all interfaces on a switch are configured as static router ports in a VLAN, you can use this command to conserve bandwidth by preventing multicast data from being sent to these interfaces.

Precautions

This command can only be used in VLANs with Layer 2 multicast snooping disabled. After running this command in a VLAN, enable Layer 2 multicast snooping in the VLAN for the configuration to take effect.

- On an IPv4 network, run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- On an IPv6 network, run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

Example

Disable the switch from forwarding multicast data to routed ports in VLAN 10 on an IPv4 network.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] l2-multicast router-port-discard
[HUAWEI-vlan10] igmp-snooping enable
```

Disable the switch from forwarding multicast data to routed ports in VLAN 10 on an IPv6 network.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] l2-multicast router-port-discard
[HUAWEI-vlan10] mld-snooping enable
```

8.9.50 l2-multicast static-group

Function

The **l2-multicast static-group** command configures static group memberships on an interface.

The **undo l2-multicast static-group** command deletes static group memberships from an interface.

By default, no static group membership is configured on an interface.

Format

Configure a single static multicast group:

l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address* **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address* **vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Configure a series of static multicast groups:

l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address1* **to** *group-ip-address2* **vlan** *vlan-id*

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address1* **to** *group-ip-address2* **vlan** *vlan-id*

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address all vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Parameters

Parameter	Description	Value
source-address *source-ip-address*	Specifies the IP address of a multicast source.	The value of *source-ip-address* can be any Class A, Class B, or Class C address, in dotted decimal notation.

Parameter	Description	Value
group-address *group-ip-address*	Specifies the IP address of a multicast group.	The value of *group-ip-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.
vlan { *vlan-id1* [**to** *vlan-id2*] }	Specifies the VLANs that the interface belongs to. *vlan-id1* [**to** *vlan-id2*] specifies a range of VLAN IDs. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. If **to** *vlan-id2* is not specified, the interface is bound only to the multicast group in the VLAN specified by *vlan-id1*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. *vlan-id2* must be larger than *vlan-id1*.
all	Deletes all group memberships from the interface. ● In **group-address all**, **all** indicates that the interface is removed from all multicast groups. ● In **vlan** { **all** | {*vlan-id1* [**to** *vlan-id2*] } &<1-10> }, **all** indicates that the interface is removed from multicast groups in all VLANs.	-
group-ip-address1 **to** *group-ip-address2*	Configures multiple static group memberships on the interface. *group-ip-address1* and *group-ip-address2* identify a range of multicast group addresses.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation. The values of *group-ip-address1* and *group-ip-address2* must be in the same network segment (with a 24-bit mask).

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to dynamic multicast forwarding entries generated by Layer 2 multicast protocols, you can configure static Layer 2 multicast forwarding entries by binding interfaces to multicast groups. After an interface is statically bound to a multicast group, users connected to this interface can receive multicast data of the multicast group over a long time. The interface then becomes a static member interface.

Configuring static member interfaces has the following advantages:

- Protects the system against attacks from protocol packets.
- Reduces the network delay by directly forwarding multicast packets based on static forwarding entries.
- Prevents unregistered users from receiving multicast flows, improving information security and protecting service providers' interests.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect only when both the following conditions are met:
  - IGMP snooping is enabled in the specified VLANs using the **igmp-snooping enable (VLAN view)**.
  - The specified VLANs have been created and the interface has been added to these VLANs.
  - The specified group address is not a reserved group address.
- If a device is configured to forward Layer 2 multicast traffic on a network configured with MUX VLAN using the **multicast-snooping mux-vlan enable** command, the VLAN specified in the **l2-multicast static-group** command must not be a MUX VLAN (include principal VLAN and subordinate VLAN).
- After the **igmp-snooping version 3 mode asm-ssm** command is configured in a VLAN, no (S, G) entry can be generated if the **l2-multicast static-group** command is run to add an interface to a specified multicast group with a non-SSM multicast address to receive multicast packets from a multicast source. For example, when the **igmp-snooping version 3 mode asm-ssm** command is configured in VLAN 10 and the **l2-multicast static-group**

source-address 2.1.1.1 group-address 225.0.0.1 vlan 10 command is configured on an interface, the (2.1.1.1, 225.0.0.1) entry cannot be generated.

Example

Configure a static multicast group 224.1.1.1 on GE0/0/1 in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 2
[HUAWEI-GigabitEthernet0/0/1] l2-multicast static-group group-address 224.1.1.1 vlan 2
```

Configure static multicast groups 224.1.1.1 to 224.1.1.3 on GE0/0/1 in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 2
[HUAWEI-GigabitEthernet0/0/1] l2-multicast static-group group-address 224.1.1.1 to 224.1.1.3 vlan 2
```

Delete static multicast group 224.1.1.1 from GE0/0/1 in all VLANs.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo l2-multicast static-group group-address 224.1.1.1 vlan all
```

8.9.51 multicast drop-unknown

Function

The **multicast drop-unknown** command configures the switch to drop unknown multicast flows in a VLAN.

The **undo multicast drop-unknown** command restores the default measure taken for unknown multicast flows.

The default method that a switch uses to process unknown multicast flows depends on whether Layer 2 multicast is enabled and which Layer 2 multicast forwarding mode is used.

Format

multicast drop-unknown

undo multicast drop-unknown

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Unknown multicast flows are those that do not match any entry in the multicast forwarding table or match multicast forwarding entries with an empty outbound interface list. These flows are not requested by users. The default method that a switch uses to process unknown IPv4 multicast flows depends on whether Layer 2 multicast is enabled and which Layer 2 multicast forwarding mode is used:

- If Layer 2 multicast is not enabled on the switch, the switch broadcasts unknown multicast flows in the corresponding VLAN.
- If Layer 2 multicast is enabled on the S1720GW-E and S1720GWR-E, they broadcast unknown multicast flows in the corresponding VLAN.
- If Layer 2 multicast is enabled on other switch models, they broadcast unknown multicast flows in the corresponding VLAN in MAC address-based forwarding mode and drop unknown multicast flows in IP address-based forwarding mode.

If a switch broadcasts unknown multicast flows in a VLAN, you can configure the switch to drop unknown multicast flows, reducing instant bandwidth usage.

Configuration Impact

After the **multicast drop-unknown** command is executed, all unknown IPv4 and IPv6 multicast packets are dropped, including the protocol packets that are transparently transmitted within the VLAN and use the reserved multicast address.

After the **multicast drop-unknown** command is run on the following models, protocol packets that are transparently transmitted within the VLAN and use the reserved multicast address will not be discarded: S5731-H, S5731S-H, S5732-H, S5731-S, S5731S-S, S6730-H S6730S-H, S6730-S, and S6730S-S

After the **multicast drop-unknown** command is run on the following models, protocol packets that are transparently transmitted within the VLAN and use the reserved multicast address 224.0.0.9 will not be discarded: S1720GW-E, S1720GWR-E, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, and S6720S-S.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if MAC address-based forwarding is configured as the Layer 2 multicast forwarding mode and the **multicast drop-unknown** command is executed, unknown multicast packets destined for the following reserved network segments and IP address cannot be dropped: 239.0.0.0/8, 224.0.0.0/24, 224.0.1.0/24, FF0X:0:0:0:0:0:0:0/96, FF0X::DB8:0:0/96, and the IPv6 address with the last 32 bits being 0000:00XX. To drop such unknown multicast packets, configure a traffic policy.

Example

Drop unknown multicast packets in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] multicast drop-unknown
```

8.9.52 multicast-snooping mux-vlan enable

Function

The **multicast-snooping mux-vlan enable** command enables a device to transmit Layer 2 multicast traffic on a network configured with MUX VLAN.

The **undo multicast-snooping mux-vlan enable** command disables a device from transmitting Layer 2 multicast traffic on a network configured with MUX VLAN.

By default, a device is disabled from transmitting Layer 2 multicast traffic on a network configured with MUX VLAN.

Format

multicast-snooping mux-vlan enable

undo multicast-snooping mux-vlan enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, on a network configured with MUX VLAN, Layer 2 multicast traffic cannot be transmitted between the principal VLAN and subordinate VLANs. You can run the **multicast-snooping mux-vlan enable** command to enable Layer 2 multicast traffic to be transmitted on the network configured with MUX VLAN.

Precautions

If a MUX VLAN is bound to a static multicast group using the **l2-multicast static-group** or **mld-snooping static-group** command, the **multicast-snooping mux-vlan enable** command cannot be executed. You must delete the association between the MUX VLAN and static multicast group before running the **multicast-snooping mux-vlan enable** command.

After the **multicast-snooping mux-vlan enable** command is configured, you cannot run the **l2-multicast static-group** or **mld-snooping static-group** command to bind a MUX VLAN to a static multicast group.

Example

Enable a device to forward Layer 2 multicast traffic on a network configured with MUX VLAN.

```
<HUAWEI> system-view
[HUAWEI] multicast-snooping mux-vlan enable
```

8.9.53 multicast-source-deny

Function

The **multicast-source-deny** command discards multicast data packets sent from specified VLANs on an interface.

The **undo multicast-source-deny** command restores multicast forwarding in specified VLANs on an interface.

By default, multicast data packets from all VLANs are forwarded on an interface.

Format

multicast-source-deny [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo multicast-source-deny [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Specifies a VLAN ID. • *vlan-id1* specifies the first VLAN ID. • **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. *vlan-id1* and *vlan-id2* specify a range of VLANs. If you do not specify **to** *vlan-id2*, only one VLAN is specified.	The value is an integer that ranges from 1 to 4094.

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **multicast-source-deny** command on an interface, multicast packets received from specified VLANs are discarded on the interface. You may need to use this command in the following scenarios:

- A user-side interface receives multicast packets, but the switch does not need to receive multicast data packets from user-side interfaces. Discarding multicast data packets received on a user-side interface protects the system against forged multicast flows sent from malicious users.
- Multiple multicast sources in different VLANs are connected to the switch through a Layer 2 network, but the switch only needs to receive multicast data from some of the multicast sources.
- In some situations, for example, multicast services for users connected to an interface have expired and need to be stopped, the network administrator can use this command on this interface. Then multicast data packets from specified VLANs cannot be sent to the users.

Precautions

If you run the **multicast-source-deny** command multiple times, all the configurations take effect.

When using the **multicast-source-deny** command on an interface, ensure that the interface has been added to the specified VLANs. Otherwise, the configuration does not take effect.

This command can discard only multicast data packets that meet both of the following conditions:

- The destination MAC address is an IP multicast MAC address (IPv4 MAC address starting with 0x01-00-5e or IPv6 multicast MAC address starting with 0x3333).
- The packet encapsulation protocol is UDP.

Example

Discard multicast data packets sent from VLANs 100 to 105 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] multicast-source-deny vlan 100 to 105
```

8.9.54 reset igmp-snooping group

Function

The **reset igmp-snooping group** command deletes dynamic group memberships learned by IGMP snooping.

Format

reset igmp-snooping group { **all** | **vlan** { **all** | *vlan-id* [[**source-address** *source-address*] **group-address** *group-address*] } }

Parameters

Parameter	Description	Value
all	Deletes all dynamic group memberships learned by IGMP snooping.	-
vlan { **all** | *vlan-id* }	Deletes the dynamic group memberships of a specified VLAN. If **all** is specified, the system deletes IGMP dynamic group memberships of all VLANs.	The value of *vlan-id* is an integer that ranges from 1 to 4094.
source-address *source-address*	Deletes the dynamic group memberships of a specified source address.	The multicast source address is a Class A, Class B, or Class C IP address on a nature network segment. The value is in dotted decimal notation.
group-address *group-address*	Deletes the dynamic group memberships of a specified group address.	The value of *group-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast groups on a network change, the switch generates new Layer 2 multicast forwarding entries until the aging time of member ports expire. To enable the switch to generate new multicast forwarding entries immediately, use the **reset igmp-snooping group** command to delete existing group memberships.

Precautions

NOTICE

Deleting group memberships in a VLAN temporarily interrupts multicast forwarding in the VLAN. The switch generates new forwarding entries only when receiving IGMP Report messages from hosts in the VLAN. The hosts can then receive multicast data.

This command cannot delete static group memberships.

This command is valid only for VLANs with IGMP snooping enabled and is invalid for a VLAN if IGMP is enabled on the corresponding VLANIF interface.

Example

Delete all dynamic group memberships learned by IGMP snooping.

```
<HUAWEI> reset igmp-snooping group all
```

Delete dynamic group memberships in VLAN 3.

```
<HUAWEI> reset igmp-snooping group vlan 3
```

8.9.55 reset igmp-snooping qinq-port-info

Function

The **reset igmp-snooping qinq-port-info** command clears multicast group membership on a QinQ or Dot1q termination sub-interface.

Format

reset igmp-snooping qinq-port-info interface *interface-type interface-number*

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Clears multicast group membership on a specified interface.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast users access a multicast group through a sub-interface, multicast group members change, and the switch generates new Layer 3 multicast forwarding entries until the aging time of multicast member interfaces expires. To enable the switch to generate new multicast forwarding entries immediately, use the **reset igmp-snooping qinq-port-info** command to clear old Layer 3 multicast forwarding entries.

Configuration Impact

During the execution of the **reset igmp-snooping qinq-port-info** command on a sub-interface, multicast traffic to hosts connected to this sub-interface will be interrupted.

Precautions

This command cannot delete static group membership.

Example

Clear group membership of all multicast groups on QinQ termination sub-interface GE0/0/18.1.

```
<HUAWEI> reset igmp-snooping qinq-port-info interface GigabitEthernet 0/0/18.1
```

8.9.56 reset igmp-snooping statistics

Function

The **reset igmp-snooping statistics** command clears IGMP snooping statistics.

Format

reset igmp-snooping statistics { **all** | **vlan** { **all** | *vlan-id* } }

Parameters

Parameter	Description	Value
all	Clears all the IGMP snooping statistics.	-
vlan { **all** | *vlan-id* }	Clears IGMP snooping statistics of a specified VLAN. If **all** is specified, the system clears IGMP snooping statistics of all VLANs.	The value of *vlan-id* is an integer that ranges from 1 to 4094.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To analyze the IGMP snooping statistics collected in a certain period, run this command to clear the previous statistics. After a while, run the **display igmp-snooping statistics** command to view the IGMP snooping statistics.

Precautions

NOTICE

The cleared IGMP snooping statistics cannot be restored.

Example

Clear IGMP snooping statistics of VLAN 2.

```
<HUAWEI> reset igmp-snooping statistics vlan 2
```

8.10 VSI-based IGMP Snooping Configuration Commands

8.10.1 Command Support

Only the S5731-H, S5731S-H, S5731-S, S6730-S, S5732-H, S6720-EI, S6720S-EI, S6730S-H, and S6730-H support VSI-based IGMP Snooping.

VSI-based IGMP snooping depends on the MPLS feature.

8.10.2 display igmp-snooping

Function

The **display igmp-snooping** command displays the IGMP snooping running parameters in a VSI.

Format

display igmp-snooping [**vsi** [*vsi-name*]]

Parameters

Parameter	Description	Value
vsi [*vsi-name*]	Displays the IGMP snooping running parameters in a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing IGMP snooping configuration in a VSI, you can use this command to check IGMP snooping parameter settings. When a fault occurs in the multicast service, use this command to identify the cause of the fault.

Precautions

The IGMP snooping configuration of a VSI is displayed only when the VSI is in Up state.

Example

Display IGMP snooping running parameters in VSI company1.

```
<HUAWEI> display igmp-snooping vsi company1
  IGMP Snooping Information for VSI company1
     IGMP Snooping is Enabled
     IGMP Version is Set to default 2
     IGMP Query Interval is Set to default 125s
     IGMP Max Response Interval is Set to default 10s
     IGMP Robustness is Set to default 2
     IGMP Last Member Query Interval is Set to default 1s
     IGMP Router Port Aging Interval is Set to 180s or holdtime in hello
     IGMP Filter Group-Policy is not set
     IGMP Prompt Leave Disable
     IGMP Router Alert is Not Required
     IGMP Send Router Alert Enable
     IGMP Router Port Learning Enable
     IGMP SSM-Mapping Disable
```

Table 8-125 Description of the **display igmp-snooping** command output

Item	Description
IGMP Snooping Information for VSI company1	IGMP snooping running parameters are displayed in VSI company1.
IGMP Snooping is Enabled	IGMP snooping is enabled in the VSI. By default, IGMP snooping is disabled in a VSI. IGMP snooping can be enabled in a VSI using the **igmp-snooping enable (VSI view)** command.
IGMP Version is Set to default 2	Both IGMPv1 and IGMPv2 messages can be processed in the VSI (default configuration). This parameter is configured using the **igmp-snooping version** command.
IGMP Query Interval is Set to default 125s	The interval at which IGMP General Query messages are sent in the VSI is 125 seconds (default configuration). This parameter is configured using the **igmp-snooping query-interval** command.
IGMP Max Response Interval is Set to default 10s	The maximum response time for IGMP General Query messages in the VSI is 10 seconds (default configuration). This parameter is configured using the **igmp-snooping max-response-time** command.
IGMP Robustness is Set to default 2	The IGMP robustness variable is 2 (default configuration). This parameter is configured using the **igmp-snooping robust-count** command.
IGMP Last Member Query Interval is Set to default 1s	The interval at which IGMP Group-Specific Query messages are sent in the VSI 1 second (default configuration). This parameter is configured using the **igmp-snooping lastmember-queryinterval** command.
IGMP Router Port Aging Interval is Set to 180s or holdtime in hello	The aging time of router ports in the VSI is 180 seconds or the holdtime in PIM Hello messages (default configuration). This parameter is configured using the **igmp-snooping router-aging-time** command.
IGMP Filter Group-Policy is not set	The default multicast group policy is used in the VSI. A multicast group policy is configured using the **igmp-snooping group-policy** command.

Item	Description
IGMP Prompt Leave Disable	Prompt leave is disabled in the VSI (default configuration). The prompt leave function can be enabled using the **igmp-snooping prompt-leave** command.
IGMP Router Alert is Not Required	The device does not require that the IGMP messages received in the VSI contain the Router-Alert option in the IP header (default configuration). The switch can be configured to discard IGMP messages without the Router-Alert option using the **igmp-snooping require-router-alert** command.
IGMP Send Router Alert Enable	The device sends the IGMP messages that contain the Router-Alert option in the IP headers to the hosts in the VSI (default configuration). The switch can be configured to send IGMP messages with the Router-Alert option using the **igmp-snooping send-router-alert** command.
IGMP Router Port Learning Enable	Learning of IGMP router ports is enabled in the VSI. Router port learning can be enabled using the **igmp-snooping router-learning** command.
IGMP SSM-Mapping Disable	IGMP SSM mapping is disabled in the VSI. IGMP snooping SSM mapping can be enabled using the **igmp-snooping ssm-mapping enable** command.

8.10.3 display igmp-snooping configuration

Function

The **display igmp-snooping configuration** command displays the IGMP snooping configuration in a VSI.

Format

display igmp-snooping [**vsi** [*vsi-name*]] **configuration**

Parameters

Parameter	Description	Value
vsi [*vsi-name*]	Displays the non-default IGMP snooping configuration in a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing IGMP snooping configuration in a VSI, use this command to verify the configuration. This command displays only the IGMP snooping configuration.

Prerequisites

This command does not display information about static multicast groups and static router ports. To view information about static multicast groups and static router ports, run the **display igmp-snooping port-info** and **display igmp-snooping router-port** command.

Example

Display the IGMP snooping configuration in VSI company1.

```
<HUAWEI> display igmp-snooping vsi company1 configuration
 IGMP Snooping Configuration for VSI company1
    igmp-snooping enable
    igmp-snooping version 3
```

8.10.4 display igmp-snooping port-info

Function

The **display igmp-snooping port-info** command displays information about group member ports.

Format

display igmp-snooping port-info [**vsi** *vsi-name* [**group-address** *group-address*]] [**verbose**]

Parameters

Parameter	Description	Value
vsi *vsi-name*	Displays group memberships in a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
group-address *group-address*	Displays member ports of a specified multicast group in a VSI. *group-address* specifies the IP address of a multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
verbose	Displays detailed information about member ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After IGMP snooping is configured in a VSI on a switch, the IGMP snooping module maintains a Layer 2 multicast forwarding table by snooping the IGMP messages exchanged between the upstream router and downstream hosts. The **display igmp-snooping port-info** command shows member interfaces in the Layer 2 multicast forwarding table. According to the command output, you can know which downlink interfaces have multicast users connected, and control multicast services conveniently.

Precautions

Only multicast member ports in Up state are displayed in the command output.

Example

Display information about group member ports in the VSI **company1**.

```
<HUAWEI> display igmp-snooping port-info vsi company1
-----------------------------------------------------------------------
                (Source, Group)  Port                      Flag
 Flag: S:Static     D:Dynamic     M: Ssm-mapping
 ------------------------------------------------------------------------
 VSI company1, 3 Entry(s)
                 (*, 225.0.0.1)  GE0/0/11(VID:1001)             -D-
                                       1 port(s) include
                 (*, 225.0.0.2)  PW(10.1.1.1/100)              -D-
                                       1 port(s) include
                 (*, 225.0.0.3)  GE0/0/13                      -D-
                                       1 port(s) include
 ------------------------------------------------------------------------
```

Table 8-126 Description of the **display igmp-snooping port-info** command output

Item	Description
(Source, Group)	(S, G) entry, specifying a multicast source and multicast group.
Port	Outbound port name. **include** and **exclude** indicate the multicast source filtering mode. Different ports in the command output are described as follows: ● GE0/0/11 (VID:1001) indicates that the AC-side interface is VLANIF 1001, and the group member port is GE0/0/11 in VLAN 1001. ● PW (10.1.1.1/100) indicates that the member port is a PW-side interface. 10.1.1.1 is the IP address of the remote peer, and 100 is the VC ID of the remote peer. ● GE0/0/13 indicates that the AC-side interface is GE0/0/13 working in Layer 3 mode, and the group member port is GE0/0/13.
Flag	Type of an outbound port. ● S: static member port ● D: dynamic member port ● M: member port established through SSM mapping
VSI company1, 3 Entry(s)	Number of multicast entries in VSI company 1.

8.10.5 display igmp-snooping router-port

Function

The **display igmp-snooping router-port** command displays information about the router ports in a specified VSI, including static and dynamic router ports.

Format

display igmp-snooping router-port vsi [*vsi-name*]

Parameters

Parameter	Description	Value
vsi [*vsi-name*]	Displays information about router ports in a specified VSI. If *vsi-name* is not specified, the command displays router ports in all VSIs.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A router port connects to an upstream multicast router. The router port can be statically configured or dynamically generated after the interface receives an IGMP Query message.

After completing basic IGMP snooping configuration in a VSI, you can run the **display igmp-snooping router-port** command to view the type, name, lifetime, and remaining aging time of a router port in the VSI.

Precautions

Information about a router port is displayed only when the interface is in Up state.

Example

Display information about router ports in VSI company1.

```
<HUAWEI> display igmp-snooping router-port vsi company1
 Port Name                   UpTime        Expires       Flags
 ---------------------------------------------------------------------
 VSI company1, 3 router-port(s)
 GE0/0/21(VID:100)              18:02:13      00:02:35      DYNAMIC
 PW(1.1.1.1/2)                 03:28:16      00:01:20      DYNAMIC
 GE0/0/15                     18:02:13      00:02:35      DYNAMIC
```

Table 8-127 Description of the display igmp-snooping router-port command output

Item	Description
Port Name	Router port name. Different ports in the command output are described as follows: ● GE0/0/21(VID:100) indicates that the AC-side interface is VLANIF 100, and the router port is GE0/0/21 in VLAN 100. ● PW(1.1.1.1/2) indicates that the member port is a PW-side interface. 1.1.1.1 is the IP address of the remote peer, and 2 is the VC ID of the remote peer. ● GE0/0/15 indicates that the AC-side interface is GE0/0/15 working in Layer 3 mode, and the router port is GE0/0/15.
UpTime	Time elapsed since the interface became a router port.
Expires	Remaining aging time of the router port. ● The remaining aging time is displayed for a dynamic router port. ● For a static router port, "--" is displayed, indicating that the interface does not age.
Flags	Type of the router port. ● STATIC: static router port ● DYNAMIC: dynamic router port
VSI company1, 3 router-port(s)	Number of router ports in VSI company 1.

8.10.6 display igmp-snooping statistics

Function

The **display igmp-snooping statistics** command displays IGMP snooping statistics.

Format

display igmp-snooping statistics vsi [*vsi-name*]

Parameters

Parameter	Description	Value
vsi-name	Displays IGMP snooping statistics on a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing basic IGMP snooping configuration in a VSI, you can use the **display igmp-snooping statistics** command to view IGMP snooping statistics, including the number of IGMP messages sent and received, and the number of PIM hello messages received in each VSI. When a multicast fault occurs, the IGMP snooping statistics help you identify the cause of the fault.

Configuration Impact

When *vsi-name* is specified, this command displays IGMP snooping statistics in the specified VSI, but does not display IGMP snooping events that occur in the VSI.

Example

Display IGMP snooping statistics in VSI company1.

```
<HUAWEI> display igmp-snooping statistics vsi company1
 IGMP Snooping Packets Counter
   Statistics for VSI company1
     Recv V1 Report          0
     Recv V2 Report          304
     Recv V3 Report          0
     Recv V1 Query           0
     Recv V2 Query           523
     Recv V3 Query           0
     Recv Leave            0
     Recv Pim Hello         0
     Send Query(S=0)         0
     Send Query(S!=0)        0
```

Table 8-128 Description of the **display igmp-snooping statistics** command output

Item	Description
IGMP Snooping Packets Counter	Statistics on IGMP and PIM packets.
Statistics for VSI company1	Packet statistics in VSI company1.
Recv V1 Report	Number of received IGMPv1 Membership Report messages.
Recv V2 Report	Number of received IGMPv2 Membership Report messages.
Recv V3 Report	Number of received IGMPv3 Membership Report messages.
Recv V1 Query	Number of received IGMPv1 Query messages.
Recv V2 Query	Number of received IGMPv2 Query messages.
Recv V3 Query	Number of received IGMPv3 Query messages.
Recv Leave	Number of received IGMP Leave messages.
Recv Pim Hello	Number of received PIM Hello messages.
Send Query(S=0)	Number of sent IGMP Query messages with the source address 0.0.0.0.
Send Query(S!=0)	Number of sent IGMP Query messages with source addresses other than 0.0.0.0.

8.10.7 display l2-multicast forwarding-table vsi

Function

The **display l2-multicast forwarding-table vsi** command displays the VSI-based Layer 2 multicast forwarding table.

Format

display l2-multicast forwarding-table vsi [*vsi-name* [**group-address** { *group-address* | **router-group** }]]

Parameters

Parameter	Description	Value
vsi-name	Displays Layer 2 multicast forwarding entries in a specified VSI. If *vsi-name* is not specified, the command displays Layer 2 multicast forwarding entries in all VSIs.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
group-address { *group-address* | **router-group** }	Displays Layer 2 multicast forwarding entries of a specified multicast group or all router ports. ● If you specify *group-address*, the command displays forwarding entries of the specified multicast group. ● If you specify **router-group**, the command displays forwarding entries of all router ports.	The value of *group-address* is in dotted decimal notation and ranges from 224.0.1.0 to 239.255.255.255.

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing configuration of IGMP snooping over VPLS, you can use the **display l2-multicast forwarding-table** command to view the Layer 2 multicast forwarding table.

Precautions

This command displays multicast forwarding entries in a VSI only when the VSI is in Up state.

Example

Display the multicast forwarding entries of the VSI **company1**.

```
<HUAWEI> display l2-multicast forwarding-table vsi company1
VSI Name : company1, Forwarding Mode : MAC
Total Group(s) : 2
----------------------------------------------------------------------
Group(Mac)                  Interface     Out-Vlan/InLabel
----------------------------------------------------------------------
               Router-port   5.5.5.9/28            1036
0100-5e00-0001                  5.5.5.9/28             1036
                       GigabitEthernet0/0/21    1000
0100-5e00-0002                  5.5.5.9/28             1036
                       GigabitEthernet0/0/21    1000
                       GigabitEthernet0/0/22    0
----------------------------------------------------------------------
```

Table 8-129 Description of the **display l2-multicast forwarding-table** command output

Item	Description
VSI Name	Name of the VSI of which the multicast forwarding entries are displayed.
Forwarding Mode	Multicast forwarding mode used in the VSI. Only the MAC address-based forwarding mode is supported.
Group(Mac)	Group MAC address.
Interface	Group member ports and router ports. In this example, 5.5.5.9/28 indicates a PW-side interface, of which the remote peer IP address is 5.5.5.9 and remote peer VSI ID is 28. GigabitEthernet0/0/21 indicates an AC-side interface.
Out-Vlan/InLabel	VLAN ID or inner MPLS label of packets. The value 0 indicates that the router port or member port is an AC-side interface, which is a physical interface working in Layer 3 mode.
Router-port	Router port in the VSI.

8.10.8 igmp-snooping enable (system view)

Function

The **igmp-snooping enable** command enables IGMP snooping globally.

The **undo igmp-snooping enable** command disables IGMP snooping globally.

By default, IGMP snooping is disabled globally.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After IGMP snooping is enabled in a VSI, IGMP snooping runs on PE devices in the VSI and maintains a multicast forwarding table by snooping IGMP messages forwarded between the PE devices. The PE devices can manage and control Layer 2 multicast forwarding based on the multicast forwarding table.

Before configuring IGMP snooping in a VSI, enable IGMP snooping globally. Other IGMP snooping configuration commands can be used only after you run the **igmp-snooping enable** command in the system view.

Precautions

NOTICE

When you run the **undo igmp-snooping enable** command in the system view, the system displays a message, asking you whether to disable IGMP snooping globally. When you disable IGMP snooping globally, all the IGMP snooping configurations are deleted. When you run the **igmp-snooping enable** command to enable IGMP snooping globally again, the device uses the default IGMP snooping configuration.

Example

Enable IGMP snooping globally.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
```

8.10.9 igmp-snooping enable (VSI view)

Function

The **igmp-snooping enable** command enables IGMP snooping in a VSI.

The **undo igmp-snooping enable** command disables IGMP snooping in a VSI.

By default, IGMP snooping is disabled in a VSI.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, IGMP snooping not enabled in a VSI after being enabled in the system view. To enable IGMP snooping in a VSI, run the **igmp-snooping enable** command in the VSI view.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Example

Enable IGMP snooping in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
```

8.10.10 igmp-snooping group-limit

Function

The **igmp-snooping group-limit** command sets the maximum number of Layer 2 multicast entries that an AC-side interface can learn.

The **undo igmp-snooping group-limit** command cancels the limit on the number of Layer 2 multicast entries that an AC-side interface can learn.

By default, the number of Layer 2 multicast entries that an AC-side interface can learn is not limited.

Format

igmp-snooping group-limit *group-limit* **vsi** *vsi-name*

undo igmp-snooping group-limit [*group-limit*] **vsi** *vsi-name*

Parameters

Parameter	Description	Value
group-limit	Specifies the maximum number of Layer 2 multicast entries that an AC-side interface can learn.	The value is an integer ranging from 1 to 4096.
vsi *vsi-name*	Limits the number of Layer 2 multicast entries that can be learned in a VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

GE interface view, 100GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By limiting the number of Layer 2 multicast entries learned on an interface, you can control the number of programs users connected to the interface can order. This configuration limits the multicast data traffic volume on the interface.

On a VPLS network, the maximum number of Layer 2 multicast entries can only be configured on an AC-side interface. The configuration method varies according to the type of the AC-side interface:

- If the AC-side interface bound to a VSI is a VLANIF interface, configure the maximum number of Layer 2 multicast entries on the Layer 2 interface in the corresponding VLAN. For details, see the **igmp-snooping group-limit** command in "VLAN-based IGMP Snooping Configuration Commands."
- If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **igmp-snooping group-limit** *group-limit* **vsi** *vsi-name* command on this interface.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Configuration Impact

If the number of Layer 2 multicast entries on the interface already exceeds the configured limit, the number of Layer 2 multicast entries on the interface does not change and the interface cannot learn new Layer 2 multicast entries.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (VSI view)** command to enable IGMP snooping in the VSI.

Example

Set the maximum number of Layer 2 multicast entries on the AC-side interface GE0/0/1 bound to the VSI **company1** to 10. (IGMP snooping has been enabled globally and in the VSI.)

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-limit 10 vsi company1
```

8.10.11 igmp-snooping group-policy (interface view)

Function

The **igmp-snooping group-policy** command applies a multicast group policy on an AC-side interface.

The **undo igmp-snooping group-policy** command deletes a multicast group policy from an AC-side interface.

By default, no multicast group policy is available on an AC-side interface bound to a VSI, and hosts in sites connected to the interface can join any multicast group.

Format

igmp-snooping group-policy *acl-number* [**version** *version-number*] **vsi** *vsi-name*

undo igmp-snooping group-policy [*acl-number* [**version** *version-number*]] **vsi** *vsi-name*

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the ACL that limits the multicast groups that hosts in a VSI can join.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.

Parameter	Description	Value
version *version-number*	Applies the multicast group policy only to the IGMP messages of the specified version.	The value is an integer that ranges from 1 to 3. - 1: IGMPv1 - 2: IGMPv2 - 3: IGMPv3
vsi *vsi-name*	Specifies the VSI to which the multicast group policy is applied.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

GE interface view, 100GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group policy controls the multicast programs that users can order on a device with IGMP snooping enabled. In multicast applications, user hosts send IGMP Report messages to join a group when they order programs of this group. When the upstream Layer 2 device receives the Report messages, the switch matches the Report messages with the ACL referenced in the group policy configured on the interface. If the messages match the ACL, the switch allows user hosts in the VSI to join the group and accepts the Report messages. If the messages do not match the ACL, the switch prevents the user hosts in the VSI from joining the group.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- Before running the **igmp-snooping group-policy (interface view)** command, run the **acl** command to configure the ACL that you want to apply to the

group policy to limit the range of multicast groups that hosts connected to the VLAN can join.

  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that the VLAN can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that the VLAN can join.

  After the **igmp-snooping group-policy (interface view)** command is executed on an interface:

  - The VLAN filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The VLAN discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.
- The **igmp-snooping group-policy (interface view)** applies a multicast group policy to the sites connected to an AC-side interface. You can also apply a multicast group policy to a VSI using the **igmp-snooping group-policy (VSI view)** command. If multicast group policies are configured for the same VSI in the VSI view and interface view, the system first uses the policy configured in the interface to filter the groups that hosts in the VSI can join, and then use the group configured in the VSI view.
- On a VPLS network, ACs can be set up on different types of interfaces. The method to apply a multicast group policy to an AC-side interface various according to the type of the AC-side interface:
  - If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **igmp-snooping group-policy** command on this interface.
  - If the AC-side interface bound to a VSI instance is a VLANIF interface, configure a multicast group policy on the Layer 2 interface in the corresponding VLAN. For details, see the **igmp-snooping group-policy (interface view)** commands in "VLAN-based IGMP Snooping Configuration Commands."

Example

Apply a multicast group policy to AC-side interface GE0/0/1 bound to the VSI **company1**, which allows hosts in the sites connected to GE0/0/1 to join group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
```

```
[HUAWEI-vsi-company1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping group-policy 2000 vsi company1
```

8.10.12 igmp-snooping group-policy (VSI view)

Function

The **igmp-snooping group-policy** command configures a multicast group policy in a VSI.

The **undo igmp-snooping group-policy** command deletes a multicast group policy from a VSI.

By default, no multicast group policy is available in a VSI, and hosts in the VSI can join any multicast group.

Format

igmp-snooping group-policy *acl-number* [**version** *version-number*]

undo igmp-snooping group-policy

Parameters

Parameter	Description	Value
acl-number	Specifies the number of the ACL that limits the multicast groups that hosts in a VSI can join.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
version *version-number*	Applies the multicast group policy only to the IGMP messages of the specified version.	The value is an integer that ranges from 1 to 3. ● 1: IGMPv1 ● 2: IGMPv2 ● 3: IGMPv3

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group policy controls the multicast programs that users can order on a device with IGMP snooping enabled. In multicast applications, user hosts send IGMP Report messages to join a group when they order programs of this group. When the upstream Layer 2 device receives the Report messages, the switch matches the Report messages with the ACL referenced in the group policy configured in the VSI. If the messages match the ACL, the switch allows user hosts in the VSI to join the group and accepts the Report messages. If the messages do not match the ACL, the switch prevents the user hosts in the VSI from joining the group.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- Before running the **igmp-snooping group-policy (VSI view)** command, run the **acl** command to configure the ACL that you want to apply to the group policy to limit the range of multicast groups that hosts connected to the VSI can join.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that a VSI can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that a VSI can join.

  After the **igmp-snooping group-policy (VSI view)** command is executed on a VSI:
  - The VSI filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The VSI discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.
- The **igmp-snooping group-policy (VSI view)** command applies a multicast group policy to a VSI. You can also apply a multicast group to the sites connected to an AC-side interface by using either of the following methods:
  - If the AC-side interface bound to a VSI instance is a VLANIF interface, configure a multicast group policy on the Layer 2 interface in the corresponding VLAN. For details, see the **igmp-snooping group-policy (interface view)** commands in "VLAN-based IGMP Snooping Configuration Commands."
  - If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **igmp-snooping group-policy** *acl-number* [**version** *version-number*] **vsi** *vsi-name* command on this interface.

If multicast group policies are configured for the same VSI in the VSI view and interface view, the system first uses the policy configured in the interface to filter the groups that hosts in the VSI can join, and then use the group configured in the VSI view.

Example

Allow hosts in the VSI **company1** to join group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping group-policy 2000
```

8.10.13 igmp-snooping lastmember-queryinterval

Function

The **igmp-snooping lastmember-queryinterval** command sets the last member query interval in a VSI, that is, the interval at which Group-Specific Query messages are sent in the VSI.

The **undo igmp-snooping lastmember-queryinterval** command restores the default last member query interval in a VSI.

By default, Group-Specific Query messages are sent in a VSI at intervals of 1 second.

Format

igmp-snooping lastmember-queryinterval *lastmember-queryinterval*

undo igmp-snooping lastmember-queryinterval

Parameters

Parameter	Description	Value
lastmember-queryinterval	Specifies the interval at which IGMP Group-Specific Query messages are sent.	The value is an integer that ranges from 1 to 5, in seconds.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a member interface receives an IGMP Leave message from a downstream host, the switch starts the aging timer for the interface. The aging time is calculated using the following formula: Aging time = Last member query interval x Last member query count. The **igmp-snooping lastmember-queryinterval** command sets the last member query interval. The last member query count is set by the **igmp-snooping robust-count** command.

If the member interface receives Report messages from downstream hosts within the aging time, the switch retains the member interface in the outbound interface list of the corresponding Layer 2 multicast forwarding entry. If the member interface does not receive any Report messages within the aging time, the switch considers that no group member is connected to the interface, and therefore deletes the interface from the Layer 2 multicast forwarding entry.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Hosts running IGMPv1 do not send Leave messages when they leave a multicast group. Therefore, the **igmp-snooping lastmember-queryinterval** command is valid only when the IGMP message version is set to v2 or v3 in the VSI.

Example

Set the last member query interval in VSI company1 to 4 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping lastmember-queryinterval 4
```

8.10.14 igmp-snooping max-response-time

Function

The **igmp-snooping max-response-time** command sets the maximum response time for IGMP General Query messages in a VSI.

The **undo igmp-snooping max-response-time** command restores the default maximum response time for IGMP General Query messages in a VSI.

By default, the maximum response time for IGMP General messages in a VSI is 10 seconds.

Format

igmp-snooping max-response-time *max-response-time*

undo igmp-snooping max-response-time

Parameters

Parameter	Description	Value
max-response-time	Specifies the maximum response time for IGMP General Query messages.	The value is an integer that ranges from 1 to 25, in seconds. The default value is 10.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maximum response time for General Query messages is used to calculate the aging time of group member interfaces. When a member port receives a Report message from a downstream host, the switch starts the aging timer for the interface. The aging time is calculated using the following formula: Aging time = Query count x General query interval + Maximum response time for General Query messages. This command sets the maximum response time in the formula. The general query interval is set by the **igmp-snooping robust-count** command, and the general query interval is set by the **igmp-snooping query-interval** command.

If the member port receives Report messages from downstream hosts within the aging time, the switch retains the member port in the outbound interface list of the corresponding Layer 2 multicast forwarding entry. If the member port does not receive any Report messages within the aging time, the switch considers that no group member is connected to the interface, and therefore deletes the interface from the Layer 2 multicast forwarding entry.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Set the maximum response time for IGMP General Query messages in VSI company1 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping max-response-time 20
```

8.10.15 igmp-snooping over-vpls enable

Function

The **igmp-snooping over-vpls enable** command enables IGMP snooping for VPLS.

The **undo igmp-snooping over-vpls enable** command disables IGMP snooping for VPLS.

By default, IGMP snooping for VPLS is disabled.

Format

igmp-snooping over-vpls enable

undo igmp-snooping over-vpls enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before configuring IGMP snooping in a VSI, enable IGMP snooping globally and for VPLS in the system view.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command in the system view.

Precautions

When you run the **undo igmp-snooping over-vpls enable** command in the system view, the system displays a message, asking you whether to disable IGMP snooping for VPLS. If any IGMP snooping for VPLS configuration has been made in the system, the device prompts you to delete all the IGMP snooping for VPLS configuration.

Example

Enable IGMP snooping for VPLS.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
```

8.10.16 igmp-snooping prompt-leave

Function

The **igmp-snooping prompt-leave** command enables the fast leave function in a VSI so that member ports in the VSI can fast leave multicast groups.

The **undo igmp-snooping prompt-leave** command disables the fast leave function in a VSI.

By default, the fast leave function is disabled in a VSI.

Format

igmp-snooping prompt-leave [**group-policy** *acl-number*]

undo igmp-snooping prompt-leave

Parameters

Parameter	Description	Value
group-policy *acl-number*	Allows member ports to fast leave the multicast group specified by an ACL.	The value of *acl-number* is an integer that ranges from 2000 to 3999.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The fast leave function allows the switch to delete an interface from a group immediately after the interface receives an IGMP Leave message for the multicast group.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- The configuration is valid only when IGMPv2 or IGMPv3 messages can be processed in the VSI.
- If you do not specify **group-policy** when configuring the fast leave function, this function applies to all groups. To specify a group policy in the command, create an ACL and configure rules for the ACL before running the command. The default ACL rule denies all multicast groups. If you do not want to apply the fast leave to a group, use the **rule permit source any** command.

Example

Allow member ports in the VSI **company1** to fast leave group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping prompt-leave group-policy 2000
```

Prevent member ports in the VSI **company1** from fast leaving group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping prompt-leave group-policy 2000
```

8.10.17 igmp-snooping query-interval

Function

The **igmp-snooping query-interval** command sets the general query interval in a VSI, that is, the interval at which IGMP General Query messages are sent in the VSI.

The **undo igmp-snooping query-interval** command restores the default general query interval in a VSI.

By default, Group-Specific Query messages are sent in a VSI at an interval of 125 seconds.

Format

igmp-snooping query-interval *query-interval*

undo igmp-snooping query-interval

Parameters

Parameter	Description	Value
query-interval	Specifies the interval at which IGMP General Query messages are sent.	The value is an integer that ranges from 1 to 65535, in seconds. The default value is 125.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The general query interval is used to calculate the aging time of group member ports. When a member port receives an IGMP Report message from a host, the switch starts the aging timer for the interface. The aging time is calculated using the following formula: Aging time = IGMP robustness variable x General query interval + Maximum response time for General Query messages. The **igmp-snooping query-interval** command sets the general query interval. The general query count is set by the **igmp-snooping robust-count** command, and the maximum response time for General Query messages is set by the **igmp-snooping max-response-time** command.

If the member port receives Report messages from downstream hosts within the aging time, the switch retains the member port in the outbound interface list of the corresponding Layer 2 multicast forwarding entry. If the member port does not receive any Report messages within the aging time, the switch considers that no group member is connected to the interface, and therefore deletes the interface from the Layer 2 multicast forwarding entry.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Set the general query interval in VSI company1 to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
```

```
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping query-interval 100
```

8.10.18 igmp-snooping require-router-alert

Function

The **igmp-snooping require-router-alert** command configures the switch to drop the IGMP messages without the Router-Alert option in the IP header received from a VSI.

The **undo igmp-snooping require-router-alert** command restores the default setting.

By default, the switch does not check the Router-Alert option of IGMP messages and processes all the received IGMP messages, regardless of whether they carry the Router-Alert option in the IP header.

Format

igmp-snooping require-router-alert

undo igmp-snooping require-router-alert

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol packets that need to be processed by upper-layer routing protocols.

By default, the switch does not check whether IGMP messages contain the Router-Alert option and sends all the IGMP messages to the upper-layer routing protocol. After the **igmp-snooping require-router-alert** command is executed, the switch checks each IGMP message for the Router-Alert option and discards those IGMP messages with this option. This improves device performance, reduces cost, and enhances security of the upper-layer routing protocol.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Configure the switch to discard the IGMP messages without the Router-Alert option in the IP header received from VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping require-router-alert
```

8.10.19 igmp-snooping robust-count

Function

The **igmp-snooping robust-count** command sets the IGMP robustness variable in a VSI, which specifies the query count.

The **undo igmp-snooping robust-count** command restores the default IGMP robustness variable in a VSI.

By default, the robustness variable in a VSI is 2.

Format

igmp-snooping robust-count *robust-count*

undo igmp-snooping robust-count

Parameters

Parameter	Description	Value
robust-count	Specifies the IGMP robustness variable in a VSI.	The value is an integer that ranges from 2 to 5. The default value is 2.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The IGMP robustness variable is used to adjust the aging time of group member interfaces.

- When a member port receives an IGMP Report message from a downstream host, the switch sets the aging time of the interface to: General query count x General query interval + Maximum response time for General Query messages. The **igmp-snooping robust-count** command sets the general query count. The general query interval is set by the **igmp-snooping query-interval** command, and the maximum response time for General Query messages is set by the **igmp-snooping max-response-time** command.
- When the member port receives a Leave message from a downstream host, the switch starts the aging timer of the interface to: Last member query interval x Last member query count. The **igmp-snooping robust-count** command sets the general query count. The last member query interval is set by the **igmp-snooping lastmember-queryinterval** command.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Set the IGMP robustness variable to 5 in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping robust-count 5
```

8.10.20 igmp-snooping router-aging-time

Function

The **igmp-snooping router-aging-time** command sets the aging time of dynamic router ports in a VSI.

The **undo igmp-snooping router-aging-time** command restores the default aging time of dynamic router ports in a VSI.

By default, the aging time of dynamic router ports in a VSI is 180 seconds.

Format

igmp-snooping router-aging-time *router-aging-time*

undo igmp-snooping router-aging-time

Parameters

Parameter	Description	Value
router-aging-time	Specifies the aging time of dynamic router ports in a VSI.	The value is an integer that ranges from 1 to 1000, in seconds. The default value is 180 seconds.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a short-term congestion occurs on the network, it takes a longer time to transmit Query messages from the IGMP querier to the switch. If a router port on the switch ages in this period, the switch does not send Report or Leave messages to the router port. As a result, multicast data forwarding may be interrupted. Therefore, set a long aging time for router ports if the network is unstable.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Configuration Impact

If a router port receives an IGMP Query message, the switch sets the remaining aging time of the router port to the configured value.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

A too short aging time causes frequent aging of router ports and degrades system performance.

Example

Set the aging time of router ports in VSI company1 to 500 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping router-aging-time 500
```

8.10.21 igmp-snooping router-learning

Function

The **igmp-snooping router-learning** command enables router port learning in a VSI.

The **undo igmp-snooping router-learning** command disables router port learning in a VSI.

By default, router port learning is enabled in a VSI.

Format

igmp-snooping router-learning

undo igmp-snooping router-learning

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A switch running IGMP snooping considers an interface as a dynamic router port when the interface receives an IGMP General Query message with any source IP address except 0.0.0.0. Router ports are configured to guide forwarding of IGMP Report/Leave messages. To prevent interfaces in a VSI from becoming a router port, disable router port learning in the VSI.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Follow-up Procedure

The switch does not listen on IGMP Query messages in a VSI after router port learning is disabled in the VSI. Therefore, run the **igmp-snooping static-router-port** command to configure a static router port.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Disable router port learning in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] undo igmp-snooping router-learning
```

8.10.22 igmp-snooping send-router-alert

Function

The **igmp-snooping send-router-alert** command configures the switch to send IGMP messages with the Router-Alert option in the IP header to a VSI.

The **undo igmp-snooping send-router-alert** command configures the switch to send IGMP messages without the Router-Alert option in the IP header to a VSI.

By default, the switch sends the IGMP messages with the Router-Alert option in the IP header.

Format

igmp-snooping send-router-alert

undo igmp-snooping send-router-alert

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol packets that need to be processed by upper-layer routing protocols.

By default, the switch does not check whether IGMP messages contain the Router-Alert option and sends all the IGMP messages to the upper-layer routing protocol. Sending IGMP messages without the Router-Alert option improves device performance, reduces cost, and enhances security of the upper-layer routing protocol.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Configure the switch to send IGMP messages without the Router-Alert option in the IP header to VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] undo igmp-snooping send-router-alert
```

8.10.23 igmp-snooping ssm-mapping

Function

The **igmp-snooping ssm-mapping** command configures the mapping between a multicast group and a multicast source in a VSI.

The **undo igmp-snooping ssm-mapping** command deletes the mapping between a multicast group and a multicast source in a VSI.

By default, no mappings between multicast groups and multicast sources exist in a VSI.

Format

igmp-snooping ssm-mapping *ip-group-address* { *ip-group-mask* | *mask-length* } *ip-source-address*

undo igmp-snooping ssm-mapping *ip-group-address* { *ip-group-mask* | *mask-length* } *ip-source-address*

Parameters

Parameter	Description	Value
ip-group-address	Specifies the IP address of a multicast group.	The value is in dotted decimal notation, and the value range is specified by the **igmp-snooping ssm-policy** command.
ip-group-mask	Specifies the mask of the multicast group address.	The value is in dotted decimal notation.

Parameter	Description	Value
mask-length	Specifies the mask length of the multicast group address.	The value is an integer that ranges from 4 to 32.
ip-source-address	Specifies the IP address of a multicast source.	The value is in dotted decimal notation.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SSM mapping mechanism converts IGMPv1 and IGMPv2 Report messages into messages with (S, G) information. This mechanism enables hosts that do not support IGMPv3 to work with SSM. To use this mechanism, enable SSM mapping and configure mappings between a multicast group G and multicast sources such as S1, S2 on the switch connected to user hosts. When the switch receives IGMPv1 and IGMPv2 Report messages for a multicast group, it checks the group address of the messages. If the group address is in the SSM group range, the switch converts the messages into one or more IGMPv3 IS_IN (S1, S2...) messages with the group address G.

Prerequisites

- IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command.
- The IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the VSI.
- An SSM group policy has been configured using the **igmp-snooping ssm-policy** command in the VSI to add the multicast group address to the SSM group range. This prerequisite is required when the multicast group address is an any-source multicast (ASM) address.
- SSM mapping is enabled using the **igmp-snooping ssm-mapping enable** command.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Map multicast group 238.0.0.1 to multicast source 10.1.1.1 in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping version 3
[HUAWEI-vsi-company1] igmp-snooping ssm-mapping enable
[HUAWEI-vsi-company1] igmp-snooping ssm-mapping 238.0.0.1 32 10.1.1.1
```

8.10.24 igmp-snooping ssm-mapping enable

Function

The **igmp-snooping ssm-mapping enable** command enables source-specific multicast (SSM) mapping in a VSI.

The **undo igmp-snooping ssm-mapping enable** command disables SSM mapping in a VSI.

By default, SSM mapping is disabled in a VSI.

Format

igmp-snooping ssm-mapping enable

undo igmp-snooping ssm-mapping enable

Parameters

None

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an SSM network, hosts running IGMPv1 or IGMPv2 cannot select multicast sources when they join a multicast group. To provide SSM services for these hosts, enable SSM mapping on the switch.

Prerequisites

- IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command.
- The IGMP message version is set to v3 using the **igmp-snooping version** command in the VSI.

Follow-up Procedure

If the multicast group address is an any-source multicast (ASM) address, configure an SSM group policy to add the multicast group address to the SSM group range using the **igmp-snooping ssm-policy** command in the VSI view.

Run the **igmp-snooping ssm-mapping** command to configure mapping between multicast groups and multicast sources.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Enable SSM mapping in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping version 3
[HUAWEI-vsi-company1] igmp-snooping ssm-mapping enable
```

8.10.25 igmp-snooping ssm-policy

Function

The **igmp-snooping ssm-policy** command configures an SSM group policy in a VSI. All the multicast groups permitted by the SSM group policy are SSM groups.

The **undo igmp-snooping ssm-policy** command deletes the SSM group policy from a VSI.

By default, no SSM group policy is available in a VSI.

Format

igmp-snooping ssm-policy *basic-acl-number*

undo igmp-snooping ssm-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of the basic ACL that defines the range of SSM groups.	The value is an integer that ranges from 2000 to 2999.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

SSM allows multicast group addresses in the range of 232.0.0.0 to 232.255.255.255. If hosts need to join multicast groups out of this range or they are allowed to join only some of multicast groups in the range, configure an SSM group range for the hosts.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The **igmp-snooping ssm-policy** command takes effect only when the following configurations are complete:

- IGMP snooping has been enabled in the specified VSI using the **igmp-snooping enable (VSI view)** command.
- SSM mapping has been enabled in the specified VSI using the **igmp-snooping ssm-mapping enable** command.
- If IGMPv1 or IGMPv2 packets are sent by user hosts, the IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the VSI.
- The ACL has been created and configured rules for the ACL. By default, the ACL applied to an SSM group policy denies all multicast groups. Therefore, to exclude specific group addresses from the SSM group address range, use a **rule permit source any** rule with **deny** rules in the ACL. For details about ACL configuration commands, see **14.1 ACL Configuration Commands**.

Example

Specify multicast group 225.1.1.123 as an SSM group in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping ssm-mapping enable
[HUAWEI-vsi-company1] igmp-snooping ssm-policy 2000
```

8.10.26 igmp-snooping static-router-port (interface view)

Function

The **igmp-snooping static-router-port** command configures an AC-side interface in a VSI as a static router port.

The **undo igmp-snooping static-router-port** command deletes the static router port configuration.

By default, no AC-side interface in a VSI is configured as a static router port.

Format

igmp-snooping static-router-port vsi *vsi-name*

undo igmp-snooping static-router-port vsi *vsi-name*

Parameters

Parameter	Description	Value
vsi *vsi-name*	Specifies the VSI to which a static router port belongs.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

GE interface view, 100GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To allow the interface connected to an upstream router to keep receiving or forwarding IGMP Report/Leave packets for a long time, configure the interface as a static router port.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- Interfaces on a VPLS network include PW-side interfaces and AC-side interfaces. This command configures an AC-side interface as a static router port. To configure a PW-side interface as a static router port, run the **igmp-snooping static-router-port (VSI view)** command.

- On a VPLS network, ACs can be set up on different types of interfaces. The method to configure an AC-side interface as a static router port varies according to the type of the AC-side interface:
  - If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **igmp-snooping static-router-port** command on this interface.
  - If the AC-side interface bound to a VSI is a VLANIF interface, configure the Layer 2 interface in the corresponding VLAN as a static router port. For details, see the **igmp-snooping static-router-port vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command in "VLAN-based IGMP Snooping Configuration Commands."

Example

Configure GE0/0/1 as a static router port in the VSI **company1**. (GE0/0/1 has been bound to the VSI **company1**. IGMP snooping has been enabled globally and in the VSI **company1**.)

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping static-router-port vsi company1
```

8.10.27 igmp-snooping static-router-port (VSI view)

Function

The **igmp-snooping static-router-port** command configures a PW-side interface in a VSI as a static router port.

The **undo igmp-snooping static-router-port** command deletes the static router port configuration.

By default, no PW-side interface in a VSI is configured as a static router port.

Format

igmp-snooping static-router-port remote-peer *ip-address* [**negotiation-vc-id** *vc-id*]

undo igmp-snooping static-router-port remote-peer *ip-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
remote-peer *ip-address*	Specifies the IP address of the remote peer.	The value is in dotted decimal notation.

Parameter	Description	Value
negotiation-vc-id *vc-id*	Specifies a virtual circuit ID. Generally, this parameter is specified when two ends of a PW have different VSI names. The *vc-id* parameter must specify an unused VC ID. That is, the specified VC ID cannot be the same as the VSI ID configured for any other VSI or the VC ID specified by **negotiation-vc-id** *vc-id* in another VSI.	The value is an integer that ranges from 1 to 4294967295.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To allow the interface connected to an upstream router to keep receiving or forwarding IGMP Report/Leave packets for a long time, configure the interface as a static router port.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Interfaces on a VPLS network include PW-side interfaces and AC-side interfaces. This command configures a PW-side interface as a static router port. The method to configure an AC-side interface as a static router port varies according to the type of the AC-side interface:

- If the AC-side interface bound to a VSI is a VLANIF interface, configure the Layer 2 interface in the corresponding VLAN as a static router port. For details, see the **igmp-snooping static-router-port vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10> command in "VLAN-based IGMP Snooping Configuration Commands."

- If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **igmp-snooping static-router-port vsi** *vsi-name* command on this interface.

Example

Configure the PW-side interface (with remote peer 1.1.1.1) as a static router port.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping static-router-port remote-peer 1.1.1.1
```

8.10.28 igmp-snooping version

Function

The **igmp-snooping version** command configures the version of IGMP messages that can be processed by IGMP snooping in a VSI.

The **undo igmp-snooping version** command restores the default IGMP snooping version.

By default, the IGMP snooping version is 2, indicating that IGMP snooping can process IGMPv1 and IGMPv2 messages.

Format

igmp-snooping version *version*

undo igmp-snooping version

Parameters

Parameter	Description	Value
version	Specifies the version of IGMP messages that can be processed in a VSI.	The value is an integer that ranges from 1 to 3. • 1: indicates that IGMP snooping processes only IGMPv1 messages. • 2: indicates that IGMP snooping processes IGMPv1 and IGMPv2 messages. • 3: indicates that IGMP snooping processes IGMPv1, IGMPv2, and IGMPv3 messages.

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When hosts in a VSI run different IGMP versions, run the **igmp-snooping version** command to enable the switch to process IGMP message from all the hosts.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Set the IGMP snooping version to IGMPv1 in VSI company1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] igmp-snooping version 1
```

8.10.29 l2-multicast backup-query forward

Function

The **l2-multicast backup-query forward** command configures the switch to forward IGMP Query messages to the backup PW.

The **undo l2-multicast backup-query forward** command disables the switch from forwarding IGMP Query messages to the backup PW.

By default, the switch does not forward IGMP Query messages to the backup PW.

Format

l2-multicast backup-query forward [**source-mac-replace**]

undo l2-multicast backup-query forward

Parameters

Parameter	Description	Value
source-mac-replace	Replaces the source MAC addresses in Query messages to the device MAC address before forwarding the Query messages.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, two PWs are deployed on a VPLS network to ensure reliable service traffic transmission. The two PWs provide redundancy protection for service transmission. If IGMP snooping over VPLS is configured on the switch, the switch does not forward IGMP protocol packets to the backup PW by default. In this case, devices on the backup PW cannot create Layer 2 multicast forwarding entries because they cannot receive IGMP protocol packets. When the primary PW is Down and the backup PW becomes the new primary PW, multicast data traffic will be interrupted for a short time because devices on the new primary PW have not learned Layer 2 multicast forwarding entries. To solve this problem, configure the switch to forward IGMP protocol packets to the backup PW so that multicast data traffic can be quickly switched to the new primary PW.

This command configures the switch to forward IGMP Query messages to the backup PW.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Configure the switch to forward IGMP Query messages to the backup PW.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] l2-multicast backup-query forward
```

8.10.30 l2-multicast backup-report forward

Function

The **l2-multicast backup-report forward** command configures the switch to forward IGMP Report/Leave messages to the backup PW.

The **undo l2-multicast backup-report forward** command disables the switch from forwarding IGMP Report/Leave messages to the backup PW.

By default, the switch does not forward IGMP Report/Leave messages to the backup PW.

Format

l2-multicast backup-report forward [**source-mac-replace**]

undo l2-multicast backup-report forward

Parameters

Parameter	Description	Value
source-mac-replace	Replaces the source MAC addresses in Report/Leave messages to the device MAC address before forwarding the Report/Leave messages.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, two PWs are deployed on a VPLS network to ensure reliable service traffic transmission. The two PWs provide redundancy protection for service transmission. If IGMP snooping over VPLS is configured on the switch, the switch does not forward IGMP protocol packets to the backup PW by default. In this case, devices on the backup PW cannot create Layer 2 multicast forwarding entries because they cannot receive IGMP protocol packets. When the primary PW is Down and the backup PW becomes the new primary PW, multicast data traffic will be interrupted for a short time because devices on the new primary PW have not learned Layer 2 multicast forwarding entries. To solve this problem, configure the switch to forward IGMP protocol packets to the backup PW so that multicast data traffic can be quickly switched to the new primary PW.

This command configures the switch to forward IGMP Report/Leave messages to the backup PW.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.

Example

Configure the switch to forward IGMP Report/Leave messages to the backup PW.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] l2-multicast backup-report forward
```

8.10.31 l2-multicast static-group (interface view)

Function

The **l2-multicast static-group** command statically binds a multicast group to an AC-side interface in a VSI.

The **undo l2-multicast static-group** command deletes a static multicast from an AC-side interface.

By default, no multicast group is statically bound to an AC-side interface in a VSI.

Format

l2-multicast static-group [**source-address** *source-address*] **group-address** *group-address1* [**to** *group-address2*] **vsi** *vsi-name*

undo l2-multicast static-group [**source-address** *source-address*] **group-address** { *group-address1* [**to** *group-address2*] | **all** } **vsi** *vsi-name*

Parameters

Parameter	Description	Value
source-address *source-address*	Specifies the IP address of a multicast source.	The value is in dotted decimal notation.
group-address *group-address1* [**to** *group-address2*]	Specifies the IP address of a static multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.

Parameter	Description	Value
vsi *vsi-name*	Specifies the name of a VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
all	Deletes all static multicast groups.	-

GE interface view, 100GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to dynamic multicast forwarding entries generated by Layer 2 protocol protocols, you can configure static Layer 2 multicast forwarding entries by binding groups to interfaces. After a group is statically bound to an interface, users connected to this interface can keep receiving multicast data of the group over a long time.

Static Layer 2 multicast has the following advantages:

- Protects the system against attacks from protocol packets.
- Reduces the network delay by directly forwarding multicast packets based on static forwarding entries.
- Prevents unregistered users from receiving multicast flows, improving information security and protecting service providers' interests.

Prerequisites

IGMP snooping has been enabled globally using the **igmp-snooping enable (system view)** command.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- A static multicast member port does not respond to Query messages sent from an IGMP querier. When a group or (S, G) is statically bound to or

unbound from an interface, the interface does not send an IGMP Membership Report message or Leave message.

- Interfaces on a VPLS network include PW-side interfaces and AC-side interfaces. This command statically binds a group to an AC-side interface. To statically bind a group to a PW-side interface, run the **l2-multicast static-group (VSI view)** command.
- On a VPLS network, ACs can be set up on different types of interfaces. The method to statically bind a group to an AC-side interface varies according to the type of the AC-side interface:
  - If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **l2-multicast static-group** command on this interface.
  - If the AC-side interface bound to a VSI is a VLANIF interface, bind a group to the Layer 2 interface in the corresponding VLAN. For details, see the **l2-multicast static-group** command in "VLAN-based IGMP Snooping Configuration Commands."

Example

Statically bind group 225.0.0.1 to GE0/0/1. (GE0/0/1 has been bound to the VSI **company1**. IGMP snooping has been enabled globally and in the VSI **company1**.)

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] l2-multicast static-group group-address 225.0.0.1 vsi company1
```

8.10.32 l2-multicast static-group (VSI view)

Function

The **l2-multicast static-group** command statically binds a multicast group to a PW-side interface in a VSI.

The **undo l2-multicast static-group** command deletes a static multicast from a PW-side interface.

By default, no multicast group is statically bound to a PW-side interface in a VSI.

Format

l2-multicast static-group [**source-address** *source-address*] **group-address** *group-address* **remote-peer** *ip-address* [**negotiation-vc-id** *vc-id*]

undo l2-multicast static-group [**source-address** *source-address*] **group-address** { *group-address* | **all** } **remote-peer** *ip-address* [**negotiation-vc-id** *vc-id*]

Parameters

Parameter	Description	Value
source-address *source-address*	Specifies the IP address of a multicast source.	The value is in dotted decimal notation.

Parameter	Description	Value
group-address *group-address*	Specifies the IP address of a static multicast group.	The value of *group-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.
remote-peer *ip-address*	Indicates the IP address of the remote peer.	The value is in dotted decimal notation.
negotiation-vc-id *vc-id*	Specifies a virtual circuit ID. Generally, this parameter is specified when two ends of a PW have different VSI names.	The *vc-id* parameter must specify an unused VC ID. That is, the specified VC ID cannot be the same as the VSI ID configured for any other VSI or the VC ID specified by **negotiation-vc-id** *vc-id* in another VSI. The value is an integer that ranges from 1 to 4294967295.
all	Deletes all static multicast groups.	-

Views

VSI view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to dynamic multicast forwarding entries generated by Layer 2 protocol protocols, you can configure static Layer 2 multicast forwarding entries by binding entries to interfaces. After a multicast group is statically bound to an interface, users connected to this interface can keep receiving multicast data of the multicast group for a long time.

Static Layer 2 multicast has the following advantages:

- Protects the system against attacks from protocol packets.
- Reduces the network delay by directly forwarding multicast packets based on static forwarding entries.
- Prevents unregistered users from receiving multicast flows, improving information security and protecting service providers' interests.

Prerequisites

IGMP snooping has been enabled for VPLS using the **igmp-snooping over-vpls enable** command in the system view.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the VSI using the **igmp-snooping enable (VSI view)** command.
- A static multicast member port does not respond to Query messages sent from an IGMP querier. When an interface is statically bound to or unbound from a multicast group or (S, G), the interface does not send an IGMP Membership Report message or Leave message.
- Interfaces on a VPLS network include PW-side interfaces and AC-side interfaces. This command statically binds a group to a PW-side interface. The method to statically bind a group to an AC-side interface varies according to the type of the AC-side interface:
  - If the AC-side interface bound to a VSI is a VLANIF interface, bind a group to the Layer 2 interface in the corresponding VLAN. For details, see the **l2-multicast static-group** command in "VLAN-based IGMP Snooping Configuration Commands."
  - If the AC-side interface bound to a VSI is a physical interface that has been switched to Layer 3 mode using the **undo portswitch** command, run the **l2-multicast static-group** [**source-address** *source-address*] **group-address** *group-address1* [**to** *group-address2*] **vsi** *vsi-name* command on this interface.

Example

Statically bind group 224.1.1.1 to the PW (with the remote IP address as 1.1.1.1) in the VSI **company1**.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vpls enable
[HUAWEI] vsi company1
[HUAWEI-vsi-company1] igmp-snooping enable
[HUAWEI-vsi-company1] l2-multicast static-group group-address 224.1.1.1 remote-peer 1.1.1.1
```

8.10.33 reset igmp-snooping group

Function

The **reset igmp-snooping group** command clears dynamic multicast forwarding entries.

Format

reset igmp-snooping group { **vsi** { **name** *vsi-name* [[**source-address** *source-address*] **group-address** *group-address*] | **all** } | **all** }

Parameters

Parameter	Description	Value
name *vsi-name*	Clears the dynamic multicast forwarding entries of a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
all	Clears the dynamic multicast forwarding entries of all VSIs.	-
source-address *source-address*	Deletes the dynamic group memberships of a specified source address.	The value is in dotted decimal notation.
group-address *group-address*	Deletes the dynamic group memberships of a specified group address.	The value of *group-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast groups on interfaces change, the system generates new Layer 2 multicast forwarding entries until the aging time of multicast member interfaces expire. To enable the system to generate new multicast forwarding entries immediately, use the **reset igmp-snooping group** command to clear old multicast forwarding entries.

Precautions

NOTICE

If the command clears the dynamic forwarding entries of a VSI, the hosts in the VSI cannot receive multicast packets.

This command cannot clear static multicast forwarding entries.

Example

Delete all dynamic forwarding entries of VSI **company1**.

```
<HUAWEI> reset igmp-snooping group vsi name company1
```

8.10.34 reset igmp-snooping statistics

Function

The **reset igmp-snooping statistics** command clears IGMP snooping statistics.

Format

reset igmp-snooping statistics { **vsi** { **name** *vsi-name* | **all** } | **all** }

Parameters

Parameter	Description	Value
name *vsi-name*	Clears IGMP snooping statistics in a specified VSI.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
all	Clears all the IGMP snooping statistics.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To analyze the IGMP snooping statistics collected in a certain period, run this command to clear the previous statistics. After a while, run the **display igmp-snooping statistics** command to view the IGMP snooping statistics.

Precautions

NOTICE

The cleared IGMP snooping statistics cannot be restored.

Example

Clear IGMP snooping statistics of VSI company1.

```
<HUAWEI> reset igmp-snooping statistics vsi name company1
```

8.11 BD-based IGMP Snooping Configuration Commands

8.11.1 Command Support

Only the S6730-H, S6730S-H, S6730-S, S6730S-S, S5732-H, S5731-S, S5731S-S, S5731S-H, S5731-H, S6735-S, S6720-EI, S6720S-EI support BD-based IGMP snooping.

8.11.2 display igmp-snooping

Function

The **display igmp-snooping** command displays the IGMP snooping running parameters.

Format

display igmp-snooping [**bridge-domain** [*bd-id*]]

Parameters

Parameter	Description	Value
bridge-domain [*bd-id*]	Displays the IGMP snooping running parameters in a specified BD.	The value is an integer that ranges from 1 to 16777215.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After IGMP snooping is configured for a VXLAN network, you can use this command to view the IGMP snooping running parameters.

To view the IGMP snooping configuration, run the **display igmp-snooping configuration** command.

Example

Display the IGMP snooping running parameters.

```
<HUAWEI> display igmp-snooping bridge-domain 123
  IGMP Snooping Information for BDID 123
     IGMP Snooping is Enabled
     IGMP Version is Set to default 2
     IGMP Query Interval is 1s
     IGMP Max Response Interval is Set to default 10s
     IGMP Robustness is Set to default 2
     IGMP Last Member Query Interval is Set to default 1s
     IGMP Router Port Aging Interval is Set to 180s
     IGMP Filter Group-Policy is not set
     IGMP Prompt Leave Disable
     IGMP Router Alert is Not Required
     IGMP Send Router Alert Enable
     IGMP Report Suppress Disable
     IGMP Suppress Time is set to default 10 seconds
     IGMP Querier Enable
     IGMP Router Port Learning Enable
     IGMP SSM-Mapping Enable
     IGMP SSM-policy acl number is 2008
```

Table 8-130 Description of the **display igmp-snooping** command output

Item	Description
IGMP Snooping Information for BDID 123	The following information displayed is the IGMP snooping running parameters in BD 123.
IGMP Snooping is Enabled	IGMP snooping is enabled in the BD. By default, IGMP snooping is disabled in a BD. IGMP snooping can be enabled in a BD using the **igmp-snooping enable (BD view)** command.
IGMP Version is Set to default 2	Version of IGMP messages that can be processed in the BD. In this example, the default version 2 is displayed, indicating that both IGMPv1 and IGMPv2 messages can be processed. This parameter is configured using the **igmp-snooping version** command.
IGMP Query Interval is 1s	Interval at which IGMP General Query messages are sent. This parameter is configured using the **igmp-snooping query-interval** command.
IGMP Max Response Interval is Set to default 10s	Maximum response time for IGMP General Query messages. This parameter is configured using the **igmp-snooping max-response-time** command.

Item	Description
IGMP Robustness is Set to default 2	IGMP robustness variable. This parameter is configured using the **igmp-snooping robust-count** command.
IGMP Last Member Query Interval is Set to default 1s	Interval at which IGMP Group-Specific Query messages are sent. This parameter is configured using the **igmp-snooping lastmember-queryinterval** command.
IGMP Router Port Aging Interval is Set to 180s	Aging time of a router port. This parameter is configured using the **igmp-snooping router-aging-time** command.
IGMP Filter Group-Policy is not set	Multicast group policy. In this example, that is, no policy is configured. A multicast group policy is configured using the **igmp-snooping group-policy** command.
IGMP Prompt Leave Disable	The fast leave function is disabled for interfaces in the BD. The fast leave function can be enabled using the **igmp-snooping prompt-leave** command.
IGMP Router Alert is Not Required	The switch does not require that the IGMP messages received from the BD contain the Router-Alert option in the IP header. The switch can be configured to discard IGMP messages without the Router-Alert option using the **igmp-snooping require-router-alert** command.
IGMP Send Router Alert Enable	The switch sends the IGMP messages with the Router-Alert option to the BD. The switch can be configured to send IGMP messages with the Router-Alert option using the **igmp-snooping send-router-alert** command.
IGMP Report Suppress Disable	IGMP message suppression is disabled. IGMP message suppression can be enabled using the **igmp-snooping report-suppress** command.
IGMP Suppress Time is set to default 10 seconds	IGMP message suppression time. This parameter is configured using the **igmp-snooping suppress-time** command.
IGMP Querier Enable	IGMP snooping querier is enabled. IGMP snooping querier can be enabled using the **igmp-snooping querier enable** command.
IGMP Router Port Learning Enable	Router port learning is enabled. Router port learning can be enabled using the **igmp-snooping router-learning** command.

Item	Description
IGMP SSM-Mapping Disable	IGMP snooping SSM mapping is disabled. IGMP snooping SSM mapping can be enabled using the **igmp-snooping ssm-mapping enable** command.
IGMP SSM-policy acl number is 2008	SSM group policy for IGMP snooping. The SSM group policy for IGMP snooping can be configured using the **igmp-snooping ssm-policy** command.

8.11.3 display igmp-snooping configuration

Function

The **display igmp-snooping configuration** command displays the IGMP snooping configuration.

Format

display igmp-snooping [**bridge-domain** [*bd-id*]] **configuration**

Parameters

Parameter	Description	Value
bridge-domain [*bd-id*]	Displays IGMP snooping configurations in a specified BD.	The value is an integer that ranges from 1 to 16777215.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check whether the IGMP snooping configurations for a VXLAN network are correct.

To check all IGMP snooping running parameters, run the **display igmp-snooping** command.

Example

Display the IGMP snooping configuration in BD 123.

```
<HUAWEI> display igmp-snooping bridge-domain 123 configuration
 IGMP Snooping Configuration for BDID 123
    igmp-snooping enable
    igmp-snooping query-interval 1s
    igmp-snooping querier enable
    igmp-snooping ssm-mapping enable
    igmp-snooping ssm-policy 2008
    igmp-snooping ssm-mapping 225.0.0.1 255.255.255.255 10.0.0.1
```

8.11.4 display igmp-snooping port-info

Function

The **display igmp-snooping port-info** command displays information about multicast group member ports.

Format

display igmp-snooping port-info [**bridge-domain** *bd-id* [**group-address** *group-address*]] [**verbose**]

Parameters

Parameter	Description	Value
bridge-domain *bd-id*	Displays multicast group member ports in a specified BD.	The value is an integer that ranges from 1 to 16777215.
group-address *group-address*	Displays information about member ports of a specified multicast group. If this parameter is not specified, the system displays member ports of all multicast groups.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
verbose	Displays detailed information about multicast group member ports. If this parameter is not specified, the system displays the summary of multicast group member ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

When the switch with IGMP snooping enabled receives IGMP messages exchanged between hosts and a Layer 3 device, the switch maintains a Layer 2 multicast forwarding table based on information in the messages. The **display igmp-snooping port-info** command shows member ports in the Layer 2 multicast forwarding table. According to the command output, you can know which downlink ports of the switch have multicast users connected, and control multicast services conveniently.

Precautions

Information about multicast group member ports can be displayed only after IGMP snooping is enabled in the BD using the **igmp-snooping enable** command.

Example

Display information about multicast group member ports in BD 123.

```
<HUAWEI> display igmp-snooping port-info bridge-domain 123
-------------------------------------------------------------------------------
                      (Source, Group)   Port                       Flag
            Flag: S:Static     D:Dynamic     M: Ssm-mapping
-------------------------------------------------------------------------------
 BDID 123, 1 Entry(s)
                       (*, 225.0.0.2)  XGE0/0/4(VID:101)            S--
                                          1 port(s) include
-------------------------------------------------------------------------------
```

Table 8-131 Description of the **display igmp-snooping port-info** command output

Item	Description
(Source, Group)	(S, G) entry, specifying the multicast source and multicast group. Multicast data is sent from multicast source S to group G. If S is displayed as *, multicast data may be sent from any multicast source. If S is displayed as an IP address, multicast data is sent from this IP address.
Port	Member port. TNL indicates VXLAN tunnel information. **include** and **exclude** indicate the multicast source filtering mode.
Flag	Type of a member port, which can be: - S: static member port, which is configured using the **l2-multicast static-group** command - D: dynamic member port learned through IGMP snooping - M: member port established through SSM mapping
BDID 123, 1 Entry(s)	BD ID and the number of entries in the BD.

Display detailed information about all multicast group member ports.

```
<HUAWEI> display igmp-snooping port-info verbose
The port information of Group 225.0.0.2 on BDID 123:
    Time of this group has been up : 05:05:07

  The port information of (0.0.0.0, 225.0.0.2):
    Time of this source has been up : 05:05:07
    Port Table on this source(0.0.0.0):
    List of ports in include mode:
      No.1
        Port name : XGE0/0/4(VID:101)
        Time of this port has been up as a host-port : NA
        Remain time of port expire as dynamic host-port : NA
        Host-port flags : Static
    There are 1 port(s) in include mode.
    List of ports in exclude mode:
      No.1
        Port name : XGE0/0/5(VID:101)
        Time of this port has been up as a host-port : NA
        Remain time of port expire as dynamic host-port : NA
        Host-port flags : Static
    There are 1 port(s) in exclude mode.
```

Table 8-132 Description of the display igmp-snooping port-info verbose command output

Item	Description
The port information of Group 225.0.0.2 on BDID 123	Information about member ports of multicast group 225.0.0.2 in BD 123.
Time of this group has been up	Time that elapsed since the multicast group was set up.
The port information of (0.0.0.0, 225.0.0.2)	Information about member ports of a specified (S, G).
Time of this source has been up	Time that elapsed since the multicast source was set up.
Port Table on this source	List of member ports of the specified multicast source.
List of ports in include mode	Information about member ports that join a multicast group in INCLUDE mode.
List of ports in exclude mode	Information about member ports that join a multicast group in EXCLUDE mode.
No.1	First member port.
Port name	Type and number of the first member port.
Time of this port has been up as a host-port	Time that elapsed since the first member port was bound to a source or (S, G).

Item	Description
Remain time of port expire as dynamic host-port	Aging time of the first member port. This field displays "NA" for a static member port. The aging time of a dynamic member port is calculated using the following formula: Aging time = Robustness variable x General query interval + Maximum response time for General Query messages. The robustness variable is configured using the **igmp-snooping robust-count** command. The general query interval is configured using the **igmp-snooping query-interval** command. The maximum response time for General Query messages is configured using the **igmp-snooping max-response-time** command.
Host-port flags	Type of a member port, which can be: ● Static: static member ● Dynamic: dynamic member port learned through IGMP snooping ● Mapping: member port established through SSM mapping
There are *x* port(s) in include mode	Number of member ports that join a multicast group in INCLUDE mode.
There are *x* port(s) in exclude mode	Number of member ports that join a multicast group in EXCLUDE mode.

8.11.5 display igmp-snooping router-port

Function

The **display igmp-snooping router-port** command displays information about the router ports in a specified BD, including static and dynamic router ports.

Format

display igmp-snooping router-port bridge-domain [*bd-id*]

Parameters

Parameter	Description	Value
bridge-domain [*bd-id*]	Displays information about the router ports in a specified BD. If *bd-id* is not specified, the command displays router ports in all BDs.	The value is an integer that ranges from 1 to 16777215.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A router port connects the switch to an upstream Layer 3 multicast device. The router port can be statically configured or dynamically generated after the interface receives an IGMP Query message or a PIM Hello message.

You can run the **display igmp-snooping router-port** command to view the type, name, lifetime, and aging time of a router port.

Precautions

This command can display information about router ports in a BD only when IGMP snooping has been enabled in the BD using the **igmp-snooping enable (BD view)** command, and at least one interface in the BD is in Up state.

Example

Display information about router ports in BD 123.

```
<HUAWEI> display igmp-snooping router-port bridge-domain 123
Port Name                    UpTime        Expires       Flags
 ---------------------------------------------------------------------
 BDID 123, 2 router-port(s)
 XGE0/0/36(VID:101)             07:24:05      --            STATIC
 XGE0/0/4(VID:102)              05:15:50      --            STATIC
```

Table 8-133 Description of the display igmp-snooping router-port command output

Item	Description
Port Name	Type and number of a router port. TNL indicates VXLAN tunnel information.
UpTime	Time that elapsed since the interface became a router port.
Expires	Aging time of the router port. - The aging time is displayed for a dynamic router port. This parameter is configured using the **igmp-snooping router-aging-time** command. - For a static router port, "--" is displayed, indicating that the static router does not age.

Item	Description
Flags	Type of the router port, which can be: ● STATIC: static router port configured using the **igmp-snooping static-router-port** command. ● DYNAMIC: dynamic router port

8.11.6 display igmp-snooping statistics

Function

The **display igmp-snooping statistics** command displays IGMP snooping statistics.

Format

display igmp-snooping statistics bridge-domain [*bd-id*]

Parameters

Parameter	Description	Value
bridge-domain [*bd-id*]	Displays IGMP snooping statistics in a specified BD. If *bd-id* is not specified, the system displays IGMP snooping statistics in all BDs.	The value is an integer that ranges from 1 to 16777215.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After IGMP snooping is configured, you can run the **display igmp-snooping statistics** command to view IGMP snooping statistics, including the number of IGMP messages sent and received in each BD.

Precautions

This command displays IGMP snooping statistics only when IGMP snooping has been enabled globally using the **igmp-snooping enable (BD view)** command.

Example

Display IGMP snooping statistics in BD 123.

```
<HUAWEI> display igmp-snooping statistics bridge-domain 123
 IGMP Snooping Packets Counter
   Statistics for BDID 123
     Recv V1 Report         0
     Recv V2 Report         6621
     Recv V3 Report         0
     Recv V1 Query          0
     Recv V2 Query          335516
     Recv V3 Query          0
     Recv General Query     0
     Recv Leave             26
     Recv Pim Hello         0
     Send Query(S=0)        33
     Send Query(S!=0)       0
     Suppress Report        0
     Suppress Leave         0
     Proxy Send General Query              0
     Proxy Send Group-Specific Query       0
     Proxy Send Group-Source-Specific Query 0
```

Table 8-134 Description of the display igmp-snooping statistics command output

Item	Description
IGMP Snooping Packets Counter	Statistics on IGMP Snooping packets.
Statistics for BDID 123	Packet statistics in BD 123.
Recv V1 Report	Number of IGMPv1 Report messages received.
Recv V2 Report	Number of IGMPv2 Report messages received.
Recv V3 Report	Number of IGMPv3 Report messages received.
Recv V1 Query	Number of IGMPv1 Query messages received.
Recv V2 Query	Number of IGMPv2 Query messages received.
Recv V3 Query	Number of IGMPv3 Query messages received.
Recv General Query	Interval for sending IGMP General Query messages.
Recv Leave	Number of IGMP Leave messages received.
Recv Pim Hello	Number of PIM Hello messages received.
Send Query(S=0)	Number of IGMP Query messages sent with the source address 0.0.0.0.
Send Query(S!=0)	Number of IGMP Query messages sent with source addresses other than 0.0.0.0.

Item	Description
Suppress Report	Number of duplicate IGMP Report messages dropped.
Suppress Leave	Number of duplicate IGMP Leave messages dropped.
Proxy Send General Query	Number of General Query messages sent by the IGMP snooping proxy.
Proxy Send Group-Specific Query	Number of Group-Specific Query messages sent by the IGMP snooping proxy.
Proxy Send Group-Source-Specific Query	Number of Group-Source-Specific Query messages sent by the IGMP snooping proxy.

8.11.7 display l2-multicast forwarding-table bridge-domain

Function

The **display l2-multicast forwarding-table bridge-domain** command displays the Layer 2 multicast forwarding table in BDs.

Format

display l2-multicast forwarding-table bridge-domain [*bd-id* [[**source-address** *source-address*] **group-address** { *group-address* | **router-group** }]]

Parameters

Parameter	Description	Value
bd-id	Displays Layer 2 multicast forwarding entries in a specified BD. If *bd-id* is not specified, the command displays Layer 2 multicast forwarding entries in all BDs.	The value is an integer that ranges from 1 to 16777215.
source-address *source-address*	Displays the forwarding entries of a specified Layer 2 multicast source.	The value is in dotted decimal notation.
group-address *group-address*	Displays multicast forwarding entries of a specified Layer 2 multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.

Parameter	Description	Value
router-group	Displays Layer 2 multicast forwarding entries of all router ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After completing IGMP snooping configuration, you can use the **display l2-multicast forwarding-table** command to view the Layer 2 multicast forwarding table. This command displays statically configured and dynamically learned multicast forwarding entries.

Example

Display the Layer 2 multicast forwarding table in BD 123.

```
<HUAWEI> display l2-multicast forwarding-table bridge-domain 123
Bridge domain  : 123, Forwarding Mode : MAC
Total Group(s) : 1
--------------------------------------------------------------------------------
Group(Mac)                                Interface      Out-Vlan/InLabel
--------------------------------------------------------------------------------
                        Router-port     XGigabitEthernet0/0/36          101
                        Router-port     XGigabitEthernet0/0/4           102
0100-5e00-0002                             XGigabitEthernet0/0/4           101
                                   XGigabitEthernet0/0/36           101
                                   XGigabitEthernet0/0/4            102
--------------------------------------------------------------------------------
```

Table 8-135 Description of the **display l2-multicast forwarding-table bridge-domain** command output

Item	Description
Bridge domain	BD ID of the forwarding entries.
Forwarding Mode	Multicast forwarding mode used in the BD. Only the MAC address-based forwarding mode is supported.
Total Group(s)	Total number of multicast forwarding entries.
Group(Mac)	Group MAC address.
Interface	Outbound interface. The Router-port field indicates a router port.

Item	Description
Out-Vlan/InLabel	VLAN ID. When the **Interface** value is a VTEP IP address, this parameter is left blank.

8.11.8 igmp-snooping enable (system view)

Function

The **igmp-snooping enable** command enables IGMP snooping globally.

The **undo igmp-snooping enable** command disables IGMP snooping globally.

By default, IGMP snooping is disabled globally.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BD-based IGMP snooping runs on multiple VTEPs on a VXLAN network. A device sets up a Layer 2 multicast forwarding table by snooping IGMP messages exchanged between multicast users in a BD and the upstream device, and forwards multicast packets on the VXLAN network according to the Layer 2 multicast forwarding table.

Before configuring IGMP snooping for a VXLAN network, enable IGMP snooping globally. Other IGMP snooping configuration commands can be used only after you run the **igmp-snooping enable** command in the system view.

Precautions

When you run the **undo igmp-snooping enable** command in the system view, the system displays a message, asking you whether to disable IGMP snooping globally. When you disable IGMP snooping globally, all the IGMP snooping configurations are deleted. When you run the **igmp-snooping enable** command to enable IGMP snooping globally again, the device uses the default IGMP snooping configuration.

Example

Enable IGMP snooping globally.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
```

8.11.9 igmp-snooping enable (BD view)

Function

The **igmp-snooping enable** command enables IGMP snooping in a BD.

The **undo igmp-snooping enable** command disables IGMP snooping in a BD.

By default, IGMP snooping is disabled in a BD.

Format

igmp-snooping enable

undo igmp-snooping enable

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Application Scenario

To implement IGMP snooping on a VXLAN network, a device needs to set up Layer 2 multicast forwarding entries by snooping IGMP messages exchanged between multicast users in a BD and the upstream router. To achieve this, IGMP snooping needs to be enabled in the BD view.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Example

Enable IGMP snooping in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
```

```
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
```

8.11.10 igmp-snooping fast-switch enable

Function

The **igmp-snooping fast-switch enable** command enables fast multicast forwarding path switching upon STP topology changes.

The **undo igmp-snooping fast-switch enable** command disables fast multicast forwarding path switching upon STP topology changes.

By default, fast multicast forwarding path switching upon STP topology changes is disabled.

Format

igmp-snooping fast-switch enable

undo igmp-snooping fast-switch enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the Layer 2 network topology changes, multicast forwarding paths may change. When this occurs, the upstream querier sends a Query message to switch the multicast forwarding path. However, there is a delay (60s by default) between the time when network topology change occurs and the time when the Query message is sent. As a result, the downstream device cannot receive the Query message immediately, so the multicast forwarding path cannot be quickly switched.

If the Layer 2 network is running the Spanning Tree Protocol (STP), you can enable fast multicast forwarding path switching upon STP topology changes. When the STP topology changes, this function quickly changes the ports in Forwarding state into router ports to direct multicast data flows to the new forwarding paths.

Prerequisite

Global IGMP snooping has been enabled using the **igmp-snooping enable (system view)** command.

Precautions

- This function takes effect only when STP is used as the loop prevention protocol on a Layer 2 network and the STP operation mode is MSTP, RSTP, or STP.
- With this function configured, the switch sets all ports in Forwarding state as router ports when the STP topology changes. In this case, multicast data flows are forwarded to all the router ports before the router ports are aged. This will cause increase in multicast traffic on the network.

Example

Enable fast multicast forwarding path switching upon STP topology changes.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] igmp-snooping fast-switch enable
```

8.11.11 igmp-snooping group-policy(BD view)

Function

The **igmp-snooping group-policy** command configures a multicast group policy in a BD.

The **undo igmp-snooping group-policy** command deletes the multicast group policy from a BD.

By default, no multicast group policy is available in a BD, and hosts in the BD can join any multicast group.

Format

igmp-snooping group-policy *acl-number* [**version** *version-number*]

undo igmp-snooping group-policy

Parameters

Parameter	Description	Value
acl-number	Specifies the number of an ACL used to restrict the range of groups users can join.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.

Parameter	Description	Value
version *version-number*	Applies the multicast group policy only to the IGMP messages of the specified version. If this parameter is not specified, the multicast group policy applies to all IGMP messages.	The value is an integer that ranges from 1 to 3. ● 1: IGMPv1 ● 2: IGMPv2 ● 3: IGMPv3

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group policy controls the multicast programs that users can order on a switch with IGMP snooping enabled. When a user orders a multicast program, the user host sends a Report message, requesting to join the multicast group. After the switch receives the message, it checks whether the multicast group matches the multicast group policy applied to the BD. If the messages match the ACL, the switch allows user hosts in the BD to join the group and accepts the Report messages. If the messages do not match the ACL, the switch prevents the user hosts in the BD from joining the group.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

- The configuration takes effect only when IGMP snooping is enabled in the BD using the **igmp-snooping enable (BD view)** command..
- Before running the **igmp-snooping group-policy (BD view)** command, run the **acl** command to configure the ACL that you want to apply to the group policy to limit the range of multicast groups that hosts connected to the BD can join.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that the BD can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that the BD can join.

After the **igmp-snooping group-policy (BD view)** command is executed on the BD:

- The BD filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
- The BD discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
- If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.

Example

Prevent hosts in BD 123 from joining group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping group-policy 2000
```

Allow hosts in BD 123 to join group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping group-policy 2000
```

8.11.12 igmp-snooping lastmember-queryinterval

Function

The **igmp-snooping lastmember-queryinterval** command sets the last member query interval in a BD, that is, the interval at which Group-Specific Query messages are sent in the BD.

The **undo igmp-snooping lastmember-queryinterval** command restores the default last member query interval in a BD.

By default, Group-Specific Query messages are sent in a BD at intervals of 1 second.

Format

igmp-snooping lastmember-queryinterval *lastmember-queryinterval*

undo igmp-snooping lastmember-queryinterval

Parameters

Parameter	Description	Value
lastmember-queryinterval	Specifies the interval at which IGMP Group-Specific Query messages are sent.	The value is an integer that ranges from 1 to 5, in seconds.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the last member query interval, you can:

- Configure the switch to send IGMP Group-Specific Query messages at intervals when the querier function is enabled.
- Change the aging time of multicast group member ports.

  When the switch receives an IGMP Leave message from a host, the switch starts the aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = Last member query interval x Last member query count. The **igmp-snooping lastmember-queryinterval** command sets the last member query interval. The last member query count is set by the **igmp-snooping robust-count** command.

  If the switch (querier) receives Report messages from other hosts within the aging time, it continues to maintain memberships of the multicast group. If the switch does not receive any Report messages within the aging time, it stops maintaining memberships of the multicast group.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

The switch sets the maximum response time field in the Group-Specific Query message to the configured last member query interval. Therefore, the maximum response time for Group-Specific Query messages is the same as the interval at which Group-Specific Query messages are sent.

The configuration takes effect only when all the following conditions are met:

- IGMP snooping is enabled in the BD using the **igmp-snooping enable (BD view)** command.

- The IGMP message version is set to v2 or v3 messages in the BD. (Hosts running IGMPv1 do not send Leave messages when they leave a multicast group.)

Example

Set the last member query interval in BD 123 to 4 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping lastmember-queryinterval 4
```

8.11.13 igmp-snooping learning

Function

The **igmp-snooping learning** command enables learning of multicast group memberships on an interface.

The **undo igmp-snooping learning** command disables learning of multicast group memberships on an interface.

By default, learning of multicast group memberships is enabled on an interface.

Format

igmp-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

undo igmp-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] }	Enables learning of multicast group memberships in specified VLANs. The interface must have been added to the specified VLAN. *vlan-id1* [**to** *vlan-id2*] specifies the range of VLAN IDs. ● *vlan-id1*: specifies the first VLAN ID. ● **to** *vlan-id2*: specifies the last VLAN ID. If **to** *vlan-id2* is not specified, learning of multicast group memberships is enabled only in the VLAN specified by *vlan-id1*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. The value of *vlan-id2* must be greater than the value of *vlan-id1*. The *vlan-id1* and *vlan-id2* parameters identify a range of VLANs.
all	Enables learning of multicast group memberships in all VLANs that an interface has joined.	-

Views

MultiGE interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A group member port is a user-side interface that connects to multicast group members. Group memberships can be learned dynamically or configured statically. An interface is identified as a dynamic group member port when it receives an IGMP Report message.

If users connected to an interface need to receive data of a fixed multicast group, the interface can be statically bound to the multicast group. In this case, run the

undo igmp-snooping learning command on the interface to disable learning of group memberships. This reduces the system resources used for protocol packet exchange.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

The configuration takes effect only when all the following conditions are met:

- The VLAN specified in this command has been bound to a BD, and IGMP snooping has been enabled in the BD using the **igmp-snooping enable (BD view)** command.
- The interface belongs to the specified VLANs.

If you run the **undo igmp-snooping learning** command multiple times, all the configurations take effect.

Example

Disable learning of group memberships on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] l2 binding vlan 100
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 100
[HUAWEI-GigabitEthernet0/0/1] undo igmp-snooping learning vlan 100
```

8.11.14 igmp-snooping max-response-time

Function

The **igmp-snooping max-response-time** command sets the maximum response time for IGMP General Query messages in a BD.

The **undo igmp-snooping max-response-time** command restores the default maximum response time for IGMP General Query messages in a BD.

By default, the maximum response time for IGMP General messages in a BD is 10 seconds.

Format

igmp-snooping max-response-time *max-response-time*

undo igmp-snooping max-response-time

Parameters

Parameter	Description	Value
max-response-time	Specifies the maximum response time for IGMP General Query messages.	The value is an integer that ranges from 1 to 25, in seconds. The default value is 10.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting IGMP snooping parameters helps improve the multicast forwarding performance. By setting the maximum response time for IGMP General Query messages, you can:

- Control the deadline for a host to send an IGMP Report message. When hosts are required to respond to IGMP General Query messages quickly, set a short maximum response time. To avoid congestion caused by a large number of IGMP messages sent by hosts, set a long maximum response time.
- Adjust the aging time of member ports. When the switch receives a Report message, it starts the aging timer for the member port. The aging time is calculated using the following formula: Aging time = General query count x General query interval + Maximum response time for General Query messages. The **igmp-snooping max-response-time** command sets the maximum response time. The General query count is set by the **igmp-snooping robust-count** command, and the general query interval is set by the **igmp-snooping query-interval** command.

The switch sets the maximum response time field in General Query messages to the value set by the **igmp-snooping max-response-time** command.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

Perform the following operations to improve multicast performance:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.

The maximum response time for General Query messages must be shorter than the interval at which General Query messages are sent. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the maximum response time for IGMP Query messages in BD 123 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping max-response-time 20
```

8.11.15 igmp-snooping over-vxlan enable

Function

The **igmp-snooping over-vxlan enable** command enables IGMP snooping for VXLAN.

The **undo igmp-snooping over-vxlan enable** command disables IGMP snooping for VXLAN.

By default, IGMP snooping for VXLAN is disabled.

Format

igmp-snooping over-vxlan enable

undo igmp-snooping over-vxlan enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before configuring IGMP snooping in a VXLAN, enable IGMP snooping globally and for VXLAN in the system view.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

When you run the **undo igmp-snooping over-vxlan enable** command in the system view, the system displays a message, asking you whether to disable IGMP snooping for VXLAN. If any IGMP snooping for VXLAN configuration has been made in the system, the device prompts you to delete all the IGMP snooping for VXLAN configuration.

Example

Enable IGMP snooping for VXLAN.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
```

8.11.16 igmp-snooping prompt-leave

Function

The **igmp-snooping prompt-leave** command enables the fast leave function in a BD so that member ports in the BD can fast leave multicast groups.

The **undo igmp-snooping prompt-leave** command disables the fast leave function in a BD.

By default, the fast leave function is disabled in a BD.

Format

igmp-snooping prompt-leave [**group-policy** *acl-number*]

undo igmp-snooping prompt-leave

Parameters

Parameter	Description	Value
group-policy	Specifies a multicast group policy that allows member ports to fast leave some multicast groups. Before using this parameter, create an ACL and configure filter rules in the ACL.	-

Parameter	Description	Value
acl-number	Specifies the number of an ACL that defines a range of multicast groups. A basic or advanced ACL can be used.	The value is an integer that ranges from 2000 to 3999.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The fast leave function enables the switch to delete the multicast forwarding entry of a multicast group from an interface immediately after the interface receives an IGMP Leave message for the group. This function saves bandwidth and system resources because the switch does not need to wait until the aging timer of the interface expires.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

When an interface has more than one receiver connected, enabling the fast leave function interrupts multicast traffic of the other receivers in the multicast group. It is recommended that you enable this function only on interfaces with one receiver.

The configuration takes effect only when all the following conditions are met:

- IGMP snooping is enabled in the BD using the **igmp-snooping enable (BD view)** command.
- IGMPv2 or IGMPv3 messages can be processed in the BD.
- If you do not specify **group-policy** when configuring the fast leave function, this function takes effect for all groups. To specify a group policy in the command, create an ACL and configure rules for the ACL before running the command.

Example

Allow member ports in BD 123 to fast leave all groups.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
```

```
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping prompt-leave
```

Allow member ports in BD 123 to fast leave group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule permit source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping prompt-leave group-policy 2000
```

Prevent member ports in BD 123 from fast leaving group 225.1.1.123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] acl number 2000
[HUAWEI-acl-basic-2000] rule deny source 225.1.1.123 0
[HUAWEI-acl-basic-2000] quit
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping prompt-leave group-policy 2000
```

8.11.17 igmp-snooping querier enable

Function

The **igmp-snooping querier enable** command enables the IGMP snooping querier function in a BD.

The **undo igmp-snooping querier enable** command disables the IGMP snooping querier function in a BD.

By default, the IGMP snooping querier function is disabled in a BD.

Format

igmp-snooping querier enable

undo igmp-snooping querier enable

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an IGMP-capable network, a Layer 3 multicast device functions as a querier to send IGMP Query messages and maintain group memberships on the local network segment. If the Layer 3 multicast device does not run IGMP or it uses only static multicast forwarding entries, it cannot function as a querier. In this case, you can enable IGMP snooping querier on the downstream Layer 2 device so that it acts as a querier to send IGMP Query messages.

On a Layer 2 network that has no Layer 3 devices, multicast sources are connected to Layer 2 devices. IGMP snooping querier needs to be enabled on the Layer 2 devices so that they can maintain multicast group memberships.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

Perform the following operations as required on your network:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.
- Run the **igmp-snooping robust-count** command to set the number of times Query messages are sent.

Configuration Impact

The IGMP snooping querier does not participate in IGMP querier election. However, the IGMP snooping querier on an IGMP-capable multicast network may affect the election result, because the Query messages sent by the IGMP snooping querier may have a smaller source IP address than the Query messages sent by other devices. Therefore, the IGMP snooping querier function is not recommended on an IGMP-capable multicast network.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.

Example

Enable the querier function in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping querier enable
Warning: Please confirm that no other querier is configured on the network, otherwise this command may
cause querier re-election, continue?[Y/N]:y
```

8.11.18 igmp-snooping query-interval

Function

The **igmp-snooping query-interval** command sets the general query interval in a BD, that is, the interval at which IGMP General Query messages are sent in the BD.

The **undo igmp-snooping query-interval** command restores the default general query interval in a BD.

By default, the general query interval is 125 seconds.

Format

igmp-snooping query-interval *query-interval*

undo igmp-snooping query-interval

Parameters

Parameter	Description	Value
query-interval	Specifies the interval at which IGMP General Query messages are sent.	The value is an integer that ranges from 1 to 65535, in seconds.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the general query interval, you can:

- Configure the switch to send IGMP General Query messages at intervals to maintain memberships of interfaces. When a shorter interval is configured, the switch is more sensitive to multicast membership changes, but more bandwidth and system resources are consumed.
- Change the aging time of multicast member ports.

  When receiving an IGMP Report message from a host, the switch starts the aging timer for the multicast member port. The aging time is calculated using the following formula: Aging time = IGMP robustness variable x General query interval + Maximum response time for General Query messages. The **igmp-snooping query-interval** command sets the general query interval. The general query count is set by the **igmp-snooping robust-count** command,

and the maximum response time for General Query messages is set by the **igmp-snooping max-response-time** command.

The general query interval affects the aging time of group member ports. A shorter general query interval results in a shorter aging time of group member ports and therefore a faster update speed of Layer 2 multicast entries. However, when there are many downstream users connected to a device, a short general query interval can cause flapping of multicast entries, leading to a high CPU usage on the device. Therefore, the default general query interval is recommended. If you need to change the interval to suit service deployment, set the value according to the following table.

Number of IGMP Messages Sent from Downstream Users Within Maximum Response Time	Minimum General Query Interval Reference Value (Seconds)
1 to 1024	10
1024 to 2048	20
2048 to 5120	40

NOTE

The default general query interval defined in RFC documents is 125 seconds, but some vendors define their own default general query intervals. It is recommended that all devices on a multicast network use the same general query intervals (including IGMP and IGMP snooping general query intervals). On Huawei fixed switches, the default value of the IGMP general query interval is 60 seconds, and the default value of the IGMP snooping general query interval is 125 seconds.On Huawei modular switches, the default values of the IGMP general query interval and IGMP snooping general query interval are both 60 seconds.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

- The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.
- The interval at which General Query messages are sent must be longer than the maximum response time for General Query messages. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the general query interval in BD 123 to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping query-interval 100
```

8.11.19 igmp-snooping report-suppress

Function

The **igmp-snooping report-suppress** command enables suppression of IGMP Report and Leave messages in a BD.

The **undo igmp-snooping report-suppress** command disables suppression of IGMP Report and Leave messages in a BD.

By default, IGMP Report and Leave message suppression is disabled in a BD.

Format

igmp-snooping report-suppress

undo igmp-snooping report-suppress

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Layer 2 device receives an IGMP Membership Report message (Report or Leave message) from a group member, the Layer 2 device forwards the message to the directly connected Layer 3 device. A group member host sends a Membership Report message in the following situations:

- When joining a multicast group, a host sends a Report message. When a multicast group has multiple members in a BD, the Layer 3 device receives duplicate Report messages from the member hosts.
- When receiving an IGMP General Query message, a host sends a Report message. Hosts use a timer to suppress duplicate Report messages on the same network segment. However, if the timer values on hosts are the same, the Layer 3 device can still receive duplicate Report messages.
- A host running IGMPv2 or IGMPv3 sends a Leave message when leaving a multicast group. When a multicast group has multiple members in a BD, the Layer 3 device receives duplicate Leave messages from the member hosts.

After Report message suppression is enabled on a Layer 2 device, the device forwards only one IGMP Membership Report message to the upstream device in the following scenarios:

- When the first member joins a multicast group or a host sends a Report message in response to an IGMP Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device can create or maintain the matching forwarding entry based on the Report message.
- When the last member of a multicast group leaves the group, the Layer 2 device forwards a Leave message to the upstream device. The upstream device then deletes the matching forwarding entry.

This reduces the number of IGMP messages on the network.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Configuration Impact

- The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.
- When receiving a Leave message from a group member, the device sends Group-Specific Query messages to check whether the group has other members on the network segment.
- The device can suppress duplicate Report messages even when IGMP message suppression is disabled. The default suppression time is 10 seconds. To change the suppression time, run the **igmp-snooping suppress-time** *suppress-time* command. If the *suppress-time* is set to 0, all the membership packets are forwarded immediately.
- This function cannot suppress IGMPv3 packets.

Example

Enable suppression of Report and Leave messages in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping report-suppress
```

8.11.20 igmp-snooping require-router-alert

Function

The **igmp-snooping require-router-alert** command configures the switch to drop the IGMP messages without the Router-Alert option in the IP header received from a BD.

The **undo igmp-snooping require-router-alert** command restores the default configuration.

By default, the switch does not check the Router-Alert option of IGMP messages and processes all the received IGMP messages, regardless of whether they carry the Router-Alert option in the IP header.

Format

igmp-snooping require-router-alert

undo igmp-snooping require-router-alert

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch does not check whether IGMP messages contain the Router-Alert option and sends all the IGMP messages to the upper-layer routing protocol. After the **igmp-snooping require-router-alert** command is executed, the switch checks each IGMP message for the Router-Alert option and discards those IGMP messages without this option. This improves device performance, reduces cost, and enhances security of the upper-layer routing protocol

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.

Example

Configure the switch to forward only the IGMP messages with the Router-Alert option in the IP header received from BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping require-router-alert
```

8.11.21 igmp-snooping robust-count

Function

The **igmp-snooping robust-count** command sets the IGMP robustness variable in a BD, which specifies how many times IGMP Query messages are sent.

The **undo igmp-snooping robust-count** command restores the default IGMP robustness variable in a BD.

By default, the robustness variable in a BD is 2.

Format

igmp-snooping robust-count *robust-count*

undo igmp-snooping robust-count

Parameters

Parameter	Description	Value
robust-count	Specifies the IGMP robustness variable in a BD.	The value is an integer that ranges from 2 to 5.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting IGMP snooping parameters helps improve the multicast forwarding performance. By setting the IGMP robustness variable, you can:

- Specify the number of times the querier sends a Group-Specific Query message, which prevents packet loss on the network.

  When receiving an IGMP Leave message for a multicast group, the switch sends a Group-Specific Query message a certain number of times (specified by the IGMP robustness variable) to check whether this group has any other members. If the quality of transmission links is low, increase the IGMP robustness variable.
- Change the aging time of multicast group member ports.

  When receiving an IGMP Report message from a host, the switch starts the aging timer for the member port. The aging time is calculated using the following formula: Aging time = IGMP robustness variable x General query interval + Maximum response time for General Query messages. The **igmp-snooping robust-count** command sets the general query count.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

Perform the following operations to optimize multicast service performance:

- Run the **igmp-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **igmp-snooping max-response-time** command to set the maximum response time for General Query messages.
- Run the **igmp-snooping lastmember-queryinterval** command to set the interval at which Group-Specific Query messages are sent.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.

Example

Set the IGMP robustness variable to 5 in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping robust-count 5
```

8.11.22 igmp-snooping router-aging-time

Function

The **igmp-snooping router-aging-time** command sets the aging time of dynamic router ports in a BD.

The **undo igmp-snooping router-aging-time** command restores the default aging time of dynamic router ports in a BD.

By default, the aging time of dynamic router ports in a BD is 180 seconds or equal to the holdtime value contained in PIM Hello messages.

Format

igmp-snooping router-aging-time *router-aging-time*

undo igmp-snooping router-aging-time

Parameters

Parameter	Description	Value
router-aging-time	Specifies the aging time of dynamic router ports in a BD.	The value is an integer that ranges from 1 to 1000, in seconds.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a short-term congestion occurs on the network, it takes a longer time to transmit Query messages from the IGMP querier to the switch. If a router port on the switch ages in this period, the switch does not send Report or Leave messages to router ports. As a result, multicast data forwarding may be interrupted. Therefore, set a long aging time for the router port if the network is unstable.

When a dynamic router port on the switch receives an IGMP Query message or a PIM Hello message, the switch resets the aging time of the router port.

- If the router port receives an IGMP Query message, the switch sets the remaining aging time of the interface to the configured value.
- If the router port receives a PIM Hello message, the switch sets the aging time of the interface to the holdtime value.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.

If the aging time of a router port is too short, the router port ages frequently, degrading system performance.

Example

Set the aging time of router ports in BD 123 to 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
```

```
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping router-aging-time 300
```

8.11.23 igmp-snooping router-learning (BD view)

Function

The **igmp-snooping router-learning** command enables router port learning in a BD.

The **undo igmp-snooping router-learning** command disables router port learning in a BD.

By default, router port learning is enabled in a BD.

Format

igmp-snooping router-learning

undo igmp-snooping router-learning

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A router port is located on a Layer 2 device and connects to an upstream Layer 3 device (a multicast router or Layer 3 switch). A switch running IGMP snooping considers an interface as a dynamic router port when the interface receives an IGMP General Query message with any source IP address except 0.0.0.0 or a PIM Hello message. If the switch does not need to receive Query messages or PIM Hello messages from a BD, disable router port learning in the BD. A router port provides the following functions:

- Receives multicast data from the upstream device.
- Forwards IGMP Report/Leave messages. IGMP Report/Leave messages received in a BD are forwarded only to router ports in the BD.

By default, router port learning is enabled on an interface. To prevent interfaces in a BD from becoming a router port, disable router port learning in the BD.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

The switch does not listen on IGMP Query messages in a BD after router port learning is disabled in the BD. To ensure normal multicast forwarding in the BD, run the **igmp-snooping static-router-port** command to configure a static router port.

Precautions

If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.

Example

Disable router port learning in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] undo igmp-snooping router-learning
```

8.11.24 igmp-snooping send-router-alert

Function

The **igmp-snooping send-router-alert** command configures the switch to send IGMP messages with the Router-Alert option in the IP header to a BD.

The **undo igmp-snooping send-router-alert** command configures the switch to send IGMP messages without the Router-Alert option in the IP header to a BD.

By default, the switch sends IGMP messages with the Router-Alert option in the IP header.

Format

igmp-snooping send-router-alert

undo igmp-snooping send-router-alert

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch sends IGMP messages with the Router-Alert option. If some devices in the same BD as the switch can process only the IGMP messages without the Router-Alert option, use the **undo igmp-snooping send-router-alert** command to configure the switch to send IGMP messages without the Router-Alert option.

The switch adds the Router-Alert option only to locally originated IGMP messages and does not add this option to IGMP messages received from other devices.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.

Example

Configure the switch to send IGMP messages that do not contain the Router-Alert option in the IP header to BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] undo igmp-snooping send-router-alert
```

8.11.25 igmp-snooping ssm-mapping

Function

The **igmp-snooping ssm-mapping** command configures the mapping between a multicast group and a multicast source in a BD.

The **undo igmp-snooping ssm-mapping** command deletes the mapping between a multicast group and a multicast source in a BD.

By default, no mappings between multicast groups and multicast sources exist in a BD.

Format

igmp-snooping ssm-mapping *group-address* { *group-mask* | *mask-length* } *source-address*

undo igmp-snooping ssm-mapping *group-address* { *group-mask* | *mask-length* } *source-address*

Parameters

Parameter	Description	Value
group-address	Specifies the IP address of a multicast group.	The value is in dotted decimal notation, and the value range is specified by the **igmp-snooping ssm-policy** command.
group-mask	Specifies the mask of the multicast group address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the multicast group address.	The value is an integer that ranges from 4 to 32.
source-address	Specifies the IP address of the multicast source mapped to a multicast group.	The value is in dotted decimal notation.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SSM mapping mechanism converts IGMPv1 and IGMPv2 Report messages into messages with (S, G) information. This mechanism enables hosts that do not support IGMPv3 to work with SSM. To use this mechanism, enable SSM mapping and configure mappings between a multicast group G and multicast sources such as S1, S2 on the Layer 2 device connected to user hosts. When the Layer 2 device receives IGMPv1 and IGMPv2 Report messages for a multicast group, it checks the group address of the messages. If the group address is in the SSM group range, the Layer 2 device converts the messages into one or more IGMPv3 IS_IN (S1, S2...) messages with the group address G.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

Before configuring the mapping between a multicast group and a multicast source:

- IGMP snooping has been enabled in the specified BD using the **igmp-snooping enable (BD view)** command.
- The IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the BD.
- SSM mapping has been enabled using the **igmp-snooping ssm-mapping enable** command.
- An SSM group policy has been configured using the **igmp-snooping ssm-policy** command in the BD to add the multicast group address to the SSM group range. This prerequisite is required when the multicast group address is an any-source multicast (ASM) address.

Example

Map multicast groups 238.1.1.1 through 238.1.1.255 to multicast source 10.1.1.1 in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping version 3
[HUAWEI-bd123] igmp-snooping ssm-mapping enable
[HUAWEI-bd123] igmp-snooping ssm-mapping 238.1.1.0 24 10.1.1.1
```

8.11.26 igmp-snooping ssm-mapping enable

Function

The **igmp-snooping ssm-mapping enable** command enables Source-Specific Multicast (SSM) mapping in a BD.

The **undo igmp-snooping ssm-mapping enable** command disables SSM mapping in a BD.

By default, SSM mapping is disabled in a BD.

Format

igmp-snooping ssm-mapping enable

undo igmp-snooping ssm-mapping enable

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an SSM network, hosts running IGMPv1 or IGMPv2 cannot select multicast sources when they join a multicast group. To provide SSM services for these hosts, enable SSM mapping on the Layer 2 devices connected to the hosts.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

Run the **igmp-snooping ssm-mapping** command to configure group-source mappings.

Precautions

- If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.
- SSM mapping is applicable only to the BDs where IGMP snooping can process IGMPv3 messages. To set the IGMP message version to v3, use the **igmp-snooping version** command in the BD.
- If the multicast group address is an Any-Source Multicast (ASM) address, configure an SSM group policy to add the multicast group address to the SSM group range using the **igmp-snooping ssm-policy** command in the BD view.

Example

Enable SSM mapping in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping version 3
[HUAWEI-bd123] igmp-snooping ssm-mapping enable
```

8.11.27 igmp-snooping ssm-policy

Function

The **igmp-snooping ssm-policy** command configures an SSM group policy in a BD to specify the range of SSM groups.

The **undo igmp-snooping ssm-policy** command deletes the SSM group policy from a BD.

By default, no SSM group policy is available in a BD.

Format

igmp-snooping ssm-policy *basic-acl-number*

undo igmp-snooping ssm-policy

Parameters

Parameter	Description	Value
basic-acl-number	Specifies the number of a basic ACL that defines the range of SSM groups.	The value is an integer that ranges from 2000 to 2999.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

SSM allows multicast group addresses in the range of 232.0.0.0 to 232.255.255.255. If hosts need to join multicast groups out of this range or they are allowed to join only some of multicast groups in the range, configure an SSM group range for the hosts.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

The **igmp-snooping ssm-policy** command takes effect only when the following configurations are complete:

- IGMP snooping has been enabled in the specified BD using the **igmp-snooping enable (BD view)** command.
- SSM mapping has been enabled in the specified BD using the **igmp-snooping ssm-mapping enable** command.
- If IGMPv1 or IGMPv2 packets are sent by user hosts, the IGMP message version is set to IGMPv3 using the **igmp-snooping version** command in the BD.
- The ACL has been created and configured rules for the ACL. By default, the ACL applied to an SSM group policy denies all multicast groups. Therefore, to exclude specific group addresses from the SSM group address range, use a **rule permit source any** rule with **deny** rules in the ACL. For details about ACL configuration commands, see **14.1 ACL Configuration Commands**.

Example

Specify multicast group 225.1.1.123 as an SSM group in BD 123.

```
<HUAWEI> system-view
[HUAWEI] acl number 2000

8.11.28 igmp-snooping static-group suppress-dynamic-join

Function

The **igmp-snooping static-group suppress-dynamic-join** command disables a device from forwarding IGMP Report and Leave messages that are received from a BD and contain a static group address to upstream Layer 3 devices configured with the static group address.

The **undo igmp-snooping static-group suppress-dynamic-join** command enables a device to forward IGMP Report and Leave messages that are received from a BD and contain a static group address to upstream Layer 3 devices configured with the static group address.

By default, a device forwards IGMP Report and Leave messages that are received from a BD and contain a static group address to upstream Layer 3 devices configured with the static group address.

Format

igmp-snooping static-group suppress-dynamic-join

undo igmp-snooping static-group suppress-dynamic-join

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the upstream Layer 3 multicast device is a non-Huawei device and a static group is configured on its interface connected to the device, users cannot dynamically join or leave the multicast group. You must disable the device from sending Report and Leave messages that contain static group addresses to the Layer 3 multicast device.

This function takes effect only for IGMPv1 and IGMPv2 message and is invalid for IGMPv3 messages.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.

Example

Disable a device from forwarding IGMP Report and Leave messages that are received from BD 123 and contain a static group address to upstream Layer 3 devices configured with the static group address.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping static-group suppress-dynamic-join
```

8.11.29 igmp-snooping static-router-port

Function

The **igmp-snooping static-router-port** command configures an interface as a static router port in specified BDs.

The **undo igmp-snooping static-router-port** command cancels the router port configuration in specified BDs.

By default, an interface is not a static router port.

Format

igmp-snooping static-router-port vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo igmp-snooping static-router-port vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>	Specifies VLAN IDs. This parameter specifies in which VLANs the current interface functions as a router port. - *vlan-id1* specifies the first VLAN ID. - **to** *vlan-id2* specifies the last VLAN ID. If **to** *vlan-id2* is not specified, the interface functions as a router port only in the VLAN specified by *vlan-id1*.	The value is an integer that ranges from 1 to 4094. The value of vlan-id2 must be greater than the value of vlan-id1. The vlan-id1 and vlan-id2 parameters identify a range of VLANs.
all	Cancels the static router port configuration in all VLANs on the interface.	-

Views

GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an interface needs to keep forwarding IGMP Report/Leave messages for a long time, configure the interface as a static router port.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

- This command can be configured only on access-side interfaces of a VXLAN network, but not on tunnel-side interfaces of a VXLAN network.
- The VLAN specified in this command has been created, and the interface on which the command needs to be executed has been added to the VLAN.

- The VLAN specified in this command has been bound to a BD, and IGMP snooping has been enabled in the BD.
- If you run the **igmp-snooping static-router-port** command multiple times, all the configurations take effect.

Example

Configure GE0/0/1 as a static router port.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] l2 binding vlan 100
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] igmp-snooping static-router-port vlan 100
```

8.11.30 igmp-snooping suppress-time

Function

The **igmp-snooping suppress-time** command sets the IGMP message suppression time in a BD.

The **undo igmp-snooping suppress-time** command restores the default IGMP message suppression time in a BD.

By default, the IGMP message suppression time is 10 seconds.

Format

igmp-snooping suppress-time *suppress-time*

undo igmp-snooping suppress-time

Parameters

Parameter	Description	Value
suppress-time	Specifies the IGMP message suppression time in a BD.	The value is an integer that ranges from 0 to 300, in seconds. The value 0 indicates that IGMP messages are not suppressed.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To reduce the IGMP messages sent from a Layer 2 device to the upstream Layer 3 device and protect the Layer 3 device from attacks, enable the Layer 2 device to suppress IGMP Report and IGMP Leave messages sent by hosts in a BD. After this function is enabled, the Layer 2 device processes IGMP Report and IGMP Leave messages as follows:

- After receiving an IGMP Report/Leave message and forwarding the message, the Layer 2 device does not forward the same type of messages to the router port within the suppression time.
- If the Layer 2 device receives an IGMP General Query message or Group-Specific message, it does not suppress the first IGMP Report message that responds to the General Query message. In addition, the Layer 2 device resets the suppression timer when it receives the first IGMP Report message.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Follow-up Procedure

Run the **igmp-snooping max-response-time** command to set the maximum response time for General Query messages. It is recommended that the suppression time be the same as the maximum response time for IGMP Query messages in a BD.

Precautions

The configuration takes effect only after you run the **igmp-snooping enable (BD view)** command to enable IGMP snooping in the BD.

The configured suppression time is invalid for IGMPv3 messages.

Example

Set the IGMP message suppression time in BD 123 to 15 seconds.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping suppress-time 15
```

8.11.31 igmp-snooping version

Function

The **igmp-snooping version** command configures the version of IGMP messages that IGMP snooping can process in a BD.

The **undo igmp-snooping version** command restores the default IGMP message version.

By default, the IGMP snooping version is 2, indicating that IGMP snooping can process IGMPv1 and IGMPv2 messages.

Format

igmp-snooping version *version*

undo igmp-snooping version

Parameters

Parameter	Description	Value
version	Specifies the version of IGMP messages that can be processed in a BD.	The value is an integer ranging from 1 to 3. ● 1: indicates that IGMP snooping processes only IGMPv1 messages. ● 2: indicates that IGMP snooping processes IGMPv1 and IGMPv2 messages. ● 3: indicates that IGMP snooping processes IGMPv1, IGMPv2, and IGMPv3 messages.

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The IGMP protocol maintains group memberships between Layer 3 multicast devices and hosts. IGMP has three versions: v1, v2, and v3. This command specifies the version of IGMP messages that IGMP snooping can process. Generally, configure the same version on the Layer 2 device as that on the upstream Layer 3 multicast device. If IGMP is not enabled on the Layer 3 multicast device, configure the IGMP message version on the Layer 2 device to be later than or equal to the version running on downstream hosts.

When hosts in a BD run different IGMP versions, run the **igmp-snooping version** command to enable the Layer 2 device to process IGMP messages sent from all the hosts.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

If IGMP snooping is disabled in the specified BD, the configuration succeeds but does not take effect until IGMP snooping is enabled in the BD. To enable IGMP snooping in a BD, run the **igmp-snooping enable (BD view)** command.

If the IGMP message version is changed from IGMPv3 to IGMPv2, the system deletes all the dynamic IGMP snooping entries when the aging time expires and processes static IGMP snooping entries as follows:

- Does not delete static entries that have only multicast groups and no multicast sources.
- Deletes the static entries that have both multicast groups and multicast sources. When the IGMP message version is restored to IGMPv3, the system restores these entries.

Example

Set the version of the IGMP messages that can be processed by IGMP snooping to IGMPv1 in BD 123.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] igmp-snooping version 1
```

8.11.32 l2-multicast static-group

Function

The **l2-multicast static-group** command configures static group memberships on an interface.

The **undo l2-multicast static-group** command deletes static group memberships from an interface.

By default, no static group membership is configured on an interface.

Format

Configure a single static multicast group:

l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address* **vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address* **vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Configure a series of static multicast groups:

l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address1* **to** *group-ip-address2* **vlan** *vlan-id*

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address** *group-ip-address1* **to** *group-ip-address2* **vlan** *vlan-id*

undo l2-multicast static-group [**source-address** *source-ip-address*] **group-address all vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Parameters

Parameter	Description	Value
source-address *source-ip-address*	Specifies the IP address of a multicast source.	The value of *source-ip-address* can be any Class A, Class B, or Class C address, in dotted decimal notation.
group-address *group-ip-address*	Specifies the IP address of a multicast group.	The value of *group-ip-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.
vlan { *vlan-id1* [**to** *vlan-id2*] }	Specifies the VLANs that the interface belongs to. *vlan-id1* [**to** *vlan-id2*] specifies a range of VLAN IDs. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. If **to** *vlan-id2* is not specified, the interface is bound only to the multicast group in the VLAN specified by *vlan-id1*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. *vlan-id2* must be larger than *vlan-id1*.
all	Deletes all group memberships from the interface. ● In **group-address all**, **all** indicates that the interface is removed from all multicast groups. ● In **vlan** { **all** | {*vlan-id1* [**to** *vlan-id2*] } &<1-10> }, **all** indicates that the interface is removed from multicast groups in all VLANs.	-

Parameter	Description	Value
group-ip-address1 **to** *group-ip-address2*	Configures multiple static group memberships on the interface. *group-ip-address1* and *group-ip-address2* identify a range of multicast group addresses.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation. The values of *group-ip-address1* and *group-ip-address2* must be in the same network segment (with a 24-bit mask).

Views

GE interface view, MultiGE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to dynamic multicast forwarding entries generated by Layer 2 multicast protocols, you can configure static Layer 2 multicast forwarding entries by binding interfaces to multicast groups. After an interface is statically bound to a multicast group, users connected to this interface can receive multicast data of the multicast group over a long time. The interface then becomes a static member interface.

Configuring static member interfaces has the following advantages:

- Protects the system against attacks from protocol packets.
- Reduces the network delay by directly forwarding multicast packets based on static forwarding entries.
- Prevents unregistered users from receiving multicast flows, improving information security and protecting service providers' interests.

Prerequisites

IGMP snooping has been enabled for the VXLAN network using the **igmp-snooping over-vxlan enable** command in the system view.

Precautions

This command can be configured only on access-side interfaces of a VXLAN network, but not on tunnel-side interfaces of a VXLAN network.

The configuration takes effect only when both the following conditions are met:

- The specified VLANs have been created and the interface has been added to these VLANs.
- The VLAN specified in this command has been bound to a BD, and IGMP snooping has been enabled in the BD using the **igmp-snooping enable (BD view)** command.
- The specified group address is not a reserved group address.

Example

Configure a static multicast group 224.1.1.1 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] l2 binding vlan 2
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 2
[HUAWEI-GigabitEthernet0/0/1] l2-multicast static-group group-address 224.1.1.1 vlan 2
```

Configure static multicast groups 224.1.1.1 to 224.1.1.3 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping over-vxlan enable
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] l2 binding vlan 2
[HUAWEI-bd123] igmp-snooping enable
[HUAWEI-bd123] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 2
[HUAWEI-GigabitEthernet0/0/1] l2-multicast static-group group-address 224.1.1.1 to 224.1.1.3 vlan 2
```

Delete static multicast group 224.1.1.1 from GE0/0/1 in all VLANs.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo l2-multicast static-group group-address 224.1.1.1 vlan all
```

8.11.33 multicast drop-unknown

Function

The **multicast drop-unknown** command configures the switch to drop unknown multicast flows in a BD.

The **undo multicast drop-unknown** command restores the default measure taken for unknown multicast flows.

By default, a switch broadcasts unknown multicast packets in a BD.

Format

multicast drop-unknown

undo multicast drop-unknown

Parameters

None

Views

BD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Unknown multicast flows are those that do not match any entry in the multicast forwarding table or match multicast forwarding entries with an empty outbound interface list. These flows are not requested by users. By default, a switch broadcasts unknown multicast flows. To reduce bandwidth usage, you can configure the **multicast drop-unknown** command to discard unknown multicast flows.

Configuration Impact

After the **multicast drop-unknown** command is executed, all unknown IPv4 multicast packets in a BD are dropped.

Example

Drop unknown multicast flows in BD 123.

```
<HUAWEI> system-view
[HUAWEI] bridge-domain 123
[HUAWEI-bd123] multicast drop-unknown
```

8.11.34 reset igmp-snooping group

Function

The **reset igmp-snooping group** command deletes dynamic group memberships learned by IGMP snooping.

Format

reset igmp-snooping group bridge-domain { *bd-id* [[**source-address** *source-address*] **group-address** *group-address*] | **all** }

Parameters

Parameter	Description	Value
all	Deletes IGMP dynamic group memberships of all BDs.	-

Parameter	Description	Value
bd-id	Deletes the dynamic group memberships of a specified BD.	The value is an integer that ranges from 1 to 16777215.
source-address *source-address*	Deletes the dynamic group memberships of a specified source address.	The multicast source address is a Class A, Class B, or Class C IP address on a nature network segment. The value is in dotted decimal notation.
group-address *group-address*	Deletes the dynamic group memberships of a specified group address.	The value of *group-address* ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast groups on a network change, the switch generates new Layer 2 multicast forwarding entries until the aging time of member ports expire. To enable the switch to generate new multicast forwarding entries immediately, use the **reset igmp-snooping group** command to delete existing group memberships.

Precautions

This command cannot delete static group memberships.

NOTICE

Deleting group memberships in a BD temporarily interrupts multicast forwarding in the BD. The switch generates new forwarding entries only when receiving IGMP Report messages from hosts in the BD. The hosts can then receive multicast data.

Example

Delete dynamic group memberships in BD 123.

```
<HUAWEI> reset igmp-snooping group bridge-domain 123
```

8.11.35 reset igmp-snooping statistics

Function

The **reset igmp-snooping statistics** command clears IGMP snooping statistics.

Format

reset igmp-snooping statistics bridge-domain { *bd-id* | **all** }

Parameters

Parameter	Description	Value
all	Clears IGMP snooping statistics of all BDs.	-
bd-id	Clears IGMP snooping statistics of a specified BD.	The value is an integer that ranges from 1 to 16777215.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To analyze the IGMP snooping statistics collected in a certain period, run this command to clear the previous statistics. After a while, run the **display igmp-snooping statistics** command to view the IGMP snooping statistics.

Precautions

NOTICE

The cleared IGMP snooping statistics cannot be restored.

Example

Clear IGMP snooping statistics of BD 123.

```
<HUAWEI> reset igmp-snooping statistics bridge-domain 123
Warning: If reset statistical information, the information will be unrecoverable, continue?[Y/N]:y
```

8.12 MLD Snooping Configuration Commands

8.12.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.12.2 display l2-multicast forwarding-mode

Function

The **display l2-multicast forwarding-mode** command displays the Layer 2 multicast forwarding mode in VLANs.

Format

display l2-multicast forwarding-mode vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays the Layer 2 multicast forwarding mode in a specified VLAN. If *vlan-id* is not specified, the system displays the Layer 2 multicast forwarding mode in all VLANs.	The value is an integer ranging from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After Layer 2 multicast is enabled on the switch, the switch maintains a Layer 2 multicast forwarding table. When receiving a multicast packet, the switch searches the Layer 2 multicast forwarding table for the outbound interface based on the multicast address of the packet. The switch determines the outbound interface based on the IP multicast address or IP multicast MAC address, depending on the configured Layer 2 multicast forwarding mode.

To check which Layer 2 multicast forwarding mode is used, run the **display l2-multicast forwarding-mode** command.

Precautions

You can change the forwarding mode using the **l2-multicast forwarding-mode** command.

Example

Display the Layer 2 multicast forwarding mode in all VLANs.

```
<HUAWEI> display l2-multicast forwarding-mode vlan
VLAN                Forwarding-mode        Router-discard
------------------------------------------------------------
1                   IP                     disable
2                   IP                     disable
3                   MAC                       disable
```

Table 8-136 Description of the **display l2-multicast forwarding-mode vlan** command output

Item	Description
VLAN	VLAN ID.
Forwarding-mode	Forwarding mode used in a VLAN, which can be: - MAC address-based forwarding - IP address-based forwarding This parameter can be configured using the **l2-multicast forwarding-mode** { **ip** | **mac** } command.
Router-discard	Whether the switch is configured not to forward multicast data packets to router ports in a VLAN. - enable: The switch does not forward multicast data packets to router ports in the VLAN. - disable: The switch forwards multicast data packets to router ports in the VLAN. This function is configured using the **l2-multicast router-port-discard** command.

8.12.3 display mld-snooping

Function

The **display mld-snooping** command displays the MLD snooping running parameters in a VLAN.

Format

display mld-snooping [**vlan** *vlan-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the MLD snooping running parameters in a specified VLAN. If this parameter is not specified, the system displays the MLD running parameters in all VLANs with MLD snooping configured.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can use this command to view the MLD snooping running parameters. If you run this command after configuring MLD snooping parameters, the command displays the configured parameter values.

To view the MLD snooping configuration, run the **display mld-snooping configuration** command.

Precautions

This command can display the MLD snooping configuration in a VLAN only when at least one interface in the VLAN is in Up state and MLD snooping is enabled in the VLAN.

Example

Display the MLD snooping running parameters in VLAN 3.

```
<HUAWEI> display mld-snooping vlan 3
MLD Snooping Vlan Information for VLAN 3
   MLD Snooping is Enabled
   MLD Version is Set to default 1
   MLD Query Interval is Set to default 125s
   MLD Max Response Interval is Set to default 10s
   MLD Robustness is Set to default 2
   MLD Last Member Query Interval is Set to default 1s
```

```
MLD Router Port Aging Interval is Set to 180s or holdtime in hello
MLD Filter Group-Policy is not set
MLD Prompt Leave Disable
MLD Router Alert is Not Required
MLD Send Router Alert Enable
MLD Snooping proxy is disabled
MLD Snooping report-suppress is disabled
MLD Snooping Querier is disabled
```

Table 8-137 Description of the **display mld-snooping vlan 3** command output

Item	Description
MLD Snooping Vlan Information for VLAN 3	The following information displayed is the MLD snooping running parameters in VLAN 3.
MLD Snooping is Enabled	MLD snooping is enabled in the VLAN. By default, MLD snooping is disabled in a VLAN. MLD snooping can be enabled using the **mld-snooping enable** command.
MLD Version is Set to default 1	Version of MLD messages that can be processed in the VLAN. In this example, the default version 1 is displayed. This parameter is configured using the **mld-snooping version** command.
MLD Query Interval is Set to default 125s	Interval at which MLD General Query messages are sent. In this example, the default value (125 seconds) is displayed. This parameter is configured using the **mld-snooping query-interval** command.
MLD Max Response Interval is Set to default 10s	Maximum response time for MLD General Query messages. In this example, the default value (10 seconds) is displayed. This parameter is configured using the **mld-snooping max-response-time** command.
MLD Robustness is Set to default 2	MLD robustness variable. In this example, the default value 2 is displayed. This parameter is configured using the **mld-snooping robust-count** command.
MLD Last Member Query Interval is Set to default 1s	Interval at which MLD Group-Specific Query messages are sent. In this example, the default value (1 second) is displayed. This parameter is configured using the **mld-snooping last-listener-query-interval** command.

Item	Description
MLD Router Port Aging Interval is Set to 180s or holdtime in hello	Aging time of a router port. In this example, the default value (180 seconds or the holdtime value contained in PIM Hello messages) is displayed. This parameter is configured using the **mld-snooping router-aging-time** command.
MLD Filter Group-Policy is not set	Multicast group policy. In this example, the default configuration is displayed. That is, no policy is configured. A multicast group policy is configured using the **mld-snooping group-policy (VLAN view)** command.
MLD Prompt Leave Disable	The fast leave function is disabled for interfaces in the VLAN (default configuration). The fast leave function can be enabled using the **mld-snooping prompt-leave** command.
MLD Router Alert is Not Required	The switch does not require that MLD messages received from the VLAN contain the Router-Alert option in the IP header (default configuration). The switch can be configured to discard MLD messages without the Router-Alert option using the **mld-snooping require-router-alert** command.
MLD Send Router Alert Enable	The switch sends MLD messages with the Router-Alert option to the VLAN (default configuration). The switch can be configured to send MLD messages with the Router-Alert option using the **mld-snooping send-router-alert** command.
MLD Snooping proxy is disabled	MLD snooping proxy is disabled (default configuration). MLD snooping proxy can be enabled using the **mld-snooping proxy** command.
MLD Snooping report-suppress is disabled	MLD snooping report suppression is disabled (default configuration). MLD snooping report suppression can be enabled using the **mld-snooping report-suppress** command.
MLD Snooping Querier is disabled	MLD snooping querier is disabled (default configuration). MLD snooping querier can be enabled using the **mld-snooping querier enable** command.

8.12.4 display mld-snooping configuration

Function

The **display mld-snooping configuration** command displays the MLD snooping configuration.

Format

display mld-snooping [**vlan** *vlan-id*] **configuration**

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the MLD snooping configuration in a specified VLAN. If this parameter is not specified, the system displays the MLD snooping configuration in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

This command displays only the MLD snooping configuration so that you can check whether the MLD snooping configuration made in the system is proper.

To check all MLD snooping running parameters, run the **display mld-snooping** command.

Precautions

Before running the **display mld-snooping configuration** command, run the **mld-snooping enable** commands to enable IGMP snooping globally and in the VLAN. Otherwise, no information is displayed.

Example

Display the MLD snooping configuration in all VLANs.

```
<HUAWEI> display mld-snooping configuration
 MLD Snooping Configuration for VLAN 20
```

```
  mld-snooping enable
  mld-snooping version 2
MLD Snooping Configuration for VLAN 90
  mld-snooping enable
```

Table 8-138 Description of the **display mld-snooping configuration** command output

Item	Description
MLD Snooping Configuration for VLAN	The following information displayed is the MLD snooping configuration in a specific VLAN.
mld-snooping enable	MLD snooping is enabled in the VLAN. By default, MLD snooping is disabled in a VLAN. MLD snooping can be enabled using the **mld-snooping enable** command.
mld-snooping version 2	MLDv1 and MLDv2 messages can be processed in the VLAN. By default, only MLDv1 messages can be processed in a VLAN. This parameter is configured using the **mld-snooping version** command.

8.12.5 display mld-snooping forwarding-table

Function

The **display mld-snooping forwarding-table** command displays the Layer 2 multicast forwarding table.

Format

display mld-snooping forwarding-table vlan [*vlan-id* [[**source-address** *source-ipv6-address*] **group-address** { *group-ipv6-address* | **router-group** }]]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Displays Layer 2 multicast forwarding entries in a specified VLAN. If *vlan-id* is not specified, information about the MLD snooping forwarding table of all VLANs.	The value is an integer that ranges from 1 to 4094.

Parameter	Description	Value
source-address *source-ipv6-address*	Displays the forwarding entries of a specified Layer 2 multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
group-address *group-ipv6-address*	Displays multicast forwarding entries of a specified Layer 2 multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
router-group	Displays Layer 2 multicast forwarding entries of all router ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing MLD snooping configuration, you can use the **display mld-snooping forwarding-table** command to view the MLD snooping forwarding table. This command displays statically configured and dynamically learned multicast forwarding entries.

Each entry contains the multicast source, multicast group, list of outbound interfaces, and VLAN ID of multicast data packets. When the MLD snooping version is set to v2 in a VLAN or when the MLD snooping version is set to v2, the **display mld-snooping forwarding-table** command displays (S, G) entries.

Precautions

This command displays Layer 2 multicast forwarding entries in a VLAN only when at least one interface in the VLAN is in Up state.

Example

Display multicast forwarding entries in VLAN 10.

```
<HUAWEI> display mld-snooping forwarding-table vlan 10
VLAN ID : 10, Forwarding Mode : IP
Total Group(s): 2
--------------------------------------------------------------------------------
                    (Source, Group)     Interface                Out-Vlan
--------------------------------------------------------------------------------
```

```
                  Router-port    GigabitEthernet0/0/1             10
         (*, ff1e:0:0:0:0:0:0:1)   GigabitEthernet0/0/1             10
                                   GigabitEthernet0/0/2             10
         (*, ff1e:0:0:0:0:0:0:2)   GigabitEthernet0/0/1             10
                                   GigabitEthernet0/0/2             10
-------------------------------------------------------------------------------
```

Table 8-139 Description of the **display mld-snooping forwarding-table** command output

Item	Description
VLAN ID	VLAN ID of the forwarding entries.
Forwarding Mode	Multicast forwarding mode in the VLAN, which can be: ● IP ● MAC The multicast forwarding mode is configured using the **l2-multicast forwarding-mode** command.
(Source, Group)	(S, G) entry, specifying the multicast source and multicast group. The Router-port field indicates a router port.
Interface	Outbound interface. The value **Stream** indicates an unknown flow entry.
Out-Vlan	VLAN ID of packets.
Router-port	Router port in the VLAN.
Total Group(s)	Total number of multicast forwarding entries.

8.12.6 display mld-snooping port-info

Function

The **display mld-snooping port-info** command displays information about multicast group member ports.

Format

display mld-snooping port-info [**vlan** *vlan-id* [**group-address** *ipv6-group-address*]] [**verbose**]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays multicast group member ports in a specified VLAN. If this parameter is not specified, the system displays multicast group member ports in all VLANs.	The value is an integer that ranges from 1 to 4094.
group-address *ipv6-group-address*	Displays member ports of a specified multicast group. If this parameter is not specified, the system displays member ports of all multicast groups.	The value is an IPv6 multicast address, which is a 32-digit hexadecimal number in X:X:X:X:X:X:X:X format. The first two digits are FF.
verbose	Displays detailed information about multicast group member ports. If this parameter is not specified, the system displays the summary of multicast group member ports.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

MLD snooping creates and maintains a Layer 2 multicast forwarding table by listening on MLD messages exchanged between hosts and a Layer 3 device. The **display mld-snooping port-info** command shows member ports in the Layer 2 multicast forwarding table. According to the command output, you can know which downlink interfaces have multicast users connected, and control multicast services conveniently.

Precautions

This command can display member port information only when MLD snooping is enabled globally and in a VLAN using the **mld-snooping enable** command and the VLAN is in Up state. If interfaces in the VLAN are dynamic group member ports, the command can display information about these member port information only after they receive MLD Report messages and before their aging time expires.

Example

Display information about multicast group member ports.

```
<HUAWEI> display mld-snooping port-info
-------------------------------------------------------------------------------
                    (Source, Group)   Port                         Flag
                    Flag: S:Static    D:Dynamic
-------------------------------------------------------------------------------
VLAN 10, 1 Entry(s)
              (*, ff1e:0:0:0:0:0:0:1)  GE0/0/1                     S--
                                            1 port(s) include
-------------------------------------------------------------------------------
```

Table 8-140 Description of the **display mld-snooping port-info** command output

Item	Description
(Source, Group)	An (S, G) entry, specifying the multicast source and multicast group.
Port	Multicast group member port. **include** and **exclude** indicate the multicast source filtering mode.
Flag	Type of a member port, which can be: ● **S**: static member port, which is configured using the **mld-snooping static-group** command ● **D**: dynamic member port learned through MLD

8.12.7 display mld-snooping router-port

Function

The **display mld-snooping router-port** command displays information about router ports, including static and dynamic router ports.

Format

display mld-snooping router-port [**vlan** *vlan-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the router interfaces in a specified VLAN. If this parameter is not specified, the system displays router ports in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A router port is a switch port connected to an upstream Layer 3 multicast device. Router ports can be statically configured or dynamically created after receiving an MLD Query message or a PIM Hello message. A router port receives multicast data packets from the upstream multicast device and forwards the packets to group member ports.

The **display mld-snooping router-port** command displays information about router ports, including the type, name, age, and aging time of each router port.

Precautions

This command can display router port information only when MLD snooping is enabled globally and in a VLAN using the **mld-snooping enable** command and the VLAN is in Up state.

Example

Display information about router ports.

```
<HUAWEI> display mld-snooping router-port
 Total Number of Router Port on VLAN 2 is 1
   Port Name              UpTime          Expires          Flags
   GE0/0/1                00:00:06        --               STATIC
```

Table 8-141 Description of the **display mld-snooping router-port** command output

Item	Description
Total Number of Router Port on VLAN 2 is 1	Number of router ports in VLAN 2.
Port Name	Type and number of a router port.
UpTime	Age of a router port, that is, time that elapsed since the interface became a router port.
Expires	Aging time of the router port. ● The aging time is displayed for a dynamic router port. ● For a static router interface, "--" is displayed, indicating that the interface will never age out.
Flags	Type of the router port, which can be: ● **STATIC**: static router port, which is configured using the **mld-snooping static-router-port** command ● **DYNAMIC**: dynamic router port

8.12.8 display mld-snooping forwarding-table statistics

Function

The **display mld-snooping forwarding-table statistics** command displays statistics about Layer 2 multicast forwarding entries.

Format

display mld-snooping forwarding-table statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After configuring MLD snooping, you can use this command to view statistics about Layer 2 multicast forwarding entries.

Example

Display statistics about Layer 2 multicast forwarding entries.

```
<HUAWEI> display mld-snooping forwarding-table statistics
-------------------------------------------------------------------
0 Stream entries are calculated in statistics
1 IP entries are calculated in statistics
0 MAC entries are calculated in statistics
1 VLAN entries are calculated in statistics
-------------------------------------------------------------------
```

Table 8-142 Description of the **display mld-snooping forwarding-table statistics** command output

Item	Description
Stream entries are calculated in statistics	Number of unknown stream entries in a VLAN.
IP entries are calculated in statistics	Number of entries for IP address-based forwarding in a VLAN.
MAC entries are calculated in statistics	Number of entries for MAC address-based forwarding in a VLAN.
VLAN entries are calculated in statistics	Number of entries for IP address-based and MAC address-based forwarding in a VLAN.

8.12.9 display mld-snooping statistics

Function

The **display mld-snooping statistics** command displays MLD snooping statistics.

Format

display mld-snooping statistics [**vlan** *vlan-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays MLD snooping statistics in a specified VLAN. If this parameter is not specified, the system displays MLD snooping statistics in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing MLD snooping configuration, you can use the **display mld-snooping statistics** command to view MLD snooping statistics, including the number of MLD messages sent, number of MLD messages received, number of PIM Hello messages received in each VLAN, and number of Layer 2 events that have occurred in all VLANs. Layer 2 events include changes in interface status, changes in VLAN status, changes in VLAN member interfaces (interfaces join or leave VLANs), and MSTP events. When a multicast fault occurs, the MLD snooping statistics help you identify the cause of the fault.

Precautions

This command displays information only when global MLD snooping is enabled using the **mld-snooping enable** command.

Example

Display MLD snooping statistics in all VLANs.

```
<HUAWEI> display mld-snooping statistics
MLD Snooping Events Counter
    Recv VLAN Up Event Times      1027
    Recv VLAN Down Event Times    5
    Recv VLAN Del Event Times     0
    Recv Port Up Event Times      12
    Recv Port Down Event Times    12
    Recv Port Del Event Times     0
    Recv Port Inc Event Times     3069
    Recv Port Exc Event Times     1023
    Recv MSTP Block Event Times   7
    Recv MSTP Forward Event Times 7
    Recv LINK Change Event Times  0
 MLD Snooping Packets Counter
   Statistics for VLAN 10
    Recv V1 Report 16
    Recv V2 Report 8768
    Recv V1 Query  0
    Recv V2 Query  2243
    Recv Done      215
    Recv Pim Hello 0
    Send Query(S=0) 0
    Send Query(S!=0)0
    Send General Query              0
    Send Group-Specific Query       0
    Send Group-Source-Specific Query 0
```

Display MLD snooping in VLAN 20.

```
<HUAWEI> display mld-snooping statistics vlan 20
 MLD Snooping Packets Counter
   Statistics for VLAN 20
```

```
  Recv V1 Report  0
  Recv V2 Report  0
  Recv V1 Query   0
  Recv V2 Query   0
  Recv Done       0
  Recv Pim Hello  0
  Send Query(S=0) 0
  Send Query(S!=0)0
  Send General Query              0
  Send Group-Specific Query        0
  Send Group-Source-Specific Query 0
```

Table 8-143 Description of the **display mld-snooping statistics** command output

Item	Description
MLD Snooping Events Counter	Statistics about MLD snooping events.
Recv VLAN Up Event Times	Number of VLAN Up events.
Recv VLAN Down Event Times	Number of VLAN Down events.
Recv VLAN Del Event Times	Number of VLAN deletion events.
Recv Port Up Event Times	Number of interface Up events.
Recv Port Down Event Times	Number of interface Down events.
Recv Port Del Event Times	Number of interface deletion events.
Recv Port Inc Event Times	Number of times interfaces join VLANs.
Recv Port Exc Event Times	Number of times interfaces leave VLANs.
Recv MSTP Block Event Times	Number of times static groups fail to be created on interfaces that are blocked by MSTP and cannot forward multicast packets.
Recv MSTP Forward Event Times	Number of times static groups are successfully created on interfaces that are in MSTP forwarding state and can forward multicast packets normally.
Recv LINK Change Event Times	Number of link change events.
MLD Snooping Packets Counter	Statistics about MLD snooping packets.
Statistics for VLAN 10	Packet statistics in VLAN 10.
Recv V1 Report	Number of MLDv1 Report messages received.
Recv V2 Report	Number of MLDv2 Report messages received.
Recv V1 Query	Number of MLDv1 Query messages received.
Recv V2 Query	Number of MLDv2 Query messages received.
Recv Done	Number of MLD Leave messages received.
Recv Pim Hello	Number of PIM Hello messages received.

Item	Description
Send Query(S=0)	Number of MLD Query messages sent with the source address of ::.
Send Query(S!=0)	Number of MLD Query messages with sent source addresses other than ::.
Send General Query	Number of General Query messages sent.
Send Group-Specific Query	Number of Group-Specific Query messages sent.
Send Group-Source-Specific Query	Number of Group-Source-Specific Query messages sent.

8.12.10 l2-multicast forwarding-mode

Function

The **l2-multicast forwarding-mode** command configures the forwarding mode of multicast data in a VLAN.

The **undo l2-multicast forwarding-mode** command restores the default forwarding mode of multicast data.

By default, multicast data is forwarded in a VLAN based on IP addresses.

Format

l2-multicast forwarding-mode { **ip** | **mac** }

undo l2-multicast forwarding-mode mac

Parameters

Parameter	Description	Value
ip	Forwards multicast data based on IP addresses.	-
mac	Forwards multicast data based on MAC addresses.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After Layer 2 multicast is enabled on a Layer 2 device, the Layer 2 device maintains a Layer 2 multicast forwarding table. When receiving a multicast packet, the Layer 2 device searches the Layer 2 multicast forwarding table for the outbound interface based on the multicast address of the packet. The Layer 2 device determines the outbound interface based on the IP multicast address or IP multicast MAC address, depending on the configured Layer 2 multicast forwarding mode.

Multiple multicast IP addresses may be mapped to one MAC address. If multicast data is forwarded based on MAC addresses, multicast data may be sent to the users who do not require the multicast data. To prevent this problem, use the IP address-based forwarding mode on devices with Layer 3 functions.

Configuration Impact

To set the IGMP snooping version to IGMPv3 or the MLD snooping version to MLDv2, do not change the default forwarding mode using this command.

After the multicast data forwarding mode is set to MAC address-based forwarding in a VLAN using this command, the VLAN cannot be configured as a multicast VLAN.

Precautions

- This command can only be used in VLANs with Layer 2 multicast snooping disabled. After running this command in a VLAN, enable Layer 2 multicast snooping in the VLAN for the configuration to take effect.
  - On an IPv4 network, run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
  - On an IPv6 network, run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

Example

After IGMP snooping is enabled globally, configure the switch to forward multicast data in VLAN 100 based on MAC addresses.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] l2-multicast forwarding-mode mac
[HUAWEI-vlan100] igmp-snooping enable
```

After MLD snooping is enabled globally, configure the switch to forward multicast data in VLAN 100 based on MAC addresses.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] l2-multicast forwarding-mode mac
[HUAWEI-vlan100] mld-snooping enable
```

8.12.11 l2-multicast router-port-discard

Function

The **l2-multicast router-port-discard** command disables the switch from sending multicast data to routed ports in a VLAN.

The **undo l2-multicast router-port-discard** command restores the default configuration.

By default, multicast data can be forwarded to routed ports in a VLAN.

Format

l2-multicast router-port-discard

undo l2-multicast router-port-discard

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some scenarios, multicast data does not need to be forwarded to routed ports in a VLAN. For example, when all interfaces on a switch are configured as static router ports in a VLAN, you can use this command to conserve bandwidth by preventing multicast data from being sent to these interfaces.

Precautions

This command can only be used in VLANs with Layer 2 multicast snooping disabled. After running this command in a VLAN, enable Layer 2 multicast snooping in the VLAN for the configuration to take effect.

- On an IPv4 network, run the **igmp-snooping enable (VLAN view)** command to enable IGMP snooping in the VLAN.
- On an IPv6 network, run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

Example

Disable the switch from forwarding multicast data to routed ports in VLAN 10 on an IPv4 network.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] l2-multicast router-port-discard
[HUAWEI-vlan10] igmp-snooping enable
```

Disable the switch from forwarding multicast data to routed ports in VLAN 10 on an IPv6 network.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] l2-multicast router-port-discard
[HUAWEI-vlan10] mld-snooping enable
```

8.12.12 mld-snooping enable

Function

The **mld-snooping enable** command enables MLD snooping globally or in a VLAN.

The **undo mld-snooping enable** command disables MLD snooping globally or in a VLAN.

By default, MLD snooping is disabled.

Format

System view

mld-snooping enable [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo mld-snooping enable [**vlan** { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }]

VLAN view

mld-snooping enable

undo mld-snooping enable

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Disables MLD snooping on the specified VLANs. *vlan-id1* and *vlan-id2* identify a range of VLANs. If VLAN IDs are specified, MLD snooping is enabled in the specified VLANs. If no VLAN ID is specified, MLD snooping is enabled globally.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. *vlan-id2* must be larger than *vlan-id1*.

Parameter	Description	Value
all	Disables MLD snooping on all VLANs.	-

Views

System view, VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MLD snooping runs on a Layer 2 device between a Layer 3 multicast device and hosts, and listens on multicast protocol packets exchanged between the Layer 3 device and hosts to maintain a Layer 2 multicast forwarding table. The Layer 2 device manages and controls Layer 2 multicast forwarding based on this forwarding table.

Before configuring MLD snooping, enable global MLD snooping using the **mld-snooping enable** command in the system view. Other MLD snooping configuration commands can be used only after global MLD snooping is enabled.

You can enable MLD snooping in multiple VLANs by using the **mld-snooping enable** command in the system view.

Precautions

After MLD snooping is enabled in a VLAN, IPv6 Layer 3 multicast cannot be configured on the corresponding VLANIF interface. To use the two functions simultaneously, configure IPv6 Layer 3 multicast on the VLANIF interface before enabling MLD snooping in the VLAN.

After you run the **undo mld-snooping enable** command to disable global MLD snooping, all MLD snooping configurations on the switch are deleted. After you run the **mld-snooping enable** command to enable global MLD snooping again, the switch uses the default MLD snooping configuration.

Multicast functions (Layer 2 and Layer 3 multicast) and the flow control function (configured using the **flow-control** command) are mutually exclusive on the following models: S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L1, S5735S-L, S5735S-L-M, S500, S5735-S, S5735S-S, S5735-S-I

Example

Enable global MLD snooping.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
```

Enable MLD snooping in multiple VLANs in the system view.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] mld-snooping enable vlan 2 to 10
```

Enable MLD snooping in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] mld-snooping enable
```

8.12.13 mld-snooping group-policy (interface view)

Function

The **mld-snooping group-policy** command configures an IPv6 multicast group policy on an interface.

The **undo mld-snooping group-policy** command deletes an IPv6 multicast group policy from an interface.

By default, no IPv6 multicast group policy is available on an interface, and hosts connected to the interface can join any IPv6 multicast group.

Format

mld-snooping group-policy *acl6-number* **vlan** *vlan-id* [**version** *mld-version*]

undo mld-snooping group-policy [*acl6-number*] **vlan** *vlan-id*

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of an IPv6 ACL that defines a range of multicast groups.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
vlan *vlan-id*	Applies the IPv6 multicast group policy to a specified VLAN on an interface.	The value is an integer that ranges from 1 to 4094.
version *mld-version*	Specifies an MLD version. The multicast group policy is applied only to the MLD messages of this version. If this parameter is not specified, the multicast group policy applies to all MLD messages.	The value is 1 or 2. ● 1: MLDv1 ● 2: MLDv2

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IPv6 multicast group policy controls the multicast programs that users can order on a Layer 2 device with MLD snooping enabled. When a user orders a multicast program, the user host sends a Report message, requesting to join the multicast group. When the Layer 2 device receives the message, it checks whether the multicast group matches the multicast group policy applied to the interface. If the Report messages match the filter rule, the Layer 2 device allows the hosts in the VLAN to join the group and forwards the Report messages. If the Report messages do not match the filter rule, the Layer 2 device prevents the hosts from joining the group and drops the Report messages.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configured multicast group policy takes effect only when all the following conditions are met:

- The interface has been added to the specified VLAN.
- MLD snooping is enabled in the VLAN using the **mld-snooping enable** command.
- The ACL specified in the command has been created and had filtering rules configured.
- Run the **acl** command to configure the ACL.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that the interface can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that the interface can join.

  After the **mld-snooping group-policy (interface view)** command is executed on the interface:

  - The interface filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The interface discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch,

the switch deletes these entries when the aging time of the entries expires.

- If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.

An IPv6 multicast group policy can also be configured in the VLAN view (using the **mld-snooping group-policy (VLAN view)** command) to control the multicast groups that users in the VLAN can join. An IPv6 multicast group policy configured in the interface view controls the multicast groups that users in one or more VLANs on the interface can join. If you configure multicast group policies for the same VLAN in the interface view and VLAN view, the system first uses the policy configured in the interface view and then the policy configured in the VLAN view to determine the groups that user hosts can join.

Example

Prevent hosts in VLAN 10 on GE0/0/1 from joining IPv6 multicast group ff1c::3/32.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2000
[HUAWEI-acl6-basic-2000] rule deny source ff1c::3/32
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] mld-snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 10
[HUAWEI-GigabitEthernet0/0/1] mld-snooping group-policy 2000 vlan 10
```

Allow hosts in VLAN 10 connected to GE0/0/1 to join IPv6 multicast group ff1c::3/32.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2000
[HUAWEI-acl6-basic-2000] rule permit source ff1c::3/32
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] mld-snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 10
[HUAWEI-GigabitEthernet0/0/1] mld-snooping group-policy 2000 vlan 10
```

8.12.14 mld-snooping group-policy (VLAN view)

Function

The **mld-snooping group-policy** command configures an IPv6 multicast group policy in a VLAN.

The **undo mld-snooping group-policy** command deletes an IPv6 multicast group policy from a VLAN.

By default, no IPv6 multicast group policy is available in a VLAN, and hosts in the VLAN can join any IPv6 multicast group.

Format

mld-snooping group-policy *acl6-number* [**version** *mld-version*]

undo mld-snooping group-policy

Parameters

Parameter	Description	Value
acl6-number	Specifies the number of an IPv6 ACL that defines a range of multicast groups.	The number of a basic ACL is an integer that ranges from 2000 to 2999. The number of an advanced ACL ranges from 3000 to 3999.
mld-version	Applies the multicast group policy only to the MLD messages of the specified version. If this parameter is not specified, the multicast group policy applies to all MLD messages.	The value is 1 or 2. ● 1: MLDv1 ● 2: MLDv2

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IPv6 multicast group policy controls the multicast programs that users can order on a Layer 2 device with MLD snooping enabled. When a user orders a multicast program, the user host sends a Report message, requesting to join the multicast group. When the Layer 2 device receives the message, it checks whether the multicast group matches the multicast group policy applied to the VLAN. If the Report messages match the filter rule, the Layer 2 device allows the hosts in the VLAN to join the group and forwards the Report messages. If the Report messages do not match the filter rule, the Layer 2 device prevents the hosts from joining the group and drops the Report messages.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configured multicast group policy takes effect only when both the following conditions are met:

- MLD snooping is enabled in the VLAN using the **mld-snooping enable** command.
- Run the **acl** command to configure the ACL.
  - In the basic ACL view, set **source** in the **rule** command to the range of multicast groups that the VLAN can join.
  - In the advanced ACL view, set **source** in the **rule** command to the source address that is allowed to send multicast data to the specified multicast groups, and set **destination** to the range of multicast groups that the VLAN can join.

  After the **mld-snooping group-policy (VLAN view)** command is executed on the interface:

  - The VLAN filters the received Report messages based on the ACL and maintains memberships only for the multicast groups permitted by the ACL.
  - The VLAN discards the Report messages that are denied by the ACL. If the entries of the multicast groups denied by the ACL exist on the switch, the switch deletes these entries when the aging time of the entries expires.
  - If the IGMP version is not specified, the specified ACL applies to IGMPv1, IGMPv2, and IGMPv3 hosts.

An IPv6 multicast group policy can also be configured in the interface view using the **mld-snooping group-policy (interface view)** command to control the multicast groups that users in one or more VLANs on the interface can join. An IPv6 multicast group policy configured in the interface view controls the multicast groups that users in one or more VLANs on the interface can join. If you configure multicast group policies for the same VLAN in the interface view and VLAN view, the system first uses the policy configured in the interface view and then the policy configured in the VLAN view to determine the groups that user hosts can join.

Example

Prevent hosts in VLAN 4 from joining IPv6 multicast group ff1e::1/32.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule deny source ff1e::1/32
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 4
[HUAWEI-vlan4] mld-snooping enable
[HUAWEI-vlan4] mld-snooping group-policy 2001
```

Allow hosts in VLAN 4 to join IPv6 multicast group ff1e::1/32.

```
<HUAWEI> system-view
[HUAWEI] acl ipv6 number 2001
[HUAWEI-acl6-basic-2001] rule permit source ff1e::1/32
[HUAWEI-acl6-basic-2001] quit
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 4
[HUAWEI-vlan4] mld-snooping enable
[HUAWEI-vlan4] mld-snooping group-policy 2001
```

8.12.15 mld-snooping last-listener-query-interval

Function

The **mld-snooping last-listener-query-interval** command sets the last listener query interval, that is, the interval at which Multicast-Address-Specific Query messages are sent in MLD snooping.

The **undo mld-snooping last-listener-query-interval** command restores the default interval.

By default, the last listener query interval is 1 second.

Format

mld-snooping last-listener-query-interval *query-interval*

undo mld-snooping last-listener-query-interval

Parameters

Parameter	Description	Value
query-interval	Specifies interval at which Multicast-Address-Specific Query messages are sent.	The value ranges from 1 to 5, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By configuring the last listener query interval, you can:

- Adjust the interval at which the querier sends Multicast-Address-Specific Query messages.

  When MLD snooping querier is enabled, you can use the **mld-snooping last-listener-query-interval** command to set the interval at which the querier sends Multicast-Address-Specific Query messages.
- Change the aging time of member ports.

  When a Layer 2 device receives an MLD Done message from a host, it starts an aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = Last listener query interval x Last listener query count. This command sets the last listener query interval in the formula. The last listener query count is set by the **mld-snooping robust-count** command.

If the querier receives Report messages from other hosts within the aging time, it continues to maintain the memberships of the multicast group. If the querier does not receive any Report messages within the aging time, it stops maintaining memberships of the multicast group.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The querier sets the maximum response time field in the Multicast-Address-Specific Query messages to the configured last listener query interval. Therefore, the maximum response time for Multicast-Address-Specific Query messages is the same as the interval at which Multicast-Address-Specific Query messages are sent.

The configuration takes effect only when both the following conditions are met:

- MLD snooping is enabled in the VLAN using the **mld-snooping enable** command.
- The local device is enabled to send Query messages using the **mld-snooping querier enable** or **mld-snooping proxy** command.

Example

Set the last listener query interval to 2 seconds in VLAN 4.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 4
[HUAWEI-vlan4] mld-snooping enable
[HUAWEI-vlan4] mld-snooping last-listener-query-interval 2
```

8.12.16 mld-snooping learning

Function

The **mld-snooping learning** command enables learning of multicast group memberships on an interface.

The **undo mld-snooping learning** command disables learning of multicast group memberships on an interface.

By default, learning of multicast group memberships is enabled on an interface.

Format

mld-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

undo mld-snooping learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan { *vlan-id1* [**to** *vlan-id2*] }	Enables learning of multicast group memberships in specified VLANs. The interface must have been added to the specified VLAN. *vlan-id1* [**to** *vlan-id2*] specifies the range of VLAN IDs. ● *vlan-id1*: specifies the first VLAN ID. ● *vlan-id2*: specifies the last VLAN ID. If **to** *vlan-id2* is not specified, learning of multicast group memberships is enabled only in the VLAN specified by *vlan-id1*.	The values of *vlan-id1* and *vlan-id2* are integers that range from 1 to 4094. The value of *vlan-id2* must be greater than the value of *vlan-id1*. The *vlan-id1* and *vlan-id2* parameters identify a range of VLANs.
all	Enables learning of multicast group memberships in all VLANs that an interface has joined.	-

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A group member interface is a user-side interface that connects to multicast group members. Group memberships can be learned dynamically or configured statically. After MLD snooping is enabled in a VLAN, all interfaces in the VLAN are enabled to learn forwarding entries from multicast packets. An interface is identified as a dynamic group member interface when it receives an MLD Report message.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configuration takes effect only when all the following conditions are met:

- MLD snooping is enabled in the VLAN using the **mld-snooping enable** command.
- The interface belongs to the specified VLANs.

An interface can be statically bound to a multicast group using the **mld-snooping static-group** command. Then you can run the **undo mld-snooping learning** command on the interface to disable learning of group memberships. This reduces the system resources used for protocol packet exchange.

Example

Disable learning of group memberships in VLAN 3 and VLAN 4 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] quit
[HUAWEI] vlan 4
[HUAWEI-vlan4] mld-snooping enable
[HUAWEI-vlan4] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 3 to 4
[HUAWEI-GigabitEthernet0/0/1] undo mld-snooping learning vlan 3 to 4
```

8.12.17 mld-snooping max-response-time

Function

The **mld-snooping max-response-time** command sets the maximum response time for MLD General Query messages in a VLAN.

The **undo mld-snooping max-response-time** command restores the maximum response time for MLD General Query messages in a VLAN to the default value.

By default, the maximum response time for MLD Listener Query messages is 10 seconds.

Format

mld-snooping max-response-time *max-response-time*

undo mld-snooping max-response-time

Parameters

Parameter	Description	Value
max-response-time	Specifies the maximum response time for General Query messages.	The value is an integer that ranges from 1 to 25, in seconds. The default value is 10.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting MLD snooping parameters helps improve the multicast forwarding performance on the switch. By setting the maximum response time for MLD General messages, you can:

- Control the deadline for a host to send a Report message. When hosts are required to respond to Query messages quickly, set a short maximum response time. To avoid congestion caused by a large number of Report messages sent by hosts, set a long maximum response time.
- Adjust the aging time of member ports. When the switch receives a Report message from a host, it starts the aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = General query count x General query interval + Maximum response time for General Query messages. This command sets the maximum response time in the formula. The number of times General Query messages are sent is set by the **mld-snooping robust-count** command, and the general query interval is set by the **mld-snooping query-interval** command.

The switch sets the maximum response time field in General Query messages to the value configured by the **mld-snooping max-response-time** command.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Follow-up Procedure

Perform the following operations to improve multicast performance:

- Run the **mld-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **mld-snooping last-listener-query-interval** command to set the interval at which Multicast-Address-Specific Query messages are sent.

Precautions

To make the configured maximum response time effective in a VLAN, run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

The interval at which General Query messages are sent must be longer than the maximum response time for General Query messages. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the maximum response time for General Query messages in VLAN 3 to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping max-response-time 20
```

8.12.18 mld-snooping prompt-leave

Function

The **mld-snooping prompt-leave** command enables the fast leave function in a VLAN so that member ports in the VLAN can fast leave multicast groups.

The **undo mld-snooping prompt-leave** command disables the fast leave function in a VLAN.

By default, the fast leave function is disabled in a VLAN.

Format

mld-snooping prompt-leave [**group-policy** *acl6-number*]

undo mld-snooping prompt-leave

Parameters

Parameter	Description	Value
group-policy *acl6-number*	Allows member ports to fast leave the multicast groups matching an ACL6. *acl6-number* specifies the number of an ACL6. A basic or advanced ACL6 can be used.	The value is an integer that ranges from 2000 to 3999.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The fast leave function enables the switch to delete the multicast forwarding entry of a multicast group from an interface immediately after the interface receives a Done message for the group. This function saves bandwidth and system resources because the switch does not need to wait until the aging timer of the interface expires.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

When an interface has more than one receiver connected, enabling the fast leave function interrupts multicast traffic of the other receivers in the multicast group. It is recommended that you enable this function only on interfaces with one receiver.

The configuration takes effect only when both the following conditions are met:

- MLD snooping is enabled in the VLAN using the **mld-snooping enable** command.
- If you do not specify **group-policy** when configuring the fast leave function, this function takes effect for all groups. To specify a group policy in the command, create an ACL and configure rules for the ACL before running the command. For details about ACL configuration commands, see **14.1 ACL Configuration Commands** in "Security Commands."

Example

Allow member ports in VLAN 2 to fast leave all multicast groups.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] mld-snooping enable
[HUAWEI-vlan2] mld-snooping prompt-leave
```

Allow member ports in VLAN 3 to fast leave multicast group 0xff13::0001:0002.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] acl ipv6 number 2000
[HUAWEI-acl6-basic-2000] rule permit source ff13::0001:0002 128
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping prompt-leave group-policy 2000
```

Prevent member ports in VLAN 3 from fast leaving multicast group 0xff13::0001:0002.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] acl ipv6 number 2000
```

```
[HUAWEI-acl6-basic-2000] rule deny source ff13::0001:0002 128
[HUAWEI-acl6-basic-2000] quit
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping prompt-leave group-policy 2000
```

8.12.19 mld-snooping proxy

Function

The **mld-snooping proxy** command enables Multicast Listener Discovery (MLD) snooping proxy in a VLAN.

The **undo mld-snooping proxy** command disables MLD snooping proxy in a VLAN.

By default, MLD snooping proxy is disabled in a VLAN.

Format

mld-snooping proxy

undo mld-snooping proxy

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After MLD snooping is enabled, the switch forwards Report messages to router ports and broadcasts Query messages in a VLAN. The MLD snooping proxy function allows the switch to send Query messages in place of the upstream Layer 3 device and send Report/Done messages in place of downstream hosts. This saves the bandwidth on the link between the Layer 3 device and switch. The switch sends a Report/Done message to the upstream Layer 3 device only in the following situations:

- When the first member joins a multicast group or a host sends a Report message in response to an MLD Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device can create or maintain the matching forwarding entry based on the Report message.
- When the last member of a multicast group leaves the group, the Layer 2 device forwards a Done message to the upstream device. The upstream device then deletes the matching forwarding entry.

An upstream Layer 3 device does not send Query messages as a querier when MLD is not enabled for some reasons, for example, the Layer 3 device has only static multicast groups. In this case, the switch cannot create or maintain group memberships even though MLD snooping is enabled. The MLD snooping proxy function enables the switch to send Query messages to downstream hosts. For the hosts, the switch is a querier.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Configuration Impact

If MLD is enabled on the upstream Layer 3 device, enabling the MLD snooping proxy function on the switch may affect the querier election result. This is because the General Query messages sent by the switch may have a smaller source IP address than the General Query messages sent by the Layer 3 device. Therefore, MLD snooping proxy is not recommended on an MLD-capable multicast network.

Precautions

- The configuration takes effect only after you run the **mld-snooping enable** command to enable MLD snooping in the VLAN.
- MLD snooping proxy cannot be enabled in a VLAN if the corresponding VLANIF interface has IPv6 Layer 3 multicast function (such as MLD and IPv6 PIM) enabled.
- After MLD snooping proxy is enabled in a VLAN, MLD snooping querier and MLD message suppression cannot be enabled in the VLAN.
- If multicast VLAN replication is configured on the switch, the MLD snooping proxy function cannot be enabled in user VLANs.

Example

Enable MLD snooping proxy in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] mld-snooping enable
[HUAWEI-vlan100] mld-snooping proxy
```

8.12.20 mld-snooping querier enable

Function

The **mld-snooping querier enable** command enables the MLD snooping querier in a VLAN.

The **undo mld-snooping querier enable** command disables the MLD snooping querier in a VLAN.

By default, the MLD snooping querier is disabled in a VLAN.

Format

mld-snooping querier enable

undo mld-snooping querier enable

Parameters

None.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an MLD-capable network, a Layer 3 multicast device functions as the querier to send MLD Query messages and maintain group memberships on the local network segment. If the Layer 3 multicast device does not run MLD or it uses only static multicast forwarding entries, it cannot function as a querier. You can enable MLD snooping querier on the downstream Layer 2 device so that the device can act as a querier to send MLD Query messages.

On a Layer 2 network that has no Layer 3 devices, multicast sources are connected to Layer 2 devices. MLD snooping querier needs to be enabled on the Layer 2 devices so that they can maintain multicast group memberships.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Follow-up Procedure

Perform the following operations as required on your network:

- Set the interval at which the MLD snooping querier sends General Query messages using the **mld-snooping query-interval** command.
- Set the interval at which the MLD snooping querier sends Multicast-Address-Specific Query messages using the **mld-snooping last-listener-query-interval** command.
- Set the query count using the **mld-snooping robust-count** command.

Configuration Impact

The MLD snooping querier does not participate in MLD querier election. However, the MLD snooping querier on an MLD-capable multicast network may affect the election result, because the Query messages sent by the MLD snooping querier may have a smaller source IP address than the Query messages sent by other devices. Therefore, the MLD snooping querier function is not recommended on an MLD-enabled multicast network.

Precautions

- The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.
- The MLD snooping querier function cannot be enabled in a VLAN if the corresponding VLANIF interface has IPv6 Layer 3 multicast function (such as MLD and IPv6 PIM) enabled.
- The MLD snooping querier function and MLD snooping proxy cannot be enabled in the same VLAN.
- If multicast VLAN replication is configured, the MLD snooping querier function cannot be enabled in user VLANs.

Example

Enable the MLD snooping querier in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping querier enable
```

8.12.21 mld-snooping query-interval

Function

The **mld-snooping query-interval** command sets the general query interval in a VLAN, that is, the interval at which MLD General Query messages are sent in the VLAN.

The **undo mld-snooping query-interval** command restores the default general query interval in a VLAN.

By default, MLD General Query messages are sent at an interval of 125 seconds.

Format

mld-snooping query-interval *query-interval*

undo mld-snooping query-interval

Parameters

Parameter	Description	Value
query-interval	Specifies the interval at which General Query messages are sent.	The value is an integer that ranges from 10 to 65535, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By setting the MLD general query interval, you can:

- Specify the interval at which the querier sends MLD General Query messages.

  When the querier function is enabled in a VLAN, you can use this command to set the general query interval. Then the querier sends General Query messages at the configured interval to maintain group memberships. The querier is more sensitive when it sends General Query messages at a smaller interval, but more bandwidth and resources are consumed.
- Change the aging time of member ports.

  When receiving an MLD Report message from a host, the switch starts the aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = General query count x General query interval + Maximum response time for General Query messages. The **mld-snooping query-interval** command sets the general query interval. The general query count is set by the **mld-snooping robust-count** command, and the maximum response time for General Query messages is set by the **mld-snooping max-response-time** command.

NOTE

The default general query interval defined in RFC documents is 125 seconds, but some vendors define their own default general query intervals. It is recommended that all devices on a multicast network use the same general query intervals (including MLD and MLD snooping general query intervals). On Huawei fixed switches, the default values of the MLD general query interval and MLD snooping general query interval are both 125 seconds.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.

Use this command only when the switch can send MLD Query message. The switch can send MLD Query messages only when MLD snooping proxy is enabled using the **mld-snooping proxy** command, or MLD snooping querier is enabled using the **mld-snooping querier enable** command.

The interval at which General Query messages are sent must be longer than the maximum response time for General Query messages. Otherwise, the switch will delete multicast memberships that should not be deleted.

Example

Set the general MLD query interval in VLAN 3 to 100 seconds.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping query-interval 100
```

8.12.22 mld-snooping report-suppress

Function

The **mld-snooping report-suppress** command enables suppression of MLD Report and Done messages in a VLAN.

The **undo mld-snooping report-suppress** command disables suppression of MLD Report and Done messages in a VLAN.

By default, MLD Report and Done message suppression is disabled in a VLAN.

Format

mld-snooping report-suppress

undo mld-snooping report-suppress

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a Layer 2 device receives an MLD Membership Report message (Report or Done message) from a group member, the Layer 2 device forwards the message to the directly connected Layer 3 device. A group member host sends a Membership Report message in the following situations:

- When joining a multicast group, a host sends a Report message. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Report messages from the member hosts.
- When receiving an MLD General Query message, a host sends a Report message. Hosts use a timer to suppress duplicate Report messages on the same network segment. However, if the timer values on hosts are the same, the Layer 3 device can still receive duplicate Report messages.
- When leaving a multicast group, a host sends a Done message. When a multicast group has multiple members in a VLAN, the Layer 3 device receives duplicate Done messages from the member hosts.

When MLD Report suppression is configured on the Layer 2 device, the Layer 2 device sends only one copy of MLD Report message when members join or leave a group. When the first member joins a multicast group or a host sends a Report message in response to a Query message, the Layer 2 device forwards a Report message to the upstream device. The upstream device can create or maintain the matching forwarding entry based on the Report message. When the last member of a multicast group leaves the group, the Layer 2 device forwards a Done message to the upstream device. The upstream device then deletes the matching forwarding entry. This reduces the number of MLD messages on the network.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping_enable** command.

Precautions

- The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.
- When receiving a Done message from a group member, the device sends Group-Specific Query messages to check whether the group has other members on the network segment.
- MLD Report message suppression cannot be configured in a VLAN if the corresponding VLANIF interface has IPv6 Layer 3 multicast function (such as MLD and IPv6 PIM) enabled.
- MLD snooping proxy and MLD Report message suppression cannot be configured in the same VLAN.
- If multicast VLAN replication is configured, the MLD message suppression function cannot be enabled in user VLANs.
- The switch can suppress duplicate Report messages even when MLD message suppression is disabled. The default suppression time is 10 seconds. To change the suppression time, run the **mld-snooping suppression-time** *suppression-time* command. If *suppression-time* is set to 0, all membership packets are forwarded immediately.
- This function cannot suppress MLDv2 packets.

Example

Enable suppression of Report and Done messages in VLAN 2.

```
<HUAWEI>system view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] mld-snooping enable
[HUAWEI-vlan2] mld-snooping report-suppress
```

8.12.23 mld-snooping require-router-alert

Function

The **mld-snooping require-router-alert** command configures the switch to check the received MLD messages for the Router-Alert option and discard the MLD messages without the Router-Alert option.

The **undo mld-snooping require-router-alert** command restores the default configuration.

By default, the switch processes the received MLD messages regardless of whether the messages contain the Router-Alert option.

Format

mld-snooping require-router-alert

undo mld-snooping require-router-alert

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch does not check whether MLD messages contain the Router-Alert option and sends all the MLD messages to the upper-layer routing protocol. After the **mld-snooping require-router-alert** command is executed, the switch checks each MLD message for the Router-Alert option and discards those MLD messages without this option. This improves device performance, reduces cost, and enhances security of the upper-layer routing protocol.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

If MLD snooping is disabled in the specified VLAN, the configuration succeeds but does not take effect until MLD snooping is enabled in the VLAN. To enable MLD snooping in a VLAN, run the **mld-snooping enable** command in the VLAN view.

Example

Configure the switch to accept only MLD messages with the Router-Alert option in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
```

```
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping require-router-alert
```

8.12.24 mld-snooping robust-count

Function

The **mld-snooping robust-count** command sets the MLD robustness variable in a VLAN.

The **undo mld-snooping robust-count** command restores the default MLD robustness variable in a VLAN.

By default, the MLD robustness variable in a VLAN is 2.

Format

mld-snooping robust-count *robust-count*

undo mld-snooping robust-count

Parameters

Parameter	Description	Value
robust-count	Specifies the MLD robustness variable.	The value is an integer that ranges from 2 to 5.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Setting MLD snooping parameters helps improve the multicast forwarding performance. By setting the MLD robustness variable, you can:

- Set the last listener query count for the querier to prevent packet loss.

  When receiving an MLD Done message of a multicast group, the querier sends Multicast-Address-Specific Query messages a certain number of times specified by the robustness variable to check whether the multicast has members. If the quality of transmission links is low, increase the MLD robustness variable.
- Change the aging time of member ports.

  When receiving an MLD Report message from a host, the switch starts the aging timer for the corresponding member port. The aging time is calculated using the following formula: Aging time = MLD robustness variable x General query interval + Maximum response time for General Query messages. The **mld-snooping robust-count** command sets the MLD robustness variable.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Follow-up Procedure

Perform the following operations to optimize multicast service performance:

- Run the **mld-snooping query-interval** command to set the interval at which General Query messages are sent.
- Run the **mld-snooping max-response-time** command to set the maximum response time for General Query messages.
- Run the **mld-snooping last-listener-query-interval** command to set the interval at which Multicast-Address-Specific Query messages are sent.

Precautions

The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.

Example

Set the robustness variable to 5 in VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping robust-count 5
```

8.12.25 mld-snooping router-aging-time

Function

The **mld-snooping router-aging-time** command sets the aging time of dynamic router ports in a VLAN.

The **undo mld-snooping router-aging-time** command restores the default aging time of dynamic router ports in a VLAN.

By default, the aging time of dynamic router ports in a VLAN is 180 seconds or equal to the holdtime value contained in PIM Hello messages.

Format

mld-snooping router-aging-time *router-aging-time*

undo mld-snooping router-aging-time

Parameters

Parameter	Description	Value
router-aging-time	Indicates the aging time of a router port.	The value is an integer that ranges from 1 to 1000, in seconds.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a short-term congestion occurs on a network, it takes a longer time to transmit Query messages from the MLD querier to a Layer 2 device. If a router port on the Layer 2 device ages out within this period, the Layer 2 device does not send Report or Done messages to the router port. As a result, multicast data forwarding may be interrupted. To solve this problem, set a longer aging time for router ports if the network is unstable.

When a dynamic router port receives an MLD Query message or PIM Hello message, the Layer 2 device sets the aging time of the router port as follows:

- If the router port receives an MLD Query message, the Layer 2 device sets the aging time of the router port to the configured value.
- If the router port receives a PIM Hello packet, the Layer 2 device sets the aging time of the router port to the Holdtime value contained in the PIM Hello packet.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.

If the aging time of a router port is too short, the router port ages frequently, degrading system performance.

Example

Set the aging time of router ports in VLAN 3 to 300 seconds.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
```

```
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] mld-snooping router-aging-time 300
```

8.12.26 mld-snooping router-learning

Function

The **mld-snooping router-learning** command enables router port learning in a VLAN.

The **undo mld-snooping router-learning** command disables router port learning in a VLAN.

By default, router port learning is enabled in a VLAN.

Format

mld-snooping router-learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

undo mld-snooping router-learning vlan { { *vlan-id1* [**to** *vlan-id2*] } &<1-10> | **all** }

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Enables an interface to function as a router port in the specified VLANs.	*vlan-id1* and *vlan-id2* are integers that range from 1 to 4094.
all	Enables an interface to function as a router port in all the VLANs.	-

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A router port is located on a Layer 2 device and connects to an upstream Layer 3 device (a multicast router or Layer 3 switch). A switch running MLD snooping considers an interface as a router port when the interface receives an MLD General Query message with any source IP address except 0.0.0.0 or a PIM Hello message. A router port provides the following functions:

- Receives multicast data from the upstream device.
- Forwards MLD Report/Done messages. MLD Report/Done messages received in a VLAN are forwarded only to router ports in the VLAN.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Follow-up Procedure

The switch does not listen on MLD Query or PIM Hello messages in a VLAN after router port learning is disabled in the VLAN. To ensure normal multicast forwarding in the VLAN, run the **mld-snooping static-router-port** command to configure a static router port.

Precautions

This command takes effect only when the interface has been added to the specified VLANs and MLD snooping has been enabled in these VLANs using the **mld-snooping enable** command.

Example

Disable router port learning on GE0/0/1 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] mld-snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo mld-snooping router-learning vlan 10
```

8.12.27 mld-snooping send-query enable

Function

The **mld-snooping send-query enable** command enables the switch to send MLD General Query messages to non-router ports when receiving Layer 2 topology change events.

The **undo mld-snooping send-query enable** command disables the switch from sending MLD General Query messages when receiving Layer 2 topology change events.

By default, the switch does not send MLD General Query messages when receiving Layer 2 topology change events.

Format

mld-snooping send-query enable

undo mld-snooping send-query enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the network topology changes, the switch receives a topology change event. By default, the switch does not send MLD General Query messages in this case. The network topology change triggers recalculation of the ring network protocol used (such as STP, MSTP, RRPP, SEP, and Smart Link). If the switch cannot respond to the topology change immediately, multicast data traffic cannot be switched to the new path in a timely manner. The **mld-snooping send-query enable** command enables the switch to send MLD General Query messages to update group memberships when the network topology changes. This ensures that multicast data traffic can be switched to the new transmission path.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Follow-up Procedure

This command is used on a ring network. When the ring network topology changes, the switch sends MLD General Query messages with source IPv6 address FE80::. When this address has been occupied by another device on the network, run the **mld-snooping send-query source-address** command to set the source IPv6 address to FE80::.

Precautions

Use this command only when a ring network protocol is enabled on the switch.

Example

Enable the switch to send MLD General Query messages to non-router ports when receiving Layer 2 topology change events.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] mld-snooping send-query enable
```

8.12.28 mld-snooping send-query source-address

Function

The **mld-snooping send-query source-address** command sets the source IPv6 address of MLD General Query.

The **undo mld-snooping send-query source-address** command restores source IPv6 address of MLD General Query messages.

By default, the source IPv6 address of MLD General Query messages is FE80::.

Format

mld-snooping send-query source-address *ipv6-address*

undo mld-snooping send-query source-address

Parameters

Parameter	Description	Value
ipv6-address	Specifies the source IPv6 address of MLD General Query messages.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X, and the network prefix must be FE80::/64.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A Layer 2 device sends two types of MLD General Query messages:

- MLD General Query messages sent by the querier when the querier function is enabled using the **mld-snooping proxy** or **mld-snooping querier enable** command.
- MLD General Query messages that the Layer 2 device sends after receiving Layer 2 topology change events (configured using the **mld-snooping send-query enable** command).

By default, MLD General Query messages sent from a Layer 2 device use the source IPv6 address FE80::. When this IPv6 address is used by another device on the network, run the **mld-snooping send-query source-address** command to change the source IPv6 address of MLD General Query messages.

When multiple Layer 2 devices exist on a shared network, you can set source IPv6 addresses of MLD Query messages to identify the devices. For example, when multiple devices with different performance need to participate in querier election, you must configure a different source IPv6 address of MLD Query messages for each device.

When the MLD proxy function is enabled on a device using the **mld-snooping proxy** command or the function of suppressing Report and Leave messages is enabled in a VLAN using the **mld-snooping report-suppress** command, the device sends MLD Report and MLD Done messages on behalf of downstream users, with the default source IP address of the MLD Report and MLD Done messages being FE80::. You can run this command to change the source IP address of MLD Report and MLD Done messages.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Example

Set the source IPv6 address of MLD General Query messages to FE80::1.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] mld-snooping send-query source-address fe80::1
```

8.12.29 mld-snooping send-router-alert

Function

The **mld-snooping send-router-alert** command configures the switch to send MLD messages with the Router-Alert option in the IPv6 header to a VLAN.

The **undo mld-snooping send-router-alert** command configures the switch to send MLD messages without the Router-Alert option to a VLAN.

By default, the MLD messages sent by the switch contain the Router-Alert option.

Format

mld-snooping send-router-alert

undo mld-snooping send-router-alert

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The Router-Alert option identifies the protocol messages that need to be processed by upper-layer routing protocols.

By default, the switch sends MLD messages with the Router-Alert option. If some devices in the same VLAN as the switch can process only the MLD messages without the Router-Alert option, use the **undo igmp-snooping send-router-alert** command to configure the switch to send MLD messages without the Router-Alert option.

The switch adds the Router-Alert option only to locally originated MLD messages and does not add this option to MLD messages received from other devices.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.

Example

Configure the switch to send MLD messages that do not contain the Router-Alert option in the IPv6 header to VLAN 3.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 3
[HUAWEI-vlan3] mld-snooping enable
[HUAWEI-vlan3] undo mld-snooping send-router-alert
```

8.12.30 mld-snooping static-group

Function

The **mld-snooping static-group** command configures static IPv6 group memberships on an interface.

The **undo mld-snooping static-group** command deletes the static IPv6 group memberships on an interface.

By default, no static IPv6 group membership is configured on an interface.

Format

mld-snooping static-group *group-ipv6-address* [**source** *source-ipv6-address*] **vlan** *vlan-id*

undo mld-snooping static-group { *group-ipv6-address* [**source** *source-ipv6-address*] **vlan** *vlan-id* | **all** }

Parameters

Parameter	Description	Value
group-ipv6-address	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
source *source-ipv6-address*	Specifies the IPv6 address of a multicast source.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer that ranges from 1 to 4094.
all	Deletes all static group memberships from an interface.	-

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In addition to dynamic multicast forwarding entries generated by Layer 2 multicast protocol, you can configure static Layer 2 multicast forwarding entries by binding interfaces to multicast groups. After an interface is statically bound to a multicast group, users connected to this interface can keep receiving multicast data of the multicast group for a long time. The interface then becomes a static member interface.

Configuring static member interfaces has the following advantages:

- Protects the system against attacks from protocol packets.
- Reduces the network delay by directly forwarding multicast packets based on static forwarding entries.
- Prevents unregistered users from receiving multicast flows, improving information security and protecting service providers' interests.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

The configuration takes effect only when both the following conditions are met:

- MLD snooping is enabled in the specified VLAN using the **mld-snooping enable** command.
- The specified VLAN has been created and the interface has been added to the VLAN.

Multicast group addresses starting with FFx1 or FFx2 (x is any value) cannot be configured as static multicast group addresses.

If a device is configured to forward Layer 2 multicast traffic on a network configured with MUX VLAN using the **multicast-snooping mux-vlan enable** command, the VLAN specified in the **mld-snooping static-group** command must not be a MUX VLAN (include principal VLAN and subordinate VLAN).

Example

Statically bind GE0/0/1 in VLAN 2 to multicast group ff1a::1.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 2
[HUAWEI-GigabitEthernet0/0/1] mld-snooping static-group ff1a::1 vlan 2
```

8.12.31 mld-snooping static-router-port

Function

The **mld-snooping static-router-port** command configures a static router port in a VLAN.

The **undo mld-snooping static-router-port** command deletes a static router port in a VLAN.

By default, no static router port is configured in a VLAN.

Format

mld-snooping static-router-port vlan *vlan-id*

undo mld-snooping static-router-port { **all** | **vlan** *vlan-id* }

Parameters

Parameter	Description	Value
vlan *vlan-id*	Specifies a VLAN ID. This parameter specifies in which VLAN the current interface functions as a router port.	The value is an integer that ranges from 1 to 4094.
all	Disables the interface from functioning as a router port in all VLANs.	-

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When an interface needs to keep receiving or forwarding multicast data packets for a long time, configure the interface as a static router port.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

This command takes effect only when the interface is added to the specified VLAN.

Example

Configure GE0/0/1 as a router port in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] mld-snooping static-router-port vlan 2
```

8.12.32 mld-snooping suppression-time

Function

The **mld-snooping suppression-time** command sets the MLD message suppression time.

The **undo mld-snooping suppression-time** command restores the default MLD message suppression time.

By default, the MLD message suppression time is 10 seconds.

Format

mld-snooping suppression-time *suppression-time*

undo mld-snooping suppression-time

Parameters

Parameter	Description	Value
suppression-time	Specifies the MLD message suppression time.	The value is an integer ranging from 0 to 300, in seconds. The value 0 indicates that MLD messages are not suppressed.

Views

system view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To protect an upstream Layer 3 device from attacks and reduce the load on the Layer 3 device, a Layer 2 device can suppress duplicate MLD Report messages. The default MLD message suppression time is 10 seconds. You can change the MLD message suppression time using the **mld-snooping suppression-time** command.

After you set the MLD message suppression time on a Layer 2 multicast device, the device acts as follows:

- After the Layer 2 device receives an MLD Report message, it does not forward identical MLD Report messages to the router port within the suppression time.

- If the Layer 2 device receives an MLD General Query message or Multicast-Address-Specific Query message within the suppression time, it does not suppress the first MLD Report message sent in response to the Query message. In addition, the Layer 2 device resets the suppression timer when it receives the first MLD Report message.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

You can run this command for MLDv1 Done and MLDv2 packets, but the command does not take effect.

Example

Set the MLD message suppression time to 15 seconds.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] mld-snooping suppression-time 15
```

8.12.33 mld-snooping table limit

Function

The **mld-snooping table limit** command sets the maximum number of MLD snooping entries that can be learned on an interface.

The **undo mld-snooping table limit** command cancels the limit on the number of MLD snooping entries that can be learned on an interface.

By default, the number of multicast entries that an interface can learn is not limited.

Format

mld-snooping table limit *limit* **vlan** *vlan-id*

undo mld-snooping table limit [*limit*] **vlan** *vlan-id*

Parameters

Parameter	Description	Value
limit	Specifies the maximum number of MLD snooping entries that can be learned on an interface.	The value is an integer and the value range depends on the product model: - SS1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5731-S, S5731S-S, and S5720I-SI: 1 to 1024 - S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S500, S5735-S, S5735-S-I, and S5735S-S: 1 to 1500 - S5735S-H, S5736-S, and S6720S-S: 1 to 1536 - S5731-H, S5731S-H, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S: 1 to 4096
vlan *vlan-id*	Specifies a VLAN ID.	The value is an integer ranging from 1 to 4094.

Views

Ethernet interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The maximum number of MLD snooping entries on an interface limits the number of programs that users on the interface can order. You can set this limit to control the multicast data traffic on an interface.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Configuration Impact

If the number of multicast entries on the interface already exceeds the configured threshold, the number of multicast entries on the interface does not change and the interface cannot learn new multicast entries.

Precautions

The configuration takes effect only after you run the **mld-snooping_enable** command to enable MLD snooping in the VLAN.

Example

Set the maximum number of MLD snooping entries that can be learned on GE0/0/1 in VLAN 5 to 100. (GE0/0/1 has been added to VLAN 5, and MLD snooping has been enabled globally and in VLAN 5.)

```
<HUAWEI> system view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 5
[HUAWEI-vlan5] mld-snooping enable
[HUAWEI-vlan5] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] mld-snooping table limit 100 vlan 5
```

8.12.34 mld-snooping version

Function

The **mld-snooping version** command sets the version of MLD messages that MLD snooping can process in a VLAN.

The **undo mld-snooping version** command restores the default MLD message version.

By default, MLD snooping can process only MLDv1 messages.

Format

mld-snooping version *version*

undo mld-snooping version

Parameters

Parameter	Description	Value
version	Specifies the version of MLD messages that MLD snooping can process.	The value is 1 or 2. ● 1: Only MLDv1 messages can be processed. ● 2: Both MLDv1 and MLDv2 messages can be processed.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The MLD protocol maintains group memberships between Layer 3 multicast devices and hosts. MLD has two versions: v1 and v2. This command specifies the version of MLD messages that MLD snooping can process. Generally, configure the same version on the Layer 2 device as that on the upstream Layer 3 multicast device. If MLD is not enabled on the Layer 3 multicast device, configure the MLD message version on the Layer 2 device to be later than or equal to the MLD version running on downstream hosts.

When hosts in a VLAN run different MLD versions, run the **mld-snooping version** command to enable the Layer 2 device to process MLD messages sent from all the hosts.

Prerequisites

MLD snooping has been enabled globally using the **mld-snooping enable** command.

Precautions

This command cannot be used in user VLANs of a multicast VLAN.

When the MLD snooping version is set to MLDv2:

- The switch can use only the default Layer 2 multicast forwarding mode.
- The S1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, and S6720S-S forward multicast data by looking up the forwarding table according to the VLAN ID and group address.

The configuration takes effect only after you run the **mld-snooping enable** command to enable MLD snooping in the VLAN.

Example

Set the MLD message version to 2 in VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] mld-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] mld-snooping enable
[HUAWEI-vlan2] mld-snooping version 2
```

8.12.35 multicast drop-unknown

Function

The **multicast drop-unknown** command configures the switch to discard unknown multicast flows in a VLAN.

The **undo multicast drop-unknown** command restores the default measure taken for unknown multicast flows.

The default method that a switch uses to process unknown multicast flows depends on whether Layer 2 multicast is enabled and which Layer 2 multicast forwarding mode is used.

Format

multicast drop-unknown

undo multicast drop-unknown

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Unknown multicast flows are those that do not match any entry in the multicast forwarding table or match multicast forwarding entries with an empty outbound interface list. These flows are not requested by users. When MLD snooping is disabled, the switch broadcasts unknown IPv6 multicast flows in the corresponding VLAN. After MLD snooping is enabled, the switch broadcasts unknown IPv6 multicast flows in the corresponding VLAN in MAC address-based forwarding mode. If IP address-based forwarding is used, the following switch models broadcast unknown IPv6 multicast flows in the corresponding VLAN and other switch models discard unknown IPv6 multicast flows: S5735S-H, S5736-S (except S5736-S48S4X-A, S5736-S48S4X-D, and S5736-S24UM4XC).. If a switch broadcasts unknown multicast flows in a VLAN, you can configure the switch to drop unknown multicast flows, reducing instant bandwidth usage.

Configuration Impact

After the **multicast drop-unknown** command is executed, all unknown IPv4 and IPv6 multicast packets are discarded, including the protocol packets that are transparently transmitted within the VLAN and use the reserved multicast address.

For the S2730S-S, S5735-L-I, S5735-L1, S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S, if MAC address-based forwarding is configured as the Layer 2 multicast forwarding mode and the **multicast drop-unknown** command is executed, unknown multicast packets destined for the following reserved network segments and IP address cannot be dropped: 239.0.0.0/8, 224.0.0.0/24, 224.0.1.0/24, FF0X:0:0:0:0:0:0:0/96, FF0X::DB8:0:0/96, and the IPv6 address with the last 32 bits being 0000:00XX. To drop such unknown multicast packets, configure a traffic policy.

Example

Discard unknown multicast packets in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] multicast drop-unknown
```

8.12.36 multicast-snooping mux-vlan enable

Function

The **multicast-snooping mux-vlan enable** command enables a device to transmit Layer 2 multicast traffic on a network configured with MUX VLAN.

The **undo multicast-snooping mux-vlan enable** command disables a device from transmitting Layer 2 multicast traffic on a network configured with MUX VLAN.

By default, a device is disabled from transmitting Layer 2 multicast traffic on a network configured with MUX VLAN.

Format

multicast-snooping mux-vlan enable

undo multicast-snooping mux-vlan enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, on a network configured with MUX VLAN, Layer 2 multicast traffic cannot be transmitted between the principal VLAN and subordinate VLANs. You can run the **multicast-snooping mux-vlan enable** command to enable Layer 2 multicast traffic to be transmitted on the network configured with MUX VLAN.

Precautions

If a MUX VLAN is bound to a static multicast group using the **l2-multicast static-group** or **mld-snooping static-group** command, the **multicast-snooping mux-vlan enable** command cannot be executed. You must delete the association between the MUX VLAN and static multicast group before running the **multicast-snooping mux-vlan enable** command.

After the **multicast-snooping mux-vlan enable** command is configured, you cannot run the **l2-multicast static-group** or **mld-snooping static-group** command to bind a MUX VLAN to a static multicast group.

Example

Enable a device to forward Layer 2 multicast traffic on a network configured with MUX VLAN.

```
<HUAWEI> system-view
[HUAWEI] multicast-snooping mux-vlan enable
```

8.12.37 multicast-source-deny

Function

The **multicast-source-deny** command discards multicast data packets sent from specified VLANs on an interface.

The **undo multicast-source-deny** command restores multicast forwarding in specified VLANs on an interface.

By default, multicast data packets from all VLANs are forwarded on an interface.

Format

multicast-source-deny [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

undo multicast-source-deny [**vlan** { *vlan-id1* [**to** *vlan-id2*] } &<1-10>]

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Specifies a VLAN ID. ● *vlan-id1* specifies the first VLAN ID. ● **to** *vlan-id2* specifies the last VLAN ID. *vlan-id2* must be larger than *vlan-id1*. *vlan-id1* and *vlan-id2* specify a range of VLANs. If you do not specify **to** *vlan-id2*, only one VLAN is specified.	The value is an integer that ranges from 1 to 4094.

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After you run the **multicast-source-deny** command on an interface, multicast packets received from specified VLANs are discarded on the interface. You may need to use this command in the following scenarios:

- A user-side interface receives multicast packets, but the switch does not need to receive multicast data packets from user-side interfaces. Discarding multicast data packets received on a user-side interface protects the system against forged multicast flows sent from malicious users.
- Multiple multicast sources in different VLANs are connected to the switch through a Layer 2 network, but the switch only needs to receive multicast data from some of the multicast sources.
- In some situations, for example, multicast services for users connected to an interface have expired and need to be stopped, the network administrator can use this command on this interface. Then multicast data packets from specified VLANs cannot be sent to the users.

Precautions

If you run the **multicast-source-deny** command multiple times, all the configurations take effect.

When using the **multicast-source-deny** command on an interface, ensure that the interface has been added to the specified VLANs. Otherwise, the configuration does not take effect.

This command can discard only multicast data packets that meet both of the following conditions:

- The destination MAC address is an IP multicast MAC address (IPv4 MAC address starting with 0x01-00-5e or IPv6 multicast MAC address starting with 0x3333).
- The packet encapsulation protocol is UDP.

Example

Discard multicast data packets sent from VLANs 100 to 105 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet0/0/1
[HUAWEI-GigabitEthernet0/0/1] multicast-source-deny vlan 100 to 105
```

8.12.38 reset mld-snooping group

Function

The **reset mld-snooping group** command deletes dynamic group memberships learned by MLD snooping.

Format

reset mld-snooping group { **all** | **vlan** *vlan-id* [[**source-address** *source-ipv6-address*] **group-address** *group-ipv6-address*] }

Parameters

Parameter	Description	Value
all	Deletes dynamic group memberships learned by MLD snooping.	-
vlan *vlan-id*	Deletes dynamic group memberships in a specified VLAN.	The value of *vlan-id* is an integer that ranges from 1 to 4094.
group-ipv6-address	Deletes the dynamic group memberships of a specified source address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.

Parameter	Description	Value
source-address *source-ipv6-address*	Deletes the dynamic group memberships of a specified source address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When multicast groups change on a network, the switch generates new Layer 2 multicast forwarding entries until the aging time of member ports expire. To enable the switch to generate new multicast forwarding entries immediately, use the **reset mld-snooping group** command to delete old memberships.

Precautions

NOTICE

Deleting group memberships in a VLAN temporarily interrupts multicast forwarding in the VLAN. The switch generates new forwarding entries only when receiving MLD Report messages from hosts in the VLAN. The hosts can then receive multicast data.

This command cannot delete static group memberships.

This command is valid only for VLANs with MLD snooping enabled and is invalid for a VLAN if MLD is enabled on the corresponding VLANIF interface.

Example

Delete dynamic group memberships in VLAN 2.

```
<HUAWEI> reset mld-snooping group vlan 2
```

8.12.39 reset mld-snooping statistics

Function

The **reset mld-snooping statistics** command clears MLD snooping statistics.

Format

reset mld-snooping statistics [**vlan** *vlan-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Clears the MLD snooping statistics in a specified VLAN.	The value is an integer that ranges from 1 to 4094.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To analyze the MLD snooping statistics collected in a certain period, run this command to clear the previous statistics. After a while, run the **display mld-snooping statistics** command to view the MLD snooping statistics.

Precautions

NOTICE

The cleared MLD snooping statistics cannot be restored.

Example

Clear MLD snooping statistics in VLAN 2.

```
<HUAWEI> reset mld-snooping statistics vlan 2
```

8.13 Static Multicast MAC Address Configuration Commands

8.13.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.13.2 display mac-address multicast

Function

The **display mac-address multicast** command displays the static multicast MAC address entries.

Format

display mac-address multicast [[*mac-address*] **vlan** *vlan-id*]

Parameters

Parameter	Description	Value
mac-address	Specifies a multicast MAC address. If this parameter is not specified, the system displays all the configured multicast MAC address entries.	The value is in the H-H-H format. An H contains 1 to 4 hexadecimal digits.
vlan *vlan-id*	Displays multicast MAC address entries in a specified VLAN. If this parameter is not specified, the system displays multicast MAC address entries in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command displays static multicast MAC address entries. To configure a static multicast MAC address on the device, use the **mac-address multicast interface** or **mac-address multicast** command.

Example

Display static multicast MAC address entries in VLAN 10.

```
<HUAWEI> display mac-address multicast vlan 10
-------------------------------------------------------------------------------
```

```
MAC Address         VLANID        Out-Interface              Status
---------------------------------------------------------------------------
0111-1111-2222      10            GigabitEthernet0/0/1       InActive
                                  GigabitEthernet0/0/2       InActive
                                  2 port(s)
---------------------------------------------------------------------------
Total Group(s) : 1
```

Table 8-144 Description of the **display mac-address multicast vlan 10** command output

Item	Description
MAC Address	Static multicast MAC address.
VLANID	VLAN that the interface bound to the multicast MAC address belongs to.
Out-Interface	Interface bound to the multicast MAC address.
Status	Status of a VLAN. InActive indicates that the VLAN has not been created or no physical interface is added to the VLAN after it is created. Active indicates that the VLAN has been created and has physical interfaces in it.
Total Group(s)	Total number of multicast groups.

8.13.3 display mac-address multicast total-number

Function

The **display mac-address multicast total-number** command displays the number of static multicast MAC address entries.

Format

display mac-address multicast [**vlan** *vlan-id*] **total-number**

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays the number of static multicast MAC address entries in a specified VLAN. If this parameter is not specified, the system displays the total number of static multicast MAC address entries in all VLANs.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenarios

The **display mac-address multicast total-number** displays the number of static multicast MAC address entries.

Precautions

If no static MAC address entry is configured, the total number of MAC address entries is displayed as 0. You can use the **mac-address multicast** command to statically bind a multicast MAC address to an interface or use the **mac-address multicast interface** command to statically bind a MAC address to multiple interfaces.

Example

Display the number of static multicast MAC address entries in VLAN 10.

```
<HUAWEI> display mac-address multicast vlan 10 total-number
Total number of mac-address : 3
```

Table 8-145 Description of the **display mac-address multicast vlan 10 total-number** command output

Item	Description
Total number of mac-address	Number of static multicast MAC address entries.

8.13.4 mac-address multicast

Function

The **mac-address multicast** command configures a static multicast MAC address on an interface.

The **undo mac-address multicast** command deletes the static MAC address from an interface.

By default, no static multicast MAC address is configured on an interface.

Format

mac-address multicast *mac-address* **vlan** *vlan-id*

undo mac-address multicast *mac-address* **vlan** *vlan-id*

Parameters

Parameter	Description	Value
mac-address	Specifies a multicast MAC address.	The value is in H-H-H format. An H contains 1 to 4 hexadecimal digits.
vlan *vlan-id*	Specifies the VLAN that the interface belongs to.	The value is an integer that ranges from 1 to 4094.

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the switch broadcasts received multicast packets in a VLAN, wasting network bandwidth and threatens network security. To reduce broadcasting of multicast packets, configure IGMP snooping or MLD snooping on the switch so that the switch can generate Layer 2 multicast forwarding entries. Alternatively, configure static multicast MAC address entries by binding multicast MAC addresses to interfaces.

After a static multicast MAC address is configured on an interface, multicast packets destined for this multicast MAC address are forwarded only to the interface in the specified VLAN.

Prerequisites

- The specified VLAN exists and the interfaces have been added to the VLAN.
- The switch has been configured to forward multicast data based on MAC addresses using the **l2-multicast forwarding-mode mac** command.

Precautions

- The MAC address specified in the command must be a multicast MAC address with the rightmost bit as 1 (xxxx xxx1).
- The VLAN specified in the command cannot be a super-VLAN, control VLAN of an Ethernet Ring Protection Switching (ERPS) ring, control VLAN of a Smart Ethernet Protocol (SEP) segment, or control VLAN of a Rapid Ring Protection Protocol (RRPP) ring.

- When the static multicast MAC address configured on an interface is an IPv4 multicast MAC address starting with 0x01-00-5e or an IPv6 multicast MAC address starting with 0x3333, Layer 2 multicast snooping cannot be enabled in the VLANs on the interface.
- Before configuring static multicast MAC addresses on an interface of the SS1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, and S6720S-S, set the multicast data forwarding mode to MAC address-based mode in the VLAN to which the interface belongs.

Example

Configure static MAC address 0100-2100-2200 on GE0/0/1 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] port link-type trunk
[HUAWEI-GigabitEthernet0/0/1] port trunk allow-pass vlan 10
[HUAWEI-GigabitEthernet0/0/1] mac-address multicast 0100-2100-2200 vlan 10
```

8.13.5 mac-address multicast interface

Function

Using the **mac-address multicast interface** command, you can bind a multicast MAC address to multiple interfaces. Multicast packets destined for the specified multicast MAC address are forwarded by these interfaces.

Using the **undo mac-address multicast interface** command, you can delete a MAC address from multiple interfaces.

Format

mac-address multicast *mac-address* **interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10> **vlan** *vlan-id*

undo mac-address multicast *mac-address* **interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] } &<1-10> **vlan** *vlan-id*

undo mac-address multicast { **all** | [*mac-address*] **vlan** *vlan-id* }

Parameters

Parameter	Description	Value
mac-address	Specifies a multicast MAC address.	The value is in the H-H-H format. H is a hexadecimal number of 1 to 4 digits.
interface-type interface-number1	Specifies the start interface to which the MAC address is bound.	-

Parameter	Description	Value
to *interface-type interface-number2*	Specifies the end interface to which the MAC address is bound. The specified interfaces and *interface-number2* must be greater than *interface-number1*.	-
all	Deletes the multicast MAC address from all interfaces.	-
vlan *vlan-id*	Specifies the VLAN that the interfaces belong to.	The value is an integer that ranges from 1 to 4094.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

If Layer 2 multicast snooping is disabled on a switch, the switch broadcasts all the received multicast data packets in corresponding VLANs. This wastes network bandwidth and threatens network security.

Configuring static multicast MAC addresses on interfaces can solve this problem. This configuration ensures that multicast packets destined for a multicast MAC address are forwarded only to interfaces configured with this multicast MAC address in the VLAN.

Precautions

- If you run the **mac-address multicast** command multiple times, all the configurations take effect.
- Before running this command, ensure that the VLAN has been created, and the interface where the multicast MAC address is configured has been added to this VLAN. Otherwise, configuration of this command does not take effect.
- The MAC address specified in the command must be a multicast MAC address with the rightmost bit as 1 (xxxx xxx1).
- The VLAN specified in the command cannot be a super-VLAN, control VLAN of an Ethernet Ring Protection Switching (ERPS) ring, control VLAN of a Smart Ethernet Protocol (SEP) segment, or control VLAN of a Rapid Ring Protection Protocol (RRPP) ring.

- When the static multicast MAC address configured on an interface is an IPv4 multicast MAC address starting with 0x01-00-5e or an IPv6 multicast MAC address starting with 0x3333, Layer 2 multicast snooping cannot be enabled in the VLANs on the interface.
- Before configuring static multicast MAC addresses on an interface of the SS1720GW-E, S1720GWR-E, S5720-LI, S5720S-LI, S5720I-SI, S5735S-H, S5736-S, and S6720S-S, set the multicast data forwarding mode to MAC address-based mode in the VLAN to which the interface belongs.

Example

Bind multicast MAC address 0100-2100-2200 to interfaces GE0/0/1 to GE0/0/4 in VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] mac-address multicast 0100-2100-2200 interface gigabitethernet 0/0/1 to gigabitethernet
0/0/4 vlan 10
```

8.13.6 multicast mac-ip check enable

Function

The **multicast mac-ip check enable** command enables the function of checking the mapping between multicast IP and MAC addresses.

The **undo multicast mac-ip check enable** command disables the function of checking the mapping between multicast IP and MAC addresses.

By default, the function of checking the mapping between multicast IP and MAC addresses is disabled.

Product	Support
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S	Supported

Product	Support
SS1720GW-E, S1720GWR-E, S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, and S6720S-S	Not supported The S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S check the mapping between multicast IP and MAC addresses for received packets by default. On these models, Layer 2 multicast packets with incorrect mappings cannot be forwarded based on IP addresses but can be forwarded based on MAC addresses; Layer 3 multicast packets with incorrect mappings are discarded. Other switch models do not perform this check on multicast packets. They simply forward Layer 2 multicast packets and discard Layer 3 multicast packets.

Format

multicast mac-ip check enable

undo multicast mac-ip check enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To enable multicast sources and group members to communicate, network-layer multicast services must be provided using multicast IP addresses. To enable multicast data to be correctly transmitted on the local physical network, link-layer multicast services must be provided using multicast MAC addresses. The destination address of a multicast data packet is a group with unknown members but not a specific receiver. Therefore, multicast IP addresses must be mapped to multicast MAC addresses. For the detailed mapping between multicast IP and MAC addresses, see Multicast Addresses under **IP Multicast Configuration Guide** > **Understanding IP Multicast** in the *S300, S500, S2700, S5700, and S6700 V200R023C00 Configuration Guide*.

By default, the function of checking the mapping between multicast IP and MAC addresses is disabled. Therefore, packets with incorrect mapping will be processed normally. After the mapping between multicast IP and MAC addresses is enabled, different products process multicast packets in different modes. The following table provides the details.

Table 8-146 Methods used by different products to process multicast packets

Product	How Multicast Packets Are Processed
S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S	Packets with incorrect IP and MAC address mapping are discarded.
S6720-EI, S6735-S, and S6720S-EI	If no MAC address entries are available for the packets with incorrect IP and MAC address mapping, the packets are forwarded as unknown multicast packets. For the forwarding process of unknown multicast packets, see **multicast drop-unknown**.

Example

Enable the function of checking the mapping between multicast IP and MAC addresses.

```
<HUAWEI> system-view
[HUAWEI] multicast mac-ip check enable
```

8.14 Multicast VLAN Configuration Commands

8.14.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.14.2 display l2-multicast-bind

Function

The **display l2-multicast-bind** command displays bindings between multicast VLANs and user VLANs.

Format

display l2-multicast-bind [**mvlan** *vlan-id*]

Parameters

Parameter	Description	Value
mvlan *vlan-id*	Displays the binding between user VLANs and a specified multicast VLAN. *vlan-id* specifies a multicast VLAN ID.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After configuring multicast VLAN replication on an interface, you can run the **display l2-multicast-bind** command to view the configuration. This command can be used for fault location when multicast VLAN replication fails.

Precautions

If there is no binding between any multicast VLAN and user VLAN, the **display l2-multicast-bind** command does not display any information.

Example

Display bindings between user VLANs and multicast VLAN 400.

```
<HUAWEI> display l2-multicast-bind mvlan 400
 ------------------------------------------------------------------
 Port                         Startvlan        Endvlan        Mvlan
 ------------------------------------------------------------------
 GigabitEthernet0/0/1               222             --          400
 ------------------------------------------------------------------
 Total Table(s) : 1
```

Table 8-147 Description of the **display l2-multicast-bind** command output

Item	Description
Port	Interface where user VLANs are bound to the multicast VLAN.
Startvlan	First user VLAN ID.
Endvlan	Last user VLAN ID. If "--" is displayed, only one user VLAN is bound to the multicast VLAN.

Item	Description
Mvlan	Multicast VLAN ID.
Total Table(s)	Total number of multicast VLAN binding entries.

8.14.3 display multicast static-flow

Function

The **display multicast static-flow** command displays the configuration of the static flow in a multicast VLAN.

Format

display multicast static-flow [**vlan** *vlan-id*]

Parameters

Parameter	Description	Value
vlan *vlan-id*	Displays static multicast flows in a specified VLAN.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When a static flow is configured in a multicast VLAN, you can run the **display multicast static-flow** command to view the mapping between the multicast VLAN and (S, G) entry.

Example

Display the static flow configured in multicast VLAN 10.

```
<HUAWEI> display multicast static-flow vlan 10
---------------------------------------------------------
   Vlan           (Source, Group)
---------------------------------------------------------
    10            (*,  225.0.0.1)
---------------------------------------------------------
Total Table(s): 1
```

Table 8-148 Description of the **display multicast static-flow** command output

Item	Description
Vlan	VLAN where the static flow is configured.
(Source, Group)	(S, G) entry, specifying the multicast source and multicast group.
Total Table(s)	Total number of static multicast flows.

8.14.4 display multicast-vlan

Function

The **display multicast-vlan** command displays information about multicast VLANs.

Format

display multicast-vlan vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Specifies the ID of a multicast VLAN. - If *vlan-id* is specified, detailed information about the specified multicast VLAN and its user VLANs is displayed. - If *vlan-id* is not specified, brief information about all the multicast VLANs is displayed.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display multicast-vlan** command displays configuration of multicast VLANs. You can run the **display multicast-vlan** command to check whether any user VLAN is bound to the multicast VLAN and whether IGMP snooping or MLD snooping is enabled in the multicast VLAN and user VLAN. This command can be used to locate faults when the multicast service fails.

Example

Display information about all multicast VLANs and user VLANs.

```
<HUAWEI> display multicast-vlan vlan
 Total multicast vlan   2
 multicast-vlan     user-vlan number     snooping-state
 ----------------------------------------------------------------
 5                1                    IGMP Enable /MLD Disable
 7                2                    IGMP Enable /MLD Disable
```

Table 8-149 Description of the **display multicast-vlan vlan** command output

Item	Description
Total multicast vlan	Number of multicast VLANs.
multicast-vlan	ID of a multicast VLAN.
user-vlan number	Number of user VLANs bound to a multicast VLAN.
snooping-state	Whether IGMP snooping and MLD snooping is enabled in a multicast VLAN.

Display information about multicast VLAN 7 and its user VLANs.

```
<HUAWEI> display multicast-vlan vlan 7
 Multicast-vlan         : 7
 User-vlan Number       : 2
 IGMP snooping state    : Enable
 MLD  snooping state    : Disable
 User-vlan              Snooping-state
 Prune-source-port state: Disable
 -------------------------------------
 8                      IGMP Enable /MLD Disable
 9                      IGMP Enable /MLD Disable
```

Table 8-150 Description of the **display multicast-vlan vlan** *vlan-id* command output

Item	Description
Multicast-vlan	ID of a multicast VLAN.
User-vlan Number	Number of user VLANs bound to a multicast VLAN.
IGMP snooping state	Whether IGMP snooping is enabled in a multicast VLAN.

Item	Description
MLD snooping state	Whether MLD snooping is enabled in a multicast VLAN.
User-vlan	ID of a user VLAN.
Prune-source-port state	Whether permits Query messages received in a multicast VLAN to be sent back to from the upstream interface through user VLANs.
Snooping-state	Whether IGMP snooping and MLD snooping are enabled in a user VLAN.

8.14.5 display user-vlan

Function

Using the **display user-vlan** command, you can view information about a user VLAN.

Format

display user-vlan vlan [*vlan-id*]

Parameters

Parameter	Description	Value
vlan [*vlan-id*]	Specifies the ID of a user VLAN. If *vlan-id* is specified, information about the specified user VLAN is displayed. If *vlan-id* is not specified, information about all user VLANs is displayed.	The value is an integer that ranges from 1 to 4094.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After binding a user VLAN to a multicast VLAN, you can run the **display user-vlan** command to verify the configuration and check whether IGMP snooping or MLD

Snooping is enabled. This command can be used to locate faults when the multicast service fails.

Example

Display information about all user VLANs.

```
<HUAWEI> display user-vlan vlan
 Total user vlan   3
 user-vlan  snooping-state            multicast-vlan  snooping-state
 ------------------------------------------------------------------------------
 8          IGMP Disable/MLD Disable  7               IGMP Enable /MLD Disable
 9          IGMP Disable/MLD Disable  7               IGMP Enable /MLD Disable
 11         IGMP Disable/MLD Disable  7               IGMP Enable /MLD Disable
```

Display information about user VLAN 8.

```
<HUAWEI> display user-vlan vlan 8
 user-vlan  snooping-state            multicast-vlan
 --------------------------------------------------
 8         IGMP Disable/MLD Disable   7
```

Table 8-151 Description of the **display user-vlan** command output

Item	Description
Total user vlan	Number of user VLANs.
user-vlan	ID of a user VLAN.
multicast-vlan	ID of the multicast VLAN that a user VLAN belongs to.
snooping-state	Whether IGMP snooping and MLD snooping are enabled in a multicast VLAN or a user VLAN.

8.14.6 l2-multicast-bind vlan

Function

The **l2-multicast-bind vlan** command binds user VLANs to a multicast VLAN on an interface.

The **undo l2-multicast-bind vlan** command restores the default setting.

By default, no user VLAN is bound to a multicast VLAN on an interface.

Format

l2-multicast-bind vlan *vlan-id1* [**to** *vlan-id2*] **mvlan** *mvlan-id*

undo l2-multicast-bind vlan { *vlan-id1* [**to** *vlan-id2*] | **all** }

Parameters

Parameter	Description	Value
vlan *vlan-id1* [**to** *vlan-id2*]	Specifies the ID of a user VLAN.	The value is an integer that ranges from 1 to 4094.
mvlan *mvlan-id*	Specifies the ID of a multicast VLAN.	The value is an integer that ranges from 1 to 4094.
all	Unbinds all user VLANs from the multicast VLAN on an interface.	-

Views

MultiGE interface view, Ethernet interface view, GE interface view, XGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, port group view, Eth-Trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A carrier provides the multicast service for multiple Internet service providers (ISPs), and each ISP is assigned a multicast VLAN to isolate multicast data and routes of different ISPs. Users connected to different user-side interfaces of the switch may order multicast services of different ISPs but belong to the same user VLAN. If multicast replication based on user VLANs is used in this case, users may receive multicast data they do not require. This affects the income of the ISPs.

To solve this problem, bind the user VLAN to multicast VLANs of the ISPs whose services are ordered on user-side interfaces. Then the user-side interfaces accept only the data from multicast VLANs of the specified ISPs.

Prerequisites

IGMP snooping has been enabled using the **igmp-snooping enable (VLAN view)** command on the multicast VLAN.

Precautions

Before running this command, run the **vlan** command to create the corresponding user VLAN and multicast VLAN. Otherwise, configuration of this command does not take effect.

On an interface, a user VLAN can be bound to only one multicast VLAN.

Currently, the binding of user VLANs to a multicast VLAN on an interface is only supported on IPv4 networks.

Example

Bind user VLAN100 to multicast VLAN20 on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 100
[HUAWEI-vlan100] igmp-snooping enable
[HUAWEI-vlan100] quit
[HUAWEI] vlan 20
[HUAWEI-vlan20] igmp-snooping enable
[HUAWEI-vlan20] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] l2-multicast-bind vlan 100 mvlan 20
```

8.14.7 l2-multicast user-vlan limit

Function

The **l2-multicast user-vlan limit** command sets the number of user VLANs that are allowed.

The **undo l2-multicast user-vlan limit** command restores the default configuration.

By default, 512 user VLANs can be configured.

Format

l2-multicast user-vlan limit *number*

undo l2-multicast user-vlan limit

NOTE

This command is supported only on the S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5735-S, S500, S5735-S-I, and S5735S-S.

Parameters

Parameter	Description	Value
number	Specifies the number of user VLANs that can be configured.	The value is an integer in the range from 1 to 1000.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

User VLANs and the Layer 3 VLANIF service share resources. Too large a number of user VLANs will affect the specification of VLANIF interfaces. You can run the **l2-multicast user-vlan limit** command to adjust the number of user VLANs that can be configured based on your service requirements.

Example

Set the number of user VLANs that can be configured to 300.

```
<HUAWEI> system-view
[HUAWEI] l2-multicast user-vlan limit 300
```

8.14.8 multicast flow-trigger enable

Function

The **multicast flow-trigger enable** command enables the triggering of multicast flows in a VLAN.

The **undo multicast flow-trigger enable** command disables the triggering of multicast flows in a VLAN.

By default, the triggering of multicast flows is disabled in VLANs.

Format

multicast flow-trigger enable

undo multicast flow-trigger enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user VLAN (for example, UVLAN) needs to join multiple multicast VLANs (for example, MVLAN1 to MVLAN*n*), you need to perform the following operations to ensure that N-to-N mappings based on {UVLAN, Source, Group} can be created between UVLANs and MVLANs and multicast entries can be generated when UVLANs send VOD requests to the MVLANs:

1. Run the **multicast flow-trigger enable** command in the UVLAN to enable triggering of multicast flows.

2. Run the **multicast-vlan user-vlan** command in each MVLAN to configure mappings between the UVLAN and MVLANs.
3. Run the **multicast static-flow** command in each MVLAN to configure a static flow.

Precautions

The **multicast flow-trigger enable** and **multicast-vlan enable** commands cannot be configured in the same VLAN.

Example

Enable the triggering of multicast flows in VLAN 100.

```
<HUAWEI> system-view
[HUAWEI] vlan 100
[HUAWEI-vlan100] multicast flow-trigger enable
```

8.14.9 multicast static-flow

Function

The **multicast static-flow** command configures static flows in a multicast VLAN.

The **undo multicast static-flow** command deletes static flows from a multicast VLAN.

By default, no static flow is configured in multicast VLANs.

Format

multicast static-flow { *ipv4-group-address1* [**to** *ipv4-group-address2*] [**source** *ipv4-source-address*] | **ipv6** *ipv6-group-address1* [**to** *ipv6-group-address2*] [**source** *ipv6-source-address*] }

undo multicast static-flow { *ipv4-group-address1* [**to** *ipv4-group-address2*] [**source** *ipv4-source-address*] | **ipv6** *ipv6-group-address1* [**to** *ipv6-group-address2*] [**source** *ipv6-source-address*] | **all** }

Parameters

Parameter	Description	Value
ipv4-group-address1 [**to** *ipv4-group-address2*]	Specifies the IPv4 address of a multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255, in dotted decimal notation.
source *ipv4-source-address*	Specifies the source IPv4 address.	The value is in dotted decimal notation.

Parameter	Description	Value
ipv6 *ipv6-group-address1* [**to** *ipv6-group-address2*]	Specifies the IPv6 address of a multicast group.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. An IPv6 multicast address starts with FF.
source *ipv6-source-address*	Specifies the source IPv6 address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
all	Deletes all static multicast flows in a VLAN.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a user VLAN (for example, UVLAN) needs to join multiple multicast VLANs (for example, MVLAN1 to MVLANn), you need to run the **multicast flow-trigger enable** command in the view of user VLAN to enable the triggering of multicast flows, and then configure static flows in each multicast VLAN. In this manner, the many-to-many mapping based on {UVLAN, Source, Group} is set up between user VLANs and multicast VLANs.

Precautions

Any two static flows in a multicast VLAN cannot be the same. Note that flows of the same multicast group with different source IP addresses are considered as different flows.

When you use the **multicast static-flow** { *ipv4-group-address1* **to** *ipv4-group-address2* | *ipv6-group-address1* **to** *ipv6-group-address2* } command to configure static multicast flows in batches, a maximum of 256 flows can be configured each time. When configuring an IPv4 multicast address segment, ensure that the consecutive addresses are in a multicast address segment with a 24-bit mask. When configuring an IPv6 multicast address segment, ensure that the consecutive addresses are in a multicast address segment with a 120-bit prefix. For example, the **multicast static-flow 225.0.0.255 to 225.0.1.1** command will not take effect because the addresses belong to two different segments: 225.0.0.0/24 and 225.0.1.0/24.

Example

Configure a static flow with the source address being 10.0.0.1 and group address being 232.0.0.1 in multicast VLAN 10.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] igmp-snooping version 3
[HUAWEI-vlan10] multicast-vlan enable
[HUAWEI-vlan10] multicast static-flow 232.0.0.1 source 10.0.0.1
```

Configure a static flow with the source address being FE80::1 and group address being FF23::123 in multicast VLAN 20.

```
<HUAWEI> system-view
[HUAWEI] vlan 20
[HUAWEI-vlan20] mld-snooping enable
[HUAWEI-vlan20] mld-snooping version 2
[HUAWEI-vlan20] multicast-vlan enable
[HUAWEI-vlan20] multicast static-flow ipv6 ff23::123 source fe80::1
```

8.14.10 multicast-vlan enable

Function

The **multicast-vlan enable** command configures a VLAN as a multicast VLAN.

The **undo multicast-vlan enable** command restores the default configuration.

By default, a VLAN is a common VLAN.

Format

multicast-vlan enable

undo multicast-vlan enable

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Generally, a switch needs to replicate multicast packets for each VLAN when users in different VLANs need to receive multicast data from the same multicast source. If a multicast VLAN is configured and the VLANs that users belong to are configured as the user VLANs of the multicast VLAN, the switch only needs to replicate the multicast data for the multicast VLAN. Multicast data is then replicated to the user VLANs by the multicast VLAN. This reduces load on the upstream router and separates the multicast source from the users.

Prerequisites

IGMP snooping or MLD snooping has been enabled in a VLAN using the **igmp-snooping enable (VLAN view)** or **mld-snooping enable** command.

Follow-up Procedure

Run the **multicast-vlan user-vlan** command to bind user VLANs to the multicast VLAN.

Precautions

- A multicast VLAN cannot be configured as a user VLAN. A user VLAN cannot be configured as a multicast VLAN.
- If MAC address-based forwarding is configured using the **l2-multicast forwarding-mode** command in a VLAN, the VLAN cannot be configured as a multicast VLAN.
- Before running the **undo multicast-vlan enable** command in a multicast VLAN, delete all the user VLANs from the multicast VLAN. If OAM is bound to the multicast VLAN, unbind OAM from the multicast VLAN first.
- The **multicast flow-trigger enable** and **multicast-vlan enable** commands cannot be configured in the same VLAN.

Example

Configure VLAN 2 as a multicast VLAN.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] multicast-vlan enable
```

8.14.11 multicast-vlan send-query prune-source-port

Function

The **multicast-vlan send-query prune-source-port** command prevents the upstream interface from sending Query messages received in a multicast VLAN back to upstream devices through user VLANs.

The **undo multicast-vlan send-query prune-source-port** command restores the default configuration.

By default, an upstream interface can send Query messages received in a multicast VLAN back to upstream devices through user VLANs.

Format

multicast-vlan send-query prune-source-port

undo multicast-vlan send-query prune-source-port

Parameters

None

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In multicast VLAN application, an upstream interface usually belongs to a multicast VLAN and user VLANs bound to the multicast VLAN. By default, an upstream interface can send Query messages received in a multicast VLAN back to upstream devices through user VLANs.

To prevent Query messages from being sent back to upstream devices, run this command in the multicast VLAN.

Prerequisites

The multicast VLAN function has been enabled using the **multicast-vlan enable** command in the VLAN view.

Example

Prevent the upstream interface from sending Query messages received in multicast VLAN 10 back to upstream devices through user VLANs.

```
<HUAWEI> system-view
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] multicast-vlan enable
[HUAWEI-vlan10] multicast-vlan send-query prune-source-port
```

8.14.12 multicast-vlan user-vlan

Function

The **multicast-vlan user-vlan** command binds user VLANs to a multicast VLAN.

The **undo multicast-vlan user-vlan** command unbinds user VLANs from a multicast VLAN.

By default, a multicast VLAN does not have any user VLAN.

Format

multicast-vlan user-vlan { *vlan-id1* [**to** *vlan-id2*] } &<1-10>

undo multicast-vlan user-vlan { **all** | { *vlan-id1* [**to** *vlan-id2*] } &<1-10> }

Parameters

Parameter	Description	Value
vlan-id1 [**to** *vlan-id2*]	Specifies IDs of the user VLANs. - *vlan-id1* specifies the start VLAN ID. - *vlan-id2* specifies the end VLAN ID. The value of *vlan-id2* must be greater than the value of *vlan-id1*. The *vlan-id1* and *vlan-id2* parameters identify a range of VLANs. If **to** *vlan-id2* is not specified, only one user VLAN is bound to the multicast VLAN.	The settings of the parameters are as follows: - The value of *vlan-id1* is an integer that ranges from 1 to 4094. - The value of *vlan-id2* is an integer that ranges from 1 to 4094.
all	Deletes all the user VLANs from a multicast VLAN.	-

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After configuring a multicast VLAN, you can use the **multicast-vlan user-vlan** command to bind user VLANs to the multicast VLAN. The Layer 3 device replicates multicast data only in the multicast VLAN and sends the multicast data to the Layer 2 device. This saves bandwidth and reduces load on the Layer 3 device because it does not need to replicate multicast data in every user VLAN.

Prerequisites

- Before running this command, run the **igmp-snooping enable** or **mld-snooping enable** command to enable IGMP snooping or MLD snooping globally, in the user VLANs, and in the multicast VLAN.
- Before running this command, run the **multicast-vlan enable** command to enable the multicast VLAN function in the multicast VLAN.

Precautions

- A user VLAN cannot be configured as a multicast VLAN.
- The user VLANs must exist.
- For the S6720-EI, S6735-S, and S6720S-EI, if the received multicast packets carry double VLAN tags, the inner VLAN tag will be removed and the double VLAN tags will be replaced with a single user VLAN tag when the multicast-vlan user-vlan command is run to bind user VLANs to the multicast VLAN.

Example

Bind user VLAN 10 to multicast VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] vlan batch 2 10
[HUAWEI] igmp-snooping enable
[HUAWEI] vlan 10
[HUAWEI-vlan10] igmp-snooping enable
[HUAWEI-vlan10] quit
[HUAWEI] vlan 2
[HUAWEI-vlan2] igmp-snooping enable
[HUAWEI-vlan2] multicast-vlan enable
[HUAWEI-vlan2] multicast-vlan user-vlan 10
```

Bind user VLANs 3 to 10 to multicast VLAN 2.

```
<HUAWEI> system-view
[HUAWEI] vlan batch 2 to 10
[HUAWEI] igmp-snooping enable
[HUAWEI] igmp-snooping enable vlan 2 to 10
[HUAWEI] vlan 2
[HUAWEI-vlan2] multicast-vlan enable
[HUAWEI-vlan2] multicast-vlan user-vlan 3 to 10
```

8.15 Controllable Multicast Configuration Commands

8.15.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.15.2 add multicast-group

Function

The **add multicast-group** command adds multicast groups to a multicast group list.

The **undo add multicast-group** command removes multicast groups from a multicast group list.

By default, no multicast group is contained in a multicast group list.

Format

add multicast-group { **name** *group-name* | **index** *start-index* **to** *end-index* }

undo add multicast-group { **name** *group-name* | **index** *start-index* **to** *end-index* }

Parameters

Parameter	Description	Value
name *group-name*	Specifies the name of a multicast group.	The value is a string of 1 to 31 case-insensitive characters without spaces.
index *start-index* **to** *end-index*	Specifies the index of a multicast group. *start-index* specifies the start index of a multicast group, and *end-index* specifies the end index of a multicast group.	The value is an integer that ranges from 1 to 1024.

Views

Multicast group list view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group is at the lowest level of the three-level control mechanism for controllable multicast. A multicast group corresponds to a multicast address such as 224.1.1.1. A multicast group can be regarded as a channel or program of IPTV. When configuring controllable multicast, you must create a multicast group and add the group to a multicast group list.

Prerequisites

The specified multicast group has been created.

Example

Add the multicast group named **test** to the multicast group list **list1**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-group test ip-address 225.1.1.1
[HUAWEI-btv] multicast-list list1
[HUAWEI-btv-list-list1] add multicast-group name test
```

Add the multicast groups whose indexes range from 2 to 4 to the multicast group list **list1**.

```
<HUAWEI> system-view
[HUAWEI] btv
```

```
[HUAWEI-btv] multicast-list list1
[HUAWEI-btv-list-list1] add multicast-group index 2 to 4
```

8.15.3 add multicast-list

Function

The **add multicast-list** command adds multicast group lists in a multicast profile.

The **undo add multicast-list** command removes multicast group lists from a multicast profile.

By default, no multicast group list is referenced in a multicast profile.

Format

add multicast-list { **name** *list-name* | **index** *start-index* **to** *end-index* } { **preview** | **watch** }

undo add multicast-list { **name** *list-name* | **index** *start-index* **to** *end-index* }

Parameters

Parameter	Description	Value
name *list-name*	Indicates the name of a multicast group list.	The value is a string of 1 to 31 case-insensitive characters without spaces.
index *start-index* **to** *end-index*	Specifies the index of a multicast group list. *start-index* specifies the start index of a multicast group list, and *end-index* specifies the end index of a multicast group list.	The value is an integer that ranges from 1 to 128.
preview	Indicates that multicast group lists are added to a multicast profile in preview mode. Users applying this profile can preview all programs in the multicast group lists.	-
watch	Indicates that multicast group lists are added to a multicast profile in watch mode. Users applying this profile can watch all programs in the multicast group lists.	-

Views

Multicast profile view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group list is in the middle of the three-level control mechanism for controllable multicast, and is a set of multicast groups. A multicast group list can contain multiple multicast groups. For example, multicast group list l1 contains g1, g2, g3, and g4. A multicast group can be contained in multiple multicast group lists. For example, g3 is contained in l1 and l2. When you configure controllable multicast, you must add the multicast group list to a multicast profile.

Prerequisites

The specified multicast group list has been created.

Example

Reference the multicast group list named **list1** in the multicast profile **profile1**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-list list1
[HUAWEI-btv-list-list1] quit
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] add multicast-list name list1 watch
```

Reference the multicast group lists with indexes 1 to 10 in the multicast profile **profile1**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] add multicast-list index 1 to 10 watch
```

8.15.4 attach multicast-profile

Function

The **attach multicast-profile** command binds a multicast profile to a user.

The **undo attach multicast-profile** command cancels the binding between a multicast profile and a user.

By default, no multicast profile is bound to a user.

Format

attach multicast-profile *profile-name* [**interface** *interface-type interface-number* | **mac-address** *mac-address*] *

undo attach multicast-profile [*profile-name* [**interface** *interface-type interface-number* | **mac-address** *mac-address*] *]

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a multicast profile.	The value is a string of 1 to 31 case-insensitive characters without spaces.
interface *interface-type interface-number*	Specifies a user interface. *interface-type* specifies the type of the user interface. *interface-number* specifies the number of the user interface.	-
mac-address *mac-address*	Specifies the MAC address of a user host.	The MAC address is in the format of H-H-H. Each H stands for four hexadecimal numbers.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Traditional multicast services are uncontrollable. User hosts send IGMP/MLD Report packets to join a specified multicast group. Then they can receive multicast packets of the group. With the development of IPTV services, uncontrollable multicast services cannot meet carriers' requirements. You can configure controllable multicast to authenticate user rights in the VLAN that join a multicast group. The controllable multicast function authenticates users in a VLAN that need to join a multicast group using the multicast group, multicast group list, and multicast profile. After a multicast profile is configured, bind this profile to a VLAN. When a user host sends a request to join a channel, the request is snooped if the channel requested by the user host is not in the multicast profile.

Prerequisites

The specified multicast profile has been created.

Precautions

The switch supports the port+VLAN multicast control mode. To configure the multicast service for multiple user interfaces in the same VLAN, you need to specify a multicast profile for each interface individually by specifying the **interface** *interface-type interface-number* parameter.

Example

Bind **profile1** to the user with the MAC address being 1-2-3 on GE0/0/1 in VLAN 4.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] quit
[HUAWEI-btv] quit
[HUAWEI] vlan 4
[HUAWEI-vlan4] attach multicast-profile profile1 interface gigabitethernet 0/0/1 mac-address 1-2-3
```

8.15.5 btv

Function

The **btv** command enables controllable multicast and displays the BTV view.

The **undo btv** command disables controllable multicast and deletes all configurations in the BTV view.

By default, controllable multicast is disabled.

Format

btv

undo btv

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **btv** command allows you to configure controllable multicast in the BTV view.

NOTICE

The **undo btv** deletes all the controllable multicast configurations. Exercise caution when you run this command.

Example

Enter the BTV view.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv]
```

8.15.6 display multicast-group

Function

The **display multicast-group** command displays the configuration of a multicast group.

Format

display multicast-group [*group-name*]

Parameters

Parameter	Description	Value
group-name	Specifies the name of a multicast group.	The value is a string of 1 to 31 case-insensitive characters without spaces.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display multicast-group** command, you can view details about a specified multicast group, if *group-name* is specified. Otherwise, you can view brief information about all multicast groups.

Example

Display brief information about all multicast groups.

```
<HUAWEI> display multicast-group
--------------------------------------------------------------------------
 Index       Multicast-group-name             Address
 --------------------------------------------------------------------------
  1          g1                               232.0.0.1[10.1.1.1]
  2          g2                               232.0.0.2[10.2.1.1]

 Total: 2
```

Display details about the multicast group named **g1**.

```
<HUAWEI> display multicast-group g1
 Multicast-group-name        : g1
 Address                     : 232.0.0.1[10.1.1.1]
 Referenced list :
        l1

 Total: 1
```

Table 8-152 Description of the **display multicast-group** command output

Item	Description
Index	Index of a multicast group
Multicast-group-name	Name of a multicast group
Address	Multicast group and source address
Referenced list	Multicast group list that a multicast group is added to
Total	Total number of multicast groups

8.15.7 display multicast-list

Function

The **display multicast-list** command displays the configuration of a multicast group list.

Format

display multicast-list [*list-name*]

Parameters

Parameter	Description	Value
list-name	Specifies the name of a multicast group list.	The value is a string of 1 to 31 case-insensitive characters without spaces.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you specify the name of a multicast group list in the **display multicast-list** command, detailed information about the specified multicast group list is displayed. If you do not specify a multicast group list in the command, the summary information about all multicast group lists is displayed.

Example

Display brief information about all multicast group lists.

```
<HUAWEI> display multicast-list
 -------------------------------------------------------------------------
 Index        Multicast-list-name             Multicast-group
 -------------------------------------------------------------------------
  1            l1                                    2

 Total: 1
```

Display details about the multicast group list named **l1**.

```
<HUAWEI> display multicast-list l1
 Multicast-list-name : l1

 Referenced multicast-group  (Total: 2)
        g1                           232.0.0.1[10.1.1.1]
        g2                           232.0.0.2[10.2.1.1]

 Referenced multicast-profile  (Total: 2)
        p1                           [w]
        p2                           [w]
```

Table 8-153 Description of the **display multicast-list** command output

Item	Description
Index	Index of a multicast group list.
Multicast-list-name	Name of a multicast group list.
Multicast-group	Number of multicast groups contained in a multicast group list.
Referenced multicast-group	Multicast groups contained in a multicast group list. For example, g1 and 232.0.0.1 are the name and address of the multicast group, while 10.1.1.1 is a multicast source address.
Referenced multicast-profile	Profile that a multicast group list is added to. p1 is the name of the multicast profile. [w] means that the profile is in watching state, and [p] indicates that the profile is in preview state.

Item	Description
Total	- The first **Total** field indicates the total number of multicast group lists. - The second **Total** field indicates the number of multicast groups in the specified multicast group list. - The third **Total** field indicates the number of multicast profiles that references the multicast group list.

8.15.8 display multicast-profile

Function

The **display multicast-profile** command displays information about multicast profile.

Format

display multicast-profile [*profile-name* [**verbose**]]

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a multicast profile.	The value is a string of 1 to 31 case-insensitive characters without spaces.
verbose	Indicates detailed information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you specify *profile-name*, this command displays information about a specified multicast profile. If you do not specify *profile-name*, this command displays brief information about all multicast profiles.

Example

Display brief information about all multicast profiles.

```
<HUAWEI> display multicast-profile
 ---------------------------------------------------------------------------
 Index       Profile-Name                      Multicast-list  Attach-User
 ---------------------------------------------------------------------------
  1          p1                                1             2
  2          p2                                2             2

 Total: 2
```

Display detailed information about the multicast profile **p1**.

```
<HUAWEI> display multicast-profile p1 verbose
 Profile-name : p1
 Referenced multicast-group  (Total: 2)
       g1                              225.0.0.1        [w]
       g2                              225.0.0.2        [w]
```

Table 8-154 Description of the **display multicast-profile** command output

Item	Description
Index	Index of a multicast profile.
Profile-Name	Name of the multicast profile.
Multicast-list	Number of multicast group lists contained in the multicast profile.
Attach-User	Number of user VLANs that the multicast profile is bound to.
Referenced multicast-group	Number of multicast groups in the multicast profile. In this example, g1 is the multicast group name, 225.0.0.1 is the group address. [w] means that the profile is in watching state, and [p] indicates that the profile is in preview state.
Total	● The first **Total** field indicates the total number of multicast profiles. ● The second **Total** field indicates the number of multicast groups in the specified multicast profile.

8.15.9 display multicast-profile-apply

Function

The **display multicast-profile-apply** command displays bindings between multicast profiles and VLANs.

Format

display multicast-profile-apply

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the multicast profiles applied to different VLANs.

Example

Display bindings between multicast profiles and VLANs on the switch.

```
<HUAWEI> display multicast-profile-apply
-----------------------------------------------------------------------------
 Vlan-id  Port                   SMAC                          Max-Users
                Index              Profile-name
 -----------------------------------------------------------------------------
 Vlan1    --                    --                            8
                 1                 p1
 Vlan2    --                    --                            8
                 1                 p1
 Vlan3    --                    --                            8
                 2                 p2
 Vlan4    --                    --                            8
                 2                 p2

 Total: 4
```

Table 8-155 Description of the **display multicast-profile-apply** command output

Item	Description
Vlan-id	ID of a VLAN bound to a multicast profile.
Port	Interface in the VLAN. -- indicates that no interfaces are bound to the multicast profile in this VLAN.
Index	Index of a multicast profile.
SMAC	MAC address of a user. -- indicates that no user hosts are bound to the multicast profile in this VLAN.
Profile-name	Name of a multicast profile.

Item	Description
Max-Users	Maximum number of programs that users can watch and preview at the same time. If the value is set in a VLAN and the multicast profile bound to the VLAN, only the configuration in the VLAN takes effect. If the value is not set in a VLAN: ● The configuration in the multicast profile takes effect if the VLAN is bound to only one multicast profile. ● The default value 8 is used if the VLAN is bound to multiple multicast profiles.
Total	Total number of binding entries between VLANs and multicast profiles.

8.15.10 max-program-num (multicast profile view)

Function

The **max-program-num** command sets the maximum number of programs that users can receive simultaneously.

The **undo max-program-num** command restores the maximum number of programs for a user to the default value.

By default, users can receive a maximum of 8 programs simultaneously.

Format

max-program-num *max-value*

undo max-program-num [*max-value*]

Parameters

Item	Description	Value
max-value	Indicates the maximum number of programs that users can receive simultaneously.	The value ranges from 1 to 8.

Views

Multicast profile view

Default Level

2: Configuration level

Usage Guidelines

Run the **max-program-num (VLAN view)** command in the VLAN view to set the maximum number of multicast groups that users can simultaneously join. If the value is set in a VLAN and the multicast profile bound to the VLAN, only the configuration in the VLAN takes effect. If the value is not set in a VLAN:

- The configuration in the multicast profile takes effect if the VLAN is bound to only one multicast profile.
- The default value 8 is used if the VLAN is bound to multiple multicast profiles.

Example

Set the maximum number of programs that multicast profile **p1** allows users to receive simultaneously to 4.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile p1
[HUAWEI-btv-profile-p1] max-program-num 4
```

8.15.11 max-program-num (VLAN view)

Function

The **max-program-num** command sets the maximum number of programs that users can receive simultaneously.

The **undo max-program-num** command restores the maximum number of programs for a user to the default value.

By default, users can receive a maximum of 8 programs simultaneously.

Format

max-program-num *max-value* [**interface** *interface-type interface-number* | **mac-address** *mac-address*] *

undo max-program-num [**interface** *interface-type interface-number* | **mac-address** *mac-address*] *

Parameters

Item	Description	Value
max-value	Indicates the maximum number of programs that users can receive simultaneously.	The value ranges from 1 to 8.

Item	Description	Value
interface *interface-type interface-number*	Indicates the maximum number of programs that users on a specified interface can watch simultaneously.	-
mac-address *mac-address*	Indicates the maximum number of programs that users with specified MAC addresses can watch simultaneously.	The value is in H-H-H format, in which H is a 4-digit hexadecimal number.

Views

VLAN view

Default Level

2: Configuration level

Usage Guidelines

Run the **max-program-num (multicast profile view)** command in the multicast profile view to set the maximum number of multicast groups that users can simultaneously join. If the value is set in a VLAN and the multicast profile bound to the VLAN, only the configuration in the VLAN takes effect. If the value is not set in a VLAN:

- The configuration in the multicast profile takes effect if the VLAN is bound to only one multicast profile.
- The default value 8 is used if the VLAN is bound to multiple multicast profiles.

The **interface** *interface-type interface-number* and **mac-address** *mac-address* parameters specified in the command must be the same as those specified in the **attach multicast-profile** command.

Example

Allow users in VLAN 10 to watch four programs simultaneously.

```
<HUAWEI> system-view
[HUAWEI] vlan 10
[HUAWEI-vlan10] max-program-num 4
```

8.15.12 multicast-group

Function

The **multicast-group** command creates a controllable multicast group.

The **undo multicast-group** command deletes a controllable multicast group.

By default, no multicast group is created.

Format

multicast-group *group-name* { **ip-address** *ipv4-group-address* [**source** *ipv4-source-address*] | **ipv6-address** *ipv6-group-address* [**source** *ipv6-source-address*] }

undo multicast-group { **all** | *group-name* | **index** *start-index* **to** *end-index* }

Parameters

Parameter	Description	Value
group-name	Specifies the name of a multicast group.	The value is a string of 1 to 31 case-insensitive characters without spaces.
ip-address *ipv4-group-address*	Specifies the address of a multicast group.	The value ranges from 224.0.1.0 to 239.255.255.255 in dotted decimal notation.
source *ipv4-source-address*	Specifies an IPv4 source address.	It is in dotted decimal notation.
ipv6-address *ipv6-group-address*	Specifies an IPv6 multicast group address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X. The value ranges from FF00:: to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF, excluding the multicast addresses reserved for protocols.
source *ipv6-source-address*	Specifies an IPv6 source address.	The address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
all	Deletes all multicast groups.	-
index *start-index* **to** *end-index*	Specifies the index of a multicast group. *start-index* specifies the start index of a multicast group, and *end-index* specifies the end index of a multicast group.	The value is an integer that ranges from 1 to 1024.

Views

Broadband TV (BTV) view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A multicast group is at the lowest level of the three-level control mechanism for controllable multicast. A multicast group corresponds to a multicast address such as 224.1.1.1. A multicast group can be regarded as a channel or program of IPTV.

Precautions

If two programs have the same multicast IP address but different source addresses, the two programs are considered different.

Example

Configure the IP address of a multicast group to 225.0.0.1 and name the multicast program **tv-1**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-group tv-1 ip-address 225.0.0.1
```

Configure the IP address of a multicast group to ff1e::1234 and name the multicast program **tv-2**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-group tv-2 ipv6-address ff1e::1234
```

Configure the IP address of a multicast group to 232.0.0.1, specify the source IP address to 192.168.1.1, and name the multicast program **tv-3**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-group tv-3 ip-address 232.0.0.1 source 192.168.1.1
```

8.15.13 multicast-list

Function

The **multicast-list** command creates a multicast group list.

The **undo multicast-list** command deletes a multicast group list.

By default, no multicast group list is configured.

Format

multicast-list *list-name*

undo multicast-list { *list-name* | **index** *start-index* **to** *end-index* | **all** }

Parameters

Parameter	Description	Value
list-name	Specifies the name of a multicast group list.	The value is a string of 1 to 31 case-insensitive characters without spaces.
index *start-index* **to** *end-index*	Specifies the index of a multicast group list. *start-index* specifies the start index of a multicast group, and *end-index* specifies the end index of a multicast group.	The value is an integer that ranges from 1 to 128.
all	Deletes all multicast group lists.	-

Views

BTV view

Default Level

2: Configuration level

Usage Guidelines

A multicast group list is in the middle of the three-level control mechanism for controllable multicast, and is a set of multicast groups. A multicast group list can contain multiple multicast groups. For example, multicast group list L1 contains G1, G2, G3, and G4. A multicast group can be contained in multiple multicast group lists. For example, G3 is contained in L1 and L2. When you configure controllable multicast, you must add the multicast group list to a multicast profile.

Using the **multicast-list** command, you can create a multicast group list and enter the multicast group list view. If a multicast group list is already created, you can directly enter the multicast group list view.

Example

Create the multicast group list named **list1**.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-list list1
[HUAWEI-btv-list-list1]
```

8.15.14 multicast-preview interval

Function

The **multicast-preview interval** command sets the interval between the first and second previews on a multicast group.

The **undo multicast-preview interval** command restores the default interval between the first and second previews on a multicast group.

By default, the interval between the first and second previews on a multicast group is 5 minutes.

Format

multicast-preview interval *interval*

undo multicast-preview interval [*interval*]

Parameters

Parameter	Description	Value
interval	Specifies the interval between the first and second previews on a multicast group.	The value is an integer that ranges from 1 to 30, in minutes.

Views

Multicast profile view

Default Level

2: Configuration level

Usage Guidelines

Controllable multicast allows users to preview programs. The **multicast-preview interval** command sets the interval between the first and second previews. Users can preview the same program after this interval.

Example

Set the interval between the first and second previews on a multicast profile named **profile1** to 15 minutes.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] multicast-preview interval 15
```

8.15.15 multicast-preview minutes

Function

The **multicast-preview minutes** command sets the period for a user to preview a multicast group each time.

The **undo multicast-preview minutes** command restores the default preview period.

By default, the period for a user to preview a multicast group each time is 5 minutes.

Format

multicast-preview minutes *minutes*

undo multicast-preview minutes [*minutes*]

Parameters

Parameter	Description	Value
minutes	Specifies the period for a user to preview a multicast group each time.	The value is an integer that ranges from 1 to 10, in minutes.

Views

Multicast profile view

Default Level

2: Configuration level

Usage Guidelines

Controllable multicast allows users to preview programs. The **multicast-preview minutes** command sets the period for a user to preview a multicast group. Users are not allowed to preview the program after the configured period is reached.

Example

Set the period for previewing the multicast profile named **profile1** each day to 9 minutes.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] multicast-preview minutes 9
```

8.15.16 multicast-preview times

Function

The **multicast-preview times** command sets the number of times for a user to preview a multicast group each day.

The **undo multicast-preview times** command restores the default number of previews each day.

By default, the number of times a user can preview a multicast group each day is 10.

Format

multicast-preview times *times*

undo multicast-preview times [*times*]

Parameters

Parameter	Description	Value
times	Specifies the number of times for a user to preview a multicast group each day.	The value is an integer that ranges from 1 to 10.

Views

Multicast profile view

Default Level

2: Configuration level

Usage Guidelines

Controllable multicast allows users to preview programs. The **multicast-preview times** command sets the number of times for a user to preview a multicast group each day.

Example

Set the number of times for a user to preview the multicast profile named **profile1** each day to 8.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1] multicast-preview times 8
```

8.15.17 multicast-profile

Function

The **multicast-profile** command creates a multicast profile and enters the multicast profile view. If a multicast profile is already created, you can directly enter the multicast profile view.

The **undo multicast-profile** command deletes a multicast profile.

By default, no multicast profile is configured.

Format

multicast-profile *profile-name*

undo multicast-profile { *profile-name* | **index** *start-index* **to** *end-index* | **all** }

Parameters

Parameter	Description	Value
profile-name	Specifies the name of a multicast profile.	The value is a string of 1 to 31 case-insensitive characters without spaces.
index *start-index* **to** *end-index*	Specifies the index of a multicast profile. *start-index* specifies the start index of a multicast profile, and *end-index* specifies the end index of a multicast profile.	The value is an integer that ranges from 1 to 64.
all	Deletes all multicast profiles.	-

Views

BTV view

Default Level

2: Configuration level

Usage Guidelines

A multicast profile is a set of multicast group lists, and it defines user rights to join related multicast groups. A multicast profile can contain multiple multicast group lists. For example, multicast profile P1 contains L1, L2, and L3. A multicast group list can be contained in several multicast profiles. For example, L2 is contained in

P1 and P2. Multicast group lists that are added to a profile have their attributes, that is, preview or watch. If a multicast group list is added to a multicast profile in watch mode, users bound to the multicast profile can watch all multicast groups in the list. If a multicast group list is added to a multicast profile in preview mode, users bound to the multicast profile can only preview all multicast groups in the list.

Example

Create the multicast profile named **profile1** and enter the multicast profile view.

```
<HUAWEI> system-view
[HUAWEI] btv
[HUAWEI-btv] multicast-profile profile1
[HUAWEI-btv-profile-profile1]
```

8.16 Multicast Network Management Commands

8.16.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

8.16.2 display multicast threshold-alarm

Function

The **display multicast threshold-alarm** command displays the alarm thresholds for multicast entry resource usage.

Format

display multicast threshold-alarm

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can use this command to check the alarm thresholds for multicast entry resource usage.

Example

Display the alarm thresholds for multicast entry resource usage.

```
<HUAWEI> display multicast threshold-alarm
Multicast table trap threshold value
Upperlimit value: 86%
Lowerlimit value: 78%
```

Table 8-156 Description of the **display multicast threshold-alarm** command output

Item	Description
Multicast table trap threshold value	Alarm thresholds for multicast entry resource usage.
Upperlimit value	Upper threshold value. This parameter is configured using the **multicast threshold-alarm upper-limit** *upper-limit* **lower-limit** *lower-limit* command.
Lowerlimit value	Lower threshold value. This parameter is configured using the **multicast threshold-alarm upper-limit** *upper-limit* **lower-limit** *lower-limit* command.

8.16.3 display pim mib-control-message

Function

The **display pim mib-control-message** command displays PIM-related statistics and counts of various messages received the last time.

Format

display pim mib-control-message { **counters** | **join-prune** | **assert** | **register** }

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
counters	Indicates related PIM counters.	-

Parameter	Description	Value
join-prune	Indicates the number of invalid Join/Prune messages that are received at the last time.	-
assert	Indicates the number of Assert messages that are received or sent at the last time.	-
register	Indicates the number of invalid Register messages that are received at the last time.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display pim mib-control-message counters** command displays the number of neighbor loss events, the number of DR elections, the number of invalid Join/Prune messages, the number of invalid Register messages, the number of RP-mapping changes, and the number of received and sent Assert messages.

The **display pim mib-control-message join-prune** command displays the source address, group address, and RP address carried in the last received invalid Join/Prune message.

The **display pim mib-control-message assert** command displays the source address and group address carried in the last received or sent Assert message.

The **display pim mib-control-message register** command displays the source address, group address, and RP address carried in the last received invalid Register message.

Example

Display the number of neighbor loss events, the number of times for DR election, the number of invalid Join/Prune messages, the number of invalid Register messages, the number of RP-Mapping, the number of received and sent Assert messages.

```
<HUAWEI> display pim mib-control-message counters
 pim mib-control-message counters
 Neighbor-loss (times)        : 0
 DR-Election(times)          : 0
 Invalid-join-prune (times)   : 0
 RP-Mapping (times)           : 0
 Invalid-register (times)     : 0
 Assert-received(times)      : 0
 Assert-send(times)          : 0
```

Display the invalid Join/Prune message that is received at the last time.

```
<HUAWEI> display pim mib-control-message join-prune
The last invalid join-prune message received information:
Group address  : 225.1.1.1
Source address : 0.0.0.0
RP address     : 10.0.5.5
```

Display the Assert message that is sent or received at the last time. If the interface that receives or sends the Assert message is pulled out when this command is used, the prompt that "The last assert message was received or sent on lost interface" is displayed.

```
<HUAWEI> display pim mib-control-message assert
The last assert message received or sent on Vlanif100
Group address   : 226.3.3.3
Source address  : 10.0.5.55
```

Display the invalid Register message that is received at the last time.

```
<HUAWEI> display pim mib-control-message register
The last invalid register message received information:
Group address  : 225.1.1.1
Source address : 10.0.5.100
RP address     : 10.0.3.1
```

Table 8-157 Description of the **display pim mib-control-message** command output

Item	Description
pim mib-control-message counters	Numbers of neighbor loss events, DR election events, invalid Join/Prune messages, invalid Register messages, RP-mapping changes, and received and sent Assert messages.
The last invalid join-prune message received information	Invalid Join/Prune message received the last time.
The last assert message received or sent on Vlanif100	Assert message sent or received the last time.
The last invalid register message received information	Invalid Register message received the last time.
Neighbor-loss(times)	Number of neighbor loss events.
DR-Election (times)	Number of DR election events.
Invalid-join-prune(times)	Number of invalid Join/Prune messages.
RP-Mapping(times)	Number of RP-Mapping changes.
Invalid-register(times)	Number of invalid Register messages.
Assert-received(times)	Number of received Assert messages.
Assert-send(times)	Number of sent Assert messages.
Group address	Multicast group address.
Source address	Multicast source address

Item	Description
RP address	IP address of the RP.

8.16.4 display pim mib-notification interval

Function

The **display pim mib-notification interval** command displays the interval for sending PIM notification messages.

Format

display pim mib-notification interval

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the interval for sending PIM notification messages is set or modified by using the **pim mib-notification interval** command, you can run the **display pim mib-notification interval** command to view the configured interval.

Example

Display the interval for sending PIM notification messages.

```
<HUAWEI> display pim mib-notification interval
Neighbor-loss notification interval      : 0 s
Invalid-join-prune notification interval : 50 s
RP-mapping-change notification interval  : 100 s
Interface-election notification interval : 2000 s
Invalid-register notification interval   : 60000 s
New-neighbor notification interval       : 0 s
Mrt-limit notification interval          : never
```

Table 8-158 Description of the **display pim mib-notification interval** command output

Item	Description
Neighbor-loss notification interval	Interval for sending the notification messages about the neighbor loss
Invalid-join-prune notification interval	Interval for sending the notification messages about invalid Join/Prune messages
RP-mapping-change notification interval	Interval for sending the notification messages about RP-mapping changes
Interface-election notification interval	Interval for sending the notification messages about interface election
Invalid-register notification interval	Interval for sending the notification messages about invalid Register messages
New-neighbor notification interval	Interval for sending trap messages about neighbor addition.
Mrt-limit notification interval	Interval for sending trap messages about the failure in joining multicast groups because the number of PIM entries reaches the upper limit.

8.16.5 igmp trap-interval limit

Function

The **igmp trap-interval limit** command configures the interval for sending trap messages on failures to join IGMP groups because the number of the IGMP entries exceeds the limit.

The **undo igmp trap-interval limit** command deletes the interval for sending trap messages on failures to join IGMP groups because the number of the IGMP entries exceeds the limit. When a group joining failure occurs, a trap message is sent immediately.

By default, a trap message is sent immediately when an IGMP group joining failure occurs because the number of the IGMP entries exceeds the limit.

Format

igmp trap-interval limit *min-interval*

undo igmp trap-interval limit

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
min-interval	Specifies the interval for sending trap messages of the failure of IGMP joining because the number of the IGMP entries exceeds the limit.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 0 seconds.

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

If the interval is set to 0, a trap message will be sent immediately when an IGMP group joining failure occurs because the number of the IGMP entries exceeds the limit; otherwise, the interval for sending such trap messages should be equal to or longer than the configured one.

Example

Set the interval for sending trap messages on failures to join IGMP groups because the number of the IGMP entries exceeds the limit to 50 seconds.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] igmp trap-interval limit 50
```

8.16.6 mgmd total-number threshold-alarm

Function

The **mgmd total-number threshold-alarm** command sets the upper and lower alarm thresholds for IGMP/MLD entries.

The **undo mgmd total-number threshold-alarm** command restores the default alarm thresholds for IGMP/MLD entries.

By default, the upper and lower alarm thresholds are 80% and 75% respectively.

Format

mgmd total-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mgmd total-number threshold-alarm

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for IGMP/MLD entries, in percentage.	The value is an integer ranging from 1 to 100.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for IGMP/MLD entries, in percentage.	The value is an integer ranging from 1 to 100. *lower-limit-value* must be smaller than *upper-limit-value*.

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device supports a limited number of IGMP/MLD entries. After the number of IGMP/MLD entries reaches the maximum value, no more IGMP/MLD entries can be created. As a result, some multicast traffic cannot be forwarded. To facilitate network operation and maintenance, configure the upper and lower alarm thresholds for IGMP/MLD entries. IGMP/MLD entry alarms and clear alarms quickly notify you of IGMP/MLD entry usage. The **mgmd total-number threshold-alarm** command allows you to flexibly adjust the alarm thresholds for IGMP/MLD entries based on service requirements. Note that:

- If the proportion of existing IGMP/MLD entries to the maximum number reaches *upper-limit-value*, an IGMP/MLD entry alarm is reported for all VPN instances. This alarm is informational only and does not affect creation of new IGMP/MLD entries.

- If the proportion of existing IGMP/MLD entries to the maximum number falls below *lower-limit-value*, an IGMP/MLD entry clear alarm is reported for all VPN instances.

Prerequisites

This command only configures the alarm thresholds for IGMP/MLD entries. To enable the configured alarm thresholds to take effect, run the **snmp-agent trap enable feature-name igmp trap-name** { **hwmgmdtotallimitthresholdexceed** | **hwmgmdtotallimitthresholdexceedclear** } command twice to enable the device to report IGMP/MLD entry alarms and clear alarms.

Precautions

If the **mgmd total-number threshold-alarm** command is executed multiple times, only the latest configuration takes effect.

Example

Configure the upper and lower alarm thresholds for IGMP/MLD entries.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] mgmd total-number threshold-alarm upper-limit 88 lower-limit 77
```

8.16.7 mgmd host threshold-alarm

Function

The **mgmd host threshold-alarm** command configures the upper and lower alarm thresholds for the multicast entry usage of all instances on a user-side IGMP/MLD device.

The **undo mgmd host threshold-alarm** command restores the default upper and lower alarm thresholds.

By default, the upper and lower alarm thresholds are 80% and 75%, respectively.

Format

mgmd host { **star-group-number** | **source-group-number** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mgmd host { **star-group-number** | **source-group-number** } **threshold-alarm**

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
star-group-number	Enables you to configure the upper and lower alarm thresholds for the (*, G) entry usage of all instances.	-
source-group-number	Enables you to configure the upper and lower alarm thresholds for the (S, G) entry usage of all instances.	-
upper-limit *upper-limit-value*	Configures an upper alarm threshold for the multicast entry usage of all instances, in percentage.	The value is an integer ranging from 1 to 100.
lower-limit *lower-limit-value*	Configures a lower alarm threshold for the multicast entry usage of all instances, in percentage.	The value is an integer ranging from 1 to 100. *lower-limit-value* must be smaller than *upper-limit-value*.

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A user-side IGMP/MLD device has an upper limit for the number of multicast entries. When this upper limit is reached, the device cannot create new entries, so it will reject new multicast service requests. To resolve this issue and improve device maintenance, run the **mgmd host threshold-alarm** command to configure the upper and lower alarm thresholds for the multicast entry usage on a user-side IGMP/MLD device, enabling you to learn the multicast entry usage status. After the **mgmd host threshold-alarm** command is executed:

- When the value of *upper-limit-value* is reached, the device triggers a multicast entry usage alarm. Such an alarm is a notification only, and the device can still create new multicast entries before the multicast entry usage reaches 100%.
- When the multicast entry usage falls below the value specified by *lower-limit-value*, the device triggers a clear alarm for the multicast entry usage alarm.

Prerequisites

The **mgmd host threshold-alarm** command works with the **snmp-agent trap enable feature-name igmp trap-name** { **hwmgmdhoststargthresholdexceed** | **hwmgmdhoststargthresholdexceedclear** | **hwmgmdhostsgthresholdexceed** | **hwmgmdhostsgthresholdexceedclear** } command. The former configures the upper and lower alarm thresholds, while the latter enables or disables the function to report alarms.

Precautions

If the **mgmd host threshold-alarm** command is run more than once, the latest configuration overrides the previous one.

Example

Configure the upper and lower alarm thresholds for the (*, G) entry usage of all instances.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] mgmd host star-group-number threshold-alarm upper-limit 88 lower-limit 77
```

Configure the upper and lower alarm thresholds for the (S, G) entry usage of all instances.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] mgmd host source-group-number threshold-alarm upper-limit 88 lower-limit 77
```

8.16.8 multicast forwarding-table source-group-number threshold-alarm

Function

The **multicast forwarding-table source-group-number threshold-alarm** command configures the upper and lower alarm thresholds for multicast forwarding entries.

The **undo multicast forwarding-table source-group-number threshold-alarm** command restores the default alarm thresholds for multicast forwarding entries.

By default, the upper and lower alarm thresholds are 80% and 75% respectively.

Format

multicast forwarding-table source-group-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo multicast forwarding-table source-group-number threshold-alarm

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for multicast forwarding entries, in percentage.	The value is an integer ranging from 1 to 100.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for multicast forwarding entries, in percentage.	The value is an integer ranging from 1 to 100. *lower-limit-value* must be smaller than *upper-limit-value*.

Prerequisites

This command only configures the alarm thresholds for multicast forwarding entries. To enable the configured alarm thresholds to take effect, run the **snmp-agent trap enable feature-name mrm trap-name** { **hwipmcastsgthresholdexceed** | **hwipmcastsgthresholdexceedclear** } command twice to enable the device to report multicast forwarding entry alarms and clear alarms.

Precautions

If the **multicast forwarding-table source-group-number threshold-alarm** command is executed multiple times, only the latest configuration takes effect.

Example

Configure the upper and lower alarm thresholds for multicast forwarding entries.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] multicast forwarding-table source-group-number threshold-alarm upper-limit
88 lower-limit 77
```

8.16.9 multicast mib-notification join-leave frequency

Function

The **multicast mib-notification join-leave frequency** command sets the maximum number of trap messages sent by the system per second when IGMP/MLD joining or leaving events occur.

The **undo multicast mib-notification join-leave frequency** command restores the default number of trap messages sent by the system per second when IGMP/MLD joining or leaving events occur.

By default, the system does not send any trap message when IGMP/MLD joining or leaving events occur.

Format

multicast mib-notification join-leave frequency *count*

undo multicast mib-notification join-leave frequency

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
count	Specifies the maximum number of trap messages sent by the system per second when IGMP/MLD joining or leaving events occur.	The value is an integer that ranges from 0 to 240. The unit is in packets per second. The default value is 0.

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

If network administrators need to know which receivers join or leave multicast groups in real time, run this command. The switch will send trap messages after receivers join or leave multicast groups.

Example

Set the maximum number of trap messages sent by the system per second to 30 when IGMP/MLD joining or leaving events occur.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] multicast mib-notification join-leave frequency 30
```

8.16.10 multicast-mib

Function

The **multicast-mib** command enables the multicast MIB and displays the multicast MIB view.

The **undo multicast-mib** command deletes all configurations in the multicast MIB view.

By default, the multicast MIB is not enabled.

Format

multicast-mib

undo multicast-mib

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Run the **undo multicast-mib** command to delete all configurations in the multicast MIB view.

NOTICE

When using the **undo multicast-mib** command, you need to enter Y or N to confirm the action. This command will clear global multicast MIB configurations. So, use this command with caution.

Example

Enable multicast MIB and enter the multicast MIB view.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib]
```

8.16.11 multicast threshold-alarm

Function

The **multicast threshold-alarm** command configures an alarm threshold for the usage of multicast entry resources.

The **undo multicast threshold-alarm** command restores the default alarm threshold for the usage of multicast entry resources.

By default, the upper and lower alarm thresholds are 85% and 75% respectively.

Format

multicast threshold-alarm upper-limit *upper-limit* **lower-limit** *lower-limit*

undo multicast threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit*	Indicates the upper threshold for the usage of multicast entry resources.	The value is an integer that ranges from 2 to 100, in percentage.
lower-limit *lower-limit*	Indicates the lower threshold for the usage of multicast entry resources.	The value is an integer that ranges from (*upper-limit* - 10) to (*upper-limit* - 1), in percentage.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Multicast packets are forwarded based on multicast forwarding entries no matter whether the Layer 2 or Layer 3 multicast mode is used. A high entries resource usage indicates that the switch has forwarded too many multicast packets and there is a heavy load on it. If the resources for multicast forwarding entries are used up, multicast packets cannot be forwarded.

After the alarm threshold is set, the switch sends a trap when entries resource usage reaches the threshold. You can monitor multicast entries resource usage. When entries resource usage reaches the upper threshold, the alarm 1.3.6.1.4.1.2011.5.25.227.2.1.8, 1.3.6.1.4.1.2011.5.25.227.2.1.10, or 1.3.6.1.4.1.2011.5.25.227.2.1.62 is generated, indicating that the entries resources will be used up. When entries resource usage falls below the lower threshold, the alarm 1.3.6.1.4.1.2011.5.25.227.2.1.9, 1.3.6.1.4.1.2011.5.25.227.2.1.11, or 1.3.6.1.4.1.2011.5.25.227.2.1.63 is generated, indicating that entries resource usage is restored to an acceptable range.

Example

Set the upper threshold to 80% and lower threshold to 70%.

```
<HUAWEI> system-view
[HUAWEI] multicast threshold-alarm upper-limit 80 lower-limit 70
```

8.16.12 pim mib-notification interval

Function

The **pim mib-notification interval** command sets the interval for sending trap messages about various PIM events.

The **undo pim mib-notification interval** command restores the default interval for sending trap messages about various PIM events.

By default, an alarm is generated only when a neighbor loss event or a neighbor addition event occurs. No alarm is generated when the other events occur.

Format

pim mib-notification interval { **interface-election-dr** *election-value* | **invalid-join-prune** *jp-value* | **invalid-register** *register-value* | **neighbor-loss** *loss-value* | **new-neighbor** *new-value* | **rp-mapping-change** *change-value* | **mrt-limit** *mrt-value* }

undo pim mib-notification interval { **all** | **interface-election-dr** | **invalid-join-prune** | **invalid-register** | **neighbor-loss** | **new-neighbor** | **rp-mapping-change** | **mrt-limit** }

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
interface-election-dr *election-value*	Specifies the minimum interval for sending trap messages about DR election.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 65535 seconds.
invalid-join-prune *jp-value*	Specifies the minimum interval for sending trap messages about invalid Join/Prune messages.	The value is an integer that ranges from 10 to 65535, in seconds. The default value is 65535 seconds.
invalid-register *register-value*	Specifies the minimum interval for sending trap messages about invalid Register messages.	The value is an integer that ranges from 10 to 65535, in seconds. The default value is 65535 seconds.
neighbor-loss *loss-value*	Specifies the minimum interval for sending trap messages about neighbor loss.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 0 seconds.
new-neighbor *new-value*	Specifies the minimum interval for sending trap messages about neighbor addition.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 0 seconds.
rp-mapping-change *change-value*	Specifies the minimum interval for sending trap messages about the RP-mapping change.	The value is an integer that ranges from 0 to 65535, in seconds. The default value is 65535 seconds.
mrt-limit *mrt-value*	Specifies the minimum interval for sending trap messages about the failure in joining multicast groups because the number of PIM entries reaches the upper limit.	The value is an integer that ranges from 10 to 65535, in seconds. By default, the value is 65535 seconds.

Parameter	Description	Value
all	Restore the default interval for PIM to send all trap messages.	-

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

The **pim mib-notification interval** command sets the interval for sending trap messages. When an event occurs but the period from when the last trap message was sent to the current time is shorter than the configured interval, the system does not send any trap message.

- If the default interval is 0, a trap message is sent immediately after an event occurs.
- If the default interval is 65535, no trap message is sent after an event occurs. In this case, run this command to adjust the interval to a smaller value so that a trap message can be sent after an event occurs.

Example

Set the interval for PIM to send trap messages about invalid Join/Prune messages.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] pim mib-notification interval invalid-join-prune 50
```

8.16.13 pim threshold-alarm

Function

The **pim threshold-alarm** command configures the upper and lower alarm thresholds for PIM entries.

The **undo pim threshold-alarm** command restores the default alarm thresholds for PIM entries.

By default, the upper and lower alarm thresholds are 80% and 75% respectively.

Format

pim { **star-group-number** | **source-group-number** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo pim { **star-group-number** | **source-group-number** } **threshold-alarm**

NOTE

Only the S5720I-SI, S5720-LI, S2730S-S, S5735-L-I, S5735-L1,S300, S5735-L, S5735S-L, S5735S-L1, S5735S-L-M, S5720S-LI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Parameters

Parameter	Description	Value
star-group-number	Sets the alarm thresholds for PIM (*, G) entries.	-
source-group-number	Sets the alarm thresholds for PIM (S, G) entries.	-
upper-limit *upper-limit-value*	Specifies the upper alarm threshold value for PIM entries, in percentage.	The value is an integer ranging from 1 to 100.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold value for PIM entries, in percentage.	The value is an integer ranging from 1 to 100. *lower-limit-value* must be smaller than *upper-limit-value*.

Views

Multicast MIB view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A device supports a limited number of PIM entries. After the number of PIM entries reaches the maximum value, no more PIM entries can be created. As a result, some multicast traffic cannot be forwarded. To facilitate network operations and maintenance, configure the upper and lower alarm thresholds for PIM entries. PIM entry alarms and clear alarms quickly notify you of PIM entry usage. The **pim threshold-alarm** command allows you to adjust the alarm thresholds for PIM entries based on service requirements. Note that:

- If the proportion of existing PIM entries to the maximum number reaches *upper-limit-value*, a PIM entry alarm is reported. This alarm is informational only and does not affect creation of new PIM entries.
- If the proportion of existing PIM entries to the maximum number falls below *lower-limit-value*, a PIM entry clear alarm is reported.

Prerequisites

This command only configures the alarm thresholds for PIM entries. To enable the configured alarm thresholds to take effect, run the **snmp-agent trap enable feature-name pim trap-name** { **hwpimsgthresholdexceed** | **hwpimsgthresholdexceedclear** | **hwpimstargthresholdexceed** | **hwpimstargthresholdexceedclear** } command twice to enable the device to report PIM entry alarms and clear alarms.

Precautions

If the **pim threshold-alarm** command is executed multiple times, only the latest configuration takes effect.

Example

Configure the upper and lower alarm thresholds for PIM (*, G) entries.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] pim star-group-number threshold-alarm upper-limit 88 lower-limit 77
```

Configure the upper and lower alarm thresholds for PIM (S, G) entries.

```
<HUAWEI> system-view
[HUAWEI] multicast-mib
[HUAWEI-mcast-mib] pim source-group-number threshold-alarm upper-limit 88 lower-limit 77
```

9 MPLS Configuration Commands

9.1 Basic MPLS Configuration Commands

9.1.1 Command Support

Only the following switch models support MPLS:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

9.1.2 authentication exclude

Function

The **authentication exclude** command configures LDP peers in a batch that a local device does not authenticate after LDP keychain or LDP MD5 is configured to authenticate all LDP peers or LDP peers in a specified group.

The **undo authentication exclude** command enables a local device to authenticate all LDP peers using LDP keychain or LDP MD5.

By default, a local device is enabled to authenticate all LDP peers using LDP keychain or LDP MD5.

Format

authentication exclude peer *peer-id*

undo authentication exclude peer *peer-id*

Parameters

Parameter	Description	Value
peer *peer-id*	Specifies the ID of an LDP peer.	This value is in dotted decimal notation.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, a local device is enabled to authenticate all LDP peers using LDP keychain or LDP MD5 after LDP keychain or LDP MD5 is configured for a peer group or all LDP peers. To disable the local device from authenticating some LDP peers, run the **authentication exclude** command.

Precautions

The following commands are mutually exclusive for a specified LDP peer:

- **authentication key-chain peer** *peer-id* **name** *keychain-name*
- **md5-password** { **plain** | **cipher** } *peer-lsr-id password*

Example

Disable a local device from authenticating an LDP peer with IP address **10.1.1.1** after LDP keychain or MD5 is configured for all LDP peers or LDP peers in a specified group.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] authentication exclude peer 10.1.1.1
```

9.1.3 authentication key-chain

Function

The **authentication key-chain** command enables Label Distribution Protocol (LDP) keychain authentication.

The **undo authentication key-chain** command disables Label Distribution Protocol (LDP) keychain authentication.

By default, LDP keychain authentication is disabled.

Format

authentication key-chain peer *peer-id* **name** *keychain-name*

undo authentication key-chain peer *peer-id*

Parameters

Parameter	Description	Value
peer *peer-id*	Specifies the ID of an LDP peer enabled with LDP keychain. The parameter is specified in the **mpls lsr-id** command.	The value is in dotted decimal notation.
name *keychain-name*	Specifies the keychain name. The keychain name is specified in the **keychain** command.	The value is an existing keychain name.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Information spoofing may occur during an LDP session. To enhance security of an LDP session, configure keychain authentication for a TCP connection over which an LDP session is created.

During keychain authentication, a group of passwords are defined to form a password string, and each password is specified with the encryption and decryption algorithms such as MD5 and SHA-1, and is configured with a validity period. When sending or receiving a packet, the system selects a valid password based on the user's configuration. Within the password validity period, the system either uses the encryption algorithm matching the password to encrypt the packet before sending it or uses the decryption algorithm matching the password to decrypt the packet before receiving it. In addition, the system automatically uses a new password after the previous one expires, preventing the password from being decrypted.

The keychain authentication password, the encryption and decryption algorithms, and password validity period that construct a keychain configuration node are configured using different commands. A keychain configuration node requires at least one password along with encryption and decryption algorithms.

To reference a keychain configuration node, specify the required peer and the node name in the MPLS-LDP view. In this manner, an LDP session is encrypted. Different peers can reference the same keychain configuration node.

Keychain authentication involves a set of passwords. It uses a new password when the previous one expires. Keychain authentication is complex to configure and is therefore recommended only for networks requiring high security.

Prerequisites

You have performed the following operations:

- Enable MPLS LDP globally using the **mpls ldp (system view)** command.
- Configure keychain authentication globally using the **keychain** command.

Precautions

- MD5 authentication and keychain authentication cannot be configured together on one peer.
- Configuring LDP keychain authentication leads to reestablishment of an LDP session and deletes the Label Switched Path (LSP) associated with the LDP session.

Example

Configure LDP keychain authentication for the peer with an LSR ID of **10.1.1.1**. The referenced keychain name is **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] quit
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] authentication key-chain peer 10.1.1.1 name kc1
```

9.1.4 authentication key-chain all

Function

The **authentication key-chain all** command enables keychain authentication in a batch for all LDP peers.

The **undo authentication key-chain all** command disables keychain authentication in a batch for all LDP peers.

By default, keychain authentication in a batch is disabled for all LDP peers. LDP keychain authentication is recommended to ensure security.

Format

authentication key-chain all name *keychain-name*

undo authentication key-chain all

Parameters

Parameter	Description	Value
name *keychain-name*	Specifies a keychain name. The keychain name is configured using the **keychain** command.	The value is a string of 1 to 47 case-insensitive characters. The string does not contain question marks or spaces. The string can contain spaces if it is enclosed with double quotation marks (").

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To improve LDP session security, keychain authentication can be configured for a TCP connection over which an LDP session has been established. If a great number of LDP peers are configured, run the **authentication key-chain all** command to enable keychain authentication in a batch for all LDP peers.

Prerequisites

A keychain has been configured using the **keychain** command.

Precautions

- LDP authentication configurations are prioritized in descending order: for a single peer, for a specified peer group, for all peers. Keychain and MD5 configurations of the same priority are mutually exclusive. Keychain authentication and MD5 authentication can be configured simultaneously for a specified LDP peer, for this LDP peer in a specified peer group, and for all LDP peers. The configuration with a higher priority takes effect. For example, if MD5 authentication is configured for Peer1 and then keychain authentication is configured for all LDP peers, MD5 authentication takes effect on Peer1. Keychain authentication takes effect on other peers.
- Configuring LDP keychain authentication causes the reestablishment of LDP sessions.
- After the **authentication key-chain all** command is run, the referenced keychain is applied to all LDP peers. If keychain authentication fails, an LDP session fails to be established.

Example

Configure LDP keychain authentication for all LDP peers and use the keychain named **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] key-id 1
[HUAWEI-keychain-kc1-keyid-1] algorithm sha-256
[HUAWEI-keychain-kc1-keyid-1] key-string YsHsjx_202206
[HUAWEI-keychain-kc1-keyid-1] send-time 14:30 2016-10-10 to 14:50 2016-10-10
[HUAWEI-keychain-kc1-keyid-1] receive-time 14:40 2016-10-10 to 14:50 2016-10-10
[HUAWEI-keychain-kc1-keyid-1] default send-key-id
[HUAWEI-keychain-kc1-keyid-1] quit
[HUAWEI-keychain-kc1] quit
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] authentication key-chain all name kc1
```

9.1.5 authentication key-chain peer-group

Function

The **authentication key-chain peer-group** command enables keychain authentication in a batch for a specified LDP peer group.

The **undo authentication key-chain peer-group** command disables keychain authentication in a batch for a specified LDP peer group.

By default, keychain authentication in a batch is disabled for all peer groups. LDP keychain authentication is recommended to ensure security.

Format

authentication key-chain peer-group *ip-prefix-name* **name** *keychain-name*

undo authentication key-chain peer-group

Parameters

Parameter	Description	Value
ip-prefix-name	Specifies the name of an IP prefix list. The IP prefix list name is configured using the **ip ip-prefix** command.	The value is a string of 1 to 169 case-sensitive characters, spaces not supported. The string can contain spaces if it is enclosed with double quotation marks (").
name *keychain-name*	Specifies a keychain name. The keychain name is configured using the **keychain** command.	The value is a string of 1 to 47 case-insensitive characters. The string does not contain question marks or spaces. The string can contain spaces if it is enclosed with double quotation marks (").

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To help improve LDP session security, keychain authentication can be configured for a TCP connection over which an LDP session has been established. If a great number of LDP peers are configured, run the **authentication key-chain peer-group** command to enable keychain authentication in a batch for LDP peers in a specified peer group. An IP prefix list can be specified to define the range of IP addresses in a group.

Prerequisites

The following steps have been performed:

- An IP prefix list has been configured using the **ip ip-prefix** command.
- A keychain has been configured using the **keychain** command.

Precautions

- LDP authentication configurations are prioritized in descending order: for a single peer, for a specified peer group, for all peers. Keychain and MD5 configurations of the same priority are mutually exclusive. Keychain authentication and MD5 authentication can be configured simultaneously for a specified LDP peer, for this LDP peer in a specified peer group, and for all LDP peers. The configuration with a higher priority takes effect. For example, if MD5 authentication is configured for Peer1 and then keychain authentication is configured for all LDP peers, MD5 authentication takes effect on Peer1.
- Configuring LDP keychain authentication causes the reestablishment of LDP sessions.
- After the **authentication key-chain peer-group** command is run, the referenced Keychain authentication is applied to a specified peer. If keychain authentication fails, an LDP session fails to be established.
- Before a peer group is referenced, create it. By default, a nonexistent peer group cannot be specified in this command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent peer group is specified in this command, a local device performs keychain authentication for each LDP session connected to each LDP peer.

Example

Enable LDP keychain authentication for LDP peers with IP addresses matching the IP prefix list named **list1** in a specified peer group and use a keychain named **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] key-id 1
[HUAWEI-keychain-kc1-keyid-1] algorithm sha-256
[HUAWEI-keychain-kc1-keyid-1] key-string YsHsjx_202206
[HUAWEI-keychain-kc1-keyid-1] send-time 14:30 2016-10-10 to 14:50 2016-10-10
[HUAWEI-keychain-kc1-keyid-1] receive-time 14:40 2016-10-10 to 14:50 2016-10-10
[HUAWEI-keychain-kc1-keyid-1] default send-key-id
[HUAWEI-keychain-kc1-keyid-1] quit
[HUAWEI-keychain-kc1] quit
[HUAWEI] ip ip-prefix list1 permit 10.1.1.1 32
```

```
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] authentication key-chain peer-group list1 name kc1
```

9.1.6 auto-frr lsp-trigger

Function

The **auto-frr lsp-trigger** command configures a policy for triggering LDP to establish backup LSPs based on backup routes.

The **undo auto-frr lsp-trigger** command restores the default setting.

By default, LDP uses backup routes with 32-bit addresses to establish backup LSPs.

Format

auto-frr lsp-trigger { **all** | **host** | **ip-prefix** *ip-prefix-name* | **none** }

undo auto-frr lsp-trigger

Parameters

Parameter	Description	Value
all	Specifies all backup routes to trigger LDP to establish backup LSPs.	-
host	Specifies backup routes with 32-bit addresses to trigger LDP to establish backup LSPs.	-
ip-prefix *ip-prefix-name*	Specifies IP prefix list to trigger LDP to establish backup LSPs.	The value is an existing IP prefix list name.
none	Specifies no backup routes to trigger LDP to establish backup LSPs.	-

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an MPLS network with a backup link, if a link fault occurs, Interior Gateway Protocol (IGP) routes converge and routes related to the backup link become available. After IGP route convergence is complete, an LDP LSP over the backup link becomes available. During this process, traffic is interrupted. To prevent traffic interruption, you can configure LDP fast reroute (FRR). On the network enabled with LDP FRR, if an interface failure (detected by the interface itself or by an associated BFD session) or a primary LSP failure (detected by an associated BFD session) occurs, LDP FRR is notified of the failure and rapidly forwards traffic to a backup LSP, protecting traffic on the primary LSP. The traffic switchover is performed within 50 milliseconds, avoiding traffic interruption.

LDP FRR is classified into the following types:

- LDP manual FRR: A backup LSP is configured manually by specifying an outbound interface or a next hop. The configuration is complex but flexible because a backup LSP can be configured manually. LDP manual FRR applies to simple networks.
- Auto LDP FRR: A backup LSP is automatically created based on a specified policy. The configuration is simple and loop-free. Auto LDP FRR applies to complex and large networks.

Auto LDP FRR depends on the automatic reroute function of IGP. Auto LDP FRR is automatically enabled after IGP automatic reroute is enabled using the **frr (IS-IS)** command. To change the policy for triggering LDP to establish backup LSPs, run the **auto-frr lsp-trigger** command.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp(system view)** command in the system view.

Precautions

During LDP GR, changing the policy for triggering the setup of backup LSPs is not allowed.

If both the **auto-frr lsp-trigger** command and the **lsp-trigger** command are run, the established backup LSPs are controlled by both the policy for triggering LDP LSP establishment and the policy for triggering backup LDP LSP establishment. For example, if the policy for triggering LDP LSP establishment is **none** and that for triggering backup LDP LSP establishment is **all**, the backup LDP LSP is established using the **none** policy.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all backup routes trigger backup LDP LSP establishment.

Example

#Configure the policy for specifying no backup routes to trigger LDP to establish backup LSPs.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] auto-frr lsp-trigger none
```

9.1.7 backoff timer

Function

The **backoff timer** command sets the initial and maximum values for an Exponential backoff timer.

The **undo backoff timer** command restores the default settings.

By default, the initial value is 15 and the maximum value is 120, in seconds.

Format

backoff timer *init max*

undo backoff timer

Parameters

Parameter	Description	Value
init	Specifies the initial value of an Exponential backoff timer.	The value is an integer ranging from 5 to 2147483, in seconds.
max	Specifies the maximum value of an Exponential backoff timer.	The value is an integer ranging from 5 to 2147483, in seconds.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an LSR fails to process an LDP Initialization message or is informed that the peer LSR rejects the received LDP Initialization message, the LSR starts the Exponential backoff timer and periodically resends an LDP Initialization message to initiate an LDP session before the Exponential backoff timer expires.

When the Exponential backoff timer starts, the active role waits a period of time equal to the initial value of the Exponential backoff timer to attempt to set up an LDP session for the first time. Subsequently, the active role waits a period of time twice as long as the previous one to attempt to set up an LDP session. When the waiting period reaches the maximum value of the Exponential backoff timer, the active role waits a period of time equal to the maximum value of the Exponential backoff timer to attempt to set up an LDP session.

Run the **backoff timer** command to change the interval at which the active role attempts to set up a session.

By setting the initial value and maximum value for the Exponential backoff timer, you can flexibly control the reestablishment of sessions in different network environments.

- When a device is being upgraded, increase the initial and maximum values to set a large interval at which the active role attempts to set up a session.
- When a device that is transmitting services is prone to intermittent disconnections, reduce the initial and maximum values to set a small interval at which the active role attempts to set up a session.

NOTE

The initial value for the Exponential backoff timer cannot be smaller than 15, and the maximum value cannot be smaller than 120.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp (system view)** command.

Precautions

If a session is disconnected after the **backoff timer** command is run, the device attempts to set up a session based on the set initial and maximum values of the Exponential backoff timer.

Example

Set the initial value to 20s and the maximum value to 160s for the Exponential backoff timer.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] backoff timer 20 160
```

9.1.8 bfd bind ldp-lsp

Function

The **bfd bind ldp-lsp** command creates a bidirectional forwarding detection (BFD) session for detecting LDP LSPs.

The **undo bfd** command deletes a specified BFD session.

By default, no BFD session is created for detecting LDP LSPs.

Format

bfd *cfg-name* **bind ldp-lsp peer-ip** *ip-address* **nexthop** *ip-address* [**interface** *interface-type interface-number*]

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the name of a BFD session.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
peer-ip *ip-address*	Specifies the peer IP address bound to the BFD session.	The value is in dotted decimal notation.
nexthop*ip-address*	Specifies the next hop IP address of the detected LSP.	The value is in dotted decimal notation.
interface*interface-type interface-number*	Specifies the outbound interface that is bound to a BFD session. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A dynamic LSP is established using LDP on an MPLS network. It takes an interface a long period of time to detect a link fault. After a static BFD session is bound to the LDP LSP, the interface can quickly detect faults on LDP LSPs. This method applies to small networks.

Prerequisites

BFD has been enabled globally using the **bfd** command.

Precautions

- When the IP address of the outbound interface of the detected LSP is lent or borrowed, an outbound interface must be specified.

- When the LDP LSP is deleted but the LDP session exists, the BFD session is in Down state, but the configuration of the BFD session bound to the LDP session is not deleted.
- When configuring static BFD for LDP LSP on a network deployed with LDP over TE, specify **interface** *interface-type interface-number* as the tunnel interface.

Example

Create a BFD session to detect the LDP LSP with the egress IP address being 10.2.1.1, the next hop IP address being 10.1.1.1, and the outbound interface being VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] bfd 1to4 bind ldp-lsp peer-ip 10.2.1.1 nexthop 10.1.1.1 interface vlanif 100
[HUAWEI-bfd-lsp-session-1to4]
```

9.1.9 bfd bind static-lsp

Function

The **bfd bind static-lsp** command creates a BFD session to detect static LSPs.

The **undo bfd** command deletes a specified BFD session.

By default, no BFD session is created to detect static LSPs.

Format

bfd *cfg-name* **bind static-lsp** *lsp-name*

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the BFD configuration name.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
lsp-name	Specifies the name of the static LSP bound to the BFD session.	The value is an existing static LSP name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can deploy MPLS services by manually configuring static LSPs on small networks with simple topology and stable performance. It takes an interface a long period of time to detect a link fault. After a static BFD session is bound to the LDP LSP, the interface can quickly detect faults on LDP LSPs.

Prerequisites

BFD has been enabled globally using the **bfd** command in the system view.

Precautions

- If the specified static LSP does not exist or the BFD configuration name exists, the BFD session cannot be created.
- The **commit** command must be run to make the configured BFD parameters take effect before a BFD session is created.
- When the status of the static LSP is Down, a BFD session cannot be created.

Example

Create a BFD session to detect the static LSP named **1to4**.

```
<HUAWEI> system-view
[HUAWEI] bfd bfd1to4 bind static-lsp 1to4
[HUAWEI-bfd-lsp-session-bfd1to4]
```

9.1.10 display default-parameter mpls ldp

Function

The **display default-parameter mpls ldp** command displays the default configurations of MPLS LDP.

Format

display default-parameter mpls ldp

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the default configurations of MPLS LDP, run the **display default-parameter mpls ldp** command.

Example

Display the default configurations of MPLS LDP.

```
<HUAWEI> display default-parameter mpls ldp

 LDP Default Values:

Table 9-1 Description of the **display default-parameter mpls ldp** command output

Item	Description
Protocol version	LDP version number.
Graceful restart	LDP GR capability status. - On: LDP GR is enabled. - Off: LDP GR is disabled. By default, LDP GR is disabled. You can configure the LDP GR capability status using the **graceful-restart** command.

Item	Description
Neighbor liveness(sec)	Value of the neighbor-liveness timer, in seconds. The default value is 600s. You can set this value using the **graceful-restart timer neighbor-liveness** command.
FT reconnect timer(sec)	Value of the reconnect timer of an LDP session, in seconds. The default value is 300s. You can set this value using the **graceful-restart timer reconnect** command.
Recovery timer(sec)	Value of the recovery timer of an LDP LSP, in seconds. The default value is 300s. You can set this value using the **graceful-restart timer recovery** command.
MTU signaling	MTU TLV status. ● On: MTU TLV is enabled. ● Off: MTU TLV is disabled. By default, MTU TLV is enabled.
Label retention mode	LDP label retention modes include: ● Liberal: free mode. ● Conservative: conservative mode. The default label retention mode is liberal.
Label distribution mode	LDP label distribution mode. Currently, only the ordered mode is supported.
Label advertisement	LDP label advertisement modes include: ● DU: downstream unsolicited mode. ● DOD: downstream on demand mode. The default label advertisement mode is DU. You can set the LDP label advertisement mode using the **mpls ldp advertisement** command.
Local hello-hold timer(sec)	Value of the local Hello hold timer, in seconds. The default value is 15s. You can set this value using the **mpls ldp timer hello-hold** command.
Remote hello-hold timer(sec)	Value of the remote Hello hold timer, in seconds. The default value is 45s. You can set this value using the **mpls ldp timer hello-hold** command.
Keepalive-hold timer(sec)	Value of the keepalive hold timer for the local and remote LDP sessions, in seconds. The default value is 45s. You can set this value using the **mpls ldp timer keepalive-hold** command.
Backoff timer init(sec)	Initial value of the Exponential backoff timer, in seconds. The default value is 15s. You can set this value using the **backoff timer** command.

Item	Description
Backoff timer max(sec)	Maximum value of the Exponential backoff timer, in seconds. The default value is 120s. You can set this value using the **backoff timer** command.
IGP-Sync delay timer(sec)	Value of the LDP-IGP association timer, in seconds. The default value is 10s. You can set this value using the **mpls ldp timer igp-sync-delay** command.
Graceful delete	Graceful deletion. This function is disabled and not supported currently.
Graceful delete timer(sec)	Value of the graceful deletion timer, in seconds. The default value is 5s.
Capability-announcement	Dynamic capability announcement function. This function is disabled and not supported currently.
mLDP MBB Capability	Whether the mLDP make-before-break capability is enabled. The default value is "Off", indicating that mLDP make-before-break is disabled.
Wait-ack timer(sec)	Time (in seconds) elapses before a local device receives a Make-before-break (MBB) ACK Notification message
Switch-delay timer(ms)	Delay time (in seconds) for switching traffic to an MBB LSP
mLDP P2MP Capability	Whether mLDP P2MP is enabled globally. The default value is "Off", indicating that mLDP P2MP is disabled globally.
mLDP MP2MP Capability	Whether mLDP multipoint-to-multipoint (MP2MP) is enabled globally. The default value is "Off", indicating that mLDP MP2MP is disabled globally.
Label withdraw-delay	Whether the label withdraw delay function is enabled. The default value is "Off", indicating that this function is disabled.
Withdraw-delay timer(sec)	Default value of the label withdraw delay timer (in seconds).
Send LSP down reason	Whether a node is enabled to report the fault cause to the ingress. The default value is "Off", indicating that the faulty node is disabled from reporting the fault cause to the ingress.
Ingress LSP Load-balance Num	Default maximum number of equal-cost LDP LSPs that can be established on the ingress.
Transit LSP Load-balance Num	Default maximum number of equal-cost LDP LSPs that can be established on a transit node.

Item	Description
Smart-policy Ingress	Whether the smart LDP ingress policy is enabled.
Smart-policy Auto-dod-request	Whether on-demand LDP request trigger is enabled.
Label default-route	Whether the device is enabled to assign a label to a default IGP route. You can set this value using the **label distribution default-route** command.

9.1.11 display default-parameter mpls management

Function

The **display default-parameter mpls management** command displays default configurations of the MPLS management module.

Format

display default-parameter mpls management

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the default configurations of MPLS management module, run the **display default-parameter mpls management** command.

Example

Display the default configurations of the MPLS management module.

```
<HUAWEI> display default-parameter mpls management

 Global Information:

Table 9-2 Description of the display default-parameter mpls management command output

Item	Description
BFD detect-multiplier	BFD detection multiplier. The default value is 3. You can set this value using the **mpls bfd** command.
BFD min-tx-interval(ms)	Interval for sending BFD packets. You can set this value using the **mpls bfd** command.
BFD min-rx-interval(ms)	Interval for receiving BFD packets. You can set this value using the **mpls bfd** command.
Label advertisement mode	Mode in which the egress node assigns labels to the penultimate hop. ● Implicit null: The egress node assigns an implicit empty label to the penultimate hop. The value of the label is 3. ● Explicit null: The egress node assigns an explicit empty label to the penultimate hop. The value of the label is 0. ● Non null: The egress node assigns a label to the penultimate hop properly. The value of the label is not smaller than 16. By default, the implicit null mode is used. You can set the label advertisement mode using the **label advertise** command.
LSP trigger mode	Policy for triggering LSP setup. ● All: All static routes and IGP routing entries trigger the setup of LSPs. ● Host: The IP route of the 32-bit address host triggers the setup of LSPs. ● Ip-prefix: Only FECs that match entries in the IP address prefix list trigger the setup of LSPs. ● None: The setup of LSPs is not triggered. The default trigger policy is **Host**. You can set the LSP trigger mode using the **lsp-trigger** command.
LDP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for LDP LSPs. You can set the LSP trigger mode using the **mpls ldp-lsp-number threshold-alarm** command.
LDP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for LDP LSPs. You can set the LSP trigger mode using the **mpls ldp-lsp-number threshold-alarm** command.
BGP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for BGP LSPs. You can set the LSP trigger mode using the **mpls bgp-lsp-number threshold-alarm** command.

Item	Description
BGP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for BGP LSPs. You can set the LSP trigger mode using the **mpls bgp-lsp-number threshold-alarm** command.
BGP V6 LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for BGP IPv6 LSPs. You can set the LSP trigger mode using the **mpls bgpv6-lsp-number threshold-alarm** command.
BGP V6 LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for BGP IPv6 LSPs. You can set the LSP trigger mode using the **mpls bgpv6-lsp-number threshold-alarm** command.
Dynamic Label number threshold-alarm upper limit	Upper limit of the alarm threshold for dynamic label usage. You can set the LSP trigger mode using the **mpls dynamic-label-number threshold-alarm** command.
Dynamic Label number threshold-alarm lower limit	Lower limit of the alarm threshold for dynamic label usage. You can set the LSP trigger mode using the **mpls dynamic-label-number threshold-alarm** command.
RSVP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for RSVP LSPs. You can set the LSP trigger mode using the **mpls rsvp-lsp-number threshold-alarm** command.
RSVP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for RSVP LSPs. You can set the LSP trigger mode using the **mpls rsvp-lsp-number threshold-alarm** command.
Total LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total LSPs. You can set the LSP trigger mode using the **mpls total-lsp-number threshold-alarm** command.
Total LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total LSPs. You can set the LSP trigger mode using the **mpls total-lsp-number threshold-alarm** command.
Total CR LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total CR-LSPs. You can set the LSP trigger mode using the **mpls total-crlsp-number threshold-alarm** command.
Total CR LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total CR-LSPs. You can set the LSP trigger mode using the **mpls total-crlsp-number threshold-alarm** command.
Ingress LDP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for ingress LDP LSP

Item	Description
Ingress LDP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for ingress LDP LSP
Transit LDP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for transit LDP LSP
Transit LDP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for transit LDP LSP
Egress LDP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for egress LDP LSP
Egress LDP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for egress LDP LSP
Ingress BGP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for ingress BGP LSP
Ingress BGP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for ingress BGP LSP
Egress BGP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for egress BGP LSP
Egress BGP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for egress BGP LSP
Egress BGP V6 LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for egress BGP V6 LSP
Egress BGP V6 LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for egress BGP V6 LSP
Ingress RSVP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for ingress RSVP LSP
Ingress RSVP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for ingress RSVP LSP

Item	Description
Transit RSVP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for transit RSVP LSP
Transit RSVP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for transit RSVP LSP
Egress RSVP LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for egress RSVP LSP
Egress RSVP LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for egress RSVP LSP
Total ingress LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total ingress LSP
Total ingress LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total ingress LSP
Total transit LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total transit LSP
Total transit LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total transit LSP
Total egress LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total egress LSP
Total egress LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total egress LSP
Total ingress CR LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total ingress CR-LSP
Total ingress CR LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total ingress CR-LSP
Total transit CR LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total transit CR-LSP

Item	Description
Total transit CR LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total transit CR-LSP
Total egress CR LSP number threshold-alarm upper limit	Upper limit of the alarm threshold for total egress CR-LSP
Total egress CR LSP number threshold-alarm lower limit	Lower limit of the alarm threshold for total egress CR-LSP
Auto bypass tunnel interface number threshold-alarm upper limit	Upper limit of the alarm threshold for auto bypass tunnel interface
Auto bypass tunnel interface number threshold-alarm lower limit	Lower limit of the alarm threshold for auto bypass tunnel interface
P2MP auto tunnel interface number threshold-alarm upper limit	Upper limit of the alarm threshold for P2MP auto tunnel interface
P2MP auto tunnel interface number threshold-alarm lower limit	Lower limit of the alarm threshold for P2MP auto tunnel interface
TE dynamic bfd number threshold-alarm upper limit	Upper limit of the alarm threshold for TE dynamic bfd
TE dynamic bfd number threshold-alarm lower limit	Lower limit of the alarm threshold for TE dynamic bfd
LDP dynamic bfd number threshold-alarm upper limit	Upper limit of the alarm threshold for LDP dynamic bfd
LDP dynamic bfd number threshold-alarm lower limit	Lower limit of the alarm threshold for LDP dynamic bfd
Total MLDP tree number threshold-alarm upper limit	Upper limit of the alarm threshold for total MLDP tree

Item	Description
Total MLDP tree number threshold-alarm lower limit	Lower limit of the alarm threshold for total MLDP tree
Total MLDP branch number threshold-alarm upper limit	Upper limit of the alarm threshold for total MLDP branch
Total MLDP branch number threshold-alarm lower limit	Lower limit of the alarm threshold for total MLDP branch
Total LDP remote adjacency number threshold-alarm upper limit	Upper limit of the alarm threshold for total LDP remote adjacency
Total LDP remote adjacency number threshold-alarm lower limit	Lower limit of the alarm threshold for total LDP remote adjacency
Total LDP local adjacency number threshold-alarm upper limit	Upper limit of the alarm threshold for total LDP local adjacency
Total LDP local adjacency number threshold-alarm lower limit	Lower limit of the alarm threshold for total LDP local adjacency
Total CSPF node number threshold-alarm upper limit	Upper limit of the alarm threshold for total CSPF node
Total CSPF node number threshold-alarm lower limit	Lower limit of the alarm threshold for total CSPF node
Total CSPF link number threshold-alarm upper limit	Upper limit of the alarm threshold for total CSPF link
Total CSPF link number threshold-alarm lower limit	Lower limit of the alarm threshold for total CSPF link
Total CSPF network-lsa number threshold-alarm upper limit	Upper limit of the alarm threshold for total CSPF network-lsa
Total CSPF network-lsa number threshold-alarm lower limit	Lower limit of the alarm threshold for total CSPF network-lsa

Item	Description
Total CSPF SRLG number threshold-alarm upper limit	Upper limit of the alarm threshold for total CSPF SRLG
Total CSPF SRLG number threshold-alarm lower limit	Lower limit of the alarm threshold for total CSPF SRLG
RSVP peer number threshold-alarm upper limit	Upper limit of the alarm threshold for RSVP peer
RSVP peer number threshold-alarm lower limit	Lower limit of the alarm threshold for RSVP peer

9.1.12 display isis ldp-sync interface

Function

The **display isis ldp-sync interface** command displays information about LDP and IS-IS synchronization on an interface.

Format

display isis [*process-id* | **vpn-instance** *vpn-instance-name*] **ldp-sync interface**

Parameters

Parameter	Description	Value
process-id	Specifies the IS-IS process ID.	The value is an integer ranging from 1 to 65535.
vpn-instance *vpn-instance-name*	Specifies the VPN instance name.	The value must be an existing VPN instance name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

For all the interfaces that are enabled with LDP and IS-IS synchronization, run the **display isis ldp-sync** command to view information about LDP and IS-IS synchronization.

Example

Display information about LDP and IS-IS synchronization on an interface.

```
<HUAWEI> display isis ldp-sync interface

               Ldp Sync interface information for ISIS(1)
               ------------------------------------------
Interface    HoldDownTimer    HoldMaxCostTimer   LDP State   Sync State
Vlanif100     10               10                Down        Init
```

Table 9-3 Description of the display isis ldp-sync interface command output

Item	Description
Interface	Interface connected to neighbors.
HoldDownTimer	Interval during which the interface waits for the LDP session establishment and does not create the IS-IS neighbor relationship. The default value is 10 seconds. You can set this value using the **isis timer ldp-sync hold-down** command.
HoldMaxCostTimer	Interval for IS-IS to notify the local device of the maximum metric in the link state PDU (LSP). The default value is 10 seconds. You can set this value using the **isis timer ldp-sync hold-max-cost** command. **NOTE** If the value of this field is **infinite**, IS-IS permanently notifies the local device of the maximum metric in the LSP before an LDP session is established.
LDP State	LDP session status, which can be: - Up: The LDP session is normal. - Down: The LDP session is disconnected. - GR: The LDP session is in GR state. If the interface is maintaining the session before GR, the LDP status is displayed as GR state during GR.

Item	Description
Sync State	Status of synchronization between LDP and IS-IS: ● Sync-Achieved: The creation of an LDP session and establishment of the IS-IS neighbor relationship are synchronized. ● HoldDown: indicates the state in which the interface waits to create an LDP session without creating the IS-IS neighbor relationship. ● HoldMaxCost: indicates the state in which IS-IS advertises the maximum metric in LSPs sent by the local device. ● Init: indicates the initial state.

9.1.13 display lspv configuration

Function

The **display lspv configuration** command displays the current configuration of LSPV tracert.

Format

display lspv configuration

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display lspv configuration** command to check the current LSPV configurations.

Example

Display the current configuration of LSPV tracert.

```
<HUAWEI> display lspv configuration
lspv packet filter 2100
undo lspv mpls-lsp-ping echo enable
```

Table 9-4 Description of the **display lspv configuration** command output

Item	Description
lspv packet filter 2100	Filters the LSPV tracert packet with the specific source address according to ACL 2100. To configure the filtering of the LSPV tracert packet with the specific source address, run the **lspv packet-filter** command.
undo lspv mpls-lsp-ping echo enable	Disables the response to MPLS Ping packets. To configure a device to respond to MPLS Echo Request packets, run the **lspv mpls-lsp-ping echo enable** command.

9.1.14 display lspv statistics

Function

The **display lspv statistics** command displays LSPV statistics.

Format

display lspv statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

In MPLS network management, the **ping lsp** or **tracert lsp** command can be used for LSP detection.

If the LSP detection fails, you can run the **display lspv statistics** command to view statistics about MPLS packets sent and received on the local device. If the number of MPLS packets that the local device sends is the same as the number of MPLS packets that the local device receives, but the ping or trace operation fails, the detection failure is caused by the fault of the local device, not the LSP.

Precautions

Before running the **display lspv statistics** command to collect LSPV statistics, run the **reset lspv statistics** command to clear the existing statistics.

Example

Display LSPV statistics on the device.

```
<HUAWEI> display lspv statistics
Total sent: 0 packet(s)
Total received: 0 packet(s)
MPLS echo request sent: 0 packet(s), received: 0 packet(s)
MPLS echo reply sent: 0 packet(s), received: 0 packet(s)
-------------------------------------------------------------------
Statistics base on ReturnCode:
0 - No return code,1 - Malformed echo request received,2 - One or more
of the TLVs was not understood,3 - Replying router is an egress for
the FEC at stack-depth, 4 - Replying router has no mapping for the FEC
at stack-depth,5 - Downstream Mapping Mismatch, 6 - Upstream Interface
Index Unknown, 7 - Reserved, 8 - Label switched at stack-depth,9 -
Label switched but no MPLS forwarding at stack-depth,10 - Mapping for
this FEC is not the given label at stack-depth,11 - No label entry at
stack-depth,12 - Protocol not associated with interface at FEC
stack-epth,13 - Premature termination of ping due to label stack
shrinking to a single label.:
-------------------------------------------------------------------
Value     SendNum     RecvNum     Value     SendNum     RecvNum
   0          0           0          1          0          0
   2          0           0          3          0          0
   4          0           0          5          0          0
   6          0           0          7          0          0
   8          0           0          9          0          0
  10          0           0         11          0          0
  12          0           0         13          0          0
-------------------------------------------------------------------
```

Table 9-5 Description of the **display lspv statistics** command output

Item	Description
Total sent	Total number of sent MPLS Echo Request and MPLS Echo Reply packets
Total received	Total number of received MPLS Echo Request and MPLS Echo Reply packets
MPLS echo request sent, received	Number of sent and received MPLS Echo Request packets
MPLS echo reply sent, received	Number of sent and received MPLS Echo Reply packets

Item	Description
Statistics base on ReturnCode	Statistics base on ReturnCode: - 0: No return code - 1: Malformed echo request received - 2: One or more of the TLVs was not understood - 3: Replying router is an egress for the FEC at stack-depth - 4: Replying router has no mapping for the FEC at stack-depth - 5: Downstream Mapping Mismatch - 6: Upstream Interface Index Unknown - 7: Reserved - 8: Label switched at stack-depth - 9: Label switched but no MPLS forwarding at stack-depth - 10: Mapping for this FEC is not the given label at stack-depth - 11: No label entry at stack-depth - 12: Protocol not associated with interface at FEC stack-epth - 13: Premature termination of ping due to label stack shrinking to a single label
Value	The value of ReturnCode in sent or received LSP verification packets.
SendNum	Number of sent packets with this ReturnCode.
RecvNum	Number of received packets with this ReturnCode.

9.1.15 display mpls bfd session

Function

The **display mpls bfd session** command displays information about BFD sessions for MPLS.

Format

display mpls bfd session [**fec** *fec-address* | **monitor** | **nexthop** *ip-address* | **outgoing-interface** *interface-type interface-number* | **statistics** | **verbose**]

display mpls bfd session protocol ldp [**fec** *fec-address* [**verbose**]]

display mpls bfd session protocol { **cr-static** | **rsvp-te** } [**lsp-id** *ingress-lsr-id session-id lsp-id* [**verbose**]]

display mpls bfd session protocol bgp [**fec** *fec-address* [**verbose**]]

Parameters

Parameter	Description	Value
fec *fec-address*	Displays information about the BFD session of a specified FEC.	The value is in dotted decimal notation.
monitor	Displays monitoring information of BFD sessions.	-
nexthop *ip-address*	Displays information about the BFD session of a specified next hop.	The value is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Displays information about the BFD session of the LSP with a specified outbound interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
protocol	Indicates the type of the protocol.	-
cr-static	Displays information about the BFD session for static CR-LSP.	-
ldp	Displays information about the BFD session for LDP.	-
rsvp-te	Displays information about the BFD session for RSVP-TE.	-
statistics	Displays statistics about BFD sessions such as the total number of BFD sessions.	-
verbose	Displays detailed information about BFD sessions.	-
lsp-id *ingress-lsr-id*	Specifies the LSR ID of the ingress.	The value is in dotted decimal notation.
session-id	Specifies the ID of a session.	The value is an integer ranging from 0 to 65535.
lsp-id	Specifies the LSP ID.	The value is an integer ranging from 0 to 65535.
bgp	Displays information about BFD sessions for BGP.	-

1: Monitoring level

Usage Guidelines

Run the **display mpls bfd session** command to view information about a BFD session and the LSP detected by BFD, including the destination address and outbound interface of the LSP, the local discriminator of the BFD session, and the status of an MPLS BFD session.

Example

Display information about the BFD session.

```
<HUAWEI> display mpls bfd session
--------------------------------------------------------------------------------
              BFD Information: LDP  LSP
--------------------------------------------------------------------------------
FEC            DISC  OUT-IF      NEXTHOP        TUNNEL         STATE
3.3.3.3        8     VLANIF100   10.1.1.2       Tunnel1        Up
```

Table 9-6 Description of the display mpls bfd session command output

Item	Description
FEC	Forwarding equivalence class.
DISC	Local discriminator of a BFD session.
OUT-IF	Outbound interface.
NEXTHOP	IP address of the next hop.
TUNNEL	Name of a tunnel.
STATE	Status of an MPLS BFD session. ● Up ● Down

Display detailed information about a BFD session with the specified protocol type and LSP ID.

```
<HUAWEI> display mpls bfd session protocol rsvp-te lsp-id 3.3.3.3 3 1 verbose

Bgp Bfd Capability	Whether BFD for BGP tunnel is enabled: ● Enable ● Disable
Te Bfd Capability	Whether BFD for Traffic Engineering (TE) is enabled: ● Enable ● Disable

Item	Description
Bfd Session Full	Whether the number of created BFD sessions reaches the upper limit: - Full: The number of created BFD sessions reached the upper limit. - Not-full: The number of created BFD sessions is lower than the upper limit.
Bfd Clearing	Whether BFD is disabled globally: - Yes - No
Lsp Type	LSP type
Min-Val	Minimum number of supported LSPs specified in the license file.
Max-Val	Maximum number of supported LSPs specified in the license file.
Avail-Val	Average number of supported LSPs specified in the license file.
Created	Number of established LSPs.

9.1.16 display mpls graceful-restart

Function

The **display mpls graceful-restart** command displays graceful restart (GR) information about all protocols related to MPLS.

Format

display mpls graceful-restart

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When MPLS is used together with other protocols, run the **display mpls graceful-restart** command to view GR information about protocols related to MPLS, including the GR status, GR start time, and GR type.

Example

Display GR information related to all protocols.

```
<HUAWEI> display mpls graceful-restart
Protocol       GR state       GR start time            GR type
LDP            Normal         -                        -
CRLDP          Normal         -                        -
RSVP           Normal         -                        -
BGP            Normal         -                        -
L3VPN          Normal         -                        -
STATIC         Normal         -                        -
CRSTATIC       Normal         -                        -
BGP IPV6       Normal         -                        -
STATIC HA      Normal         -                        -
L3VPN IPV6     Normal         -                        -
STATIC TP      Normal         -                        -
```

Table 9-10 Description of the display mpls graceful-restart command output

Item	Description
Protocol	Protocol type: LDP, CRLDP, RSVP, BGP, L3VPN, STATIC, CRSTATIC, BGP IPV6, STATIC HA, L3VPN IPV6, and STATIC TP.
GR state	GR status of a protocol: ● Restarting: The protocol is in the GR process. ● Normal: The protocol is not in the GR process.
GR start time	Time when the GR process starts When the GR process does not start, a hyphen (-) is displayed.
GR type	GR type: ● System restart: indicates the system GR. ● Protocol restart: indicates the protocol GR. When the GR process does not start, a hyphen (-) is displayed.

9.1.17 display mpls interface

Function

The **display mpls interface** command displays information about all MPLS-enabled interfaces.

Format

display mpls interface [*interface-type interface-number*] [**verbose**]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface.	-
verbose	Displays detailed information about the interface enabled with MPLS.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After enabling MPLS functions, run the **display mpls interface** command to view information about the interface enabled with MPLS.

Example

Display information about all MPLS-enabled interfaces.

```
<HUAWEI> display mpls interface
Interface            Status    TE Attr    LSP Count   CRLSP Count Effective MTU
Vlanif100              Up        Dis        2           0           1500
```

Table 9-11 Description of the display mpls interface command output

Item	Description
Interface	The interface enabled with MPLS.
Status	Interface status: ● Up ● Down
TE Attr	Status of the TE attributes on an interface: ● Dis: MPLS TE is disabled on the interface. ● En: MPLS TE is enabled on the interface.
LSP Count	Number of LSPs established on an interface.
CRLSP Count	Number of CR-LSPs established on an interface.

Item	Description
Effective MTU	MPLS MTU used during data forwarding: ● If the MPLS MTU is not set, the interface MTU takes effect. ● If the MPLS MTU is set, the smaller one between the MPLS MTU and the interface MTU takes effect. To set the MPLS MTU, run the **mpls mtu** command. To set the interface MTU, run the **mtu** command.

Display detailed information about a specified MPLS-enabled interface.

```
<HUAWEI> display mpls interface vlanif 100 verbose
No                    :  1
Interface             :  Vlanif100
Status                :  Up
TE Attribute          :  Disable
Static LSPCount       :  0
Static CR-LSPCount    :  0
LDP LSPCount          :  0
RSVP LSPCount         :  0
MPLS MTU              :  -
Interface MTU         :  1500
Effective MTU         :  1500
TE FRR                :  Disable
Interface Index       :  0xd1
```

Table 9-12 Description of the display mpls interface verbose command output

Item	Description
No	Serial number.
Interface	The interface enabled with MPLS.
Status	Interface status: ● Up ● Down
TE Attribute	Status of the TE attributes on the interface: ● Disable: MPLS TE is disabled on the interface. ● Enable: MPLS TE is enabled on the interface.
Static LSPCount	Number of static LSPs established on the interface.
Static CR-LSPCount	Number of static CR-LSPs established on the interface.
LDP LSPCount	Number of LDP LSPs created on the interface.
RSVP LSPCount	Number of RSVP-TE LSPs established on the interface.
MPLS MTU	MPLS MTU value configured using the **mpls mtu** command. When no MPLS MTU is set, a hyphen (-) is displayed.

Item	Description
Interface MTU	MTU value configured on an interface. To set the interface MTU, run the **mtu** command.
Effective MTU	MPLS MTU used during data forwarding: ● If no MPLS MTU is set, the interface MTU takes effect. ● If the MPLS MTU is set, the smaller one between the MPLS MTU and the interface MTU takes effect. To set the MPLS MTU, run the **mpls mtu** command. To set the interface MTU, run the **mtu** command.
TE FRR	Whether the TE FRR is enabled or disabled on the interface: ● Disable: No bypass tunnel is set up in manual FRR mode to protect the interface. ● Enable: A bypass tunnel is set up in manual FRR mode to protect the interface.
Interface Index	Interface index value.

9.1.18 display mpls label static available

Function

The **display mpls label static available** command displays information about labels available for transmitting static services.

Format

display mpls label static available [[**label-from** *label-index*] **label-number** *label-number*]

Parameters

Parameter	Description	Value
label-from *label-index*	Specifies the start label value.	The value is an integer ranging from 16 to 1023.
label-number *label-number*	Specifies the number of the required labels.	The value is an integer ranging from 1 to 1008.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

By default, the system reserves separate label spaces for dynamic and static services, allowing labels for dynamic and static services to be stored in separate spaces.

Before specifying a label for static services, ensure that the specified label is available. You can run the **display mpls label static available** command to view labels for static services.

In the command output, a hyphen is used to specify a range. For example, labels 1000, 1001, and 1002 are displayed as 1000-1002.

Follow-up Procedure

Labels displayed in the command output can be allocated for static services.

Example

Display information about labels available for transmitting static services.

```
<HUAWEI> display mpls label static available
16-1023
```

9.1.19 display mpls label-stack ilm inlabel

Function

The **display mpls label-stack ilm inlabel** command displays information about the label stack for packets with a specified incoming label.

Format

display mpls label-stack ilm inlabel *in-label*

Parameters

Parameter	Description	Value
in-label	Specifies the incoming label for the packets about which label-stack information is to be displayed.	The value is an integer ranging from 16 to 1048575.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to query information about the outgoing label stack for packets based on the incoming label. The supported public network tunnels include static LSP tunnels, LDP LSPs, dynamic TE tunnels, and static TE tunnels. This command cannot be used in the following situations:

- Tunnels overlap.
- Tunnels load-balance traffic.
- The primary and secondary SPE egresses are used.
- Routes recurse to a ring network.
- Layer 3 labels are used.

Example

Display the outgoing label, outbound interface, and tunnel type in the packets with the incoming label value of 1028.

```
<HUAWEI> display mpls label-stack ilm inlabel 1028
Label-stack  : 1
Level        : 1
Type         : LDP
Label        : 1025
OutInterface : Vlanif111
```

Table 9-13 Description of the **display mpls label-stack ilm inlabel** command output

Item	Description
Label-stack	Number of label stacks
Level	Number of labels
Type	Tunnel type
Label	Value of the outgoing label
OutInterface	Outbound interface

9.1.20 display mpls last-info lsp-down

Function

The **display mpls last-info lsp-down** command displays information about LSPs in Down state.

Format

display mpls last-info lsp-down [**protocol ldp**] [**verbose**]

Parameters

Parameter	Description	Value
protocol ldp	Displays information about LSPs in Down state.	-
verbose	Displays detailed information about LDP LSPs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If LSPs fail and enter the Down state, run the **display mpls last-info lsp-down** command to view the faults that cause the latest 64 LSPs to go Down.

Example

Display brief information about LDP LSPs that just enter the Down state.

```
<HUAWEI> display mpls last-info lsp-down
-------------------------------------------------------------------------------
                 LDP LSP Information: Host Address
-------------------------------------------------------------------------------
FEC                In/Out Label  Out Interface       Down Reason
10.12.12.12/32     1029/3        vlanif10            route changed
10.12.12.12/32     NULL/3         vlanif10            route changed
10.11.11.11/32     1034/3        vlanif10            cannot recovery from GR
10.11.11.11/32     NULL/3         vlanif10            cannot recovery from GR
10.11.11.11/32     1033/3        vlanif10            DS lost
10.11.11.11/32     NULL/3         vlanif10            DS lost
```

Table 9-14 Description of the display mpls last-info lsp-down command output

Item	Description
FEC	Forwarding equivalence class.
In/Out Label	Values of the incoming and outgoing labels.
Out Interface	Outbound interface.

Item	Description
Down Reason	LSPs go Down due to the following causes: - route changed: A route was changed. - adjacency changed: An adjacency was changed. - cannot recovery from GR: The LDP LSP failed to be reestablished during GR. - recv release msg: A Release message was received. - recv withdraw msg: A Withdraw message was received. - US lost: The session with the upstream node went Down. - DS lost: The session with the downstream node went Down. - policy changed: The policy to establish LSPs was changed (Generally, configurations of the policy was changed). - reach paf limit: PAF resources are insufficient. - GR aging: The LSP aged after GR. - others

Display detailed information about LDP LSPs that just enter the Down state.

```
<HUAWEI> display mpls last-info lsp-down protocol ldp verbose

Table 9-15 Description of the display mpls last-info lsp-down protocol ldp verbose command output

Item	Description
No	Record No.
VrfIndex	Index of a VRF instance.
Fec	Forwarding equivalence class.
Nexthop	Next hop IP address.
In-Label	Value of the incoming label.
Out-Label	Value of the outgoing label.
Out-Interface	Outbound interface.
LspIndex	Index of an LSP.
Token	Token value, in the hexadecimal format.
LsrType	Type of an LSR on an LSP, which can be ingress, transit, or egress.
Outgoing token	Outgoing token value, in the hexadecimal format.
Label Operation	Label operation, which can be PUSH, POP, SWAP, or SWAPPUSH.
Down Time	Time when an LSP goes Down.
Exist time	Existing period of an LDP LSP, in seconds.

Item	Description
Down Reason	LSPs go Down due to the following causes: ● route changed: A route was changed. ● adjacency changed: An adjacency was changed. ● cannot recovery from GR: The LDP LSP failed to be reestablished during GR. ● recv release msg: A Release message was received. ● recv withdraw msg: A Withdraw message was received. ● US lost: The session with the upstream node went Down. ● DS lost: The session with the downstream node went Down. ● policy changed: The policy to establish LSPs was changed (Generally, configurations of the policy was changed). ● reach paf limit: PAF resources are insufficient. ● GR aging: The LSP aged after GR. ● others

9.1.21 display mpls ldp

Function

The **display mpls ldp** command displays global LDP configurations.

Format

display mpls ldp [**all**] [**verbose**]

Parameters

Parameter	Description	Value
all	Displays all LDP information.	-
verbose	Displays detailed information about the LDP protocol and the LSR.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After global MPLS is enabled, run the **display mpls ldp** command to view LDP configurations, including configurations of the GR timer, label distribution, and label management.

Prerequisites

MPLS has been enabled globally using the **mpls** command, and MPLS LDP has been enabled globally using the **mpls ldp** command.

Example

Display global LDP configurations.

```
<HUAWEI> display mpls ldp

                         LDP Global Information
 ------------------------------------------------------------------------------
 Protocol Version        : V1            Neighbor Liveness    : 600 Sec
 Graceful Restart        : Off           FT Reconnect Timer   : 300 Sec
 MTU Signaling           : On            Recovery Timer       : 300 Sec
 Capability-Announcement : On            Longest-match        : Off
 mLDP P2MP Capability    : Off           mLDP MBB Capability  : Off
 mLDP MP2MP Capability   : Off

                         LDP Instance Information
 ------------------------------------------------------------------------------
 Instance ID             : 0             VPN-Instance         :
 Instance Status         : Active        LSR ID               : 10.1.1.1
 Loop Detection          : Off           Path Vector Limit    : 32
 Label Distribution Mode : Ordered
 Label Retention Mode    : Liberal(DU)/Conservative(DOD)
 Instance Deleting State : No            Instance Resetting State : No
 Graceful-Delete         : Off           Graceful-Delete Timer : 5 Sec
 ------------------------------------------------------------------------------
```

Table 9-16 Description of the display mpls ldp command output

Item	Description
LDP Global Information	Global LDP information.
Protocol Version	LDP protocol version.
Neighbor Liveness	Timeout period of the GR Neighbor-liveness timer. To set the timeout period of the GR Neighbor-liveness timer, run the **graceful-restart timer neighbor-liveness** command.

Item	Description
Graceful Restart	Whether LDP is enabled with GR: - On: GR is enabled. - Off: GR is disabled. To enable LDP GR, run the **graceful-restart** command.
FT Reconnect Timer	Timeout period of the GR reconnect timer. To set the timeout period of the GR reconnect timer, run the **graceful-restart timer reconnect** command.
MTU Signaling	Whether the MTU signaling is enabled: - On: The private MTU TLV is sent. - Off: The MTU TLV is not supported. - On(apply-tlv): The MTU TLV is sent according to RFC 3988. To set the MTU signaling, run the **mtu-signalling** command.
Recovery Timer	Timeout period of the GR Recovery timer. To set the timeout period of the GR Recovery timer, run the **graceful-restart timer recovery** command.
Capability-Announcement	Status of the LDP dynamic capability announcement function: - On: LDP dynamic capability announcement is enabled. - Off: LDP dynamic capability announcement is disabled. **NOTE** The switch does not support this parameter.
Longest-match	Status of LDP extension for inter-area LSP: - On: LDP extension for inter-area LSP is enabled. - Off: LDP extension for inter-area LSP is disabled. To set the status of LDP extension for inter-area LSP, run the **longest-match** command.
mLDP P2MP Capability	Whether mLDP P2MP is globally enabled: - On: mLDP P2MP is enabled globally. - Off: mLDP P2MP is disabled globally. **NOTE** The switch does not support this parameter.

Item	Description
mLDP MBB Capability	Whether the mLDP make-before-break capability is enabled: - On: mLDP make-before-break is enabled. - Off: mLDP make-before-break is disabled. **NOTE** The switch does not support this parameter.
mLDP MP2MP Capability	Whether multipoint extensions for LDP (mLDP) multipoint-to-multipoint (MP2MP) is globally enabled: - On: mLDP MP2MP is enabled globally. - Off: mLDP MP2MP is disabled globally. **NOTE** The switch does not support this parameter.
LDP Instance Information	Information about the LDP multi-instance.
Instance ID	ID of a VPN instance in the integer format.
VPN-Instance	Name of a VPN instance. The default name is **null**. **NOTE** The switch does not support this parameter.
Instance Status	Status of an instance: - Active: The instance is in the Active state. - NotInService: The instance is in the NotInService state temporarily due to certain operations. For example, after the **reset mpls ldp** or **graceful-restart** command is used, the instance is unavailable temporarily. - Destroy: The instance is in the Destroy state. For example, after the **undo mpls ldp** command is used, the instance is in the Destroy state.
LSR ID	LSR ID of an LDP instance.
Loop Detection	Loop detection status: - On: Loop detection is enabled. - Off: Loop detection is disabled. To set the status of the loop detection, run the **loop-detect** command.
Path Vector Limit	Path vector limit for loop detection. To set the path vector limit for loop detection, run the **path-vectors** command.

Item	Description
Label Distribution Mode	Label distribution mode: ● Ordered ● Independent Currently, the switch supports only the ordered mode.
Label Retention Mode	● If label advertisement mode is DU, label retention mode will be Liberal. ● If label advertisement mode is DOD, label retention mode will be Conservative.
Instance Deleting State	Deletion status of an instance: ● Yes: The instance is being deleted. ● No: The instance is not being deleted.
Instance Resetting State	Resetting status of an instance: ● Yes: The instance is being reset. ● No: The instance is not being reset.
Graceful-Delete	Whether graceful deletion is enabled: ● On: enables graceful deletion. ● Off: disables graceful deletion. **NOTE** The switch does not support this parameter.
Graceful-Delete Timer	Value of the Graceful-delete Timer, in seconds.

9.1.22 display mpls ldp adjacency

Function

The **display mpls ldp adjacency** command displays information about LDP adjacencies.

Format

display mpls ldp adjacency [**interface** *interface-type interface-number* | **remote**] [**peer** *peer-id*] [**verbose**]

display mpls ldp adjacency all [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type* *interface-number*	Displays information about the LDP adjacency of a specified interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
remote	Displays information about the LDP adjacency of a specified remote end.	-
peer *peer-id*	Displays information about the LDP adjacency of a specified peer.	The value is in dotted decimal notation.
verbose	Displays detailed information about LDP adjacencies.	-
all	Displays information about all the LDP adjacencies.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After an LDP session is established, run the **display mpls ldp adjacency** command to view real-time information about LDP adjacencies, for example, the number of received Hello messages.

Example

Display information about LDP adjacencies.

```
<HUAWEI> display mpls ldp adjacency

 LDP Adjacency Information in Public Network
 Codes: R: Remote Adjacency, L: Local Adjacency
 A '*' before an adjacency means the adjacency is being deleted.
 -------------------------------------------------------------------------
 SN   SourceAddr      PeerID          VrfID AdjAge(DDDD:HH:MM) RcvdHello Type
 -------------------------------------------------------------------------
  1   10.1.2.2        2.2.2.2         0      0000:00:22        527       L
  2   10.2.3.3        3.3.3.3         0      0000:00:20        254       L
  3   3.3.3.3         3.3.3.3         0      0000:00:18        79        R
 -------------------------------------------------------------------------
 TOTAL: 3 Record(s) found.
```

Table 9-17 Description of the display mpls ldp adjacency command output

Item	Description
SN	Serial number.
SourceAddr	Source address of the Hello message received by an LDP adjacency.
PeerID	LSR ID of an LDP peer.
VrfID	ID of a VPN instance.
AdjAge(DDDD:HH:MM)	Time elapsed since the LDP adjacency was created, in DDDD:HH:MM format.
RcvdHello	Number of Hello messages received by an LDP adjacency.
Type	Type of an LDP adjacency: ● L: local LDP adjacency. ● R: remote LDP adjacency.

Display detailed information about the LDP adjacency of the remote peer with the LSR ID of 3.3.3.3/32.

```
<HUAWEI> display mpls ldp adjacency remote peer 3.3.3.3 verbose

 LDP Adjacency Information in Public Network
 -------------------------------------------------------------------------------
                          LDP Peer ID : 3.3.3.3
                     VPNInstance name : -
                           CreateDate : 2005-07-27
                           CreateTime : 11:15:41+00:00
                        Adjacency Age : 0000:03:44
                        AdjacencyType : Remote Adjacency
                     Discovery-Source : -
                   UDP Source Address : 3.3.3.3
                        UDP Socket ID : 33
                         Sequence No. : 0
  Configuration Hello Hold Timer(sec) : 45
                   Hello Message Rcvd : 899
            Adjacency Deletion Status : No
 -------------------------------------------------------------------------------
 TOTAL: 1 Adjacency(s) found.
```

Table 9-18 Description of the display mpls ldp adjacency remote peer command output

Item	Description
LDP Peer ID	LSR ID of an LDP peer.
VPNInstance name	Name of a VPN instance. **NOTE** The switch does not support this parameter.
CreateDate	Creation date of an LDP adjacency.

Item	Description
CreateTime	Creation time of an LDP adjacency.
Adjacency Age	Time elapsed since the LDP adjacency was created, in DDDD:HH:MM format.
AdjacencyType	Type of an LDP adjacency: ● Local Adjacency. ● Remote Adjacency.
Discovery-Source	Discovery source of an LDP adjacency: ● Interface: a discovery source of the local LDP adjacency. ● Null: a discovery source of the remote LDP adjacency.
UDP Source Address	Source address of the UDP packet contained in the Hello message received by an LDP adjacency.
UDP Socket ID	Socket ID of the LDP adjacency to receive Hello message.
Sequence No	Serial number carried in the received Hello message. The default value is 0.
Configuration Hello Hold Timer(sec)	Hello hold timer configured on the peer, in seconds: ● Link Hello hold timer: maintains the local LDP adjacency. The default value is 15. ● Target Hello hold timer: maintains the remote LDP adjacency. The default value is 45.
Hello Message Rcvd	Number of Hello messages received by an LDP adjacency.
Adjacency Deletion Status	Deletion status of an LDP adjacency: ● Yes: The LDP adjacency is being deleted. ● No: The LDP adjacency is not being deleted.

9.1.23 display mpls ldp adjacency statistics

Function

The **display mpls ldp adjacency statistics** command displays statistics about LDP adjacencies.

Format

display mpls ldp adjacency statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mpls ldp adjacency statistics** command to view the number of LDP adjacencies that are classified into local and remote LDP adjacencies.

Example

Display statistics about LDP adjacencies.

```
<HUAWEI> display mpls ldp adjacency statistics

 LDP Adjacency Statistics Information
 -------------------------------------------------
 AdjacencyType          Local   Remote   Total
 -------------------------------------------------
 AdjacencyNumber          1       2        3
 -------------------------------------------------
```

Table 9-19 Description of the display mpls ldp adjacency statistics command output

Item	Description
AdjacencyType	Type of LDP adjacencies.
AdjacencyNumber	Number of LDP adjacencies.
Local	Number of local LDP adjacencies.
Remote	Number of remote LDP adjacencies.
Total	Total number of LDP adjacencies.

9.1.24 display mpls ldp error packet

Function

The **display mpls ldp error packet** command displays information about LDP-related error messages.

Format

display mpls ldp error packet { **tcp** | **udp** | **l2vpn** } [*number*]

Parameters

Parameter	Description	Value
tcp	Displays information about TCP error messages related to LDP sessions.	-
udp	Displays information about UDP error messages related to LDP sessions.	-
l2vpn	Displays information about L2VPN error messages related to LDP sessions.	-
number	Specifies the number of LDP-related error messages to be displayed.	The value is an integer ranging from 1 to 100.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an exception occurs on an MPLS network, run the **display mpls ldp error packet** command to view information about LDP-related error messages such as the number of received error messages.

Example

Displays information about error UDP packets related to LDP.

```
<HUAWEI> display mpls ldp error packet udp

 LDP Error UDP Packet
 Total received error packet number: 58
 Record error packet number         : 10
 Max Record error packet number     : 10
------------------- Number 1 ----------------------
 Date&Time          : 2011-11-08 16:39:59+08:00
 Error Reason       : unknown
 Interface          : Vlanif100
 Instance ID        : 0
 Message Type       : Hello
 Length             : 34
 Packet content     :
 01 64 00 14 00 00 00 32 04 00 00 04 00 0f 00 00
 04 01 00 04 01 01 01 01 00 00 00 00 00 00 00 00
 00 00
```

Table 9-20 Description of the **display mpls ldp error packet** command output

Item	Description
Total received error packet number	Number of received error messages related to LDP sessions.
Record error packet number	Number of recorded error messages related to LDP sessions.
Max Record error packet number	Maximum number of error messages that can be recorded.
Date&Time	Date and time when an error message was received.
Error Reason	Cause for an error.
Interface	An interface that receives the message.
Instance ID	ID of an LDP instance to which the error message belongs.
Message Type	Message type, which includes but is not limited to the following: ● Address ● Address Withdraw ● Capability ● Hello ● Initialization ● KeepAlive ● Label Request ● Label Mapping ● Label Withdraw ● Label Release ● Label Abort Request ● Notification ● Unknown
Length	Length of the error message
Packet content	Contents of the error message in the binary format.

9.1.25 display mpls ldp error packet state

Function

The **display mpls ldp error packet state** command displays the record status of LDP-related error messages.

Format

display mpls ldp error packet state

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an exception occurs on an MPLS network, run the **display mpls ldp error packet state** command to view the record status of UDP, TCP, and L2VPN error messages related to LDP sessions.

Example

Display the record status of LDP-related error messages.

```
<HUAWEI> display mpls ldp error packet state
-------------------------------------------
 Error UDP packet state            : ON
 Max UDP error packet number       : 100
 Current UDP error packet number   : 0
 Error TCP packet state            : ON
 Max TCP error packet number       : 100
 Current TCP error packet number   : 0
 Error L2VPN packet state          : ON
 Max L2VPN error packet number     : 100
 Current L2VPN error packet number : 0
-------------------------------------------
```

Table 9-21 Description of the display mpls ldp error packet state command output

Item	Description
Error UDP packet state	Whether UDP error messages can be detected and recorded: ● ON: UDP error message detection is enabled. ● OFF: UDP error message detection is disabled.
Max UDP error packet number	Maximum number of UDP error messages that can be recorded.
Current UDP error packet number	Number of recorded UDP error messages.

Item	Description
Error TCP packet state	Whether TCP error messages can be detected and recorded: - ON: TCP error message detection is enabled. - OFF: TCP error message detection is disabled.
Max TCP error packet number	Maximum number of TCP error messages that can be recorded.
Current TCP error packet number	Number of recorded TCP error messages.
Error L2VPN packet state	Whether L2VPN error messages can be detected and recorded: - ON: L2VPN error message detection is enabled. - OFF: L2VPN error message detection is disabled.
Max L2VPN error packet number	Maximum number of L2VPN error messages that can be recorded.
Current L2VPN error packet number	Number of recorded L2VPN error messages.

9.1.26 display mpls ldp event adjacency-down

Function

The **display mpls ldp event adjacency-down** command displays events that LDP adjacencies go Down.

Format

display mpls ldp event adjacency-down [**interface** *interface-type interface-number* | **remote**] [**peer** *peer-id*] [**verbose**]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays events that LDP adjacencies on a specified interface go Down. - *interface-type* specifies the type of the interface. - *interface-number* specifies the number of the interface.	-

Parameter	Description	Value
remote	Indicates the remote LDP peer.	-
peer *peer-id*	Specifies the LSR ID of an LDP peer.	The value is in dotted decimal notation.
verbose	Displays details about events that LDP adjacencies go Down.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

Run the **display mpls ldp event adjacency-down** command to view the event that an LDP adjacency went Down. The information includes the time, reason, and the duration of the LDP adjacency.

Precautions

A maximum of 1024 events can be displayed.

Example

Display the events that LDP adjacencies go Down.

```
<HUAWEI> display mpls ldp event adjacency-down

 LDP Adjacency Down Information
 ------------------------------------------------------------------------
 PeerID           Down       Down                  Duration      Reason
                 Date       Time                  Time
 ------------------------------------------------------------------------
 2.2.2.2:0        2012-04-24 17:08:59+00:00        0h44m54s      C
 2.2.2.2:0        2012-04-26 15:43:54+00:00        46h34m54s     A
 ----------------------------------------------------------------------------
 TOTAL: 2 Record(s) Found.
 A : The Adjacency is down because Hello Timer Expired.
 C : The administrator configuration to trigger.
 D : The Adjacency is down because delay-deleting timer expired.
 P : The Adjacency is down because the peer is being deleted.
 O : Other reason.
```

Table 9-22 Description of the display mpls ldp event adjacency-down command output

Item	Description
PeerID	LSR ID of an LDP peer.

Item	Description
Down Date	Date when an LDP adjacency went Down.
Down Time	Time when an LDP adjacency went Down.
Duration Time	Time elapsed since an LDP adjacency established.
Reason	Causes for the LDP adjacency Down event: ● A: The Hello timer expires. ● C: The configuration is changed. ● D: The delay deleting timer expires. ● P: The peer is deleted. ● O: other causes.

Display detailed information that LDP adjacencies go Down.

```
<HUAWEI> display mpls ldp event adjacency-down verbose

 LDP Adjacency-Down Information
 ------------------------------------------------------------------------
 SN                               : 1

 -------------------------------------------------------------------------------
  TOTAL: 2 Record(s) Found.
```

Table 9-23 Description of the display mpls ldp event adjacency-down verbose command output

Item	Description
SN	Serial number.
PeerID	LSR ID of an LDP peer.

Item	Description
VrfID	ID of a VPN instance.
DownDate	Date when an LDP adjacency went Down.
DownTime	Time when an LDP adjacency went Down.
DurationTime	Time elapsed since an LDP adjacency established.
MaxInterval (sec)	Maximum interval for sending a Hello message.
Reason	Reason for the LDP adjacency Down event: ● A: The Hello timer expires. ● C: The configuration is changed. ● D: The delay deleting timer expires. ● P: The peer is deleted. ● O: other causes.
Type	Adjacency type: ● Local Adjacency: Directly connected adjacency. ● Remote Adjacency: Indirectly connected adjacency.
DiscoverySource	Interface where an LDP peer is discovered.

9.1.27 display mpls ldp event gr-helper

Function

The **display mpls ldp event gr-helper** command displays GR Helper information.

Format

display mpls ldp event gr-helper [**all** | *peer-id*]

Parameters

Parameter	Description	Value
all	Displays information about all GR Helpers.	-

Parameter	Description	Value
peer-id	Displays information about a GR Helper on a specified LDP peer.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If GR Helpers are configured, run the **display mpls ldp event gr-helper** command to view GR Helper information.

Example

Display GR Helper information.

```
<HUAWEI> display mpls ldp event gr-helper
 LDP GR-Helper Peer Info
 ------------------------------------------------------------------
 LDP InstanceId              : 0          Vpn Instance Name:
 Peer ID                     : 1.1.1.1
 Label Advertisement Mode   : Downstream Unsolicited
 Timer State                 :
 Recovery Timer Left         : 229(s)
 Peer Gr Timer Configuration:
 Reconnect Timer             : 300(s)     Recovery Timer   : 300(s)
 Stale Lsp State             :
 USCB Counter                : 3          DSCB Counter     : 3
 ------------------------------------------------------------------
 Total GR Peer Counter: 1
```

Table 9-24 Description of the display mpls ldp event gr-helper command output

Item	Description
LDP InstanceId	LDP instance name.
Vpn Instance Name	VPN instance name. **NOTE** The device does not support this parameter.
Peer ID	LSR ID of an LDP peer.
Label Advertisement Mode	Mode used by LDP to advertise labels. To set the mode used by LDP to advertise labels, run the **mpls ldp advertisement** command.
Timer State	Status of the timer.

Item	Description
Recovery Timer Left	Remaining time before an LSP starts to be reestablished.
Peer Gr Timer Configuration	Configuration of the GR timers.
Reconnect Timer	Value of the LDP session reconnection timer. To set the value of the LDP session reconnection timer, run the **graceful-restart timer reconnect** command.
Recovery Timer	Value of the LSP recovery timer. To set the value of the LSP recovery timer, run the **graceful-restart timer recovery** command.
Stale Lsp state	Status of the primary LSP.
USCB Counter	Number of upstream control blocks (USCBs).
DSCB Counter	Number of downstream control blocks (DSCBs).
Total GR Peer Counter	Number of GR Helper.

9.1.28 display mpls ldp event session-down

Function

The **display mpls ldp event session-down** command displays events that LDP sessions go Down.

Format

display mpls ldp event session-down

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display mpls ldp event session-down** command to view events that LDP sessions go Down, including the cause and time.

Example

Display events that LDP sessions go Down.

```
<HUAWEI> display mpls ldp event session-down

LDP Session Down Information
------------------------------------------------------------------------------
PeerID       Down        Down              Duration   Flag Reason
             Date        Time              Time

R: Remote peer.
L: Local peer.
B: Both of local and remote peer.
G: Graceful Restart Session.
Important notification message error code:
  0x0003: Bad PDU Length.
  0x0005: Bad Message Length.
  0x0007: Bad TLV Length.
  0x0009: Hello Hold Timer Expired.
  0x000a: Shutdown.
  0x0014: KeepAlive Timer Expired.
```

Table 9-25 Description of the display mpls ldp event session-down command output

Item	Description
PeerID	LSR ID of an LDP peer.
Down Date	Date when an LDP session went down.
Down Time	Time when an LDP session went down.
Duration Time	Time elapsed since an LDP adjacency established.
Flag	Peer type. ● R: Remote peer, indicating that a remote session has been established. ● L: Local peer, indicating that a local session has been established. ● B: Both of local and remote peer, indicating that both local and remote sessions have been established. ● G: Graceful Restart Session.
Reason	Description of the cause.

Item	Description
Important notification message error code	Important notification message error code.
Bad PDU Length	Incorrect PDU length.
Bad Message Length	Incorrect message length.
Bad TLV Length	Incorrect TLV length.
Hello Hold Timer Expired	Hello Hold timer expired.
Shutdown	The peer actively shuts down the session.
KeepAlive Timer Expired	Keepalive timer expired.

9.1.29 display mpls ldp interface

Function

The **display mpls ldp interface** command displays information about LDP-enabled interfaces.

Format

display mpls ldp interface [*interface-type interface-number* | [**all**] [**verbose**]]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. If the parameter is specified, the configurations of a specified LDP-enabled interface are displayed.	-
all	Displays information about all LDP-enabled interfaces.	-
verbose	Displays detailed information about LDP-enabled interfaces.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display mpls ldp interface** command to view configurations of LDP-enabled interfaces and some real-time information, such as the number of sent and received Hello messages.

Example

Display information about LDP-enabled interfaces.

```
<HUAWEI> display mpls ldp interface

 LDP Interface Information in Public Network
 Codes:LAM(Label Advertisement Mode), IFName(Interface name)
 A '*' before an interface means the entity is being deleted.
 ------------------------------------------------------------------------------
 IFName         Status       LAM   TransportAddress    HelloSent/Rcv
 ------------------------------------------------------------------------------
Vlanif100       Active       DU    10.1.1.1            29574/29539
 ------------------------------------------------------------------------------
```

Table 9-26 Description of the display mpls ldp interface command output

Item	Description
IFName	Name of an LDP-enabled interface.
Status	Status of the local LSR: ● Active ● Inactive
LAM	Label advertisement mode: ● DU: downstream unsolicited mode. ● DoD: downstream on demand mode. To set the label advertisement mode, run the **mpls ldp advertisement** command.
TransportAddress	IP address of a node that initiates a TCP connection for an LDP session.
HelloSent/Rcv	Number of sent and received Hello messages.

Display detailed information about LDP-enabled interfaces.

```
<HUAWEI> display mpls ldp interface verbose

 LDP Interface Information in Public Network
 ------------------------------------------------------------------------------
 Interface Name :Vlanif100
 LDP ID         : 10.1.1.1:0            Transport Address : 10.1.1.1
 Entity Status  : Active                Effective MTU : 1500

 Configured Hello Hold Timer      : 15 Sec
 Negotiated Hello Hold Timer      : 15 Sec
 Configured Hello Send Timer      : 2 Sec
 Configured Keepalive Hold Timer : 45 Sec
```

```
Configured Keepalive Send Timer : 3 Sec
Configured Delay Timer          : 10 Sec
Label Advertisement Mode        : Downstream Unsolicited
Hello Message Sent/Rcvd         : 29913/29878 (Message Count)
Entity Deletion Status          : No
mLDP P2MP Capability            : Disable
mLDP MP2MP Capability           : Disable
------------------------------------------------------------------------------
```

Table 9-27 Description of the display mpls ldp interface verbose command output

Item	Description
Interface Name	Name of an LDP-enabled interface.
LDP ID	LDP identifier.
Transport Address	IP addresses used in the TCP connection of a session.
Entity Status	Status of this entity: - Active - Inactive
Effective MTU	MTU value used for creating an LSP.
Configured Hello Hold Timer	Timeout period of the configured Hello hold timer. To set the timeout period of the Hello hold timer, run the **mpls ldp timer hello-hold** command.
Negotiated Hello Hold Timer	Negotiated value of the Hello hold timer, which is the smaller value of the Hello hold timers configured on the local and remote LDP peers.
Configured Hello Send Timer	Timeout period of the configured Hello send timer. To set the timeout period of the Hello send timer, run the **mpls ldp timer hello-send** command.
Configured Keepalive Hold Timer	Timeout period of the configured Keepalive hold timer. To set the timeout period of the Keepalive hold timer, run the **mpls ldp timer keepalive-hold** command.
Configured Keepalive Send Timer	Timeout period of the configured Keepalive send timer. To set the timeout period of the Keepalive send timer, run the **mpls ldp timer keepalive-send** command.

Item	Description
Configured Delay Timer	Timeout period of the Delay timer, which, in LDP and IGP synchronization, is the time that an interface waits to establish an LSP after an LDP session is established.
Label Advertisement Mode	Label advertisement mode: ● Downstream Unsolicited ● Downstream on Demand To set the label advertisement mode, run the **mpls ldp advertisement** command.
Hello Message Sent/Rcvd	Number of sent and received Hello messages.
Entity Deletion Status	Deletion status of an instance: ● Yes: The instance is being deleted. ● No: The instance is not being deleted.
mLDP P2MP Capability	Whether mLDP P2MP is enabled: ● Enable ● Disable **NOTE** The switch does not support this function.
mLDP MP2MP Capability	Whether mLDP MP2MP is enabled: ● Enable ● Disable **NOTE** The switch does not support this function.

9.1.30 display mpls label all summary

Function

The **display mpls label all summary** displays allocation information about all MPLS labels.

Format

display mpls label all summary

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After a session is established, the system collects statistics on label usage, including the allocation range and protocol type. You can use the **display mpls label all summary** command to view the allocation of label space and the corresponding protocol type.

Example

Display allocation information about MPLS labels.

```
<HUAWEI> display mpls label all summary
TableType      MinValue    MaxValue    AvailableNum
Reserved             0          15             16
Static              16        1023           1008
Dynamic           1024      163840         162815
Block           163841      180244          16404
```

NOTE

The preceding information is an example. The allocation ranges of labels depend on the actual situation.

Table 9-28 Description of the **display mpls label all summary** command output

Item	Description
TableType	Label type. - Reserved: indicates reserved labels. - Static: indicates static labels, mainly for MPLS TE and BGP. - Dynamic: indicates dynamic labels, mainly for LDP, MPLS TE, and BGP. - Block: indicates block labels, mainly for BGP.
MinValue	Minimum label value.
MaxValue	Maximum label value.
AvailableNum	Number of labels that can be allocated.

9.1.31 display mpls ldp lsp

Function

The **display mpls ldp lsp** command displays information about an LDP LSP.

Format

display mpls ldp lsp [**all** | *destination-address mask-length*] [**peer** *peer-id*]

display mpls ldp lsp inbound-policy

Parameters

Parameter	Description	Value
all	Displays information about all LDP LSPs.	-
destination-address	Specifies the destination IPv4 address of an LDP LSP.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the specified IPv4 address.	The value is an integer ranging from 0 to 32.
peer *peer-id*	Specifies the peer ID.	The value is in dotted decimal notation.
inbound-policy	Displays information about the LSPs that have passed an inbound policy, in addition to information about the LSPs that are established without applying the inbound policy.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After LDP LSPs are set up, run the **display mpls ldp lsp** command to view detailed information about LSPs such as the outbound interfaces, next hop addresses, total number, and types.

Example

Display information about LSPs.

```
<HUAWEI> display mpls ldp lsp

 LDP LSP Information
 -------------------------------------------------------------------------------
 Flag after Out IF: (I) - LSP Is Only Iterated by RLFA
 -------------------------------------------------------------------------------
 DestAddress/Mask   In/OutLabel    UpstreamPeer    NextHop        OutInterface
 -------------------------------------------------------------------------------
 10.3.3.3/32        3/NULL         10.4.4.9        127.0.0.1      InLoop0
 10.3.3.9/32        3/NULL         10.4.4.9        127.0.0.1      InLoop0
*10.3.3.9/32        Liberal/1024                   DS/10.4.4.9
 10.4.4.9/32        NULL/3         -               172.16.1.2     Vlanif100
 10.4.4.9/32        1029/3         10.4.4.9        172.16.1.2     Vlanif100
 -------------------------------------------------------------------------------
 TOTAL: 4 Normal LSP(s) Found.
 TOTAL: 1 Liberal LSP(s) Found.
 TOTAL: 0 Frr LSP(s) Found.
 A '*' before an LSP means the LSP is not established
 A '*' before a Label means the USCB or DSCB is stale
 A '*' before a UpstreamPeer means the session is stale
 A '*' before a DS means the session is stale
 A '*' before a NextHop means the LSP is FRR LSP
```

Table 9-29 Description of the display mpls ldp lsp command output

Item	Description
DestAddress/ Mask	Destination address and mask of an LSP.
In/OutLabel	Values of the incoming and outgoing labels. An asterisk (*) before In/OutLabel indicates that the LSP is in the Stale state and needs to be restored.
UpstreamPeer	Upstream peer of an LSP. An asterisk (*) before UpstreamPeer indicates that the session is in the GR state.
NextHop	Next hop IP address. An asterisk (*) before NextHop indicates that the LSP is an FRR LSP. DS is short for DownStream. The address next to DS/ is the LSR ID of a downstream peer.
OutInterface	Name of an outbound interface.
TOTAL: 4 Normal LSP(s) Found.	Total number of normal LSPs.
TOTAL: 1 Liberal LSP(s) Found.	Total number of liberal LSPs.
TOTAL: 0 Frr LSP(s) Found.	Total number of FRR LSPs.

9.1.32 display mpls ldp lsp statistics

Function

The **display mpls ldp lsp statistics** command displays statistics about LDP LSPs.

Format

display mpls ldp lsp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls ldp lsp statistics** command displays the statistics about an LDP LSP, whereas the **display mpls lsp statistics** command displays the statistics about all types of LSPs.

Example

Display statistics about LDP LSPs.

```
<HUAWEI> display mpls ldp lsp statistics

 LDP LSP Statistics Information
 A '*' before a number means the LSP is for longest-match
 -------------------------------------------------------------------------------
 VPNInstanceName   Total   Ingress   Transit   Egress   Liberal  FRR
 -------------------------------------------------------------------------------
 -                   14      4         4         3        3        0
                     *0     *0        *0        *0       *-       *0
 -------------------------------------------------------------------------------
```

Table 9-30 Description of the display mpls ldp lsp statistics command output

Item	Description
VPNInstanceName	Name of a VPN instance: • A hyphen (-) indicates a public network instance. • If LDP multi-instance is configured, the name of the created VPN instance is displayed. **NOTE** The switch does not support this parameter.

Item	Description
Total	Number of LDP LSPs in an instance.
Ingress	Number of ingress LSPs in an instance.
Transit	Number of transit LSPs in an instance.
Egress	Number of egress LSPs in an instance.
Liberal	Number of liberal LSPs in an instance.
FRR	Number of FRR LSPs in an instance. **NOTE** The switch does not support this parameter.

9.1.33 display mpls ldp peer

Function

The **display mpls ldp peer** command displays information about LDP peers.

Format

display mpls ldp peer [[**all**] [**verbose**] | *peer-id*]

Parameters

Parameter	Description	Value
verbose	Displays detailed information about LDP peers.	-
peer-id	Displays information about a specified LDP peer.	The value is in dotted decimal notation.
all	Displays information about all LDP peers.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If an LDP LSP fails to be established, run the **display mpls ldp peer** command to view the **DiscoverySource** field and check the interface through which the peer relationship is established.

The system supports the coexistent local and remote LDP peers. When you run the **display mpls ldp peer** command, information about both local and remote LDP peers is displayed.

You can set the *peer-id* parameter to specify a peer.

Precautions

You can view information about LDP peers only after the peers have been established using the **mpls ldp (interface view)** or **remote-ip** command.

Example

Display information about LDP peers.

```
<HUAWEI> display mpls ldp peer

 LDP Peer Information in Public network
 A '*' before a peer means the peer is being deleted.
 ------------------------------------------------------------------------------
 PeerID                 TransportAddress   DiscoverySource
 ------------------------------------------------------------------------------
 2.2.2.2:0              2.2.2.2            Remote Peer : rtb
 3.3.3.3:0              3.3.3.3            Vlanif100
 ------------------------------------------------------------------------------
 TOTAL: 2 Peer(s) Found.
```

Table 9-31 Description of the display mpls ldp peer command output

Item	Description
PeerID	LDP identifier of the peer in the format of <LSR ID>:<label space>. The value of a label space can be either of the following: ● 0: per-platform label space. ● Non-0: per-interface label space.
TransportAddress	Transport address of an LDP peer. The transport address is used to set up TCP connections.
DiscoverySource	Discovery source of an LDP peer: ● Interface name: indicates the source that discovers the local LDP peer. ● Remote LDP peer name: indicates the source that discovers the remote LDP peer.

Display detailed information about LDP peers.

```
<HUAWEI> display mpls ldp peer verbose

 LDP Peer Information in Public network
 ------------------------------------------------------------------------------
 Peer LDP ID          : 2.2.2.2:0
 Peer Max PDU Length : 4096          Peer Transport Address   : 2.2.2.2
 Peer Loop Detection : Off           Peer Path Vector Limit   : ----
 Peer FT Flag         : Off          Peer Keepalive Timer     : 45 Sec
```

```
Recovery Timer      : ----         Reconnect Timer          : ----

Capability-Announcement       : Off
Peer mLDP P2MP Capability     : Off
Peer mLDP MBB Capability      : Off
------------------------------------------------------------------------------
Peer LDP ID         : 3.3.3.3:0
Peer Max PDU Length : 4096         Peer Transport Address   : 3.3.3.3
Peer Loop Detection : Off          Peer Path Vector Limit   : ----
Peer FT Flag        : Off          Peer Keepalive Timer     : 45 Sec
Recovery Timer      : ----         Reconnect Timer          : ----
Peer Type           : Local
Peer Label Advertisement Mode : Downstream Unsolicited
Peer Discovery Source         : Vlanif100
Peer Deletion Status          : No
Capability-Announcement       : Off
Peer mLDP P2MP Capability     : Off
Peer mLDP MBB Capability      : Off
------------------------------------------------------------------------------
```

Table 9-32 Description of the display mpls ldp peer verbose command output

Item	Description
Peer LDP ID	LDP identifier of the peer in the format of <LSR ID>:<label space>. The value of a label space can be either of the following: - 0: per-platform label space. - Non-0: per-interface label space.
Peer Max PDU Length	Maximum size of a PDU sent by an LDP peer.
Peer Transport Address	Transport address of an LDP peer. The transport address is used to set up TCP connections.
Peer Loop Detection	Whether loop detection of an LDP peer is enabled: - On: Loop detection is enabled. - Off: Loop detection is disabled. To configure the loop detection function, run the **loop-detect** command.
Peer Path Vector Limit	Indicates the upper limit of the Path Vector for an LDP peer. To set the upper limit of the Path Vector for an LDP peer, run the **path-vectors** command.
Peer FT Flag	GR FT flag of an LDP peer: - On: LDP GR is enabled. - Off: LDP GR is disabled. The flag can only be set after an Initialization message containing an FT TLV is received.

Item	Description
Peer Keepalive Timer	Configured value of the Keepalive timer on an LDP peer. To set the value of the Keepalive timer, run the **mpls ldp timer keepalive-hold** command.
Recovery Timer	Timeout period of the Recovery timer of an LDP peer. The value of the Recovery Timer field is not null only when the Peer FT Flag field is On. To set the timeout period of the Recovery timer, run the **graceful-restart timer recovery** command.
Reconnect Timer	Timeout period of the Reconnect timer of an LDP peer. The value of the Recovery Timer field is not null only when the Peer FT Flag field is On. To set the timeout period of the Reconnect timer, run the **graceful-restart timer reconnect** command.
Peer Type	Type of an LDP peer: ● Local ● Remote ● Local&Remote
Peer Label Advertisement Mode	Indicates the label advertisement mode of an LDP peer: ● Downstream Unsolicited ● Downstream on Demand The switch supports the Downstream Unsolicited (DU) mode.
Peer Discovery Source	Discovery source of an LDP peer: ● If the interface is displayed, the source of the local LDP peer is the local interface. ● If the configuration name of the remote peer is displayed, the source end of the remote LDP peer is the remote peer.
Peer Deletion Status	Deletion status of an LDP peer: ● Yes: LDP peer is being deleted. ● No: LDP peer is not being deleted.

Item	Description
Capability-Announcement	Status of the LDP dynamic capability announcement function: - On: LDP dynamic capability announcement is enabled. - Off: LDP dynamic capability announcement is disabled. **NOTE** The switch does not support this parameter.
Peer mLDP P2MP Capability	Whether the LDP peer supports mLDP P2MP: - On: The LDP peer supports mLDP P2MP. - Off: The LDP peer does not support mLDP P2MP.
Peer mLDP MBB Capability	Whether the LDP peer supports make-before-break: - On: The LDP peer supports mLDP make-before-break. - Off: The LDP peer does not support mLDP make-before-break.

9.1.34 display mpls ldp peer statistics

Function

The **display mpls ldp peer statistics** command displays statistics about LDP peers.

Format

display mpls ldp peer statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display mpls ldp peer statistics** command to view the number of local LDP peers, remote LDP peers, and coexistent local and remote LDP peers.

Example

Display statistics about LDP peers.

```
<HUAWEI> display mpls ldp peer statistics

 LDP Peer Statistics Information
 ------------------------------------------------------------
 PeerType        Local   Remote   Local&Remote   Total
 ------------------------------------------------------------
 PeerNumber      0       1        1              2
 ------------------------------------------------------------
```

Table 9-33 Description of the display mpls ldp peer statistics command output

Item	Description
PeerType	Type of LDP peers.
PeerNumber	Number of LDP peers.
Local	Number of local LDP peers.
Remote	Number of remote LDP peers.
Local&Remote	Number of coexistent local and remote LDP peers.
Total	Total number of all types of LDP peers.

9.1.35 display mpls ldp remote-peer

Function

The **display mpls ldp remote-peer** command displays information about a remote LDP peer.

Format

display mpls ldp remote-peer [*remote-peer-name* | **peer-id** *lsr-id*]

Parameters

Parameter	Description	Value
remote-peer-name	Specifies the name of a remote LDP peer.	The value is an existing remote LDP peer.
peer-id *lsr-id*	Specifies the LSR ID of a remote LDP peer.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Remote LDP peers are used to set up remote LDP sessions to transmit VPN services.

To view information about the configured remote LDP peers, run the **display mpls ldp remote-peer** command.

Run the **display mpls ldp remote-peer** command to view information about the configured remote LDP peer. Different from the **display mpls ldp peer** command, the **display mpls ldp remote-peer** command is used to view the remote LDP peer that is configured on the local device if the configuration takes effect. The **display mpls ldp peer** command is used to view the LDP peer discovered by the local device only when the LDP peers are configured on local and peer devices and the LDP peer relationship is set up.

Example

Display information about remote LDP peers.

```
<HUAWEI> display mpls ldp remote-peer

                         LDP Remote Entity Information
 ------------------------------------------------------------------------------
 Remote Peer Name  : lsrc
 Remote Peer IP    : 3.3.3.9           LDP ID        : 1.1.1.9:0
 Transport Address : 1.1.1.9           Entity Status : Active

 Configured Keepalive Hold Timer : 45 Sec
 Configured Keepalive Send Timer : ---
 Configured Hello Hold Timer     : 45 Sec
 Negotiated Hello Hold Timer     : 45 Sec
 Configured Hello Send Timer     : ---
 Configured Delay Timer          : 10 Sec
 Hello Packet sent/received      : 61/59
 Label Advertisement Mode        : Downstream Unsolicited
 Remote Peer Deletion Status     : No
 Auto-config                     : ---
------------------------------------------------------------------------------
 TOTAL: 1 Peer(s) Found.
```

Table 9-34 Description of the **display mpls ldp remote-peer** command output

Item	Description
Remote Peer Name	Name of a remote LDP peer.
Remote Peer IP	IP address of a remote LDP peer.
LDP ID	Local LDP ID.
Transport Address	Transport address, which is used to set up the LDP session between the local and remote peers.

Item	Description
Entity Status	Status of a remote LDP peer: - Active - Inactive
Configured Keepalive Hold Timer	Timeout period of the configured Keepalive hold timer.
Configured Keepalive Send Timer	Timeout period of the configured Keepalive send timer.
Configured Hello Hold Timer	Timeout period of the configured Hello hold timer.
Negotiated Hello Hold Timer	Timeout period of the negotiated Hello hold timer.
Configured Hello Send Timer	Timeout period of the configured Hello send timer.
Configured Delay Timer	Timeout period of the Delay timer, which, in LDP and IGP synchronization, is the time that an interface waits to establish an LSP after an LDP session is established.
Hello Packet sent/received	Number of sent and received Hello packets.
Label Advertisement Mode	Label advertisement mode in an LDP session. The default mode is DU. To set the label advertisement mode, run the **mpls ldp advertisement** command.
Remote Peer Deletion Status	Deletion status of an LDP peer: - Yes: The LDP peer is being deleted. - No: The LDP peer is not being deleted.
Auto-config	Source that triggers the creation of a remote peer: - ---: created using LDP configurations. - L2VPN: After an L2VPN is configured, the remote LDP peer is automatically configured. LDP configurations can also be involved. - RLFA: created using remote LFA. - Auto Accept: The remote LDP session is automatically established after a local device receives Targeted Hello messages.

9.1.36 display mpls ldp session

Function

The **display mpls ldp session** command displays information about LDP sessions.

Format

display mpls ldp session [*peer-id* | [**all**] [**verbose**]]

Parameters

Parameter	Description	Value
peer-id	Displays information about LDP sessions of a specified LSR ID.	The value is in dotted decimal notation.
all	Displays information about all LDP sessions.	-
verbose	Displays detailed information about LDP sessions.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After creating an LDP session, run the **display mpls ldp session** command to verify that the LDP session is created successfully and view information about the LDP session, such as the number of sent or received Keepalive messages.

Prerequisites

MPLS has been enabled globally using the **mpls** command, and MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

If you run the **display mpls ldp session** command without specifying any parameter, information about all LDP sessions is displayed.

Example

Display information about all LDP sessions.

```
<HUAWEI> display mpls ldp session
 LDP Session(s) in Public Network
 Codes: LAM(Label Advertisement Mode), SsnAge Unit(DDDD:HH:MM)
 A '*' before a session means the session is being deleted.
 ------------------------------------------------------------------------------
 PeerID             Status      LAM  SsnRole  SsnAge      KASent/Rcv
 ------------------------------------------------------------------------------
 2.2.2.2:0          Operational DU   Passive  0000:01:36  387/386
 3.3.3.3:0          Operational DU   Passive  0000:01:30  361/361
 ------------------------------------------------------------------------------
 TOTAL: 2 session(s) Found.
```

Table 9-35 Description of the display mpls ldp session command output

Item	Description
PeerID	LDP identifier of the peer in the format of <LSR ID>:<label space>. The value of a label space can be either of the following: ● 0: per-platform label space. ● 1: per-interface label space.
Status	Status of an LDP session: ● NonExistent: LDP peers at both ends of the LDP session exchange Hello messages to negotiate a TCP connection. After the TCP connection is established, the LDP session enters the Initialized state. The Non-Existent state is the initial state in the LDP session state machine. ● Initialized: The LDP session is in the initialization state. ● Open Sent: The LSR playing the active role in the LDP session sends an Initialization message to the LSR playing the passive role and waits for a reply during initialization. ● Open Recv: LDP peers at both ends of the LDP session wait for receiving a Keepalive message from each other during initialization. If they receive a Keepalive message from each other, the LDP session enters the Operational state. ● Operational: An LDP session is established successfully.
LAM	Label advertisement mode of an LDP peer. The default mode is DU. To set the label advertisement mode, run the **mpls ldp advertisement** command.

Item	Description
SsnRole	Role that an LSR plays in an LDP session: - Active: an LSR with a larger LSR ID between two LSRs. - Passive: an LSR with a smaller LSR ID between two LSRs.
SsnAge	Time elapsed since an LDP session was set up in DDDD:HH:MM format.
KASent/Rcv	Number of Keepalive messages sent and received by an LDP session.

Display detailed information about all LDP sessions.

```
<HUAWEI> display mpls ldp session verbose

 LDP Session(s) in Public Network
 ------------------------------------------------------------------------------
 Peer LDP ID      : 2.2.2.2:0           Local LDP ID    : 1.1.1.1:0
 TCP Connection   : 1.1.1.1 <- 2.2.2.2

```

Table 9-36 Description of the display mpls ldp session verbose command output

Item	Description
Peer LDP ID	LDP identifier of the peer in the format of <LSR ID>:<label space>. The value of a label space can be either of the following: - 0: per-platform label space. - 1: per-interface label space.

Item	Description
Local LDP ID	Local LDP identifier in the format of <LSR ID>:<label space>. The value of a label space can be either of the following: ● 0: per-platform label space. ● 1: per-interface label space.
TCP Connection	TCP connection of an LDP session: ● The LSR with a larger LSR ID value plays an active role in establishing the TCP connection. ● The LSR with a smaller LSR ID value plays a passive role in establishing the TCP connection.
Session State	Status of an LDP session: ● NonExistent: LDP peers at both ends of the LDP session exchange Hello messages to negotiate a TCP connection. After the TCP connection is established, the LDP session enters the Initialized state. The Non-Existent state is the initial state in the LDP session state machine. ● Initialized: The LDP session is in the initialization state. ● Open Sent: The LSR playing the active role in the LDP session sends an Initialization message to the LSR playing the passive role and waits for a reply during initialization. ● Open Recv: LDP peers at both ends of the LDP session wait for receiving a Keepalive message from each other during initialization. If they receive a Keepalive message from each other, the LDP session enters the Operational state. ● Operational: An LDP session is established successfully.
Session Role	Role that an LSR plays in an LDP session: ● Active: an LSR with a larger LSR ID between two LSRs. ● Passive: an LSR with a smaller LSR ID between two LSRs.

Item	Description
Session FT Flag	Negotiated LDP GR capability: - On: Negotiated LDP GR capability is enabled. - Off: Negotiated LDP GR capability is disabled.
MD5 Flag	MD5 authentication flag: - On: MD5 authentication is enabled during the TCP connection establishment. - Off: MD5 authentication is disabled during the TCP connection establishment.
Reconnect Timer	Negotiated timeout period of the Reconnect timer. The value of the Recovery Timer field is not null only when the Session FT Flag field is On.
Recovery Timer	Negotiated timeout period of the Recovery timer. The value of the Recovery Timer field is not null only when the Session FT Flag field is On.
Keychain Name	Referenced keychain authentication name.
Authentication applied	Existing authentication mode: - Peer: single peer authentication - Peer-group PeerGroupName: peer-group authentication. PeerGroupName indicates a peer group name. - ALl: All authentication
Negotiated Keepalive Hold Timer	Negotiated value of the Keepalive hold timer, which is the smallest value of the Keepalive hold timers configured on the local and remote LDP peers.
Configured Keepalive Send Timer	Timeout period of the configured Keepalive send timer.
Keepalive Message Sent/Rcvd	Number of Keepalive messages sent and received by an LDP session.

Item	Description
Label Advertisement Mode	Label advertisement mode: ● Downstream Unsolicited ● Downstream on Demand The default mode is Downstream Unsolicited (DU). To set the label advertisement mode, run the **mpls ldp advertisement** command.
Label Resource Status(Peer/ Local)	Label resource status of the remote and local peers.
Session Age	Time elapsed since an LDP session was set up.
Session Deletion Status	Deletion status of an LDP session: ● Yes: The LDP session is being deleted. ● No: The LDP session is not being deleted.
Capability	LDP capability.
Capability-Announcement	LDP dynamic capability announcement function: ● On: LDP dynamic capability announcement is enabled. ● Off: LDP dynamic capability announcement is disabled. **NOTE** The switch does not support this parameter.
mLDP P2MP Capability	Whether mLDP P2MP is supported after a session is negotiated: ● On: mLDP P2MP is supported. ● Off: mLDP P2MP is not supported. **NOTE** The switch does not support this parameter.
mLDP MP2MP Capability	Whether mLDP MP2MP is supported after a session is negotiated: ● On: mLDP MP2MP is supported. ● Off: mLDP MP2MP is not supported. **NOTE** The switch does not support this parameter.

Item	Description
mLDP MBB Capability	Whether mLDP make-before-break is supported after a session is negotiated: ● On: mLDP make-before-break is supported. ● Off: mLDP make-before-break is not supported. **NOTE** The switch does not support this parameter.
Outbound&Inbound Policies applied	Outbound and inbound policies on the local node.
Addresses received from peer	Contents of an Address message sent by an LDP peer. The contents include the LSR ID of the peer and the IP address of the LDP-enabled interface.

9.1.37 display mpls ldp session statistics

Function

The **display mpls ldp session statistics** command displays statistics about sessions between LDP peers.

Format

display mpls ldp session statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display mpls ldp session statistics** command to view the number of sessions between LDP peers. Statistics are collected based on the session type and status. The session type can be local, remote, or coexistent local and remote. The session status can be Not Operational or Operational.

Example

Display statistics about LDP sessions.

```
<HUAWEI> display mpls ldp session statistics

 LDP Session Statistics Information
 ------------------------------------------------------------
 SessionType        Local   Remote   Local&Remote   Total
 ------------------------------------------------------------
 Not Operational     0       0        0              0
 Operational         0       1        1              2
 ------------------------------------------------------------
 SessionStatistics   0       1        1              2
 ------------------------------------------------------------
```

Table 9-37 Description of the display mpls ldp session statistics command output

Item	Description
SessionType	Type of LDP sessions.
Local	Number of local LDP sessions.
Remote	Number of remote LDP sessions.
Local&Remote	Number of coexistent local and remote LDP sessions.
Total	Total number of sessions.
Not Operational	Number of sessions in the Not Operational state.
Operational	Number of sessions in the Operational state.
SessionStatistics	Total number of local sessions, remote sessions, and coexistent local and remote sessions.

9.1.38 display mpls lsp

Function

The **display mpls lsp** command displays information about LSPs.

The **display mpls lsp lsp-id** command displays information about CR-LSPs only.

Format

display mpls lsp lsp-id *ingress-lsr-id session-id lsp-id* [**verbose**]

display mpls lsp [[**vpn-instance** *vpn-instance-name* [**ipv4-family** | **ipv6-family**]] [**protocol** { **bgp** | **bgp-ipv6** | **rsvp-te** | **static** | **static-cr** }] | **asbr**] [{ **exclude** | **include** } *ip-address mask-length*] [**incoming-interface** *interface-type interface-number*] [**outgoing-interface** *interface-type interface-number*]

[**in-label** *in-label-value*] [**out-label** *out-label-value*] [**nexthop** *ip-address*] [**lsr-role** { **egress** | **ingress** | **transit** }] [**verbose**]

display mpls lsp [**vpn-instance** *vpn-instance-name* [**ipv4-family** | **ipv6-family**]] **protocol ldp** [{ **exclude** | **include** } *ip-address mask-length*] [**outgoing-interface** *interface-type interface-number*] [**in-label** *in-label-value*] [**out-label** *out-label-value*] [**nexthop** *ip-address*] [**lsr-role** { **egress** | **ingress** | **transit** }] [**verbose**]

display mpls lsp stale-incoming-interface *interface-index* [**outgoing-interface** *interface-type interface-number*] [**in-label** *in-label-value*] [**out-label** *out-label-value*] [**nexthop** *ip-address*] [**lsr-role** { **egress** | **ingress** | **transit** }] [**verbose**]

display mpls lsp stale-outgoing-interface *interface-index* [**in-label** *in-label-value*] [**out-label** *out-label-value*] [**nexthop** *ip-address*] [**lsr-role** { **egress** | **ingress** | **transit** }] [**verbose**]

Parameters

Parameter	Description	Value
lsp-id	Specifies the LSP ID.	The value is an integer ranging from 0 to 65535.
ingress-lsr-id	Specifies the ID of the ingress LSR.	The value is in dotted decimal notation.
session-id	Specifies the ID of a session.	The value is an integer ranging from 0 to 65535.
vpn-instance *vpn-instance-name*	Displays detailed configurations of LSPs of a specified VPN instance.	The value must be an existing VPN instance name.
ipv4-family	Indicates the IPv4 unicast address-family.	-
ipv6-family	Indicates the IPv6 unicast address-family.	-
protocol	Displays information about LSPs of a specified type.	-
ldp	Indicates LDP.	-
bgp	Indicates BGP.	-
bgp-ipv6	Indicates BGP IPv6.	-

Parameter	Description	Value
rsvp-te	Indicates RSVP-TE.	-
static	Indicates Static.	-
static-cr	Indicates Static-CR.	-
asbr	Displays information about LSPs of a specified ASBR.	-
exclude	Displays information about LSPs, excluding information about the specific FEC.	-
include	Displays information about LSPs, including information about the specific FEC.	-
ip-address	Displays information about LSPs of a specified IPv4 address or a specified IPv6 address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of the specified IPv4 address or a specified IPv6 address.	The value is an integer ranging from 0 to 32. Alternatively, it specifies the mask length of the specified IPv6 address. The value is an integer ranging from 0 to 128.
incoming-interface *interface-type interface-number*	Specifies the type and number of an inbound interface. You can view the configuration of an LSP on a specified interface.	-
outgoing-interface *interface-type interface-number*	Indicates the type and number of an outbound interface. You can view the configuration of an LSP on a specified interface.	-
in-label *in-label-value*	Displays information about LSPs of a specified incoming label.	The value is an integer ranging from 0 to 1048575.
out-label *out-label-value*	Displays information about LSPs of a specified outgoing label.	The value is an integer ranging from 0 to 1048575.

Parameter	Description	Value
nexthop *ip-address*	Displays information about LSPs of a specified IPv4 or IPv6 next hop address.	The value is in dotted decimal notation.
lsr-role	Displays information about all LSPs on the current LSR that plays a specified role.	-
egress	Displays information about LSPs of an egress LSR.	-
ingress	Displays information about LSPs of an ingress LSR.	-
transit	Displays information about LSPs of a transit LSR.	-
verbose	Displays detailed information about LSPs.	-
stale-incoming-interface	Displays information about the stale inbound interface of an LSP.	-
stale-outgoing-interface	Displays information about the stale outbound interface of an LSP.	-
interface-index	Specifies the index of a specified stale interface.	The value is a hexadecimal integer ranging from 1 to FFFFFFFE.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you do not specify a parameter, information about all LSPs is displayed.

Run the **display mpls stale-interface** command without specifying a parameter to view the index of a stale interface.

Example

Display information about all types of LSPs.

```
<HUAWEI> display mpls lsp
-------------------------------------------------------------------------------
               LSP Information: RSVP LSP
-------------------------------------------------------------------------------
 FEC                In/Out Label  In/Out IF                    Vrf Name
 10.2.2.9/32        NULL/11264    -/Vlanif10

Flag after Out IF: (I) - LSP Is Only Iterated by RLFA
-------------------------------------------------------------------------------
               LSP Information: LDP LSP
-------------------------------------------------------------------------------
 FEC                In/Out Label  In/Out IF                    Vrf Name

 10.2.2.9/32        NULL/3         -/Vlanif10
 10.2.2.9/32        1024/3        -/Vlanif10
 10.3.3.9/32        NULL/3         -/Vlanif20
 10.3.3.9/32        1025/3        -/Vlanif20
```

Display information about all LSPs with the next hop of 192.168.1.1.

```
<HUAWEI> display mpls lsp nexthop 192.168.1.1

Flag after Out IF: (I) - LSP Is Only Iterated by RLFA
-------------------------------------------------------------------------------
           LSP Information: L3VPN Label-Per-Nexthop LSP
-------------------------------------------------------------------------------

Table 9-38 Description of the display mpls lsp command output

Item	Description
LSP Information	LSP information: • STATIC LSP: manually created. • LDP LSP: created using LDP. • STATIC CR-LSP: a static MPLS TE tunnel created manually. • RSVP LSP: an MPLS TE tunnel created using RSVP-TE. • BGP LSP: an LSP created using BGP based on private or public IPv4 BGP routes. • L3VPN LSP: an LSP based on IPv4 VPN routes received by means of BGP. • BGP IPV6 LSP: an LSP based on private-network IPv6 routes received by means of BGP. • L3VPN IPV6 LSP: an LSP based on IPv6 VPN routes received by means of BGP.
FEC/Fec	Forwarding equivalence class. Usually, the value is the destination address of an LSP.
In/Out Label	Values of the incoming and outgoing labels.

Item	Description
In/Out IF	Names of the incoming and outbound interfaces.
Vrf Name	Name of a VPN instance.
IndirectID	Index of the next hop of a BGP route.
No	Serial number of an LSP.
SessionID	Session ID of a CR-LSP.
IngressLsrID	Ingress LSR ID of a CR-LSP.
LocalLspID	Local LSP ID of a CR-LSP.
Tunnel-Interface	Tunnel interface.
VrfName	Name of a VPN instance. This value is available for only non-CR-LSPs.
Nexthop	IP address of the next hop of an LSP.
TunnelTableIndex	Index of a tunnel table.
In-Label	Value of an incoming label.
Out-Label	Value of an outgoing label.
In-Interface	Name of an inbound interface.
Out-Interface	Name of an outbound interface.
LspIndex	Index number of an LSP, which uniquely identifies an LSP that is established using a specific protocol.
Token	LSP token. It guides the packet forwarding.
FrrToken	Token of a standby LDP LSP. This value is available for only non-CR-LSPs.
LsrType	Role of an LSR on an LSP: ● Ingress ● Transit ● Egress
Outgoing token	Token that guides the packet forwarding, which is available for only non-CR-LSPs.
Label Operation	Type of a label operation, which is available for only non-CR-LSPs: ● PUSH ● SWAP ● POP ● SWAPPUSH

Item	Description
Mpls-Mtu	Maximum transmission unit (MTU) of an interface of an LSP.
TimeStamp	Time elapsed since an LSP was set up.
Bfd-State	BFD status.
CBfd-Event	Error code event that BFD reports to the RSVP LSP on the ingress node.
Bed-State	Error code status of an RSVP LSP on the ingress node.
Bed-LastNotifyValue	Error code association of which the RSVP LSP notifies BFD on the egress node.
Bed-LastNotifyLspId	ID of the reversed LSP that corresponds to the error code association event on the egress node. The association event is notified of BFD by the RSVP LSP.
BGPKey	Index of BGP.

9.1.39 display mpls lsp statistics

Function

The **display mpls lsp statistics** command displays statistics about the LSPs that are in the Up state and the number of the LSPs that are activated on the ingress, transit, and egress nodes.

Format

display mpls lsp statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display mpls lsp statistics** command to view statistics about the LSPs and CR-LSPs that are in the Up state.

To view detailed information about the LSPs and CR-LSPs, run the **display mpls lsp** command.

Example

Display statistics about LSPs.

```
<HUAWEI> display mpls lsp statistics
Lsp Type       Total     Ingress   Transit   Egress
STATIC LSP     0         0         0         0
STATIC CRLSP   0         0         0         0
LDP LSP        4         3         0         1
RSVP CRLSP     0         0         0         0
BGP LSP        1         0         0         1
ASBR LSP       0         0         0         0
BGP IPV6 LSP   0         0         0         0
L3VPN IPV6 LSP 0         0         0         0
-------------------------------------------------------------------------
LSP            5         3         0         2
CRLSP          0         0         0         0
-------------------------------------------------------------------------
Lsp Type       IngressLspBypassState         TransitLspBypassState
               ExistNotUsed   InUse          ExistNotUsed   InUse
RSVP CRLSP     0              0              0              0
-------------------------------------------------------------------------
```

Table 9-39 Description of the display mpls lsp statistics command output

Item	Description
Lsp Type	Type of an LSP: - STATIC LSP: a static LSP. - STATIC CRLSP: a static CR-LSP. - LDP LSP: created using LDP. - RSVP CRLSP: an MPLS TE tunnel created using RSVP-TE. - BGP LSP: an LSP created using BGP based on private or public IPv4 BGP routes. - ASBR LSP: created using BGP based on received IPv4 VPN route. - BGP IPV6 LSP: an LSP created using BGP based on private IPv6 routes. - L3VPN IPV6 LSP: created using BGP based on received IPv6 VPN routes. - LSP: Label Switched Path. - CRLSP: Constraint-based Routed Label Switched Path.
Total	Number of LSPs of a specific type.
Ingress	Number of LSPs on the local ingress LSR.

Item	Description
Transit	Number of LSPs on the local transit LSR.
Egress	Number of LSPs on the local egress LSR.
IngressLspBypassState	State of the ingress LSP enabled with FRR: - ExistNotUsed: Bypass LSP that is bound to the primary LSP but has no traffic. - InUse: Traffic switched to the bypass LSP.
TransitLspBypassState	State of the Transit LSP enabled with FRR: - ExistNotUsed: Bypass LSP that is bound to the primary LSP but has no traffic. - InUse: Traffic switched to the bypass LSP.

9.1.40 display mpls route-state

Function

The **display mpls route-state** command displays routing information about a dynamic LSP.

Format

display mpls route-state [**vpn-instance** *vpn-instance-name*] [{ **exclude** | **include** } { **idle** | **ready** | **settingup** } * | *destination-address mask-length*] [**verbose**]

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
exclude	Displays routing information excluding the specified route.	-

Parameter	Description	Value
include	Displays information about a specified route.	-
idle	Indicates that a route is not used to establish an LSP.	-
ready	Indicates that a route has been used to establish an LSP.	-
settingup	Indicates that a signaling protocol is creating an LSP.	-
destination-address	Specifies the destination address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of a specified destination address.	The value is an integer ranging from 0 to 32.
verbose	Displays detailed routing information about an LSP.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

After completing LDP LSP configurations, run the **display mpls ldp lsp** command to view information about an LDP LSP. If the command output displays no information about the LDP LSP, run the **display mpls route-state** command to view LDP LSP routing information.

Precautions

Only routing states of the LSPs that are set up based on dynamic signaling protocols can be changed. Therefore, the **display mpls route-state** command displays only routing states of dynamic LSPs, but not routing information about static LSPs.

Example

Display detailed information about routes of dynamic LSPs.

```
<HUAWEI> display mpls route-state verbose

Codes: B(BGP), I(IGP), L(Public Label BGP), O(Original BGP), U(Unknown)
-------------------------------------------------------------------------------
Dest/Mask         Next-Hop       Out-Interface        State    LSP   VRF Type
-------------------------------------------------------------------------------
10.21.21.21/32    10.22.22.21    Vlanif100            READY    2     0   I
     LspIndex: 30720     InLabel: NULL      OutLabel: 3
     LspIndex: 32728     InLabel: 1024      OutLabel: 3
10.0.0.6/32       10.21.22.21    Vlanif100            READY    1     0   I
     LspIndex: 33053     InLabel: NULL      OutLabel: 3338
```

Table 9-40 Description of the display mpls route-state verbose command output

Item	Description
Dest/Mask	Destination IP address and mask length.
Next-Hop	Next hop IP address.
Out-Interface	Outbound interface.
State	Routing state of the MPLS control plane: ● IDLE: The route is not used to establish an LSP. ● SETTINGUP: A signaling protocol is creating an LSP. ● READY: The route has been used to establish an LSP. Static LSPs are only in READY state.
LSP	Number of LSPs reachable to the destination address. If the displayed value is not 0, there are LSPs reachable to the destination address and LSP information about these LSPs is also displayed.
VRF	Index of a VPN instance. The value 0 indicates the public network.
Type	Route type: ● B: BGP routes ● I: IGP routes ● L: labeled BGP routes of a public network ● O: original BGP routes ● U: unidentified routes (such as multicast routes)
LspIndex	Index of an LSP established using the route.
InLabel	Incoming label of an LSP established using the route. If NULL is displayed, the current node is the ingress node of the LSP; if a number is displayed, the current node is the transit or egress node of the LSP.
OutLabel	Outgoing label of an LSP established using the route.

9.1.41 display mpls static-lsp

Function

The **display mpls static-lsp** command displays information about static LSPs.

Format

display mpls static-lsp [*lsp-name*] [{ **include** | **exclude** } *ip-address mask-length*] [**verbose**]

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of an LSP.	The value is an existing static LSP name.
include	Displays information about LSPs, including information about the specific FEC.	-
exclude	Displays information about LSPs, excluding information about the specific FEC.	-
ip-address	Specifies the destination IPv4 address.	The value is in dotted decimal notation.
mask-length	Specifies the length of an IPv4 mask.	The value is an integer ranging from 0 to 32.
verbose	Displays detailed information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Static LSPs are configured locally, so you need to run the **ping lsp** command to check whether the static LSP can work normally. If the static LSP cannot work normally, run the **display mpls static-lsp** command to view information about static LSPs.

Example

Display brief information about static LSPs.

```
<HUAWEI> display mpls static-lsp
TOTAL          : 1       STATIC LSP(S)
```

```
UP              : 1       STATIC LSP(S)
DOWN            : 0       STATIC LSP(S)
Name       FEC              I/O Label  I/O If               Status
lsp1       3.3.3.9/32       NULL/100   -/Vlanif100          Up
```

Table 9-41 Description of the display mpls static-lsp command output

Item	Description
TOTAL	Total number of static LSPs.
UP	Number of static LSPs that are in the Up state.
DOWN	Number of static LSPs that are in the Down state.
Name	Name of an LSP.
FEC	Destination IP address and mask length of an LSP.
I/O Label	Incoming and outgoing labels.
I/O If	Incoming and outbound interfaces.
Status	Current status of an LSP: ● Up ● Down

Display detailed information about static LSPs.

```
<HUAWEI> display mpls static-lsp verbose
No              : 1
LSP-Name        : lsp1
LSR-Type        : Ingress
FEC             : 3.3.3.9/32
In-Label        : NULL
Out-Label       : 100
In-Interface    : -
Out-Interface   : Vlanif100
NextHop         : 10.1.1.2
Static-Lsp Type: Normal
Lsp Status      : Up
```

Table 9-42 Description of the display mpls static-lsp verbose command output

Item	Description
No	Serial number.
LSP-Name	Name of an LSP.
LSR-Type	Role of the current LSR on a static LSP: ● Ingress ● Transit ● Egress
FEC	Destination IP address and mask length of an LSP.

Item	Description
In-Label	Incoming label.
Out-Label	Outgoing label.
In-Interface	Inbound interface.
Out-Interface	Outbound interface.
NextHop	Next hop IP address.
Static-Lsp Type	Type of a static LSP.
Lsp Status	LSP status: ● Up ● Down

9.1.42 display ospf ldp-sync interface

Function

The **display ospf ldp-sync interface** command displays the status of LDP and OSPF synchronization on an interface.

Format

display ospf ldp-sync interface { **all** \| *interface-type interface-number* }

Parameters

Parameter	Description	Value
all	Displays information about the synchronization status on all interfaces enabled with LDP and OSPF synchronization.	-
interface-type interface-number	Displays information about the synchronization status on a specified interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

For all interfaces that are enabled with LDP and OSPF synchronization, run the **display ospf ldp-sync interface** command to view information about the status of LDP and OSPF synchronization.

Example

Display information about the status of LDP and OSPF synchronization on a specified interface.

```
<HUAWEI> display ospf ldp-sync interface vlanif 100
 Interface Vlanif100   HoldDown Timer: 9         HoldMaxCost Timer: 50
 LDP State: Up             OSPF Sync State: Sync-Achieved
```

Table 9-43 Description of the display ospf ldp-sync interface command output

Item	Description
Interface	Interface connected to neighbors.
HoldDown Timer	Interval at which the interface waits to create an LDP session without creating the OSPF neighbor relationship. The default interval is 10 seconds. To set the interval at which the interface waits to create an LDP session without creating the OSPF neighbor relationship, run the **ospf timer ldp-sync hold-down** command.
HoldMaxCost Timer	Interval at which OSPF advertises the maximum metric in LSAs sent by the local device. The default interval is 10 seconds. To set the interval at which OSPF advertises the maximum metric in LSAs sent by the local device, run the **ospf timer ldp-sync hold-max-cost** command. **NOTE** If the value of this field is **infinite**, OSPF keeps advertising the maximum metric value in LSAs sent by the local device before the LDP session is reestablished.
LDP State	Status of an LDP session: ● Up ● Down

Item	Description
OSPF Sync State	Status of LDP and OSPF synchronization: ● Sync-Achieved: The creation of an LDP session and establishment of the OSPF neighbor relationship are synchronized. ● HoldDown: The interface is waiting to create an LDP session without creating the OSPF neighbor relationship. ● HoldMaxCost: OSPF advertises the maximum metric in LSAs or LSPs sent by the local device. ● Init: the initial state.

9.1.43 display static-route ldp-sync

Function

The **display static-route ldp-sync** command displays information about the outbound interface of a static route configured with synchronization between LDP and static routes.

Format

display static-route ldp-sync [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Run the **display static-route ldp-sync** command to view synchronization between LDP and static routes to diagnose faults in static routes.

- If no outbound interface is specified, information about all outbound interfaces of the static routes configured with synchronization between LDP and static routes is displayed.

- If an outbound interface is specified, information about the specified outbound interface of the static routes configured with synchronization between LDP and static routes is displayed.

Example

Display information about the outbound interface of the static route configured with synchronization between LDP and static routes.

```
<HUAWEI> display static-route ldp-sync
Total number of routes enable Ldp-Sync: 2
-----------------------------------------------------
Interface GigabitEthernet0/0/1
Enable ldp-sync static routes number: 1
Static-route ldp-sync holddown timer: 20s
Sync state: Normal
Dest = 4.4.4.4, Mask = 32, NextHop = 10.1.1.1.
-----------------------------------------------------
Interface GigabitEthernet0/0/2
Enable ldp-sync static routes number: 1
Static-route ldp-sync holddown timer: 10s
Sync state: Normal
Dest = 4.4.4.4, Mask = 32, NextHop = 20.1.1.1.
-----------------------------------------------------
```

Table 9-44 Description of the display static-route ldp-sync command output

Item	Description
Total number of routes enable Ldp-Sync	Number of static routes configured with synchronization between LDP and static routes.
Interface GigabitEthernet0/0/1	Outbound interface of the static route configured with synchronization between LDP and static routes.
Enable ldp-sync static routes number	Number of static routes enabled with synchronization between LDP and static routes, with an outbound interface of GE1/0/0.
Static-route ldp-sync holddown timer	Time during which the static route remains inactive and waits for an LDP session to be established.
Sync state	Status of synchronization between LDP and static routes: ● Normal ● HoldDown
Dest	Destination address of the static route.
Mask	Mask length of the destination address of the static route.
NextHop	Next hop address of the static route.

9.1.44 fec-list

Function

The **fec-list** command creates a FEC list used in dynamic BFD for LDP LSP.

The **undo fec-list** command deletes a FEC list.

By default, no FEC list is created.

Format

fec-list *list-name*

undo fec-list *list-name*

Parameters

Parameter	Description	Value
list-name	Specifies the name of a FEC list.	The value is a string of 1 to 31 case-sensitive characters without spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When a BFD session is established based on the FEC list, run the **fec-list** command to create a FEC list. Run the **fec-node** command to specify a host route to trigger the establishment of BFD sessions.

Only a single FEC list can be configured globally.

Example

Create FEC list 1.

```
<HUAWEI> system-view
[HUAWEI] fec-list 1
```

9.1.45 fec-node

Function

The **fec-node** command adds an FEC node.

The **undo fec-node** command deletes an FEC node.

By default, no FEC node is created.

Format

fec-node *ip-address* [**nexthop** *ip-address* | **outgoing-interface** *interface-type interface-number*]*

undo fec-node *ip-address* [**nexthop** *ip-address* | **outgoing-interface** *interface-type interface-number*]*

Parameters

Parameter	Description	Value
ip-address	Specifies the FEC address.	The value is in dotted decimal notation.
nexthop *ip-address*	Specifies the next-hop address.	The value is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Specifies the outbound interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-

Views

FEC-list view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the establishment of BFD sessions is triggered in FEC list mode, the system sets up BFD sessions for the added FEC nodes.

Prerequisites

An FEC list has been created by running the **fec-list** command.

Example

Create FEC nodes in the FEC list.

```
<HUAWEI> system-view
[HUAWEI] fec-list 1
[HUAWEI-fec-list-1] fec-node 10.1.1.1 nexthop 10.2.1.1 outgoing-interface vlanif 100
```

9.1.46 graceful-restart (MPLS-LDP view)

Function

The **graceful-restart** command enables LDP GR.

The **undo graceful-restart** command disables LDP GR.

By default, LDP GR is disabled.

Format

graceful-restart

undo graceful-restart

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In LDP GR mode, when AMB/SMB switchover or protocol restart occurs on the neighboring device of the local device, the local device (GR helper) helps the device (restarter) to restart without interrupting packet forwarding.

If LDP GR is not enabled, during the AMB/SMB switchover or upgrade, the neighboring device deletes the LSP because the session is in the Down state. As a result, the traffic is interrupted in a short time. If LDP GR is enabled, the labels before and after unexpected AMB/SMB switchover or protocol restart can be consistent, and uninterrupted MPLS forwarding is ensured.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp(system view)** command in the system view.

Precautions

Enabling or disabling GR causes the reestablishment of all LDP sessions.

LDP GR must be enabled on both the GR Restarter and Helper.

Example

Enable LDP GR.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] graceful-restart
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.47 graceful-restart timer neighbor-liveness

Function

The **graceful-restart timer neighbor-liveness** command sets the value of the Neighbor-liveness timer.

The **undo graceful-restart timer neighbor-liveness** command restores the default setting.

By default, the value of the Neighbor-liveness timer is 600 seconds.

Format

graceful-restart timer neighbor-liveness *time*

undo graceful-restart timer neighbor-liveness

Parameters

Parameter	Description	Value
time	Specifies the value of the Neighbor-liveness timer.	The value is an integer ranging from 3 to 3600, in seconds.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The value of the neighbor-liveness timer defines the LDP GR period.

During LDP GR, the reestablishment time of the LDP session is negotiated as the smaller value between the value of the neighbor-liveness timer on the GR helper and the value of the Reconnect timer on the GR restarter.

In general, the default value of the timer is recommended. When the number of LSPs on a network is small, you can set a smaller value for the neighbor-liveness timer to shorten the GR period.

Prerequisites

MPLS and MPLS LDP have been enabled globally.

LDP GR has been enabled globally.

Precautions

Changing the value of the neighbor-liveness timer causes the reestablishment of all the LDP sessions.

Example

Set the value of the Neighbor-liveness timer to 500 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] graceful-restart
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
[HUAWEI-mpls-ldp] graceful-restart timer neighbor-liveness 500
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.48 graceful-restart timer reconnect

Function

The **graceful-restart timer reconnect** command sets the value of the Reconnect timer of an LDP session.

The **undo graceful-restart timer reconnect** command restores the default setting.

By default, the Reconnect timer is set to 300 seconds.

Format

graceful-restart timer reconnect *time*

undo graceful-restart timer reconnect

Parameters

Parameter	Description	Value
time	Specifies the value of a Reconnect timer of an LDP session.	The value is an integer ranging from 3 to 3600, in seconds.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the GR restarter performs the active/standby switchover, the GR helper detects that the LDP session with the GR restarter fails, and then starts the Reconnect timer and waits for the reestablishment of the LDP session.

- If no LDP session between the GR helper and the GR restarter has been established after the Reconnect timer times out, the GR helper immediately deletes the MPLS forwarding entries associated with the GR restarter and exits from the GR help process.
- If the LDP session between the GR helper and the GR restarter is established before the Reconnect timer times out, the GR helper deletes the timer and starts the Recovery timer.

During LDP GR, when the reestablishment time of the LDP session is negotiated, the value of the Reconnect timer that actually takes effect on the local end is the smaller value between the value of the neighbor-liveness timer on the GR helper and the value of the Reconnect timer on the GR restarter.

Prerequisites

MPLS and MPLS LDP have been enabled globally.

LDP GR has been enabled globally.

Precautions

Changing the value of the Reconnect timer causes the reestablishment of all the LDP sessions.

Example

Set the time of the Reconnect timer of an LDP session to 270 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] graceful-restart
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
[HUAWEI-mpls-ldp] graceful-restart timer reconnect 270
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.49 graceful-restart timer recovery

Function

The **graceful-restart timer recovery** command sets the value of the LSP Recovery timer.

The **undo graceful-restart timer recovery** command restores the default setting.

By default, the LSP Recovery timer is set to 300 seconds.

Format

graceful-restart timer recovery *time*

undo graceful-restart timer recovery

Parameters

Parameter	Description	Value
time	Specifies the value of an LSP Recovery timer.	The value is an integer ranging from 3 to 3600, in seconds.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the LDP session is reestablished, the GR helper starts the Recovery timer and waits for the recovery of the LSP.

- If the Recovery timer times out, the GR helper considers that the GR process is complete on the GR restarter and deletes the unrecovered LSPs.
- If all the LSPs recover before the Recovery timer times out, the GR helper considers that the GR process is complete on the GR restarter only after the Recovery timer times out.

When a network with a large number of routes is faulty, run the **graceful-restart timer recovery** command to increase the value of the Recovery timer to ensure that all the LSPs recover within the timeout period of the timer.

During the LDP GR process, the value of the LSP Recovery timer that actually takes effect on the local end is negotiated as the smaller one of the values of the LSP Recovery timers configured on both ends of an LDP session.

Prerequisites

MPLS and MPLS LDP have been enabled globally.

LDP GR has been enabled globally.

Precautions

Changing the value of the LSP Recovery timer causes the reestablishment of all the LDP sessions.

Example

Set the value of the LSP Recovery timer to 330 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] graceful-restart
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
[HUAWEI-mpls-ldp] graceful-restart timer recovery 330
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.50 gtsm peer valid-ttl-hops

Function

The **gtsm peer valid-ttl-hops** command configures the generalized TTL security mechanism (GTSM) on a specified LDP peer.

The **undo gtsm** command deletes the GTSM on all LDP peers or a specified LDP peer.

By default, no LDP peer is configured with the GTSM.

Format

gtsm peer *ip-address* **valid-ttl-hops** *hops*

undo gtsm { **all** | **peer** *ip-address* }

Parameters

Parameter	Description	Value
peer *ip-address*	Specifies the transport address of an LDP peer.	The value is in dotted decimal notation.
valid-ttl-hops *hops*	Specifies the maximum number of valid hops permitted by the GTSM.	The value is an integer ranging from 1 to 255.
all	Indicates all LDP peers.	-

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The GTSM checks TTL values to verify packets and protect devices against attacks. LDP peers are configured with the GTSM and a valid TTL range to check TTLs in LDP packets exchanged between them. If the TTL in an LDP packet is out of the valid range, this LDP packet is considered invalid and discarded. The GTSM defends against CPU-based attacks initiated using a large number of forged packets and protects upper-layer protocols.

If the value of *hops* is set to the maximum number of valid hops permitted by GTSM, when the TTL values carried in the packets sent by an LDP peer are within the range [255 - Number of hops +1, 255], the packets are received; otherwise, the packets are discarded.

NOTE

Configuring the GTSM on both ends of an LDP session is recommended.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp (system view)** command.

Precautions

The valid TTL range is from 1 to 255 or from 1 to 64, depending on the specific vendor. If a Huawei device is connected to a non-Huawei device, set *hops* to a value in a valid range that both devices support; otherwise, the Huawei device will discard packets sent by the non-Huawei device, resulting in LDP session interruption.

Example

On the LSR, set valid TTL values carried in LDP packets sent by the peer with transport address 10.1.1.1 to 254 and 255.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] gtsm peer 10.1.1.1 valid-ttl-hops 2
```

9.1.51 inbound peer fec

Function

The **inbound peer fec** command configures an inbound policy, which allows the LSR to receive Label Mapping messages for IGP routes only from a specified peer.

The **undo inbound peer fec** command restores the default setting.

By default, no inbound policy is configured.

Format

inbound peer { *peer-id* | **peer-group** *peer-group-name* | **all** } **fec** { **none** | **host** | **ip-prefix** *prefix-name* }

undo inbound peer { *peer-id* | **peer-group** *peer-group-name* | **all** } **fec**

undo inbound peer all

Parameters

Parameter	Description	Value
peer-id	Specifies the ID of an LDP peer.	The value is in dotted decimal notation.

Parameter	Description	Value
peer-group *peer-group-name*	Specifies the name of a peer group.	The value is an existing peer group name.
all	Indicates all LDP peers.	-
none	Forbids all Label Mapping messages. After the parameter **none** is configured, the specified LSR does not receive Label Mapping messages for IGP routes from its peers.	-
host	Allows only Label Mapping messages for host routes. After the parameter **host** is configured, the specified LSR receives only Label Mapping messages for host routes from its peers.	-
ip-prefix *prefix-name*	Allows only Label Mapping messages for IGP routes that are defined in the IP prefix list. After the parameter **ip-prefix** is configured, the specified LSR receives Label Mapping messages only for IGP routes that are defined in the IP prefix list by its peers.	The value is an existing IP prefix list name.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, an LSR receives Label Mapping messages from all LDP peers to speed up LDP LSP convergence. This leads to establishment of a great number of unwanted LSPs, which wastes resources. To reduce the number of LSPs and save memory resources, configure an inbound policy to filter out LDP LSPs not matching the policy.

When running the **inbound peer fec** command to specify the peer ID and FEC of the IGP route, configure the peer to receive only Label Mapping messages for specified IGP routes.

To apply a policy associated with the same FEC range to an LDP peer group or all LDP peers receiving Label Mapping messages, configure either **peer-group** *peer-group-name* or **all** in the command.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

If multiple inbound policies are configured for a specified LDP peer, the earliest configuration takes effect. For example, the following two inbound policies are configured:

```
inbound peer 2.2.2.2 fec host
inbound peer peer-group group1 fec none
```

As group1 also contains an LDP peer with *peer-id* of 2.2.2.2, the following inbound policy takes effect:

```
inbound peer 2.2.2.2 fec host
```

If two inbound policies are configured in sequence and the **peer** parameters in the two commands are the same, the second command overrides the first one. For example, the following two outbound policies are configured:

```
inbound peer 2.2.2.2 fec host
inbound peer 2.2.2.2 fec none
```

The second configuration overrides the first one. This means that the following inbound policy takes effect on the LDP peer with *peer-id* of 2.2.2.2:

```
inbound peer 2.2.2.2 fec none
```

Creating a peer group before it is referenced is recommended. By default, nonexistent peer groups cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent peer group is referenced using the current command, the current command applies to all LDP peers.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, the device receives Label Mapping messages of all LDP FECs from the specified peer.

Example

Configure all LSRs to receive Label Mapping messages only for host routes from peers.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] inbound peer all fec host
```

9.1.52 ip route-static ldp-sync

Function

The **ip route-static ldp-sync** command configures unicast static routes for synchronization with LDP.

The **undo ip route-static ldp-sync** command deletes unicast static routes for synchronization with LDP.

By default, unicast static routes for synchronization with LDP are not configured.

Format

ip route-static *ip-address* { *mask* | *mask-length* } *interface-type interface-number* [*nexthop-address*] [**preference** *preference* | **tag** *tag*] * **ldp-sync** [**description** *text*]

undo ip route-static *ip-address* { *mask* | *mask-length* } *interface-type interface-number* [*nexthop-address*] [**preference** *preference* | **tag** *tag*] * **ldp-sync**

ip route-static vpn-instance *vpn-source-name ip-address* { *mask* | *mask-length* } { *nexthop-address* [**public**] | *interface-type interface-number* [*nexthop-address*] | **vpn-instance** *vpn-destination-name nexthop-address* } [**preference** *preference* | **tag** *tag*] * **ldp-sync** [**description** *text*]

undo ip route-static vpn-instance *vpn-source-name ip-address* { *mask* | *mask-length* } [*nexthop-address* | *interface-type interface-number* [*nexthop-address*]] [**preference** *preference* | **tag** *tag*] * **ldp-sync**

Parameters

Parameter	Description	Value
vpn-instance *vpn-source-name*	Specifies the name of the source VPN instance. Each VPN instance has its own routing table. The configured static routes are added to the routing table of the specified VPN instance.	The value must be an existing VPN instance name.
vpn-instance *vpn-destination-name*	Specifies the name of the destination VPN instance.	The value must be an existing VPN instance name.
ip-address	Specifies a destination IP address.	The value is in dotted decimal notation.
mask	Specifies the subnet mask.	The value is in dotted decimal notation.
mask-length	Specifies the mask length. As 1s in a 32-bit mask must be consecutive, the mask in dotted decimal notation can be replaced by the mask length.	The value is an integer that ranges from 0 to 32.
interface-type interface-number	Specifies the type and number of the interface that forwards packets.	-
nexthop-address	Specifies the next-hop address.	The value is in dotted decimal notation.
public	Specifies the next-hop address as a public network address but not an address in the source VPN instance.	-
preference *preference*	Specifies the preference of a static route. A smaller value indicates a higher preference.	The value is an integer that ranges from 1 to 255. The default value is 60.

Parameter	Description	Value
tag *tag*	Specifies the tag value of a static route. By configuring different tag values, you can classify static routes to implement different routing policies. For example, other routing protocols can import static routes with specified tag values through routing policies.	The value is an integer that ranges from 1 to 4294967295. The default value is 0.
description *text*	Configures the description of a static route.	The value is a string of 1 to 80 characters that can contain spaces.

System view

Default Level

2: Configuration level

Usage Guidelines

On an MPLS network with primary and backup links, LSRs establish LSPs based on static routes. When the LDP session of the primary link becomes faulty (the fault is not caused by a link failure) or the primary link recovers, configuring synchronization between LDP and static routes minimizes traffic loss during traffic switchover and switchback.

After synchronization between LDP and static routes is enabled, the recovered static route becomes temporarily inactive. It waits for the establishment of an LDP session before the Hold-down timer expires, which synchronizes LDP and the static route.

Example

Configure static routes for synchronization with LDP.

```
<HUAWEI> system-view
[HUAWEI] ip route-static 10.1.1.0 255.255.255.0 vlanif 100 ldp-sync
```

9.1.53 isis ldp-sync

Function

The **isis ldp-sync** command enables synchronization between LDP and IS-IS on an interface.

The **undo isis ldp-sync** command disables synchronization between LDP and IS-IS on an interface.

By default, synchronization between LDP and IS-IS is disabled on an interface.

Format

isis ldp-sync

undo isis ldp-sync

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The LDP convergence speed depends on the convergence speed of IS-IS routes. To enable MPLS LDP on a network with the primary and backup links, the following problems may occur:

- Upon a fault on the primary link, IS-IS routes and ISP are both switched to the backup link using LDP FRR. When the primary link recovers, IS-IS routes are switched back to the primary link earlier than LDP traffic because IGP route convergence is faster than LDP convergence. As a result, LSP traffic is lost.
- If a fault occurs on the LDP session between nodes on the primary link where the IS-IS routes are working properly, the IS-IS routes still use the primary link and the LSP on the primary link is deleted. No IS-IS route exists on the backup link; therefore, no LSP can be established on the backup link. LSP traffic is lost.

Run the **isis ldp-sync** command to enable synchronization between LDP and IS-IS to prevent traffic loss in the preceding problems. Run this command on the interfaces on both ends of the link between the node where the primary LSP and the backup LSP diverge from each other and its LDP peer on the primary LSP.

Prerequisites

The IS-IS process has been started using the **isis enable** command in the interface view.

Example

Enable synchronization between LDP and IS-IS on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis ldp-sync
```

Enable synchronization between LDP and IS-IS on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
```

```
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis ldp-sync
```

9.1.54 isis ldp-sync block

Function

The **isis ldp-sync block** command blocks synchronization between LDP and IS-IS on an interface.

The **undo isis ldp-sync block** command restores the default setting.

By default, synchronization between LDP and IS-IS is not blocked on an interface.

Format

isis ldp-sync block

undo isis ldp-sync block

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **ldp-sync enable** command run in the IS-IS view on a device enables synchronization between LDP and IS-IS on all local IS-IS interfaces. On an IS-IS interface transmits importance services, LDP and IS-IS synchronization may affect service transmission. If the link is working properly and an LDP session over the link fails, IS-IS sends link state PDUs (LSPs) to advertise the maximum cost of the link. As a result, IS-IS does not select the route for the link, which affects important service transmission.

To prevent the preceding problem, run the **isis ldp-sync block** command to block synchronization between LDP and IS-IS on the IS-IS interface that transmits important services.

Prerequisites

The IS-IS process has been started using the **isis enable** command in the interface view.

Example

Block synchronization between LDP and IS-IS on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis ldp-sync block
```

Block synchronization between LDP and IS-IS on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis ldp-sync block
```

9.1.55 isis timer ldp-sync hold-down

Function

The **isis timer ldp-sync hold-down** command sets the interval during which an interface waits for creating an LDP session before setting up the IS-IS neighbor relationship.

The **undo isis timer ldp-sync hold-down** command restores the default setting.

By default, the interval is 10 seconds.

Format

isis timer ldp-sync hold-down *value*

undo isis timer ldp-sync hold-down

Parameters

Parameter	Description	Value
value	Specifies the interval during which an interface waits for creating an LDP session before setting up the IS-IS neighbor relationship.	The value is an integer ranging from 0 to 65535, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network with both active and standby links, if the active link fails, traffic switches to a standby link. Therefore, the standby IS-IS route and backup LDP label switched path (LSP) along the standby link become reachable. After the active link recovers, its IS-IS route converges more rapidly than the LDP LSP. As a result, the IS-IS neighbor relationship is established earlier than the LDP session on the active link. Although traffic is directed over the IS-IS route to the active link, traffic fails to be forwarded because no LDP LSP is established.

To prevent the traffic forwarding failure, LDP and IS-IS synchronization can be configured. After the active link recovers from a physical fault, the IS-IS route for the active link is set to the Hold-down state, and the Hold-down timer starts. After an LDP session is established over the active link or the Hold-down timer expires, the IS-IS neighbor relationship starts to be established. This allows the LDP LSP and IS-IS route to go Up simultaneously. To set the Hold-down timer, run the **isis timer ldp-sync hold-down** command.

Prerequisites

The IS-IS process has been started using the **isis enable** command in the interface view.

Precautions

This command is circular in nature, and the latest configuration overrides the previous configurations.

Example

Set the value of the Hold-down timer for VLANIF100 to 15 seconds, during which the interface waits for the establishment of an LDP session before setting up the IS-IS neighbor relationship.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer ldp-sync hold-down 15
```

Set the value of the Hold-down timer for GE0/0/1 to 15 seconds, during which the interface waits for the establishment of an LDP session before setting up the IS-IS neighbor relationship.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer ldp-sync hold-down 15
```

9.1.56 isis timer ldp-sync hold-max-cost

Function

The **isis timer ldp-sync hold-max-cost** command sets the interval during which IS-IS sends LSPs to advertise the maximum metric on the local device.

The **undo isis timer ldp-sync hold-max-cost** command restores the default setting.

By default, the interval is 10 seconds.

Format

isis timer ldp-sync hold-max-cost { *value* | **infinite** }

undo isis timer ldp-sync hold-max-cost

Parameters

Parameter	Description	Value
value	Specifies the interval during which IS-IS sends LSPs to advertise the maximum metric on the local device.	The value is an integer ranging from 0 to 65535, in seconds.
infinite	Indicates that IS-IS keeps advertising the maximum metric in LSPs on the local device before an LDP session is reestablished.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network with active and standby links, when the IS-IS route of the active link is reachable and an LDP session between two nodes on the active link fails, traffic is transmitted over the IS-IS route of the active link, whereas the label switched path (LSP) on the active link fails. Although LSP traffic attempts to be switched to the backup LSP, the active IS-IS route is selected to direct traffic. As a result, traffic on the primary LSP is lost.

To prevent the traffic forwarding failure, LDP and IS-IS synchronization can be configured. If the LDP session over the active link fails, IS-IS advertises the maximum cost of the active link route. The IS-IS route for the standby link is selected, and the Hold-max-cost timer starts. After the LDP LSP over the standby link is established, and the IS-IS route for the standby link is reachable, traffic switches to the standby link. After the LDP session on the active link recovers or the Hold-max-cost timer expires, IS-IS advertises the actual cost of the active link route. To set the Hold-max-cost timer, run the **isis timer ldp-sync hold-max-cost** command.

Select one of the following parameters as required:

- When IS-IS carries LDP services only, configure **infinite** to keep the IS-IS route and LSP over the same link.
- If IS-IS carries multiple types of services including LDP services in the networking, configure *value* to ensure that interruption of an LDP session over the active link does not affect IS-IS routing and other services. The default is 10, in seconds, which is a recommended value.

Prerequisites

The IS-IS process has been started using the **isis enable** command in the interface view.

Precautions

This command is circular in nature, and the latest configuration overrides the previous configurations.

Example

Set the interval to 8 seconds, during which IS-IS sends LSPs to advertise the maximum metric on the local device.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] isis enable 1
[HUAWEI-Vlanif100] isis timer ldp-sync hold-max-cost 8
```

Set the interval to 8 seconds, during which IS-IS sends LSPs to advertise the maximum metric on the local device.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] isis enable 1
[HUAWEI-GigabitEthernet0/0/1] isis timer ldp-sync hold-max-cost 8
```

9.1.57 label advertise

Function

The **label advertise** command enables the egress node to advertise labels of a specified type to the penultimate hop.

The **undo label advertise** command restores the default setting.

By default, the egress node assigns implicit null labels to the penultimate hop.

Format

label advertise { **explicit-null** | **implicit-null** | **non-null** }

undo label advertise

Parameters

Parameter	Description	Value
explicit-null	Disables Penultimate Hop Popping (PHP) and enables the egress node to assign explicit null labels to the penultimate hop.	The value of the explicit null label is 0.
implicit-null	Enables PHP and enables the egress node to assign implicit null labels to the penultimate hop.	The value of the implicit null label is 3.

Parameter	Description	Value
non-null	Disables PHP and enable the egress node to assign normal labels to the penultimate hop.	The value is equal to or greater than 16.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MPLS transmits packets along label switched paths (LSPs). The egress at the last hop on the LSP removes MPLS labels from packets before forwarding the packets over IP links or using next layer labels. MPLS labels are useless at the last hop on an LSP. Therefore, penultimate hop popping (PHP) can be configured to enable the penultimate hop to remove labels, which improves forwarding efficiency.

By default, PHP is enabled, and the egress assigns implicit-null labels to the penultimate hop. To specify the type of label that the egress assigns to the penultimate hop, run the following commands:

- In a bidirectional association LSP scenario, run the **label advertise non-null** command to enable the egress to assign a normal label to the penultimate hop.
- In an MPLS QoS scenario, run the **label advertise explicit-null** command to enable the egress to assign an explicit null label to the penultimate hop.

Prerequisites

MPLS has been enabled globally using the **mpls (system view)** command in the system view.

Precautions

After the **label advertise** command is run to specify a label, the egress on a newly established LDP LSP or constraint-based routed label switched path (CR-LSP) assigns the specified label to the penultimate hop. The **label advertise** command can take effect on existing LDP LSPs or CR-LSPs when one of the following conditions is met:

- A master/slave main control board switchover is performed.
- The **reset mpls ldp** command is run to reset an LDP public instance for an LDP LSP.
- If a CR-LSP is established, the **reset mpls rsvp-te** command is run to reset Resource Reservation Protocol-Traffic Engineering (RSVP-TE), or the **reset mpls te tunnel-interface tunnel** command is run to restart a specified TE tunnel.

If the **label advertise** command is run more than once, the latest configuration overrides the previous one.

Example

Configure the egress node to assign explicit null labels to the penultimate hop.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] label advertise explicit-null
```

9.1.58 label distribution default-route

Function

The **label distribution default-route** command enables a device to assign a label to a default IGP route.

The **undo label distribution default-route** command restores the default configuration.

By default, the device is disabled from assigning a label to a default IGP route.

Format

label distribution default-route

undo label distribution default-route

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenarios

To enable a device to use MPLS assign a label to a default IGP route in independent mode, run the **label distribution default-route** command. An LSP can be established using the default route.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Example

Enable a device to assign a label to a default IGP route.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] label distribution default-route
```

9.1.59 label-withdraw-delay

Function

The **label-withdraw-delay** command enables a node to delay sending Label Withdraw messages.

The **undo label-withdraw-delay** command disables a node from delaying sending Label Withdraw messages.

By default, the label withdraw delay function is disabled.

Format

label-withdraw-delay

undo label-withdraw-delay

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The label withdraw delay function prevents downstream LSP flapping from spreading to upstream nodes. For example, an LSP on a local node flaps because an LDP session between the node and its downstream peer flaps, a route flaps, or an LDP policy is modified. The local node repeatedly sends Label Withdraw and Label Mapping messages in sequence to upstream nodes. This causes the upstream nodes to repeatedly tear down and reestablish LSPs. As a result, the entire LDP LSP flaps. The label withdraw delay function can be enabled on each node of the LDP LSP to suppress the spread of LSP flapping.

Follow-up Procedure

Use the default delay time of 5s or run the **label-withdraw-delay timer** command to set the delay time.

Example

Enable the label withdraw delay function.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] label-withdraw-delay
```

9.1.60 label-withdraw-delay timer

Function

The **label-withdraw-delay timer** command sets the delay time before a node sends a Label Withdraw message.

The **undo label-withdraw-delay timer** command restores the default delay time.

The default delay time is 5 seconds.

Format

label-withdraw-delay timer *time*

undo label-withdraw-delay timer

Parameters

Parameter	Description	Value
time	Specifies the delay time before a Label Withdraw message can be sent.	The value is an integer ranging from 1 to 65535, in seconds.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The label withdraw delay function prevents downstream LSP flapping from spreading to upstream nodes. For example, an LSP on a local node flaps because an LDP session between the node and its downstream peer flaps, a route flaps, or an LDP policy is modified. The local node repeatedly sends Label Withdraw and Label Mapping messages in sequence to upstream nodes. This causes the upstream nodes to repeatedly tear down and reestablish LSPs. As a result, the entire LDP LSP flaps. To suppress the spread of LSP flapping, run the **label-withdraw-delay** command to enable the label withdraw delay function on each node and the **label-withdraw-delay timer** command to set the delay time before a node sends a Label Withdraw message to its upstream node.

Prerequisites

The label withdraw delay function has been enabled using the **label-withdraw-delay** command.

Example

Enable the label withdraw delay function on the node and set the delay time to 10s.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] label-withdraw-delay
[HUAWEI-mpls-ldp] label-withdraw-delay timer 10
```

9.1.61 ldp-over-te enable

Function

The **ldp-over-te enable** command enables LDP over Traffic Engineering (TE).

The **undo ldp-over-te enable** command disables LDP over TE.

By default, LDP over TE is not enabled.

Format

ldp-over-te enable

undo ldp-over-te enable

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MPLS TE supports strong traffic engineering capabilities and provides various QoS guarantees. Due to live network limitations, such as application types and costs, deploying MPLS TE on the entire network is difficult. Therefore, LDP over TE can be used to deploy MPLS TE on a core area and LDP on non-core areas.

To enable LDP over TE on the ingress of a TE tunnel, run the **ldp-over-te enable** command.

Precautions

In LDP over TE networking, load balancing is supported when the ingress node of a TE tunnel is an S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, or S6730-H. When there are multiple TE tunnels or there are both TE tunnels and LDP tunnels in the MPLS TE domain, LDP LSP service traffic can be load balanced among multiple tunnels. To adjust the load balancing mode, run the **mpls ecmp load-balance** command in the system-view.

Example

Enable LDP over TE.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] ldp-over-te enable
```

9.1.62 ldp-sync enable

Function

The **ldp-sync enable** command enables synchronization between LDP and IS-IS on all interfaces in an IS-IS process.

The **undo ldp-sync enable** command disables synchronization between LDP and IS-IS on all interfaces in an IS-IS process.

By default, synchronization between LDP and IS-IS is disabled on all interfaces in an IS-IS process.

Format

ldp-sync enable [**mpls-binding-only**]

undo ldp-sync enable

Parameters

Parameter	Description	Value
mpls-binding-only	Synchronization between LDP and IS-IS can only be enabled on MPLS LDP-enabled interfaces.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Synchronization between LDP and IGP reduces LSP traffic loss on a network with both primary and backup LSPs. Traffic loss occurs in either of the following situations:

- The primary LSP works properly and an LDP session between two nodes on the primary LSP fails. IGP guides traffic still through the primary LSP even though a primary/backup LSP switchover is performed.
- If a link on the primary LSP or the primary LSP recovers, IGP routes converge. IGP routes associated with the primary LSP become reachable earlier than the primary LSP because IGP routes converge faster than LDP routes. IGP routes guide traffic through the primary LSP before the primary LSP recovers.

Synchronization between LDP and IGP delays IGP route advertisement so that the LDP session and IGP route can converge simultaneously.

The **ldp-sync enable** command run in the IS-IS view can enable synchronization between LDP and IS-IS on all interfaces within a specified IS-IS process.

Follow-up Procedure

Run the **isis ldp-sync block** command to disable synchronization between LDP and IGP on desired IS-IS interfaces.

Precautions

Although the **undo ldp-sync enable** command has been run, synchronization between LDP and IS-IS configured using the **isis ldp-sync** command still takes effect on an IS-IS interface.

Example

Enable synchronization between LDP and IS-IS on all interfaces in an IS-IS instance.

```
<HUAWEI> system-view
[HUAWEI] isis 100
[HUAWEI-isis-100] ldp-sync enable
```

9.1.63 longest-match

Function

The **longest-match** command configures inter-domain LDP extension capability and enables LDP to search for routes to establish LSPs based on the longest match rule.

The **undo longest-match** command restores the default setting.

By default, LDP searches for routes to establish LSPs based on the exact matching rule.

Format

longest-match

undo longest-match

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large network, multiple IGP areas need to be configured for flexible network deployment and fast route convergence. In this situation, when advertising routes between IGP areas, to prevent a large number of routes from consuming too many resources, an Area Border Router (ABR) needs to aggregate the routes in an area and then advertise the aggregated route to neighbor IGP areas. By default, when establishing LSPs, LDP searches the routing table for the route that exactly matches the forwarding equivalence class (FEC) carried in the received Label Mapping message. For aggregated routes, only liberal LDP LSPs, not inter-area LDP LSPs, can be set up.

In this case, run the **longest-match** command to enable LDP to search for routes or establishing inter-area LDP LSPs based on the longest match rule.

Precautions

Configuring this command is not allowed during LDP GR.

Example

Enable LDP to search for routes for establishing LDP LSPs based on the longest match rule.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] longest-match
```

9.1.64 loop-detect

Function

The **loop-detect** command enables a device to advertise the capability of loop detection during the initialization of an LDP session.

The **undo loop-detect** command disables a device from advertising the capability of loop detection during the initialization of an LDP session.

By default, a device cannot advertise the capability of loop detection during the initialization of an LDP session.

Format

loop-detect

undo loop-detect

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

The switch does not support the loop detection function. In the scenario where its neighbor supports the loop detection function and requires that the notification about whether the loop detection function is enabled be consistent on the two ends, run the **loop-detect** command to ensure that the switch sets up an LDP session with this neighbor.

Though the **loop-detect** command is run, the switch still does not support the LDP loop detection function but only has the loop detection negotiation capability.

Example

Enable the device to advertise the capability of loop detection during the initialization of an LDP session.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] loop-detect
```

9.1.65 lsp-trigger bgp-label-route

Function

The **lsp-trigger bgp-label-route** command enables LDP to allocate labels to labeled BGP routes on the public network.

The **undo lsp-trigger bgp-label-route** command restores the default setting.

By default, LDP does not allocate labels to labeled BGP routes on the public network.

Format

lsp-trigger bgp-label-route [**ip-prefix** *ip-prefix-name*] [**not-only-host**]

undo lsp-trigger bgp-label-route

Parameters

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list that triggers the labeled BGP routes on the public network to set up LDP LSPs.	The value is an existing IP prefix list name.
not-only-host	Uses labeled public network BGP routes with 0-bit to 32-bit masks based on the IP prefix list to establish LDP LSPs.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Both the **lsp-trigger bgp-label-route** command and the **lsp-trigger** command can be used to configure policies to trigger the establishment of LDP LSPs. The former command is used for labeled public network BGP routes with 0-bit to 32-bit masks, and the latter command is used for static routes and IGP routes.

If **not-only-host** is not configured, LDP distributes labels only for labeled public network BGP routes with 32-bit masks. If **not-only-host** is configured, LDP distributes labels for labeled public network BGP routes with 0-bit to 32-bit masks.

Precautions

Modifying the LSP-triggering policy during the LDP GR period is invalid.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all public-network labeled BGP routes trigger LDP LSP establishment.

Example

Trigger the establishment of LDP LSPs according to labeled public network BGP routes with 32-bit masks.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] lsp-trigger bgp-label-route
```

9.1.66 lsp-trigger

Function

The **lsp-trigger** command sets a policy for establishing LDP LSPs.

The **undo lsp-trigger** command restores the default setting.

By default, LDP uses IP host routes with 32-bit addresses (excluding host routes with 32-bit interface addresses) to establish LSPs.

Format

lsp-trigger { **all** | **host** | **ip-prefix** *ip-prefix-name* | **none** }

undo lsp-trigger

Parameters

Parameter	Description	Value
all	Indicates that all static and IGP routes trigger the establishment of LSPs.	-
host	Indicates that IP host routes with 32-bit addresses (excluding host routes with 32-bit interface addresses) trigger the establishment of LSPs.	-
ip-prefix *ip-prefix-name*	Specifies the name of the IP prefix list that triggers the establishment of LSPs.	The value is an existing IP prefix list name.
none	Indicates that the establishment of an LSP is not triggered.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After MPLS LDP is enabled, LSPs are automatically established. If no policy is configured, an increasing number of LSPs are established, wasting resources.

The **lsp-trigger** command configures a policy to allow LDP to use specified routes to establish LSPs. This setting prevents unwanted LSPs from being established and helps reduce resource wastes.

NOTE

The **lsp-trigger all** command is not recommended. If this command is run, LDP uses all IGP routes to establish LSPs, causing a large number of unwanted LSPs to be established and wasting system resources. Before using this command, configure a policy for filtering out routes unnecessary for the LSP establishment. The policy helps reduce the number of LSPs to be established and save system resources.

Prerequisites

MPLS has been enabled globally using the **mpls (system view)** command.

Precautions

- Modifying the LSP-triggering policy during the LDP GR period is invalid.
- The **lsp-trigger** command can be used to configure policies only for ingress and egress LSPs on the public network and ingress and egress LSPs on the private network that are established using IGP routes. To configure a policy for triggering the transit LSP establishment, run the **propagate mapping** command.
- The **lsp-trigger host** command can be run on either of the following nodes to provide a specific function:
  - Ingress: This command enables the ingress to use all routes with a 32-bit mask to establish LDP LSPs.
  - Egress: This command enables the egress to use local routes with a 32-bit mask to establish LDP LSPs.

  The **lsp-trigger** { **all** | **ip-prefix** *ip-prefix-name* } command can be used to establish proxy egress LSPs. The **lsp-trigger host** command, however, cannot be used to establish proxy egress LSPs.
- Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all static and IGP routes trigger LDP LSP establishment.

Example

Trigger the establishment of LSPs based on all static and IGP routes.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] lsp-trigger all
```

9.1.67 lspv mpls-lsp-ping echo enable

Function

The **lspv mpls-lsp-ping echo enable** command enables a device to respond to MPLS Echo Request packets.

The **undo lspv mpls-lsp-ping echo enable** command disables a device from responding to MPLS Echo Request packets.

By default, a device is enabled to respond to MPLS Echo Request packets.

Format

lspv mpls-lsp-ping echo enable

undo lspv mpls-lsp-ping echo enable

Parameters

None.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The ping and trace tests use ICMP packets to locate faulty nodes on a forwarding path. When an LSP fails, IP forwarding-based ICMP packets cannot be used to detect the faulty node.

In this case, the **ping lsp** and **tracert lsp** command can be used to locate the faulty node on the LSP. These commands use MPLS Echo Request and MPLS Echo Reply packets to detect the connectivity of an LSP. Both MPLS Echo Request and MPLS Echo Reply packets are encapsulated into UDP packets and transmitted through port 3503. The receiver distinguishes MPLS Echo Request and MPLS Echo Reply packets based on the port number. An MPLS Echo Request packet carries FEC information to be detected, and is sent along the same LSP as other packets with the same FEC information. In this manner, the connectivity of the LSP is checked. MPLS Echo Request packets are transmitted to the destination through MPLS, whereas MPLS Echo Reply packets are transmitted to the source through IP.

For network security or management, you can run the **lspv mpls-lsp-ping echo enable** command to enable a device to respond to MPLS Echo Request packets or run the **undo lspv mpls-lsp-ping echo enable** command to disable the device from responding to MPLS Echo Request packets. This function is implemented by enabling or disabling port 3503. By default, port 3503 is enabled.

After you run the **ping lsp** and **tracert lsp** command to detect the connectivity of an LSP, you are advised to run the **undo lspv mpls-lsp-ping echo enable** command to disable the device from responding to MPLS Echo Request packets to avoid occupation of system resources.

Precautions

If you run the **undo lspv mpls-lsp-ping echo enable** command to disable a device from responding to MPLS Echo Request packets, this device does not respond to the **ping lsp** and **tracert lsp** command. As a result, the ping or trace test with the address of the device as the destination address times out.

Example

Disable a device to respond to MPLS Echo Request packets.

```
<HUAWEI> system-view
[HUAWEI] undo lspv mpls-lsp-ping echo enable
```

9.1.68 lspv packet-filter

Function

The **lspv packet-filter** command enables the filtering of MPLS Echo Request packets based on source addresses. Filtering rules are defined in ACL configurations.

The **undo lspv packet-filter** command disables the filtering of MPLS Echo Request packets based on source addresses.

By default, the filtering of MPLS Echo Request packets based on source addresses is disabled.

Format

lspv packet-filter *acl-number*

undo lspv packet-filter

Parameters

Parameter	Description	Value
acl-number	Specifies the number of an ACL.	The ACL number is a decimal integer that ranges from 2000 to 3999.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

The **lspv packet-filter** command often runs on the destination device of the LSPV check. In the case that the filtering of MPLS Echo Request packets based on source addresses is enabled, upon receiving MPLS Echo Request packets, the device matches the source addresses of the packets with a specified ACL. The packets permitted by the ACL are processed; those denied by the ACL are discarded.

Example

Enable the filtering of the MPLS Echo Request packets based on source addresses based on ACL 2100.

```
<HUAWEI> system-view
[HUAWEI] lspv packet-filter 2100
```

9.1.69 lsr-id

Function

The **lsr-id** command sets the LSR ID of an LDP instance.

The **undo lsr-id** command restores the default setting.

By default, the LSR ID of an LDP instance is the LSR ID of the LSR where the LDP instance is configured

Format

lsr-id *lsr-id*

undo lsr-id

Parameters

Parameter	Description	Value
lsr-id	Specifies the LSR ID of an LDP instance.	The value is in dotted decimal notation.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, the LSR ID of an LDP instance is the same as the MPLS LSR ID configured using the **mpls lsr-id** command. On some networks such as the BGP/MPLS VPNs to which VPN instances apply, if the VPN address space and the public network address space overlap, configure LSR IDs for LDP instances to ensure the correct establishment of TCP connections.

Prerequisites

- MPLS has been enabled globally using the **mpls (system view)** command.
- MPLS LDP has been enabled globally using the **mpls ldp (system view)** command.

Precautions

Modifying or deleting the LSR ID of an LDP instance causes the reestablishment of all sessions in the LDP instance.

Example

Set the LSR ID of an LDP instance to 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] lsr-id 10.1.1.1
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.70 maintain-session received-error-message

Function

The **maintain-session received-error-message** command enables LDP to maintain a session after receiving error TCP packets.

The **undo maintain-session received-error-message** command restores the default configuration.

By default, LDP tears down a session after receiving error TCP packets.

Format

maintain-session received-error-message

undo maintain-session received-error-message

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

According to RFC5036, LDP tears down a session after receiving error TCP packets. When a device from another vendor fails or a link fails, the LDP session alternates between Up and Down after processing in this way. If the LDP transmits L2VPN services, the L2VPN services will be interrupted. To prevent this problem, run the **maintain-session received-error-message** command to enable LDP to maintain a session after receiving error TCP packets. This prevents LDP session flapping and helps maintain upper-layer L2VPN services.

Example

Enable LDP to maintain a session after receiving error TCP packets.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] maintain-session received-error-message
```

9.1.71 md5-password

Function

The **md5-password** command sets the password that is used by a TCP connection during the creation of an LDP session.

The **undo md5-password** command disables MD5 authentication.

By default, MD5 authentication is disabled during the creation of an LDP session.

Format

md5-password { **plain** | **cipher** } *peer-lsr-id password*

undo md5-password [**plain** | **cipher**] *peer-lsr-id*

Parameters

Parameter	Description	Value
plain	Displays the password in plain text. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. In this case, users at a lower level can easily obtain the password by viewing the configuration file. This brings security risks. Therefore, it is recommended that you select **cipher** to save the password in cipher text.	-
cipher	Displays the password in cipher text.	-
peer-lsr-id	Specifies the LSR ID of the peer, which identifies the peer LSR.	The value is in dotted decimal notation.

Parameter	Description	Value
password	Specifies the password.	The value is a string of characters, spaces not supported. For a plain password, the string is 1 to 255 characters. For an encrypted password, the string is 20 to 392 characters. When double quotation marks are used around the string, spaces are allowed in the string.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MD5 authentication can be configured for a TCP connection over which an LDP session is established, improving security. Note that the peers of an LDP session can be configured with different encryption modes (plain or cipher text mode), but must be configured with a single password.

LDP MD5 authentication generates a unique digest for an information segment to prevent LDP packets from being modified. LDP MD5 authentication is stricter than common checksum verification for TCP connections.

A password can be set either in cipher text or plain text. A plain text password is a character string that is pre-configured and directly recorded in a configuration file. A cipher text password is a character string that is recorded in a configuration file after being encrypted using a specified algorithm.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

- MD5 authentication and keychain authentication cannot be configured together on one peer. Note that MD5 encryption algorithm cannot ensure security. Keychain authentication is recommended.
- If the password on a peer changes, the LDP session is reestablished and the LSP associated with the original LDP session is deleted.

Example

Configure the local node to perform MD5 authentication when it establishes an LDP session with its peer.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] md5-password cipher 2.2.2.2 YsHsjx_202206
```

9.1.72 md5-password all

Function

The **md5-password all** command enables LDP MD5 authentication in a batch for all LDP peers.

The **undo md5-password all** command disables LDP MD5 authentication in a batch for all LDP peers.

By default, MD5 authentication in a batch is disabled for all LDP peers.

Format

md5-password { **plain** | **cipher** } **all** *password*

undo md5-password all

Parameters

Parameter	Description	Value
plain	Indicates a simple text password. A simple text password is saved in simple text in a configuration file. This format poses risks. A ciphertext password is recommended. To improve device security, periodically modify the password.	-
cipher	Indicates a ciphertext password.	-
password	Specifies an authentication password.	A password must not contain spaces. A simple text password is a string of 1 to 255 characters. A ciphertext password is a string of 1 to 255 characters. An MD5 ciphertext password is 20 bits to 392 bits long. The string can contain spaces if it is enclosed with double quotation marks (").

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MD5 authentication can be configured for a TCP connection over which an LDP session is established, improving security. LDP MD5 authentication generates a unique digest for an information segment to prevent LDP packets from being modified. LDP MD5 authentication is stricter than common checksum verification for TCP connections.

If a great number of LDP peers are configured, run the **md5-password all** command to enable MD5 authentication in a batch for all LDP peers.

Precautions

- LDP authentication configurations are prioritized in descending order: for a single peer, for a specified peer group, for all peers. Keychain and MD5 configurations of the same priority are mutually exclusive. Keychain authentication and MD5 authentication can be configured simultaneously for a specified LDP peer, for this LDP peer in a specified peer group, and for all LDP peers. The configuration with a higher priority takes effect. For example, if MD5 authentication is configured for Peer1 and then keychain authentication is configured for all LDP peers, MD5 authentication takes effect on Peer1.
- The session is not re-established if the passwords on both ends are the same. If the interval between password settings on both ends exceeds the session Keepalive time and the passwords become different, the session is disconnected due to a timeout, causing an LSP to be deleted.
- Note that the peers of an LDP session can be configured with different authentication modes (simple text or ciphertext), but must be configured with a single password.
- After the **md5-password all** command is run, MD5 authentication takes effect on all LDP peers. If MD5 authentication fails, an LDP session fails to be established.
- MD5 encryption algorithm cannot ensure security. Keychain authentication is recommended.

Example

Enable LDP MD5 authentication for all LDP peers.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] md5-password cipher all YsHsjx_202206
```

9.1.73 md5-password peer-group

Function

The **md5-password peer-group** command enables LDP MD5 authentication in a batch for a specified LDP peer group.

The **undo md5-password peer-group** command disables LDP MD5 authentication in a batch for a specified LDP peer group.

By default, MD5 authentication in a batch is disabled for all peer groups.

Format

md5-password { **plain** | **cipher** } **peer-group** *ip-prefix-name password*

undo md5-password peer-group

Parameters

Parameter	Description	Value
plain	Indicates a simple text password. A simple text password is saved in simple text in a configuration file. This format poses risks. A ciphertext password is recommended. To improve device security, periodically modify the password.	-
cipher	Indicates a ciphertext password.	-
ip-prefix-name	Specifies the name of an IP prefix list. The IP prefix list name is configured using the **ip ip-prefix** command.	The value is a string of 1 to 169 case-sensitive characters, spaces not supported. The string can contain spaces if it is enclosed with double quotation marks (").

Parameter	Description	Value
password	Specifies an authentication password.	A password must not contain spaces. A simple text password is a string of 1 to 255 characters. A ciphertext password is a string of 1 to 255 characters. An MD5 ciphertext password is 20 bits to 392 bits long. The string can contain spaces if it is enclosed with double quotation marks (").

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MD5 authentication can be configured for a TCP connection over which an LDP session is established, improving security. LDP MD5 authentication generates a unique digest for an information segment to prevent LDP packets from being modified. LDP MD5 authentication is stricter than common checksum verification for TCP connections.

If a great number of LDP peers are configured, run the **md5-password peer-group** command to enable MD5 authentication in a batch for LDP peers in a specified peer group. An IP prefix list can be specified to define the range of IP addresses in a group.

Prerequisites

An IP prefix list has been configured using the **ip ip-prefix** command.

Precautions

- LDP authentication configurations are prioritized in descending order: for a single peer, for a specified peer group, for all peers. Keychain and MD5 configurations of the same priority are mutually exclusive. Keychain authentication and MD5 authentication can be configured simultaneously for a specified LDP peer, for this LDP peer in a specified peer group, and for all LDP peers. The configuration with a higher priority takes effect. For example, if MD5 authentication is configured for Peer1 and then keychain authentication is configured for all LDP peers, MD5 authentication takes effect on Peer1.

- The session is not re-established if the passwords on both ends are the same. If the interval between password settings on both ends exceeds the session Keepalive time and the passwords become different, the session is disconnected due to a timeout, causing an LSP to be deleted.
- Note that the peers of an LDP session can be configured with different authentication modes (simple text or ciphertext), but must be configured with a single password.
- After the **md5-password peer-group** command is run, MD5 authentication takes effect on a specified LDP peer group. If MD5 authentication fails, an LDP session fails to be established.
- MD5 encryption algorithm cannot ensure security. Keychain authentication is recommended.
- Before a peer group is referenced, create it. By default, a nonexistent peer group cannot be specified in this command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent peer group is specified in this command, a local device performs MD5 authentication for each LDP session connected to each LDP peer.

Example

Enable LDP MD5 authentication for LDP peers with IP addresses matching the IP prefix list named **list1**.

```
<HUAWEI>system-view
[HUAWEI] ip ip-prefix list1 permit 4.4.4.4 32
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] md5-password cipher peer-group list1 YsHsjx_202206
```

9.1.74 mpls (system view)

Function

The **mpls** command enables MPLS on the local node and displays the MPLS view.

The **undo mpls** command deletes all MPLS configurations.

By default, no node is enabled with MPLS.

Format

mpls

undo mpls

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run the **mpls** command on a network where MPLS services are to be deployed.

You can run MPLS-related commands only after running the **mpls** command.

Prerequisites

The LSR ID has been configured using the **mpls lsr-id** command.

Precautions

NOTICE

After the **undo mpls** command is run in the system view, MPLS services may be interrupted and all MPLS configurations in the system and interface views are deleted. To restore the MPLS services, reconfigure these commands.

Example

Enable MPLS.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
Info: Mpls starting, please wait... OK!
```

9.1.75 mpls (interface view)

Function

The **mpls** command enables MPLS on an interface.

The **undo mpls** command disables MPLS on an interface.

By default, no interface is enabled with MPLS.

Format

mpls

undo mpls

Parameters

None

Views

Interface view

NOTE

The **mpls** command does not take effect in the sub-interface view or tunnel interface view.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where MPLS services are deployed, after enabling MPLS on a node, enable MPLS on the interfaces of the node before performing other MPLS configurations.

Prerequisites

MPLS has been enabled globally using the **mpls (system view)** command.

Precautions

Running the **undo mpls** command in the interface view deletes all MPLS configurations on the interface.

Example

Enable MPLS on the interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
```

Enable MPLS on the interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
```

9.1.76 mpls bfd enable

Function

The **mpls bfd enable** command enables dynamic creation of BFD sessions on the ingress node of an LDP LSP.

The **undo mpls bfd enable** command disables the dynamic creation of BFD sessions on the ingress node of an LDP LSP.

By default, an ingress cannot dynamically create BFD sessions for monitoring LDP LSPs.

Format

mpls bfd enable

undo mpls bfd enable

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an MPLS network, use LDP to dynamically create LSP tunnels. Upon a fault on the link, the convergence is slow. Configure BFD to detect LDP LSP connectivity to speed up convergence.

To dynamically establish a BFD session, run the **mpls bfd enable** command on the source end of the LDP LSP.

NOTE

After the **mpls bfd enable** command is used, no BFD session is set up.

Prerequisites

BFD has been enabled globally using the **bfd** command.

Example

Enable the dynamic creation of BFD sessions on the ingress node of an LDP LSP.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bfd enable
```

9.1.77 mpls bfd

Function

The **mpls bfd** command sets the parameters of BFD sessions.

The **undo mpls bfd** command deletes the parameters of BFD sessions.

By default, no parameter of BFD sessions is set.

Format

mpls bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

undo mpls bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

undo mpls bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

Parameters

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-rx-interval *rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection multiplier value of a BFD session.	An integer ranging from 3 to 50. The value is 3 by default.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

On an MPLS network, use BFD to detect LSP connectivity to increase the link fault detection speed. Users can change the values of BFD parameters based on actual networking. On an unstable link, if the BFD parameters are set small, the BFD session may flap. You can increase the values of BFD parameters.

Actual interval for the local device to send BFD packets = max { interval for sending BFD packets on the local end, interval for receiving BFD packets on the peer end }; actual interval for the local device to receive BFD packets = max { interval for sending BFD packets on the peer end, interval for receiving BFD packets on the local end }; and local BFD detection time = actual interval for receiving BFD packets on the local end x BFD detection multiplier on the peer end.

If no BFD packet is received from the peer device within the detection time, the link is considered as faulty and the BFD session enters the Down state. To reduce the usage of system resources, when the BFD session is detected in Down state, the system adjusts the sending interval to a random value greater than 1000 ms. When the BFD session becomes Up, the configured interval is restored.

Example

Set the interval at which BFD packets are sent to 200 ms.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bfd min-tx-interval 200
```

9.1.78 mpls bfd-trigger

Function

The **mpls bfd-trigger** command configures a trigger policy for an LDP BFD session.

The **undo mpls bfd-trigger** command deletes a trigger policy for an LDP BFD session.

By default, no trigger policy for an LDP BFD session is configured.

Format

mpls bfd-trigger [**host** [**nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number*] * | **fec-list** *list-name*]

undo mpls bfd-trigger [**host** [**nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number*] * | **fec-list** *list-name*]

Parameters

Parameter	Description	Value
host	Indicates that all host addresses are used to create LDP BFD sessions.	-
nexthop *next-hop-address*	Specifies the next hop address on an LSP.	The value is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Specifies the type and number of an outbound interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
fec-list *list-name*	Specifies the name of a FEC list, by which the creation of an LDP BFD session is triggered.	The value is an existing FEC list name.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The trigger policy for LDP BFD has two types: the host address and FEC list.

If you want all host addresses to trigger the establishment of BFD sessions, use the host trigger mode. Specify the LSPs that can set up BFD sessions by specifying the next hop address and the outbound interface.

If you only want part of hosts to trigger the establishment of BFD sessions, use the FEC list trigger mode to specify the corresponding host addresses. Before specifying the FEC list triggering mode, run the **fec-list** and **fec-node** commands to configure a FEC list.

Prerequisites

BFD has been enabled globally using the **bfd** command.

Example

Configure the host trigger policy of BFD sessions in the MPLS view.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bfd enable
[HUAWEI-mpls] mpls bfd-trigger host
```

9.1.79 mpls bfd-ldp-number threshold-alarm

Function

The **mpls bfd-ldp-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for dynamic BFD sessions for LDP. The conditions include the upper and lower alarm thresholds (percent) for the proportion of established dynamic BFD sessions for LDP to all supported ones.

The **undo mpls bfd-ldp-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls bfd-ldp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls bfd-ldp-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold for the proportion of established dynamic BFD sessions for LDP to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Sets the lower alarm threshold for the proportion of established dynamic BFD sessions for LDP to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of dynamic BFD sessions for LDP reaches a specified upper limit, new dynamic BFD sessions for LDP cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of established dynamic BFD sessions for LDP to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls bfd-ldp-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of established dynamic BFD sessions for LDP to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of established dynamic BFD sessions for LDP to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls bfd-ldp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls bfd-ldp-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for dynamic BFD sessions for LDP.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bfd-ldp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.80 mpls bgp bfd

Function

The **mpls bgp bfd** command sets time parameters for BGP BFD sessions.

The **undo mpls bgp bfd** command restores default time parameters for BGP BFD sessions.

By default, the minimum interval for sending BFD packets is 1000 ms, the minimum interval for receiving BFD packets is 1000 ms, and the local detection multiplier is 3.

Format

mpls bgp bfd { **min-tx-interval** *interval* | **min-rx-interval** *interval* | **detect-multiplier** *multiplier* } *

undo mpls bgp bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo mpls bgp bfd { **min-tx-interval** *interval* | **min-rx-interval** *interval* | **detect-multiplier** *multiplier* } *

Parameters

Parameter	Description	Value
min-tx-interval *interval*	Specifies the minimum interval at which BGP BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-rx-interval *interval*	Specifies the minimum interval at which BGP BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local BGP BFD detection multiplier.	The value is an integer ranging from 3 to 50. The default value is 3.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

A BGP BFD session working in asynchronous mode monitor BGP label switched paths (LSPs) over BGP tunnels. The ingress and egress of E2E BGP LSPs exchange BFD packets periodically. If a node receives no BFD packet after the detection period elapses, the node considers the BGP LSP faulty.

Effective BFD time parameters are calculated using the following formulas:

- Effective local interval at which BFD packets are sent = MAX { Locally configured minimum interval at which BFD packets are sent, Remotely configured minimum interval at which BFD packets are received }
- Effective local interval at which BFD packets are received = MAX { Remotely configured minimum interval at which BFD packets are sent, Locally configured minimum interval at which BFD packets are received }
- Local BFD detection period = Effective local interval at which BFD packets are received x Remotely configured BFD detection multiplier

Example

Set the minimum interval at which BGP BFD packets are sent to **200** ms.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls bgp bfd min-tx-interval 200
```

9.1.81 mpls bgp bfd enable

Function

The **mpls bgp bfd enable** command enables the MPLS ability to dynamically create BGP BFD sessions.

The **undo mpls bgp bfd enable** command disables the MPLS ability to dynamically create BGP BFD sessions.

By default, the MPLS ability to dynamically create BGP BFD sessions is disabled.

Format

mpls bgp bfd enable

undo mpls bgp bfd enable

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD for BGP tunnel rapidly detects faults in E2E BGP tunnels. Before a BGP BFD session is established, run the **mpls bgp bfd enable** command on the ingress of a BGP tunnel to enable the MPLS ability to dynamically create a BGP BFD session.

Prerequisites

BFD has been globally enabled using the **bfd** command.

Follow-up Procedure

Run the **mpls bgp bfd-trigger-tunnel** command to establish a BGP BFD session.

Example

Enable the MPLS ability to dynamically create a BGP BFD session on the ingress of a BGP tunnel.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls bgp bfd enable
```

9.1.82 mpls bgp bfd-trigger-tunnel

Function

The **mpls bgp bfd-trigger-tunnel** command specifies a policy to establish BGP BFD sessions.

The **undo mpls bgp bfd-trigger-tunnel** command deletes a policy to establish BGP BFD sessions.

By default, no trigger policy is configured.

Format

mpls bgp bfd-trigger-tunnel { **host** | **ip-prefix** *ip-prefix-name* }

undo mpls bgp bfd-trigger-tunnel

Parameters

Parameter	Description	Value
host	Allows a device to use host addresses to establish BGP BFD sessions.	-

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Allows a device to use an IP address prefix list with a specified name to establish BGP BFD sessions.	The value is an existing IP address prefix list.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

BFD for BGP tunnel rapidly detects faults in E2E BGP tunnels. Before a BGP BFD session is established, the **mpls bgp bfd enable** command must be run to enable the MPLS ability to dynamically establish BGP BFD sessions on the ingress of a BGP tunnel. Then to specify the policy for dynamically establish BGP BFD sessions, run the **mpls bgp bfd-trigger-tunnel** command.

Either of the following trigger policies can be used:

- Host address-based policy: used when all host addresses are available to trigger the creation of BGP BFD sessions.
- IP address prefix list-based policy: used when only some host addresses can be used to establish BFD sessions.

Prerequisites

BFD has been globally enabled using the **bfd** command.

Precautions

If the **mpls bgp bfd-trigger-tunnel** command is run more than once, the latest configuration overrides the previous one.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all host addresses trigger BGP BFD session establishment.

Example

Allow a device to use host addresses to dynamically establish BGP BFD sessions.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] quit
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls bgp bfd enable
[HUAWEI-mpls] mpls bgp bfd-trigger-tunnel host
```

9.1.83 mpls bgp-lsp-number threshold-alarm

Function

The **mpls bgp-lsp-number threshold-alarm** command configures the alarm threshold for BGP LSP usage.

The **undo mpls bgp-lsp-number threshold-alarm** command restores the default settings.

The default upper limit of the alarm threshold for BGP LSP usage is 80%. The default lower limit of the clear alarm threshold for BGP LSP usage is 75%.

Format

mpls bgp-lsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls bgp-lsp-number { **ingress** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls bgp-lsp-number threshold-alarm

undo mpls bgp-lsp-number { **ingress** | **egress** } **threshold-alarm**

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for BGP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for BGP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.
ingress	Specifies the alarm threshold for ingress BGP LSPs.	-
egress	Specifies the alarm threshold for egress BGP LSPs.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of BGP LSPs in the system reaches a specific limit, establishing additional BGP LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of BGP LSPs reaches the specific limit. To configure the alarm threshold for BGP LSP usage, run the **mpls bgp-lsp-number threshold-alarm** command. The parameters in this command are described as follows:

- *upper-limit-value*: upper alarm threshold. If the proportion of BGP LSP usage to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of BGP LSP usage to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

If you want to set the alarm threshold for ingress BGP LSPs or egress BGP LSPs, run **mpls bgp-lsp-number** { **ingress** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls bgp-lsp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- This command configures the alarm threshold for BGP LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceed** is configured, and the actual BGP LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual BGP LSP usage falls below the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for BGP LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bgp-lsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.84 mpls bgpv6-lsp-number threshold-alarm

Function

The **mpls bgpv6-lsp-number threshold-alarm** command configures the alarm threshold for BGP IPv6 LSP usage.

The **undo mpls bgpv6-lsp-number threshold-alarm** command restores the default settings.

The default upper limit of the alarm threshold for BGP IPv6 LSP usage is 80%. The default lower limit of the clear alarm threshold for BGP IPv6 LSP usage is 75%.

Format

mpls bgpv6-lsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls bgpv6-lsp-number egress threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls bgpv6-lsp-number threshold-alarm

undo mpls bgpv6-lsp-number egress threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for BGP IPv6 LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for BGP IPv6 LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.
egress	Specifies the alarm threshold for egress BGP IPv6 LSPs.	-

Usage Guidelines

Usage Scenario

If the number of BGP IPv6 LSPs in the system reaches a specific limit, establishing additional BGP IPv6 LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of BGP IPv6 LSPs reaches the specific limit. To configure the alarm threshold for BGP IPv6 LSP usage, run the **mpls bgpv6-lsp-number threshold-alarm** command. The parameters in this command are described as follows:

- *upper-limit-value*: upper alarm threshold. If the proportion of BGP IPv6 LSP usage to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of BGP IPv6 LSP usage to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

If you want to set the alarm threshold for egress BGP IPv6 LSPs, run **mpls bgpv6-lsp-number egress threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls bgpv6-lsp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- This command configures the alarm threshold for BGP IPv6 LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceed** is configured, and the actual BGP IPv6 LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual BGP IPv6 LSP usage falls below the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for BGP IPv6 LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bgpv6-lsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.85 mpls dynamic-label-number threshold-alarm

Function

The **mpls dynamic-label-number threshold-alarm** command sets alarm thresholds of dynamic label usage.

The **undo mpls dynamic-label-number threshold-alarm** command restores the default settings.

By default, the upper limit is 80%, and the lower limit is 70%.

Format

mpls dynamic-label-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls dynamic-label-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of dynamic label usage.	The value is a percent integer ranging from 1 to 100. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of dynamic label usage.	The value is a percent integer ranging from 1 to 100. The lower limit must be less than the upper limit. Using the default value 70 is recommended.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If dynamic labels run out but the system receives new dynamic label requests, the system fails to satisfy the requests because the dynamic labels are insufficient. As a result, the module that fails to be assigned labels works abnormally. The modules that apply for labels including MPLS TE, MPLS LDP, BGP, L3VPN and L2VPN. To facilitate operation and maintenance, run **mpls dynamic-label-number threshold-alarm** command to set alarm thresholds of dynamic label usage. The system can alert users to the issue that dynamic labels will exhaust.

This command enables the system to generate an alarm in either of the following situations:

- *upper-limit-value*: a percent indicating the upper limit of dynamic labels. If dynamic label usage reaches the upper limit, an alarm is generated.
- *lower-limit-value*: a percent indicating the lower limit of dynamic labels. If dynamic label usage falls below the lower limit, a clear alarm can be generated.

Precautions

If the **mpls dynamic-label-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.

The **mpls dynamic-label-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsdynamiclabelthresholdexceed** | **hwmplsdynamiclabelthresholdexceedclear** } command is run to enable the device to generate a dynamic label insufficiency alarm and its clear alarm.

Example

Set the thresholds for triggering dynamic label alarms.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls dynamic-label-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.86 mpls ecmp load-balance

Function

The **mpls ecmp load-balance** command configures the load balancing mode when packets are forwarded through LSPs established by MPLS LDP.

The **undo mpls ecmp load-balance** command restores the default load balancing mode when packets are forwarded through LSPs established by MPLS LDP.

By default, the load balancing mode is **label** when packets are forwarded through LSPs established by MPLS LDP.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

mpls ecmp load-balance { **sip** | **dip** | **label** | **l4-sport** | **l4-dport** } *

undo mpls ecmp load-balance

Parameters

Parameter	Description	Value
sip	Indicates that load balancing is performed based on source IP addresses in MPLS packets.	-
dip	Indicates that load balancing is performed based on destination IP addresses in MPLS packets.	-
label	Indicates that load balancing is performed based on labels in MPLS packets.	-
l4-sport	Indicates that load balancing is performed based on the transport-layer source port in MPLS packets.	-
l4-dport	Indicates that load balancing is performed based on the transport-layer destination port in MPLS packets.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In real-world scenarios, you need to configure a proper load balancing mode based on MPLS service traffic characteristics on a transit node. If a service traffic parameter changes frequently, it is easier to load balance the traffic if you use the load balancing mode based on this parameter. For example, if the IP addresses of MPLS packets change frequently, it is easier to load balance traffic among LSPs if you use the load balancing mode based on **dip** or **sip**.

Precautions

This command takes effect only on newly established LSPs. If you want this command to take effect on previously created LSPs, run the **reset mpls ldp** command to re-establish the LSPs.

Example

Set the load balancing mode to **sip** when packets are forwarded through LSPs established by MPLS LDP.

```
<HUAWEI> system-view
[HUAWEI] mpls ecmp load-balance sip
```

9.1.87 mpls forward-resource threshold-alarm

Function

The **mpls forward-resource threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for MPLS forwarding resources.

The **undo mpls forward-resource threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 85%, and the lower alarm threshold is 75%.

Format

mpls forward-resource threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls forward-resource threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold.	The value is an integer ranging from 2 to 100, represented in percentage.
lower-limit *lower-limit-value*	Sets the lower alarm threshold.	The value is an integer ranging from 1 to (*upper-limit-value*-1), represented in percentage.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of MPLS forwarding resources reaches a specified upper limit, new MPLS forwarding entries cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of MPLS forwarding resources reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls forward-resource threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of MPLS forwarding resources reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of MPLS forwarding resources falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls forward-resource threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls forward-resource threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls trap-name** { **hwboardmplsfwdreslack** | **hwboardmplsfwdreslackresume** } command is run to enable the device to generate MPLS forwarding resources insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for MPLS forwarding resources.

```
<HUAWEI> system-view
[HUAWEI] mpls forward-resource threshold-alarm upper-limit 90 lower-limit 60
```

9.1.88 mpls remote-adjacency-number threshold-alarm

Function

The **mpls remote-adjacency-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for remote LDP adjacencies.

The **undo mpls remote-adjacency-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls remote-adjacency-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls remote-adjacency-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold for the proportion of established remote LDP adjacencies to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Sets the lower alarm threshold for the proportion of established remote LDP adjacencies to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Usage Guidelines

Usage Scenario

If the number of remote LDP adjacencies reaches a specified upper limit, new remote LDP adjacencies cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of established remote LDP adjacencies to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls remote-adjacency-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of established remote LDP adjacencies to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of established remote LDP adjacencies to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls remote-adjacency-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls remote-adjacency-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for remote LDP adjacencies.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls remote-adjacency-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.89 mpls ldp advertisement

Function

The **mpls ldp advertisement** command configures the label advertisement mode.

The **undo mpls ldp advertisement** command restores the default setting.

By default, the label advertisement mode is downstream unsolicited (DU).

Format

mpls ldp advertisement { **dod** | **du** }

undo mpls ldp advertisement

Parameters

Parameter	Description	Value
dod	Indicates the downstream on demand (DoD) mode. After the upstream requests the downstream for a label, the downstream sends a Label Mapping message to the upstream.	-
du	Indicates the DU mode. Without a request, the downstream voluntarily sends a Label Mapping message to the upstream.	-

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, downstream LSRs unsolicitedly send Label Mapping messages to upstream LSRs. Establishing a large number of LSPs burdens an LSR such as a DSLAM (a low-performance access device) deployed on an MPLS network. On a large network, run the **mpls ldp advertisement dod** command. This setting allows a DSLAM to send Label Mapping messages to upstream LSRs only after receiving requests for labels. This setting helps minimize the number of unwanted MPLS forwarding entries forwarded by the DSLAM.

Prerequisites

MPLS LDP has been enabled on the interface using the **mpls ldp (interface view)** command.

Precautions

- When multiple links exist between neighbors, all interfaces must use the same label advertisement mode.
- Modifying the label advertisement mode causes reestablishment of LDP sessions.

Example

Set the label advertisement mode to DoD.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp advertisement dod
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

Set the label advertisement mode to DoD.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp advertisement dod
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.90 mpls ldp (system view)

Function

The **mpls ldp** command enables LDP on the local node and displays the MPLS-LDP view.

The **undo mpls ldp** command deletes all LDP configurations.

By default, LDP is not enabled on a node.

Format

mpls ldp

undo mpls ldp

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where MPLS LDP needs to be deployed, run the **mpls ldp** command to enable MPLS LDP globally and create a public network instance running LDP.

Prerequisites

MPLS has been enabled globally using the **mpls (system view)** command.

Follow-up Procedure

You can perform other LDP configurations.

Precautions

NOTICE

After the **undo mpls ldp** command is run in the system view, MPLS LDP services may be interrupted and all MPLS LDP configurations in the system and interface views are deleted. To restore the MPLS LDP services, reconfigure these commands.

Example

Enable LDP.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] quit
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp]
```

9.1.91 mpls ldp (interface view)

Function

The **mpls ldp** command enables MPLS LDP function on an interface.

The **undo mpls ldp** command disables MPLS LDP function on an interface.

By default, no interface is enabled with MPLS LDP function.

Format

mpls ldp

undo mpls ldp

Parameters

None

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a network where MPLS LDP needs to be deployed, enable MPLS LDP function on an interface before configuring other LDP configurations.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

MPLS has been enabled on the interface using the **mpls** command in the interface view.

Follow-up Procedure

You can perform other MPLS LDP configurations.

Precautions

Running the **undo mpls ldp** command in the interface view deletes all MPLS LDP configurations on the interface.

Example

Enable MPLS LDP function on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls ldp
```

Enable MPLS LDP function on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
```

9.1.92 mpls ldp frr nexthop

Function

The **mpls ldp frr nexthop** command enables LDP FRR on an interface.

The **undo mpls ldp frr** command disables LDP FRR on an interface.

By default, no interface is enabled with LDP FRR.

Format

mpls ldp frr nexthop *nexthop-address* [**ip-prefix** *ip-prefix-name*] [**priority** *priority*]

undo mpls ldp frr [**nexthop** *nexthop-address*] [**ip-prefix** *ip-prefix-name*] [**priority** *priority*]

Parameters

Parameter	Description	Value
nexthop-address	Specifies the next hop address on a backup LSP.	The value is in dotted decimal notation.

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the IP prefix name. Only the FEC that matches the specified IP prefix can trigger the generation of a backup LSP.	The value is an existing IP prefix name.
priority *priority*	Specifies the priority of a backup LSP. The greater the value is, the lower priority the backup LSP has.	The value is an integer ranging from 1 to 65535. By default, the value is 50.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The traditional IP FRR technology cannot effectively protect the traffic on an MPLS network. The device provides the LDP FRR function and the solution to port protection.

In the manual LDP FRR mode, you need to configure a backup LSP by specifying the outbound interfaces or the next hops. This mode applies to simple-structured networks.

When running the **mpls ldp frr nexthop** command to configure the next hop IP address, note that:

- You can configure multiple next hops on one interface. This allows you to configure multiple backup LSPs with different outbound interfaces for the primary LSP.
- You can configure different prefix lists for the same next hop on one interface.
  - If no prefix list is specified, LDP FRR tries to establish backup LSPs along the path specified by *nexthop-address* for all primary LSPs on the interface.
  - If only the DENY item is in a specified prefix list, no backup LSP is allowed to set up along the path specified by *nexthop-address* for the primary LSP mapping to the FEC denied by the interface.
  - If only PERMIT item is in the specified prefix list, backup LSPs are allowed to set up along the path specified by *nexthop-address* only for the primary LSPs mapping to the FEC permitted by the interface.
  - If both PERMIT and DENY items are in the prefix list, only the PERMIT item is effective. That is, backup LSPs are allowed to set up along the

path specified by *nexthop-address* only for the primary LSPs mapping to the FEC permitted by the interface.

- A single interface supports LDP FRR with a maximum of 10 priorities. Only a single backup LSP is generated.

Prerequisites

MPLS has been enabled in the interface view using the **mpls** command.

Precautions

- If the **undo mpls ldp** command is run in the system view or the **undo mpls ldp** command is run in the interface view to disable LDP functions, the LDP FRR configuration in the interface remains but does not take effect. During the LDP FRR configuration, the LSP that functions as the backup LSP must be in the liberal state. For a backup LSP, the routing status of the backup LSP from the ingress node to the egress node must be Inactive Adv.
- LDP FRR cannot be enabled or disabled during LDP GR.
- When both LDP FRR and IP FRR are enabled, IP FRR takes effect.
- Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, backup LSPs are established for all LDP LSPs on the local interface along the path to the specified next-hop IP address.

Example

Enable LDP FRR on VLANIF100, and set the next hop IP address of the backup LSP to 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls ldp frr nexthop 10.1.1.2
```

Enable LDP FRR on GE0/0/1, and set the next hop IP address of the backup LSP to 10.1.1.2.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls ldp frr nexthop 10.1.1.2
```

9.1.93 mpls ldp remote-peer

Function

The **mpls ldp remote-peer** command creates a remote peer and displays the remote peer view.

The **undo mpls ldp remote-peer** command deletes a remote peer.

By default, no remote peer is created.

Format

mpls ldp remote-peer *remote-peer-name*

undo mpls ldp remote-peer *remote-peer-name*

Parameters

Parameter	Description	Value
remote-peer-name	Specifies the name of a remote LDP peer.	A string of 1 to 32 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A remote LDP session applies to the following scenarios:

- Allocate inner L2VPN labels.

  If a Martini VLL or VPLS connection is to be established between two LSRs, the remote LDP session must be established between the LSRs to allocate inner labels.

- Configure LDP over TE.

  If the core devices on an MPLS network support TE while edge devices use LDP, you need to configure a remote LDP session between the two edge LSRs on the TE network. After LDP over TE is configured, the TE tunnel is regarded as a hop of the entire LDP LSP.

A remote LDP session can be established between two indirectly connected LSRs or two directly connected LSRs.

A local and a remote LDP session can be established together between two LSRs.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp (system view)** command.

Follow-up Procedure

An IP address can be assigned to the LDP remote peer.

Precautions

When configuring a remote LDP peer, run the **mpls ldp remote-peer** command on the local LDP and remote LDP peers.

Example

Create a remote peer.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] quit
[HUAWEI] mpls ldp remote-peer BJI
[HUAWEI-mpls-ldp-remote-bji]
```

9.1.94 mpls ldp timer hello-hold

Function

The **mpls ldp timer hello-hold** command sets the value of a Hello Hold timer.

The **undo mpls ldp timer hello-hold** command restores the default value.

By default, the link Hello Hold timer is 15 seconds and the target Hello Hold timer is 45 seconds.

Format

mpls ldp timer hello-hold *interval*

undo mpls ldp timer hello-hold

Parameters

Parameter	Description	Value
interval	Specifies the value of a Hello Hold timer.	The value is an integer ranging from 3 to 65535, in seconds. Value 65535 indicates that the timer never expires.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Two LDP peers periodically exchange Hello messages to maintain the Hello adjacency. If no Hello message is received after the target Hello hold timer expires, the Hello adjacency is deleted.

The default value of the timer is recommended. On a network where the link status is unstable or a large number of packets are sent, increase the value of the timer to prevent the session flapping.

Hello hold timers are classified into the following types:

- Link-Hello hold timer: maintains the local adjacency. The **mpls ldp timer hello-hold** command in the interface view sets a value of the timer.
- Target-Hello hold timer: maintains the remote adjacency. The **mpls ldp timer hello-hold** command in the remote MPLS LDP peer view sets a value of the timer.

Prerequisites

The remote LDP peer has been configured or MPLS LDP has been enabled on the interface.

Precautions

The value of the timer that actually takes effect is the smaller one between the two Hello holder timers configured on both ends of an LDP session. If the value is smaller than 9, the Hello hold timer is 9.

Example

Set the value of the link Hello hold timer to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp timer hello-hold 30
```

Set the value of the link Hello hold timer to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp timer hello-hold 30
```

Set the value of the target Hello hold timer to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer bji
[HUAWEI-mpls-ldp-remote-bji] mpls ldp timer hello-hold 60
```

9.1.95 mpls ldp timer hello-send

Function

The **mpls ldp timer hello-send** command sets the value of a Hello send timer.

The **undo mpls ldp timer hello-send** command restores the default setting.

By default, the value of a Hello send timer is one third the value of a Hello hold timer.

Format

mpls ldp timer hello-send *interval*

undo mpls ldp timer hello-send

Parameters

Parameter	Description	Value
interval	Specifies the value of a Hello send timer.	The value is an integer ranging from 1 to 65535, in seconds.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An LSR sends Hello messages to the neighboring LSR to advertise its presence on the network and sets up the Hello adjacency. The Hello messages are sent at an interval specified by the Hello send timer.

The default value of the Hello send timer is recommended. On a network with poor performance, you can reduce the value of the Hello send timer, enabling the network to recover from faults as soon as possible.

Hello send timers are classified into the following types:

- Link-Hello send timer: maintains the local adjacency. The **mpls ldp timer hello-send** command in the interface view sets a value of the timer.
- Target-Hello send timer: maintains the remote adjacency. The **mpls ldp timer hello-send** command in the remote MPLS LDP peer view sets a value of the timer.

Prerequisites

The remote LDP peer has been configured or MPLS LDP has been enabled on the interface.

Precautions

The value of the Hello send timer that takes effect is not necessarily the same as the set value. If the value of the Hello send timer is greater than one third of the value of the Hello hold timer, the value of the Hello send timer that takes effect is equal to one third of the value of the link-Hello hold timer. Run the **mpls ldp timer hello-hold** command to set the value for the Hello hold timer.

Example

Set the value of the link Hello send timer to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp timer hello-send 10
```

Set the value of the link Hello send timer to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp timer hello-send 10
```

Set the value of the target Hello send timer to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer bji
[HUAWEI-mpls-ldp-remote-bji] mpls ldp timer hello-send 20
```

9.1.96 mpls ldp timer igp-sync-delay

Function

The **mpls ldp timer igp-sync-delay** command sets the interval during which an LSP is being set up after an LDP session is created.

The **undo mpls ldp timer igp-sync-delay** command restores the default setting.

By default, the interval is 10 seconds.

Format

mpls ldp timer igp-sync-delay *value*

undo mpls ldp timer igp-sync-delay

Parameters

Parameter	Description	Value
value	Specifies the interval, during which an LSP is being set up after an LDP session is created.	The value is an integer ranging from 0 to 65535, in seconds.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

LDP-Interior Gateway Protocol (IGP) synchronization-enabled devices complete to establish an LDP session earlier than an LSP. The **mpls ldp timer igp-sync-delay** command can be used to switch traffic to the established LSP after a specified period of time. This setting prevents traffic loss that occurs if the LDP session in the Up state attempts to switch traffic to the LSP that has not been established. Using the default delay value is recommended.

Example

After the LDP session is established on VLANIF100, the interval is set to 15 seconds, during which the LSP is being set up.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp timer igp-sync-delay 15
```

After the LDP session is established on GE0/0/1, the interval is set to 15 seconds, during which the LSP is being set up.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1]  mpls ldp
[HUAWEI-GigabitEthernet0/0/1]  mpls ldp timer igp-sync-delay 15
```

After the LDP session is established in the remote MPLS LDP peer view, the interval is set to 15 seconds, during which the LSP is being set up.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer rta
[HUAWEI-mpls-ldp-remote-rta] mpls ldp timer igp-sync-delay 15
```

9.1.97 mpls ldp timer keepalive-hold

Function

The **mpls ldp timer keepalive-hold** command sets the value of a Keepalive hold timer.

The **undo mpls ldp timer keepalive-hold** command restores the default setting.

By default, the value of the Keepalive-hold timers of both local and remote sessions is 45 seconds.

Format

mpls ldp timer keepalive-hold *interval*

undo mpls ldp timer keepalive-hold

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of a Keepalive hold timer.	The value is an integer ranging from 30 to 65535, in seconds.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

LDP peers exchange LDP PDUs over session connections to maintain LDP sessions. If a node does not receive any LDP PDU after the Keepalive hold timer expires, the node closes the connection to terminate the session.

The default value of the Keepalive hold timer is recommended. On a network with unstable links, increase the value of a Keepalive hold timer, preventing the session flapping.

Keepalive hold timers are classified into the following types:

- Keepalive hold timer of the local session: maintains the local LDP session. The **mpls ldp timer keepalive-hold** command in the interface view sets a value of the timer.
- Keepalive hold timer of the remote session: maintains the remote LDP session. The **mpls ldp timer keepalive-hold** command in the remote MPLS LDP peer view sets a value of the timer.

Prerequisites

The remote LDP peer has been configured or MPLS LDP has been enabled on the interface.

Precautions

- The value of the Keepalive hold timer that takes effect is the smaller one between the two Keepalive hold timers configured on both ends of an LDP session.
- If more than one LDP link exists between two LSRs, the values of the Keepalive hold timers set for the links must be the same; otherwise, the LDP sessions may be unstable.
- Changing the value of a Keepalive hold timer causes the reestablishment of related LDP sessions.

Example

Set the value of the Keepalive hold timer for a local session to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp timer keepalive-hold 60
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

Set the value of the Keepalive hold timer for a local session to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp timer keepalive-hold 60
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

Set the value of the Keepalive hold timer for a remote session to 50 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer bji
[HUAWEI-mpls-ldp-remote-bji] mpls ldp timer keepalive-hold 50
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.98 mpls ldp timer keepalive-send

Function

The **mpls ldp timer keepalive-send** command sets the value of a Keepalive send timer.

The **undo mpls ldp timer keepalive-send** command restores the default setting.

By default, the value of a Keepalive send timer is one third the value of a Keepalive hold timer.

Format

mpls ldp timer keepalive-send *interval*

undo mpls ldp timer keepalive-send

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of a Keepalive send timer.	The value is an integer ranging from 1 to 65535, in seconds.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After an LDP session is set up, LSRs on the two ends of the session periodically exchange Keepalive messages to maintain the LDP session.

The default value of the Keepalive send timer is recommended. On a network with poor performance, reduce the value of the Keepalive send timer, enabling the network to recover as soon as possible.

Keepalive send timers are classified into the following types:

- Keepalive send timer of the local LDP session: controls the interval at which Keepalive messages are sent to the peer end of the local session. The **mpls ldp timer keepalive-send** command in the interface view sets a value of this timer.
- Keepalive send timer of the remote LDP session: controls the interval at which Keepalive messages are sent to the peer end of the remote session. The **mpls**

ldp timer keepalive-send command in the remote MPLS LDP peer view sets a value of the timer.

Prerequisites

The remote LDP peer has been configured or MPLS LDP has been enabled on the interface.

Precautions

The value of the Keepalive send timer that actually takes effect may be different from the configured one. If the value of the Keepalive send timer is greater than one third of the value of the Keepalive hold timer, the value of the Keepalive send timer that actually takes effect is equal to one third of the value of the Keepalive hold timer.

Example

Set the value of the Keepalive send timer for setting up a local LDP session to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp timer keepalive-send 10
```

Set the value of the Keepalive send timer for setting up a local LDP session to 10 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp timer keepalive-send 10
```

Set the value of the Keepalive send timer for setting up a remote LDP session to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer bji
[HUAWEI-mpls-ldp-remote-bji] mpls ldp timer keepalive-send 20
```

9.1.99 mpls ldp transport-address

Function

The **mpls ldp transport-address** command configures an LDP transport address.

The **undo mpls ldp transport-address** command restores the default setting.

By default, the transport address for a node on a public network is the LSR ID of the node, and the transport address for a node on a private network is the primary IP address of an interface on the node.

Format

mpls ldp transport-address { *interface-type interface-number* | **interface** }

undo mpls ldp transport-address

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of an interface. LDP uses the address of the interface as the TCP transport address.	-
interface	Indicates that LDP uses the IP address of the current interface as the TCP transport address.	-

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before two LSRs establish an LDP session, the two LSRs need to establish a TCP connection to exchange label messages. Run the **mpls ldp transport-address** command to set the address (the LDP transport address) for the TCP connection.

The transport address is used to establish a TCP connection between the local node and its peer. The peer must have a reachable route to this transport address. The default transport address is the loopback interface address (an LSR ID). When the address of the loopback interface is a public network address, configure different transport addresses for LSRs so that LSRs can set up connections with private network addresses.

You can run the **mpls ldp transport-address** command in the interface view to set the transport address for a TCP connection. When more than one link exists between two LSRs, and the links are bound to VPN instances, the default transport address is the IP address of an interface rather than the LSR ID of an LSR.

NOTE

- If LDP sessions are to be established over multiple links connecting two LSRs, LDP-enabled interfaces of either LSR must use the default transport address or the same transport address. If interfaces on either of the LSRs are assigned different transport addresses, a single transport address can be used and a single LDP session can be established.
- When the LDP transport address changes, the session is not interrupted immediately. The session is interrupted after the Hello hold timer times out.

Prerequisites

MPLS LDP has been enabled on the interface using the **mpls ldp (interface view)** command.

An IP address must be assigned to the specified interface. If no IP address is assigned, 0.0.0.0 is used as a transport address, causing a failure to establish an LDP session.

Precautions

Changing an LDP transport address interrupts an LDP session. Exercise caution when running the **mpls ldp transport-address** command.

Example

Set the transport address for link Hello messages to the current interface address.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls ldp
[HUAWEI-Vlanif100] mpls ldp transport-address interface
```

Set the transport address for link Hello messages to the current interface address.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls ldp
[HUAWEI-GigabitEthernet0/0/1] mpls ldp transport-address interface
```

9.1.100 mpls ldp-lsp-number threshold-alarm

Function

The **mpls ldp-lsp-number threshold-alarm** command configures the alarm threshold for LDP LSP usage.

The **undo mpls ldp-lsp-number threshold-alarm** command restores the default settings.

By default, the upper limit of the alarm threshold for LDP LSP usage is 80%, the lower limit of the clear alarm threshold for LDP LSP usage is 75%.

Format

mpls ldp-lsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls ldp-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls ldp-lsp-number threshold-alarm

undo mpls ldp-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm**

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for LDP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for LDP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.
ingress	Specifies the alarm threshold for ingress LDP LSPs.	-
transit	Specifies the alarm threshold for transit LDP LSPs.	-
egress	Specifies the alarm threshold for egress LDP LSPs.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of LDP LSPs in the system reaches a specific limit, establishing additional LDP LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of LDP LSPs reaches the specific limit. To configure the alarm threshold for LDP LSP usage, run the **mpls ldp-lsp-number threshold-alarm** command. The parameters in this command are described as follows:

- *upper-limit-value*: upper alarm threshold. If the proportion of LDP LSP usage to all supported ones reaches the upper alarm threshold, an alarm can be generated.

- *lower-limit-value*: lower alarm threshold. If the proportion of LDP LSP usage to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

If you want to set the alarm threshold for ingress LDP LSPs, transit LDP LSPs or egress LDP LSPs, run **mpls ldp-lsp-number** { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls ldp-lsp-number threshold-alarm** command is run several times, the latest configuration overrides the previous one.
- This command configures the alarm threshold for LDP LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceed** is configured, and the actual LDP LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual LDP LSP usage fells to the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for LDP LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls ldp-lsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.101 mpls local-adjacency-number threshold-alarm

Function

The **mpls local-adjacency-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for local LDP adjacencies. The conditions include the upper and lower alarm thresholds (percent) for the proportion of established local LDP adjacencies to all supported ones.

The **undo mpls local-adjacency-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls local-adjacency-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls local-adjacency-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold for the proportion of established local LDP adjacencies to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Sets the lower alarm threshold for the proportion of established local LDP adjacencies to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of local LDP adjacencies reaches a specified upper limit, new local LDP adjacencies cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of established local LDP adjacencies to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls local-adjacency-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of established local LDP adjacencies to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of established local LDP adjacencies to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls local-adjacency-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls local-adjacency-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for local LDP adjacencies.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls local-adjacency-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.102 mpls lsr-id

Function

The **mpls lsr-id** command sets an LSR ID.

The **undo mpls lsr-id** command deletes an LSR ID.

By default, no LSR ID is set.

Format

mpls lsr-id *lsr-id*

undo mpls lsr-id

Parameters

Parameter	Description	Value
lsr-id	Specifies the LSR ID of a device, which identifies the LSR.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An LSR ID identifies an LSR on a network. On a network where MPLS services are deployed, you must configure the LSR IDs for devices.

An LSR does not have the default LSR ID, and you must configure an LSR ID for it. To enhance network reliability, you are advised to use the IP address of a loopback interface on the LSR as the LSR ID.

Follow-up Procedure

You can configure MPLS and associated services.

Precautions

Before changing or deleting a configured LSR ID, you must run the **undo mpls** command in the system view to delete all MPLS configurations. Exercise caution when you run the **undo mpls** command.

NOTICE

Running the **undo mpls** command deletes all MPLS configurations (including established LDP sessions and LSPs).

Example

Set the LSR ID to 1.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 1.1.1.1
```

9.1.103 mpls mtu

Function

The **mpls mtu** command configures the MTU of MPLS packets on an interface.

The **undo mpls mtu** command restores the default setting.

By default, the MTU of MPLS packets is equal to the interface MTU.

Format

mpls mtu *mtu*

undo mpls mtu

Parameters

Parameter	Description	Value
mtu	Specifies the MPLS MTU of an interface.	The value range varies according to the interface type.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, Tunnel interface view

NOTE

The **mpls mtu** command does not take effect in the tunnel interface view.

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An MTU value determines the maximum number of bytes that can be sent each time. If the size of packets exceeds the MTU supported by a transit node or a receiver, the transit node or receiver fragments the packets or even discards them, increasing the network transmission load. MTU values must be correctly negotiated between LSRs to enable packets to successfully reach the receiver.

To calculate the MPLS MTU, an LSR on the path to a specified FEC compares all MTUs advertised by downstream devices with the interface MTU of its own, and adds the smaller MTU (the MPLS MTU) to the MTU TLV field in the Label Mapping message, and send the Label Mapping message upstream.

If an MTU value changes (for example when the local outbound interface or its configuration changes), an LSR recalculates the MTU value and sends a Label Mapping message carrying the new MTU value to all upstream devices.

The relationships between the MPLS MTU and the interface MTU are as follows:

- If no MPLS MTU is configured on an interface, the interface MTU is used to control forwarding of MPLS packets.
- If both an MPLS MTU and an interface MTU are configured on an interface, the smaller value between the two MTUs is used to control forwarding of MPLS packets.

Prerequisites

MPLS has been enabled on the interface using the **mpls (interface view)** command.

Precautions

After changing the MTU using the **mpls mtu** or **mtu** command on an interface, you need to restart the interface to make the new MTU take effect. To restart the interface, run the **shutdown** command and then the **undo shutdown** command, or run the **restart** command in the interface view.

After the **mpls mtu** command is run, LDP compares the MPLS MTU and the interface MTU, and uses the smaller value between the two MTUs.

After the **mpls mtu** command is run:

- The device checks the MTU of packets on the control plane.
- On the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H, the MTU of packets on the forwarding plane is checked only when the following conditions are met:
  - IP packet fragmentation has been enabled using the **ipv4 fragment enable** command.
  - In an MPLS LDP, MPLS TE, static LSP, or L3VPN scenario, IP packets on a PE enter an MPLS network for MPLS encapsulation and forwarding.

Example

Set the MPLS MTU to 1500 bytes on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls mtu 1500
```

Set the MPLS MTU to 1500 bytes on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls mtu 1500
```

9.1.104 mpls total-lsp-number threshold-alarm

Function

The **mpls total-lsp-number threshold-alarm** command configures the alarm threshold for total LSP usage.

The **undo mpls total-lsp-number threshold-alarm** command restores the default settings.

The default upper limit of the alarm threshold for total LSP usage is 80%. The default lower limit of the clear alarm threshold for total LSP usage is 75%.

Format

mpls total-lsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls total-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls total-lsp-number threshold-alarm

undo mpls total-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm**

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for total LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for total LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Parameter	Description	Value
ingress	Specifies the alarm threshold for total ingress LSPs.	-
transit	Specifies the alarm threshold for total transit LSPs.	-
egress	Specifies the alarm threshold for total egress LSPs.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of total LSPs (including static LSPs, LDP LSPs, BGP LSPs, BGP IPv6 LSPs) in the system reaches a specific limit, establishing subsequent LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of total LSPs reaches the specific limit. To configure the alarm threshold for total LSP usage, run the **mpls total-lsp-number threshold-alarm** command. The parameters in this command are described as follows:

- *upper-limit-value*: upper alarm threshold. If the proportion of total LSP usage to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of total LSP usage to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

If you want to set the alarm threshold for total ingress LSPs, total transit LSPs or total egress LSPs, run **mpls total-lsp-number** { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls total-lsp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- This command configures the alarm threshold for total LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm**

trap-name hwmplslspthresholdexceed is configured, and the actual total LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the lower threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual total LSP usage falls below the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for total LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls total-lsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.1.105 mpls-passive

Function

The **mpls-passive** command enables the egress node of an LSP to passively create a BFD session.

The **undo mpls-passive** command disables the egress node of an LSP from passively creating a BFD session.

By default, the egress node of an LSP cannot passively create a BFD session.

Format

mpls-passive

undo mpls-passive

Parameters

None

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a unidirectional LSP, the ingress node creates a BFD session, which triggers the sending of an LSP ping packet. After the egress node receives the ping packet, a BFD session can be automatically created on the egress node. Run the **mpls-passive** command to enable the BFD session to be created passively on the egress node of an LSP. If the feature is disabled, the egress node cannot automatically create a BFD session.

Prerequisites

BFD has been enabled globally using the **bfd** command.

Precautions

You need to run the **mpls-passive** command on the egress node. Then, the egress node can create a BFD session in an opposite direction after receiving an LSP ping request packet carrying a BFD TLV.

Example

Enable the egress node of an LSP to automatically and passively create a BFD session.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] mpls-passive
```

9.1.106 mpls ping interval

Function

The **mpls ping interval** command sets the interval at which LSP ping packets are sent in a dynamic BFD session.

The **undo mpls ping interval** command restores the default setting.

By default, the interval at which LSP ping packets are sent in a dynamic BFD session is 60 seconds.

Format

mpls ping interval *interval*

undo mpls ping interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending LSP ping packets.	The value is an integer ranging from 30 to 600, in seconds. The default value is 60.

Views

BFD view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an LSP, when the active role (the ingress node) creates a dynamic BFD session, an LSP ping request packet carrying a BFD TLV is sent. After receiving the LSP ping request packet, the passive role (the egress node) replies with an LSP ping response packet carrying the BFD TLV. Then, a BFD session is established. To set the interval for sending the LSP ping packet by dynamic BFD, run the **mpls ping interval** command.

Prerequisites

BFD has been enabled globally using the **bfd** command in the system view.

Precautions

A small interval for sending LSP ping packets imposes a heady burden on links.

Set the interval for sending the LSP ping packet according to the actual networking because the egress node can establish a BFD session only after receiving an LSP ping packet.

Example

Set the interval to 80 seconds for sending LSP ping packets in a dynamic BFD session.

```
<HUAWEI> system-view
[HUAWEI] bfd
[HUAWEI-bfd] mpls ping interval 80
```

9.1.107 mtu-signalling

Function

The **mtu-signalling** command enables the switch to send Label Mapping messages carrying the MTU TLV and determines the MTU TLV type.

The **undo mtu-signalling** command disables the switch to send Label Mapping messages carrying the MTU TLV

By default, the switch with MPLS LDP globally enabled sends Label Mapping messages carrying the MTU TLV, in compliance with draft-ietf-mpls-ldp-mtu-extensions.

Format

mtu-signalling [**apply-tlv**]

undo mtu-signalling [**apply-tlv**]

Parameters

Parameter	Description	Value
apply-tlv	Indicates the type of MTU TLV carried in Label Mapping messages to be sent. After this parameter is configured, the implementation is in compliance with RFC 3988. If this parameter is not configured, the implementation is in compliance with draft-ietf-mpls-ldp-mtu-extensions.	-

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If different types of links on an MPLS network support different MTU values, this function enables devices to negotiate MTU values, prevents packets from being discarded if the packet size exceeds an MTU.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

By default, after MPLS LDP is globally enabled, a device sends Label Mapping messages carrying an MTU TLV in compliance with draft-ietf-mpls-ldp-mtu-extensions. If an LDP peer does not identify the MTU TLV carried in a received message, the peer must process the TLV as an unknown TLV defined in RFC 5036.

Changing the configuration disconnects an existing LDP session and causes the LDP session to be reestablished.

Example

Enable LDP to send Label Mapping messages carrying the MTU TLV, as defined in RFC3988.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] mtu-signalling apply-tlv
Warning: All the related sessions will be deleted if the operation is performed!Continue? (y/n)y
```

9.1.108 no-renegotiate session-parameter-change graceful-restart

Function

The **no-renegotiate session-parameter-change graceful-restart** command disables a device from re-establishing existing LDP sessions when LDP GR status or a GR parameter is changed.

The **undo no-renegotiate session-parameter-change graceful-restart** command restores the default configuration.

By default, a device re-establishes LDP sessions when LDP GR status or a GR parameter is changed.

Format

no-renegotiate session-parameter-change graceful-restart

undo no-renegotiate session-parameter-change graceful-restart

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

After the **no-renegotiate session-parameter-change graceful-restart** command is run, running the following commands does not affect the existing LDP sessions.

- **graceful-restart (MPLS-LDP view)**
- **graceful-restart timer neighbor-liveness**
- **graceful-restart timer reconnect**
- **graceful-restart timer recovery**

Example

Disable a device from re-establishing existing LDP sessions when LDP GR status or a GR parameter is changed.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] no-renegotiate session-parameter-change graceful-restart
```

9.1.109 ospf ldp-sync

Function

The **ospf ldp-sync** command enables synchronization between LDP and OSPF on an interface.

The **undo ospf ldp-sync** command disables synchronization between LDP and OSPF on an interface.

By default, synchronization between LDP and OSPF is disabled on an interface.

Format

ospf ldp-sync

undo ospf ldp-sync

Parameters

None

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

The LDP convergence speed depends on the convergence speed of OSPF routes. To enable MPLS LDP on a network with the primary and backup links, the following problems may occur:

- Upon a fault on the active link, OSPF routes and ISP are switched to the backup link using LDP FRR. When the primary link recovers, OSPF routes are switched back to the primary link earlier than LDP traffic because IGP route convergence is faster than LDP convergence. As a result, LSP traffic is lost.
- If a fault occurs on the LDP session between nodes on the primary link where the OSPF routes are working properly, the OSPF routes still use the primary link and the LSP on the primary link is deleted. No OSPF route exists on the backup link; therefore, no LSP can be established on the backup link. LSP traffic is lost.

Run the **ospf ldp-sync** command to enable synchronization between LDP and OSPF to prevent traffic loss in the preceding problems. Run this command on the interfaces on both ends of the link between the node where the primary LSP and the backup LSP diverge from each other and its LDP peer on the primary LSP.

Example

Enable synchronization between LDP and OSPF on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf ldp-sync
```

Enable synchronization between LDP and OSPF on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf ldp-sync
```

9.1.110 ospf timer ldp-sync hold-down

Function

The **ospf timer ldp-sync hold-down** command sets the interval during which an interface waits for creating an LDP session before setting up the OSPF neighbor relationship.

The **undo ospf timer ldp-sync hold-down** command restores the default setting.

By default, the interval during which an interface waits for creating an LDP session before setting up the OSPF neighbor relationship is 10 seconds.

Format

ospf timer ldp-sync hold-down *value*

undo ospf timer ldp-sync hold-down

Parameters

Parameter	Description	Value
value	Specifies the interval during which an interface waits for creating an LDP session before setting up the OSPF neighbor relationship.	The value is an integer ranging from 0 to 65535, in seconds.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After this command is configured, OSPF routes are not immediately switched to the primary link after the primary link is restored and before the LDP session is established. LSP traffic is transmitted through the backup link in a period of time specified by this command.

Prerequisites

LDP and OSPF synchronization has been enabled using the **ospf ldp-sync** command in the interface view.

Precautions

This command is circular in nature, and the latest configuration overrides the previous configurations.

Example

Set the value of the Hold-down timer for VLANIF100 to 15 seconds, during which the interface waits for the establishment of an LDP session before setting up the OSPF neighbor relationship.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf timer ldp-sync hold-down 15
```

Set the value of the Hold-down timer for GE0/0/1 to 15 seconds, during which the interface waits for the establishment of an LDP session before setting up the OSPF neighbor relationship.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf timer ldp-sync hold-down 15
```

9.1.111 ospf timer ldp-sync hold-max-cost

Function

The **ospf timer ldp-sync hold-max-cost** command sets the interval at which OSPF LSAs are sent to advertise the maximum metric on the local device.

The **undo ospf timer ldp-sync hold-max-cost** command restores the default setting.

By default, the interval is 10 seconds.

Format

ospf timer ldp-sync hold-max-cost { *value* | **infinite** }

undo ospf timer ldp-sync hold-max-cost

Parameters

Parameter	Description	Value
value	Specifies the interval for sending OSPF LSAs to advertise the maximum metric on the local device.	The value is an integer ranging from 0 to 65535, in seconds.
infinite	Indicates that OSPF always advertises the maximum metric in LSAs on the local device before an LDP session is reestablished.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the primary LSP recovers from a fault, run the **ospf timer ldp-sync hold-max-cost** command to set the interval during which traffic is still transmitted along the backup LSP before the LDP session of the primary LSP is reestablished.

You can choose different parameters as required.

- When OSPF carries only LDP services, to ensure that OSPF routing is always consistent with the LDP LSP, specify **infinite**.
- When OSPF carries multiple services including LDP services, to ensure that OSPF route selection and other services still run properly in case the LDP session of the primary LSP fails, specify *value*.

Prerequisites

LDP and OSPF synchronization has been enabled using the **ospf ldp-sync** command in the interface view.

Precautions

This command is circular in nature, and the latest configuration overrides the previous configurations.

Example

Set the interval at which OSPF LSAs are sent to advertise the maximum metric on the local device to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] ospf ldp-sync
[HUAWEI-Vlanif100] ospf timer ldp-sync hold-max-cost 8
```

Set the interval at which OSPF LSAs are sent to advertise the maximum metric on the local device to 8 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ospf ldp-sync
[HUAWEI-GigabitEthernet0/0/1] ospf timer ldp-sync hold-max-cost 8
```

9.1.112 outbound peer split-horizon

Function

The **outbound peer split-horizon** command enables split horizon on an LSR to allow the LSR to distribute labels only to its upstream LDP peers.

The **undo outbound peer split-horizon** command restores the default setting.

By default, split horizon is not enabled, which means that an LSR distributes labels to both upstream and downstream LDP peers.

Format

outbound peer { *peer-id* | **all** } **split-horizon**

undo outbound peer { *peer-id* | **all** } **split-horizon**

Parameters

Parameter	Description	Value
peer-id	Specifies the LSR ID of an LDP peer.	The value is in dotted decimal notation.
all	Indicates all LDP peers.	-

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An LSR sends Label Mapping messages to both upstream and downstream LDP peers by default, speeding up LDP LSP convergence. This leads to the establishment of a great number of unwanted LSPs, wasting resources. To reduce the number of LSPs and saving memory resources, run the **outbound peer** { *peer-id* | **all** } **split-horizon** command to configure an LDP split horizon policy, enabling the LSR to send Label Mapping messages only to upstream LDP peers.

In the **outbound peer split-horizon** command, configure either of the following parameters to prevent an LSR from distributing labels to specified downstream peers:

- *peer-id*: prevents the LSR from distributing labels to a specified downstream peer.
- **all**: prevents the LSR from distributing labels to all downstream peers.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

The **all** parameter takes preference over the *peer-id* parameter. For example, the **outbound peer all split-horizon** and then **outbound peer 2.2.2.2 split-horizon** commands are run, the **outbound peer all split-horizon** command can be saved in the configuration file and take effect, not the **outbound peer 2.2.2.2 split-horizon** command.

Example

Enable split horizon for all LDP peers.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] outbound peer all split-horizon
```

9.1.113 path-vectors

Function

The **path-vectors** command sets the maximum number of hops of the path vector that is used for LDP loop detection.

The **undo path-vectors** command restores the default setting.

By default, a maximum of 32 hops of the path vector are used for LDP loop detection.

Format

path-vectors *integer*

undo path-vectors

Parameters

Parameter	Description	Value
integer	Specifies the path vector.	The value is an integer ranging from 1 to 32.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A scenario assumes that LDP loop detection is configured using the path vector, and the maximum number of hops of the path vector is n. The egress LSP triggered by local routes detects loop after n + 1 hops, whereas the egress LSP triggered by non-local routes (proxy egress) detects loops after n hops.

Prerequisites

The **path-vectors** command has been configured before LDP is enabled on all interfaces. The **path-vectors** command takes effect only after **MPLS LDP** is enabled in the related view.

Example

Set the maximum value of the path vector to 3.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] path-vectors 3
```

9.1.114 ping lsp

Function

The **ping lsp** command checks the LSP connectivity and LSP forwarding status.

Format

ping lsp [**-a** *source-ip* | **-c** *count* | **-exp** *exp-value* | **-h** *ttl-value* | **-m** *interval* | **-r** *reply-mode* | **-s** *packet-size* | **-t** *time-out* | **-v**] * **ip** *destination-address mask-length* [*ip-address*] [**nexthop** *nexthop-address* | **draft6**]

ping lsp [**-a** *source-ip* | **-c** *count* | **-exp** *exp-value* | **-h** *ttl-value* | **-m** *interval* | **-r** *reply-mode* | **-s** *packet-size* | **-t** *time-out* | **-v**] * **te tunnel** *interface-number* [**hot-standby** | **primary**] [**draft6**]

ping lsp [**-a** *source-ip* | **-c** *count* | **-exp** *exp-value* | **-h** *ttl-value* | **-m** *interval* | **-r** *reply-mode* | **-s** *packet-size* | **-t** *time-out* | **-v**] * **vpn-instance** *vpn-name* **remote** *remote-address mask-length* [**vpn-frr-path**]

ping lsp [**-a** *source-ip* | **-c** *count* | **-exp** *exp-value* | **-h** *ttl-value* | **-m** *interval* | **-r** *reply-mode* | **-s** *packet-size* | **-t** *time-out* | **-v**] * **bgp** *destination-address mask-length* [*ip-address*]

Parameters

Parameter	Description	Value
-a *source-ip*	Specifies the source IP address of MPLS Echo Request packets to be sent. If the source IP address is not specified, the IP address of the outbound interface from which MPLS Echo Request packets are sent is used as the source IP address. **NOTE** If an E2E BGP LSP has been established between two devices and the LSR ID is not used on the ingress, to run the **ping lsp** command with **bgp** specified on the ingress, you must specify **-a** *source-ip* as the IP address used for establishing the E2E BGP LSP.	-
-c *count*	Specifies the number of MPLS Echo Request packets to be sent. In the case of poor network quality, you can set this parameter to a comparatively large value to check the network quality based on the packet loss rate.	The value is an integer that ranges from 1 to 4294967295. The default value is 5.
-exp *exp-value*	Specifies the EXP value of MPLS Echo Request packets to be sent. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	The value is an integer that ranges from 0 to 7. The default value is 0.

Parameter	Description	Value
-h *ttl-value*	Specifies the value of the TTL. Each time the **ping lsp** command is run, an MPLS Echo Request packet carrying a sequence number is sent. The sequence number of the MPLS Echo Request packet starts from 1 and is increased by 1. By default, a maximum of five MPLS Echo Request packets are sent. You can set the number of MPLS Echo Request packets to be sent through the parameter *ttl-value*. If the destination is reachable, the source can receive five MPLS Echo Reply packets from the destination, with sequence numbers corresponding to those of MPLS Echo Request packets. If the TTL field is decreased to 0 during packet forwarding, the switch that the packet reaches sends an MPLS timeout packet to the source, indicating that the destination is unreachable.	The value is an integer that ranges from 1 to 255. The default value is 64.
-m *interval*	Specifies the time to wait before sending the next MPLS Echo Request packet. Each time the source sends an MPLS Echo Request packet using the **ping lsp** command, the source waits a period of time (2000 ms by default) before sending the next MPLS Echo Request packet. You can set the time to wait before sending the next ICMP Echo Request message using the parameter *interval*. In the case of poor network condition, the value should be equal to or larger than 2000, in milliseconds.	The value is an integer that ranges from 1 to 10000, in milliseconds. The default value is 2000.

Parameter	Description	Value
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply packets.	The value is an integer that ranges from 1 to 4. The default value is 2. ● 1: The peer does not return MPLS Echo Reply packets. ● 2: The peer end responds to MPLS Echo Reply packets with IPv4 or IPv6 User Datagram Protocol (UDP) packets. ● 3: The peer end responds to MPLS Echo Reply packets with IPv4 or IPv6 UDP packets containing the Router alert option. ● 4: The peer end responds to MPLS Echo Reply packets through the control channel on the application plane.
-s *packet-size*	Indicates the length of the payload in a packet, excluding the IP header and UDP header.	The value is an integer that ranges from 65 to 8100, in bytes. The default value is 100. The configured value must be smaller than the MTU of the interface.
-t *time-out*	Indicates the timeout period to wait for an MPLS Echo Reply packet after an MPLS Echo Request packet is sent.	The value is an integer that ranges from 0 to 65535, in milliseconds. The default value is 2000.

Parameter	Description	Value
-v	Displays MPLS Echo Reply packets not for the local user. By default, only MPLS Echo Reply packets for the local user are displayed. - If **-v** is not specified, the system displays only the MPLS Echo Reply packets received by the local user. - If **-v** is specified, the system displays all received MPLS Echo Reply packets.	By default, the system displays only the MPLS Echo Reply packets received by the local user.
ip *destination-address mask-length*	Specifies the IPv4 address and mask length of the destination.	The destination IPv4 address is in dotted decimal notation. The mask length is an integer that ranges from 0 to 32.
ip-address	Specifies the destination IP address carried in the IP header of an MPLS Echo Request packet.	The value is in dotted decimal notation. By default, the destination IP address carried in the IP header of an MPLS Echo Request packet is 127.0.0.1.
nexthop *nexthop-address*	Specifies the IP address of the next hop.	The value is in dotted decimal notation.
draft6	Specifies the version of the **ping lsp** command. If this parameter is specified, the ping operation is performed according to "draft-ietf-mpls-lsp-ping-06". By default, the ping operation is performed according to RFC 4379.	-
te tunnel *interface-number*	Specifies the number of a tunnel interface.	-
hot-standby	Indicates that the hot-standby CR-LSP is to be detected.	-

Parameter	Description	Value
primary	Indicates that the primary CR-LSP is to be monitored.	-
vpn-instance *vpn-name*	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.
remote *remote-address mask-length*	Specifies the destination IP address and mask of the VPN LSP to be monitored.	The IP address is in dotted decimal notation. The mask length is an integer that ranges from 0 to 32.
bgp *destination-address mask-length*	Specifies the IP address and mask length of the BGP destination.	-
vpn-frr-path	Specifies that the connectivity of the backup VPN FRR LSP will be checked. **NOTE** Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this parameter.	-

Usage Guidelines

Usage Scenario

On an MPLS network, you can run the **ping lsp** command to check LSP connectivity after an LSP is established.

The LSP ping uses Echo Request messages and MPLS Echo Reply messages to monitor the connectivity of LSPs. Both Echo Request and Echo Reply messages are encapsulated into UDP packets and transmitted through port 3503. The receiver distinguishes Echo Request and MPLS Echo Reply messages based on the port number. An Echo Request message carries FEC information to be monitored and travels along the same LSP as other packets with the same Forwarding Equivalence Class (FEC) to monitor the connectivity of the LSP. Echo Request messages are transmitted to the destination using MPLS, whereas MPLS Echo Reply messages are transmitted to the source using IP.

The LSP ping can be used to monitor the following types of links:

- LDP LSP Ping: Run the **ping lsp ip** *destination-address mask-length* command on the ingress node to ping the egress node to monitor the connectivity of the LSP.
- TE Tunnel Ping: If a tunnel exists, run the **ping lsp te tunnel** *interface-number* command on the ingress node to ping the egress node to monitor the connectivity of the tunnel.
- L3VPN LSP Ping: After a VPN is correctly configured, run the **ping lsp vpn-instance** *vpn-name* **remote** *remote-address mask-length* command on the ingress node to ping the egress node to monitor the connectivity of the VPN LSP established using BGP.

If the **ping lsp** command detects a fault on an LSP that packets transmitted along this LSP cannot reach the egress node, you can run the **tracert lsp** command to locate the fault.

Prerequisites

Before running the **ping lsp** command, ensure that the MPLS module is working properly.

Precautions

To prevent the egress node from forwarding the received MPLS Echo Request packet to other nodes, the destination address in the IP header of the Echo Request packet is set to 127.0.0.1/8 (the local loopback address), and the TTL value contained in the IP header is set to 1.

Example

Ping 10.1.1.1/32 by sending ten 200-byte MPLS Echo Request packets.

```
<HUAWEI> ping lsp -c 10 -s 200 ip 10.1.1.1 32
  LSP PING FEC: IPV4 PREFIX 10.1.1.1/32/ : 200 data bytes, press CTRL_C to break
    Reply from 10.1.1.1: bytes=200 Sequence=1 time = 11 ms
    Reply from 10.1.1.1: bytes=200 Sequence=2 time = 6 ms
    Reply from 10.1.1.1: bytes=200 Sequence=3 time = 6 ms
    Reply from 10.1.1.1: bytes=200 Sequence=4 time = 6 ms
    Reply from 10.1.1.1: bytes=200 Sequence=5 time = 12 ms
    Reply from 10.1.1.1: bytes=200 Sequence=6 time = 9 ms
    Reply from 10.1.1.1: bytes=200 Sequence=7 time = 12 ms
    Reply from 10.1.1.1: bytes=200 Sequence=8 time = 9 ms
    Reply from 10.1.1.1: bytes=200 Sequence=9 time = 12 ms
    Reply from 10.1.1.1: bytes=200 Sequence=10 time = 12 ms

  --- FEC: IPV4 PREFIX 10.1.1.1/32 ping statistics ---
    10 packet(s) transmitted
    10 packet(s) received
    0.00% packet loss
    round-trip min/avg/max = 6/10/12 ms
```

Ping an MPLS TE tunnel.

```
<HUAWEI> ping lsp te tunnel 1
  LSP PING FEC: TE TUNNEL IPV4 SESSION QUERY Tunnel1 : 100 data bytes, press CTRL_C to break
    Reply from 10.1.1.2: bytes=100 Sequence=1 time = 50 ms
    Reply from 10.1.1.2: bytes=100 Sequence=2 time = 28 ms
    Reply from 10.1.1.2: bytes=100 Sequence=3 time = 33 ms
    Reply from 10.1.1.2: bytes=100 Sequence=4 time = 52 ms
```

```
  Reply from 10.1.1.2: bytes=100 Sequence=5 time = 8 ms
--- FEC: TE TUNNEL IPV4 SESSION QUERY Tunnel1 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 8/34/52 ms
```

Ping 10.2.1.1/32 and output detailed information.

```
<HUAWEI> ping lsp -v ip 10.2.1.1 32
 LSP PING FEC: IPV4 PREFIX 10.2.1.1/32 : 100 data bytes, press CTRL_C to break
  Reply from 10.2.1.1: bytes=100 Sequence=1 time = 4 ms Return Code 3, Subcode 1
  Reply from 10.2.1.1: bytes=100 Sequence=2 time = 4 ms Return Code 3, Subcode 1
  Reply from 10.2.1.1: bytes=100 Sequence=3 time = 4 ms Return Code 3, Subcode 1
  Reply from 10.2.1.1: bytes=100 Sequence=4 time = 4 ms Return Code 3, Subcode 1
  Reply from 10.2.1.1: bytes=100 Sequence=5 time = 5 ms Return Code 3, Subcode 1
 --- FEC: IPV4 PREFIX 10.2.1.1/32 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 4/4/5 ms
```

Table 9-45 Description of the **ping lsp** command output

Item	Description
Reply from	IP address in an Echo Reply packet.
bytes	Length of an Echo Reply packet.
Sequence	Serial number of an Echo Reply packet.
time	RTT of an Echo Reply packet.

Item	Description
Return Code	Return code. The meaning of each value is as follows: ● 0: No return code is received. ● 1: Incorrect request is received. ● 2: An unknown TLV is received. ● 3: There is the outbound interface of one LSP. ● 4: No mapping between the request device and the replying device exists. ● 5: The mapping does not match that on the downstream device. ● 6: An unknown upstream interface exists. ● 7: The return code is reserved. ● 8: indicates label switching. ● 9: indicates label switching without MPLS forwarding. ● 10: indicates mapping without labels. ● 11: indicates the entity without labels. ● 12: No protocol is loaded on the interface. ● 13: The ping operation is ended ahead of schedule because of shortened labels.
Subcode	Number of labels. Usually, the value is 1.

Item	Description
xxx ping statistics	Statistics collected after the ping test. The statistics include the following information: - packet(s) transmitted: indicates the number of sent ICMP Echo Request messages. - packet(s) received: indicates the number of received ICMP Echo Reply messages. - % packet loss: indicates the percentage of unresponded messages to total sent messages. - round-trip min/avg/max: indicates the minimum, average, and maximum RTTs. The unit is ms.

9.1.115 propagate mapping

Function

The **propagate mapping for ip-prefix** command allows the system to filter out the received routes using an IP prefix list. LDP uses routes that match the addresses in the prefix list to establish an LSP.

The **undo propagate mapping** command restores the default setting.

By default, when LDP establishes an LSP, LDP does not filter out received routes.

Format

propagate mapping for ip-prefix *ip-prefix-name*

undo propagate mapping

Parameters

Parameter	Description	Value
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list used to filter out routes.	The value is an existing IP prefix list name.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After MPLS LDP is enabled, LDP LSPs are automatically established, leading to a large number of LSPs and wasting resources. Run the **propagate mapping** command to configure a policy for establishing an LSP, allowing LDP to use routes that match the specified conditions to establish LSPs.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp (system view)** command.

Precautions

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, the device does not filter received routes.

Example

Allow routes that match the IP prefix list named **policy1** to set up an LSP.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] propagate mapping for ip-prefix policy1
```

9.1.116 proxy-egress disable

Function

The **proxy-egress disable** command disables a device from establishing proxy egress LSPs.

The **undo proxy-egress disable** command enables a device to establish proxy egress LSPs.

By default, a device is enabled to establish proxy egress LSPs.

Format

proxy-egress disable

undo proxy-egress disable

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a policy allows a device to use all static and IGP routes to establish LSPs or use an IP address prefix list to establish LSPs, the policy also triggers proxy egress LSP establishment. However, the proxy egress LSPs may be unavailable, which wastes system resources. To prevent this problem, run the **proxy-egress disable** command to disable a device from establishing such proxy egress LSPs.

Prerequisites

MPLS has been enabled using the **mpls** command.

Precautions

During the LDP GR, the **proxy-egress disable** command cannot be run.

Example

Disable a device from establishing proxy egress LSPs in the MPLS view.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] proxy-egress disable
```

9.1.117 remote-ip

Function

The **remote-ip** command allows you to assign an IP address to a remote LDP peer.

The **undo remote-ip** command deletes the configuration.

By default, the IP address of the remote LDP peer is not configured.

Format

remote-ip *ip-address* [**pwe3**]

undo remote-ip [**pwe3**]

Parameters

Parameter	Description	Value
ip-address	Specifies the IPv4 address of a remote peer.	The value is in decimal notation. The IPv4 address of a local interface is not supported.
pwe3	Prohibits labels from being distributed to a specified remote peer.	-

Views

Remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a remote LDP peer is configured, to assign an IP address to the remote LDP peer, run the **remote-ip** command in the remote MPLS LDP peer view.

The IP address must be the LSR ID of the remote LDP peer. When the LDP LSR ID and the MPLS LSR ID are different, the LDP LSR ID takes effect.

The remote peer uses the LSR ID as the transport address to create a TCP connection.

PEs on both ends of an MPLS L2VPN that runs LDP signaling can establish a remote LDP session. The MPLS L2VPN can be a Martini VLL, PWE3, or Martini VPLS network. The remote LDP session is expected to transmit Label Mapping messages carrying VC labels, not LDP labels. By default, the PE distributes LDP labels to its peer. To disable the PE from distributing LDP labels to its peer, run either of the following commands, which helps prevent LDP label wastes and minimize memory usage.

- **remote-ip** *ip-address* **pwe3** command: prevents the LSR from distributing labels to a specified remote peer.
- **remote-peer pwe3** command: prevents the LSR from distributing labels to all remote peers.

NOTE

When a backbone network is transmitting TE services in the LDP over TE scenario, do not disable a device from distributing labels to remote peers.

Prerequisites

Remote LDP peers have been configured.

Precautions

- Modifying or deleting the configured IP address of a remote peer leads to the deletion of a remote LDP session.
- After a remote peer IP address is specified using the **remote-ip** *ip-address* command, *ip-address* cannot be used as a local interface IP address. If it is used as a local interface IP address, the remote LDP session is interrupted.

Example

Configure the address for a remote peer.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer bji
[HUAWEI-mpls-ldp-remote-bji] remote-ip 10.3.3.3
```

Prohibit labels from being distributed to the remote peer at 10.1.1.1/32.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer rtc
[HUAWEI-mpls-ldp-remote-rtc] remote-ip 10.1.1.1 pwe3
```

9.1.118 remote-ip auto-dod-request

Function

The **remote-ip auto-dod-request** command configures automatic triggering of a request to a specified downstream remote LDP peer for a Label Mapping message in DoD mode.

The **undo remote-ip auto-dod-request** command restores the default setting.

By default, the configuration of the **remote-peer auto-dod-request** command is inherited.

Format

remote-ip auto-dod-request [**block**]

undo remote-ip auto-dod-request [**block**]

Parameters

Parameter	Description	Value
block	Disables the automatic triggering of a request to a downstream node for a Label Mapping message associated with a remote LDP peer of a specified LSR ID in DoD mode.	-

Views

Remote MPLS LDP peer view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale network, to reduce the burden on edge devices, use the DoD mode. Because edge devices cannot learn the accurate route to the remote peer, an LDP LSP cannot be set up even if LDP extensions for inter-area LSPs are configured. You can configure the DoD mode in which the local LSR requests a Label Mapping message from a specified downstream LSR or all LSRs to set up an LDP LSP.

To block this function, run the **remote-ip auto-dod-request block** command.

Precautions

Before running the **remote-ip auto-dod-request** command, ensure that the following operations has been performed:

- Configure a remote LDP session.
- Run the **longest-match** command to configure LDP extensions for inter-area LSPs.
- Run the **mpls ldp advertisement dod** command to set the DoD mode.

Example

Enable automatic triggering of a request to a downstream specified remote LDP peer for a Label Mapping message in DoD mode.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp remote-peer lsrc
[HUAWEI-mpls-ldp-remote-lsrc] remote-ip 4.4.4.4
[HUAWEI-mpls-ldp-remote-lsrc] remote-ip auto-dod-request
```

9.1.119 remote-peer auto-dod-request

Function

The **remote-peer auto-dod-request** command configures automatically trigger requests for Label Mapping messages in DoD mode from all downstream remote LDP peers.

The **undo remote-peer auto-dod-request** command restores the default setting.

By default, the device does not automatically trigger requests for Label Mapping messages in DoD mode from all downstream remote LDP peers.

Format

remote-peer auto-dod-request

undo remote-peer auto-dod-request

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On a large-scale network, to reduce the burden on edge devices, use the DoD mode. Because edge devices cannot learn the accurate route to the remote peer, an LDP LSP cannot be set up even if LDP extensions for inter-area LSPs are configured. You can configure the DoD mode in which the local LSR requests a Label Mapping message from a specified downstream LSR or all LSRs to set up an LDP LSP.

Precautions

Before running the **remote-peer auto-dod-request** command, ensure that the following operations have been performed:

- Configure a remote LDP session.
- Run the **longest-match** command to configure LDP extensions for inter-area LSPs.
- Run the **mpls ldp advertisement dod** command to set the DoD mode.

Example

Enable automatically trigger requests for Label Mapping messages in DoD mode from all downstream remote LDP peers.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] remote-peer auto-dod-request
Warning: The operation will affect all the remote peers on which the attribute is not manually configured.
Continue?[Y/N]:y
```

9.1.120 remote-peer pwe3

Function

The **remote-peer pwe3** command prevents LSP transport labels from being distributed to all remote peers.

The **undo remote-peer pwe3** command restores the default setting.

By default, an LSR is permitted to distribute LSP transport labels to all remote peers.

Format

remote-peer pwe3

undo remote-peer pwe3

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

PEs on both ends of an MPLS L2VPN that runs LDP signaling can establish a remote LDP session. The MPLS L2VPN can be a Martini VLL, PWE3, or Martini VPLS network. The remote LDP session is expected to transmit Label Mapping messages carrying VC labels, not LDP labels.

By default, the PE distributes LDP labels to its peer. To disable the PE from distributing LDP labels to its peer, run either of the following commands, which helps prevent LDP label wastes and minimize memory usage.

- The **remote-peer pwe3** command prohibits an LSR from distributing labels to all remote peers.
- The **remote-ip** *ip-address* **pwe3** command in the remote MPLS LDP peer view prohibits an LSR from distributing labels to a specified remote peer.

When you create a remote LDP session, run the **remote-peer pwe3** or **remote-ip** *ip-address* **pwe3** command to prevent LSP transport labels from being distributed to remote peers. If you do not run either of the preceding commands, the command configuration may affect system performance.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

The configuration will take effect on all remote LDP peers, including existing remote peers.

Example

Prevent LSP transport labels from being distributed to all remote peers.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
```

```
[HUAWEI-mpls-ldp] remote-peer pwe3
Warning: The modification has impact on all remote peers including the existing ones. Continue? [Y/N]: y
```

9.1.121 reset lspv statistics

Function

The **reset lspv statistics** command clears LSPV statistics.

Format

reset lspv statistics

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

The **display lspv statistics** command can be used to display LSPV statistics of an LSP ping or trace test instance. LSPV statistics of multiple test instances are accumulated, which obsesses the analysis. The **reset lspv statistics** command can be used to clear LSPV statistics.

If the **reset lspv statistics** command is run before an LSP ping or trace test instance starts, the **display lspv statistics** command displays LSPV statistics of the current test instance.

Precautions

Statistics cannot be restored after being cleared. Therefore, exercise caution before running the **reset lspv statistics** command.

Example

Clear LSPV statistics collected on the device.

```
<HUAWEI> reset lspv statistics
```

9.1.122 reset mpls ldp

Function

The **reset mpls ldp** command resets LDP instances of the public network.

The **reset mpls ldp all** command resets all LDP instances.

Format

reset mpls ldp [**peer** *peer-id*]

reset mpls ldp all

Parameters

Parameter	Description	Value
peer *peer-id*	Specifies the LSR ID of a peer.	Expressed in dotted decimal notation.
all	Specifies all LDP instances.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

When there is a new LDP configuration, to validate the configuration, you can run the **reset mpls ldp** command.

Run the **reset mpls ldp peer** command to reset sessions, and LSPs, and CR-LSPs of a specified peer.

Precautions

The **reset mpls ldp** command cannot be run during GR.

If this command is run in an attempt to restart LDP and the interval at which LDP is restarted is small, the attempt fails. The interval varies according to the number of LSPs. The more the LSPs are established, the longer the interval is. The interval can be set to 30, 60, 90, or 120, in seconds.

Example

Reset the global LDP function.

```
<HUAWEI> reset mpls ldp
Warning: The MPLS LDP services will be reset. Continue? [Y/N]:y
```

Reset all LDP instances.

```
<HUAWEI> reset mpls ldp all
Warning: The MPLS LDP services will be reset. Continue? [Y/N]:y
```

Reset the peer.

```
<HUAWEI> reset mpls ldp peer 10.2.2.9
```

9.1.123 reset mpls ldp error packet

Function

The **reset mpls ldp error packet** command deletes information about LDP-related error messages.

Format

reset mpls ldp error packet { **tcp** | **udp** | **l2vpn** | **all** }

Parameters

Parameter	Description	Value
tcp	Deletes information about TCP error messages.	-
udp	Deletes information about UDP error messages.	-
l2vpn	Deletes information about L2VPN error messages.	-
all	Deletes information about all LDP-related error messages.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

By default, the system records information about LDP-related error messages. To delete the information, run the **reset mpls ldp error packet** command.

Example

Delete information about LDP-related TCP error messages.

```
<HUAWEI> reset mpls ldp error packet tcp
```

9.1.124 reset mpls ldp event adjacency-down

Function

The **reset mpls ldp event adjacency-down** command deletes the recorded events that LDP adjacencies go Down.

Format

reset mpls ldp event adjacency-down

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

By default, the system records the events that LDP adjacencies go Down. To delete the recorded events, run the **reset mpls ldp event adjacency-down** command.

Example

Delete the recorded events that LDP adjacencies go Down.

```
<HUAWEI> reset mpls ldp event adjacency-down
```

9.1.125 reset mpls ldp event session-down

Function

The **reset mpls ldp event session-down** command deletes the recorded events that LDP sessions go Down.

Format

reset mpls ldp event session-down

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

By default, the system records events that LDP sessions go Down. To delete the recorded events, run the **reset mpls ldp event session-down** command.

Example

Delete the recorded events that LDP sessions go Down.

```
<HUAWEI> reset mpls ldp event session-down
```

9.1.126 route recursive-lookup tunnel

Function

The **route recursive-lookup tunnel** command enables tunnel recursion.

The **undo route recursive-lookup tunnel** command disables tunnel recursion.

By default, tunnel recursion is disabled.

Format

route recursive-lookup tunnel [**only**] [**ip-prefix** *ip-prefix-name*]

undo route recursive-lookup tunnel

Parameters

Parameter	Description	Value
only	Recurses unlabeled public routes only to LSPs.	-
ip-prefix *ip-prefix-name*	Specifies the name of an IP-prefix list.	The value is an existing IP-prefix list name.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

By default, an unlabeled BGP public network route or a static route can only recurse to the outbound interface and next hop, but not a tunnel. After tunnel recursion is enabled, this route preferentially recurses to an LSP. If no LSP exists, the route can also recurse to the outbound interface and next hop.

After **ip-prefix** *ip-prefix-name* is set, only the unlabeled BGP routes or static routes that match the specified IP prefix list recurse to LSPs.

If the **ip-prefix** *ip-prefix-name* parameter is not set, all static routes and non-labeled public BGP routes will preferentially recurse to LSP tunnels.

Precautions

If the **route recursive-lookup tunnel** command is run for several times, the latest configuration overrides the previous one.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes match the IP prefix list.

Example

Recurse the unlabeled public routes to the LSP tunnel.

```
<HUAWEI> system-view
[HUAWEI] route recursive-lookup tunnel
```

Recurse unlabeled public routes only to LSPs.

```
<HUAWEI> system-view
[HUAWEI] route recursive-lookup only
```

9.1.127 snmp-agent trap suppress feature-name lsp

Function

The **snmp-agent trap suppress feature-name lsp** command configures the interval for suppressing the display of excessive LSP traps.

The **undo snmp-agent trap suppress feature-name lsp** command restores the default configuration.

By default, the interval for suppressing the display of excessive LSP traps is 300 seconds, and a maximum of three LSP traps can be sent in the suppression interval.

Format

snmp-agent trap suppress feature-name lsp trap-name { **mplsxcup** | **mplsxcdown** } **trap-interval** *trap-interval* [**max-trap-number** *max-trap-number*]

undo snmp-agent trap suppress feature-name lsp trap-name { **mplsxcup** | **mplsxcdown** } **trap-interval**

Parameters

Parameter	Description	Value
mplsxcup	Indicates the excessive traps generated when an LSP goes Up.	-
mplsxcdown	Indicates the excessive traps generated when an LSP goes Down.	-

Parameter	Description	Value
trap-interval *trap-interval*	Specifies the interval for suppressing the display of excessive LSP traps.	The value is an integer ranging from 0 to 65535, in seconds. By default, the value is 300.
max-trap-number *max-trap-number*	Sets the maximum number of traps to be sent during the suppression interval.	The value is an integer ranging from 1 to 65535. By default, the value is 3. If only *trap-interval* is specified, but *max-trap-number* is not, at most one trap can be sent during the suppression interval.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

To prevent excessive traps from being displayed because of frequent LSP status changes, run the **snmp-agent trap suppress feature-name lsp** command to set the interval for suppressing the display of excessive LSP traps. During a specified suppression interval, a trap of a specified type is displayed only once. This setting reduces traps to be displayed.

For example, when the interval for suppressing the display of excessive traps when the LSP goes Down is set to 60s, only one trap indicating that the LSP goes Down is displayed every 60s. Within this interval, no other trap of the same type is displayed, but the number of the same traps generated is logged. During the next 60s, another trap indicating that an LSP goes Down can be displayed.

Example

Set the interval for suppressing the display of excessive traps when an LSP goes Up to 80s.

```
<HUAWEI> system-view
[HUAWEI] snmp-agent trap suppress feature-name lsp trap-name mplsxcup trap-interval 80
```

9.1.128 static-lsp egress

Function

The **static-lsp egress** command configures the egress node for a static LSP.

The **undo static-lsp egress** command deletes the configuration.

By default, no static LSP is configured for the egress node.

Format

static-lsp egress *lsp-name* [**incoming-interface** *interface-type interface-number*] **in-label** *in-label* [**lsrid** *ingress-lsr-id* **tunnel-id** *tunnel-id*]

undo static-lsp egress *lsp-name*

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of an LSP.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
incoming-interface *interface-type interface-number*	Specifies the inbound interface of an LSP. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
in-label	Specifies the value of an incoming label.	The value is an integer ranging from 16 to 1023.
lsrid *ingress-lsr-id*	Specifies the ingress LSR ID.	The value is in dotted decimal notation.
tunnel-id *tunnel-id*	Specifies the ID of a tunnel.	The value is an integer ranging from 1 to 65535.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run the **static-lsp egress** command on the egress node to configure a static LSP.

After configuring a static LSP, run the **display mpls static-lsp** command to verify that the static LSP is established successfully.

Precautions

To modify **incoming-interface** *interface-type interface-number* or **in-label** *in-label*, run the **static-lsp egress** command to set a new value. You do not need to run the **undo static-lsp egress** command before changing a configured value.

Example

Configure the local LSR as the egress node of the static LSP **bj-sh**, with the inbound interface of VLANIF100 and incoming label of 233.

```
<HUAWEI> system-view
[HUAWEI] static-lsp egress bj-sh incoming-interface vlanif 100 in-label 233
```

9.1.129 static-lsp ingress

Function

The **static-lsp ingress** command configures the ingress node for a static LSP.

The **undo static-lsp ingress** command deletes the configuration.

By default, no static LSP is configured for the ingress node.

Format

static-lsp ingress *lsp-name* **destination** *ip-address* { *mask-length* | *mask* } { **nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number* } * **out-label** *out-label*

static-lsp ingress tunnel-interface tunnel *interface-number* **destination** *ip-address* { **nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number* } * **out-label** *out-label*

undo static-lsp ingress { *lsp-name* | **tunnel-interface tunnel** *interface-number* }

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of an LSP.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
tunnel-interface tunnel *interface-number*	Specifies the index of a tunnel interface.	Numeral type. Range: varies with the configuration.
destination *ip-address*	Specifies the destination IP address.	It is in dotted decimal notation.
mask-length	Specifies the mask length of the destination IP address.	An integer ranging from 0 to 32.

Parameter	Description	Value
mask	Specifies the mask of the IP address.	It is in dotted decimal notation.
nexthop *next-hop-address*	Specifies the next-hop address.	It is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Specifies the type and number of an interface. ● *interface-type* specifies the type of the interface. ● *interface-number* specifies the number of the interface.	-
out-label *out-label*	Specifies the value of an outgoing label.	An integer ranging from 16 to 1048575.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run the **static-lsp ingress** command on the ingress node to configure a static LSP.

NOTE

The local IP address cannot be designated as the next hop address.

After configuring a static LSP, run the **display mpls static-lsp** command to verify that the static LSP is established successfully.

Precautions

To modify the parameter **destination** *destination-address*, **nexthop** *next-hop-address*, **outgoing-interface** *interface-type interface-number*, or **out-label** *out-label*, run the **static-lsp ingress** command to set a new value. You do not need to run the **undo static-lsp ingress** command before changing a configured value.

When configuring a static LSP, ensure that the route of the static LSP exactly matches the routing information. For example:

- If you specify a next hop when configuring a static LSP, specify a next hop when configuring a static IP route. If you do not specify a next hop, the static LSP cannot be set up. For example:

```
[HUAWEI] ip route-static 10.1.0.0 16 10.1.1.2
[HUAWEI] static-lsp ingress staticlsp1 destination 10.1.0.0 16 nexthop 10.1.1.2 out-label 100
```

- If a dynamic routing protocol applies to the link between LSRs, the next-hop IP address along the LSP must be the same as the IP address of the next hop in the routing table.

If **outgoing-interface** is configured and *next-hop-address* is not configured, Ethernet forwarding failures occur.

Example

Configure the local LSR as the ingress node of the static LSP whose destination address is 10.25.38.1, next hop IP address is 10.55.25.33, and outgoing label is 237.

```
<HUAWEI> system-view
[HUAWEI] static-lsp ingress bj-sh destination 10.25.38.1 24 nexthop 10.55.25.33 out-label 237
```

9.1.130 static-lsp transit

Function

The **static-lsp transit** command configures the transit node for the static LSP.

The **undo static-lsp transit** command deletes the configuration.

By default, the transit node for the static LSP is not configured.

Format

static-lsp transit *lsp-name* [**incoming-interface** *interface-type interface-number*] **in-label** *in-label* { **nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number* }* **out-label** *out-label*

undo static-lsp transit *lsp-name*

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of an LSP.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
incoming-interface	Specifies the inbound interface.	-
interface-type interface-number	Specifies the type and number of an interface.	-
next-hop-address	Specifies the next-hop address.	The value is in dotted decimal notation.
outgoing-interface	Specifies the outbound interface.	-

Parameter	Description	Value
in-label	Specifies the value of an incoming label.	The value is an integer ranging from 16 to 1023.
out-label	Specifies the value of an outgoing label.	The value is an integer ranging from 16 to 1048575.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run the **static-lsp transit** command on the transit node to configure a static LSP.

After configuring a static LSP, run the **display mpls static-lsp** command to verify that the static LSP is established successfully.

Precautions

To modify the parameter **incoming-interface** *interface-type interface-number*, **in-label** *in-label*, **nexthop** *next-hop-address*, **outgoing-interface** *interface-type interface-number*, or **out-label** *out-label*, run the **static-lsp transit** command to set a new value. You do not need to run the **undo static-lsp transit** command before changing a configured value.

If **outgoing-interface** is configured and *next-hop-address* is not configured, Ethernet forwarding failures occur.

Example

Configure the LSR, with the inbound interface of VLANIF100, the incoming label of 123, and the outgoing label of 253, as the transit node of a static LSP named **bj-sh**.

```
<HUAWEI> system-view
[HUAWEI] static-lsp transit bj-sh incoming-interface vlanif 100 in-label 123 nexthop 10.1.1.1 out-label
253
```

9.1.131 static-route timer ldp-sync hold-down

Function

The **static-route timer ldp-sync hold-down** command sets the time during which a static route remains inactive and waits for the establishment of an LDP session.

The **undo static-route timer ldp-sync hold-down** command restores the default setting.

By default, the time during which a static route remains inactive and waits for the establishment of an LDP session is 10 seconds.

Format

static-route timer ldp-sync hold-down { *timer* | **infinite** }

undo static-route timer ldp-sync hold-down

Parameters

Parameter	Description	Value
timer	Specifies the time during which a static route remains inactive and waits for an LDP session to be established.	The value is an integer ranging from 0 to 65535, in seconds.
infinite	Indicates that the Hold-down timer never expires. A static route becomes active only after an LDP session is established.	-

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an MPLS network with primary and backup links, LSRs establish LSPs based on static routes. When the LDP session of the primary link becomes faulty (the fault is not caused by a link failure) or the primary link recovers, configuring synchronization between LDP and static routes minimizes traffic loss during traffic switchover and switchback. After synchronization between LDP and static routes is enabled, and the **static-route timer ldp-sync hold-down** command is run, the recovered static route becomes temporarily inactive. It waits for the establishment of an LDP session before the Hold-down timer expires, which synchronizes LDP and the static route.

If the Hold-down timer expires, the static route becomes active regardless of whether an LDP session has been established.

- If the Hold-down timer is set to 0 seconds, synchronization between LDP and static routes is disabled on an interface.
- If the Hold-down timer is set to **infinite**, the timer never expires. In this case, the static route becomes active and MPLS traffic is switched only after an LDP session is established.

Precautions

The Hold-down timer cannot be set on loopback interfaces, Layer 2 Ethernet interfaces, or null interfaces.

Example

Set the time during which a static route remains inactive and waits for the establishment of an LDP session to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] static-route timer ldp-sync hold-down 20
```

9.1.132 timer ldp-sync hold-down

Function

The **timer ldp-sync hold-down** command sets the Hold-down time for all IS-IS interfaces within an IS-IS process so that these interfaces remain in the Hold-down state before LDP sessions are established.

The **undo timer ldp-sync hold-down** command restores the default Hold-down time.

The default Hold-down time is 10 seconds.

Format

timer ldp-sync hold-down *value*

undo timer ldp-sync hold-down

Parameters

Parameter	Description	Value
value	Specifies the period of time during which all IS-IS interfaces within an IS-IS process remain in the Hold-down state before LDP sessions are established.	The value is an integer ranging from 0 to 65535, in seconds.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an active link between two devices enabled with synchronization between LDP and IS-IS recovers from a fault, the IS-IS module enters the Hold-down state and starts a Hold-down timer. This timer allows the devices to create an LDP session and set up an IS-IS neighbor relationship at the same time. Traffic can be switched back to the active link over a reachable IS-IS route for an established LDP LSP.

To set the Hold-down time for all interfaces within an IS-IS process, run the **timer ldp-sync hold-down** command.

Precautions

If both the **timer ldp-sync hold-down** command and the **isis timer ldp-sync hold-down** command in the interface view are executed, the **isis timer ldp-sync hold-down** command takes effect.

Example

Set the Hold-down time for all interfaces within an IS-IS process 100 to **15** seconds.

```
<HUAWEI> system-view
[HUAWEI] isis 100
[HUAWEI-isis-100] timer ldp-sync hold-down 15
```

9.1.133 timer ldp-sync hold-max-cost

Function

The **timer ldp-sync hold-max-cost** command sets the Hold-max-cost time during which all interfaces enabled with synchronization between LDP and IS-IS advertise link state PDUs (LSPs) carrying the maximum route cost.

The **undo timer ldp-sync hold-max-cost** command restores the default setting.

The default Hold-max-cost time is 10 seconds.

Format

timer ldp-sync hold-max-cost { **infinite** | *interval* }

undo timer ldp-sync hold-max-cost

Parameters

Parameter	Description	Value
infinite	Enables IS-IS to advertise LSPs carrying the maximum route cost before LDP sessions are reestablished.	-
interval	Specifies the Hold-max-cost time during which IS-IS advertises LSPs carrying the maximum route cost on a local device.	The value is an integer ranging from 0 to 65535, in seconds.

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After synchronization between LDP and IS-IS is enabled, if the LDP session over the active link fails but the IS-IS route for the active link is reachable, IS-IS advertises the LSPs carrying the maximum route cost so that the IS-IS route and LDP session over a standby link can become reachable at the same time.

To set the Hold-max-cost time, run the **timer ldp-sync hold-max-cost** command.

Select parameters based on networking requirements:

- If an IGP carries only LDP services, configure the parameter **infinite** to ensure that a selected IGP route is kept consistent with the LDP LSP.
- If an IGP carries multiple types of services including LDP services, set the value of the parameter *interval* to ensure that a teardown of LDP sessions does not affect IGP route selection or other services.

Precautions

- If the **timer ldp-sync hold-max-cost infinite** command is executed and the LDP session is Down, interfaces enabled with LDP and IS-IS synchronization keep advertising LSPs carrying the maximum route cost, which affects IS-IS routing.
- If both the **timer ldp-sync hold-max-cost** command and the **isis timer ldp-sync hold-max-cost** command in the interface view are executed, the **isis timer ldp-sync hold-max-cost** command takes effect.

Example

Configure IS-IS to keep advertising the maximum cost by sending Link State PDUs until the LSP is established.

```
<HUAWEI> system-view
[HUAWEI] isis 100
[HUAWEI-isis-100] timer ldp-sync hold-max-cost infinite
```

9.1.134 tracert lsp

Function

The **tracert lsp** command detects the gateways along the LSP from the source to the destination.

Format

tracert lsp [**-a** *source-ip* | **-exp** *exp-value* | **-h** *ttl-value* | **-r** *reply-mode* | **-t** *time-out* | **-v**] * **ip** *destination-address mask-length* [*ip-address*] [**nexthop** *nexthop-address* | **draft6**]

tracert lsp [**-a** *source-ip* | **-exp** *exp-value* | **-h** *ttl-value* | **-r** *reply-mode* | **-t** *time-out*] * **te tunnel** *interface-number* [**hot-standby** | **primary**] [**draft6**]

tracert lsp [**-a** *source-ip* | **-exp** *exp-value* | **-h** *ttl-value* | **-r** *reply-mode* | **-t** *time-out*] * **bgp** *destination-address mask-length* [*ip-address*]

Parameters

Parameter	Description	Value
-a *source-ip*	Specifies the source IP address of Echo Request packets to be sent. If no source IP address is specified, the IP address of the outbound interface through which Echo Request packets are sent is used as a source IP address. **NOTE** If an E2E BGP LSP has been established between two devices and the LSR ID is not used on the ingress, to run the **tracert lsp** command with **bgp** specified on the ingress, you must specify **-a** *source-ip* as the IP address used for establishing the E2E BGP LSP.	-
-exp *exp-value*	Specifies the EXP value of Echo Request packets to be sent. The EXP value represents the priority of Echo Request packets. **NOTE** If DSCP priority has been configured by running the **set priority** command, the *exp-value* parameter does not take effect.	An integer that ranges from 0 to 7. The default value is 0.
-h *ttl-value*	Specifies the TTL value of MPLS Echo Request packets to be sent. The TTL field indicates the lifetime of the MPLS Echo Request packet and specifies the maximum number of hops that the packet can pass through. The TTL value is set on the source and reduced by 1 each time the packet passes through a hop. When the TTL value is reduced to 0, the packet is discarded. At the same time, an ICMP Timeout message is sent to notify the source host.	An integer that ranges from 1 to 255. The default value is 30.

Parameter	Description	Value
-r *reply-mode*	Specifies the mode in which the peer returns MPLS Echo Reply packets.	An integer that ranges from 1 to 4. The default value is 2. The meaning of each value is as follows: ● 1: No MPLS Echo Reply packet is returned. ● 2: The MPLS Echo Reply packet is encapsulated into IPv4/IPv6 UDP packets. ● 3: MPLS Echo Reply packets are encapsulated into IPv4/IPv6 UDP packets carrying the Router Alert option. ● 4: MPLS Echo Reply packets are responded using the control channels on the application plane. If the value of *reply-mode* is 1, the initiator starts a unidirectional test. If the test succeeds, the initiator prompts that the test times out; if the test fails, the initiator prompts that the LSP does not exist.
-t *time-out*	Specifies the period of time for waiting for an MPLS Echo Reply packet.	An integer that ranges from 0 to 65535, in milliseconds. The default value is 2000.
-v	Displays the MPLS label carried in the ICMP Time Exceeded packet. This parameter is used when LSP transport labels need to be displayed after tracert is initiated on the PE.	-
ip *destination-address mask-length*	Specifies the destination IPv4 address and the mask length.	The destination IPv4 address is in dotted decimal notation. The mask length is an integer that ranges from 0 to 32.

Parameter	Description	Value
ip-address	Specifies the destination IP address carried in the IP header of an MPLS Echo Request packet.	The value is in dotted decimal notation. By default, the destination IP address carried in the IP header of an MPLS Echo Request packet is 127.0.0.1.
nexthop *nexthop-address*	Specifies the next-hop address.	The value is in dotted decimal notation.
draft6	Specifies the version of the **tracert lsp** command. If this parameter is specified, the tracert operation is performed according to "draft-ietf-mpls-lsp-ping-06". By default, the tracert operation is performed according to RFC 4379.	-
te tunnel *interface-number*	Specifies the number of the TE tunnel interface.	-
hot-standby	Indicates that the hot-standby CR-LSP is to be monitored.	-
primary	Indicates that the primary CR-LSP is to be monitored.	-
bgp *destination-address mask-length*	Specifies the destination IP address and mask length of BGP.	*destination-address* is in dotted decimal notation. *mask-length* is an integer that ranges from 0 to 32.

Usage Guidelines

Usage Scenario

When a fault occurs on the LSPs of an MPLS network, you can run the **ping lsp** command to check the LSP connectivity based on the reply packet, and then run the **tracert lsp** command to locate the fault.

The **tracert lsp** command uses MPLS Echo Request messages and MPLS Echo Reply messages to monitor the connectivity of the LSP. Both MPLS Echo Request and MPLS Echo Reply messages are encapsulated into UDP packets and transmitted through port 3503. The receiver distinguishes MPLS Echo Request and MPLS Echo Reply messages based on the port number. An MPLS Echo Request message carries FEC information to be monitored, and is sent along the same LSP as other packets with the same FEC. In this manner, the connectivity of the LSP is checked. Echo Request messages are transmitted to the destination using MPLS, whereas MPLS Echo Reply messages are transmitted to the source using IP.

The LSP tracert can be used to monitor the following types of links:

- LDP LSP Tracert: Run the **tracert lsp ip** *destination-address mask-length* command on the ingress node to trace the egress node to detect the fault on the LSP.
- TE Tunnel Tracert: You can run the **tracert lsp te tunnel** *interface-number* command on the ingress node to trace the egress node to check the connectivity of a tunnel.
  - To check the connectivity of a hot-standby tunnel, run the **tracert lsp te tunnel** *interface-number* **hot-standby** command.
  - To check the connectivity of a primary tunnel, run the **tracert lsp te tunnel** *interface-number* **primary** command.

Prerequisites

- The UDP module of each node is working properly; otherwise, the tracert operation fails.
- The MPLS module of each node is enabled and is working properly.
- The ICMP module of each node is working properly; otherwise, three asterisks (* * *) are displayed.

Procedure

The execution process of the **tracert lsp** command is as follows:

- The source sends an MPLS Echo Request packet with the TTL being 1. After the TTL times out, the first hop sends an MPLS Echo Reply packet to the source.
- The source sends an MPLS Echo Request packet with the TTL being 2. After the TTL times out, the second hop sends an MPLS Echo Reply packet to the source.
- The source sends an MPLS Echo Request packet with the TTL being 3. After the TTL times out, the third hop sends an MPLS Echo Reply packet to the source.
- The preceding process proceeds until the MPLS Echo Request packet reaches the destination.

When the device on the destination hop receives the MPLS Echo Request packet, it returns an MPLS Echo Reply packet, indicating the end of the tracert. The purpose behind this is to record the source of each ICMP Timeout packet to provide a trace of the path the packet took to reach the destination.

Precautions

When you run the **tracert lsp te tunnel** *interface-number* command to detect a tunnel, if a transit node is not enabled with LDP, a packet is returned, indicating that the destination is unreachable.

To prevent the egress node from forwarding the received MPLS Echo Request packet to other nodes, you can set the destination address in the IP header of the Echo Request packet to a loopback address with the prefix being 127.0.0.1/8.

Example

Tracert the LSP to 10.4.4.9/32.

```
<HUAWEI> tracert lsp ip 10.4.4.9 32
  LSP Trace Route FEC: IPV4 PREFIX 10.4.4.9/32 , press CTRL_C to break.
  TTL   Replier            Time    Type      Downstream
  0                                Ingress   10.1.2.2/[1028 ]
  1     10.1.2.2          94 ms   Transit   10.4.4.9/[3 ]
  2     10.4.4.9          94 ms   Egress
```

Tracert the LSP to 10.3.3.9/32 with the MTU value.

```
<HUAWEI> tracert lsp -v ip 10.3.3.9 32
  LSP Trace Route FEC: IPV4 PREFIX 10.3.3.9/32 , press CTRL_C to break.
  TTL   Replier            Time    Type      Downstream/Label/MTU
  0                                Ingress   172.16.1.1/[3 ]/1500
  1     10.3.3.9          20 ms   Egress
```

Tracert a TE tunnel.

```
<HUAWEI> tracert lsp te tunnel 1
  LSP Trace Route FEC: TE TUNNEL IPV4 SESSION QUERY Tunnel1 , press CTRL_C to break.
  TTL   Replier            Time    Type      Downstream
  0                                Ingress   10.1.2.2/[13312 ]
  1     10.1.2.2          63 ms   Transit   10.4.4.9/[3 ]
  2     10.6.6.6          93 ms   Egress
```

Table 9-46 Description of the tracert lsp command output

Item	Description
TTL	Indicates the TTL value in an Echo Request packet. It represents the number of hops of the tunnel an Echo Request packet passes.
Replier	IP address of a switching node that returns an MPLS Echo Reply packet.
Time	RTT, in milliseconds.
Type	Type of a node. Available node types: ● Ingress node ● Transit node ● Egress node
Downstream	Address of a downstream device.
Label	Label of a downstream device.
MTU	Link Maximum Transmission Unit.

9.1.135 ttl expiration pop

Function

The **ttl expiration pop** command enables a device to use the local IP route to forward ICMP response packets after the MPLS TTL expires.

The **undo ttl expiration pop** command disables this function. Therefore, ICMP response packets are sent along LSPs.

By default, the LSR returns an ICMP packet using the local IP route if the received MPLS TTL-expired packet contains one label.

Format

ttl expiration pop

undo ttl expiration pop

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

On an MPLS network, when an LSR receives MPLS packets with the TTL value of 1, the LSR generates an ICMP TTL-expired message.

The LSR returns the TTL-expired message to the sender in the following ways:

- If the LSR has a reachable route to the sender, it directly sends the TTL-expired message to the sender through the IP route.
- If the LSR has no reachable route to the sender, it forwards the TTL-expired message along the LSP. The egress node forwards the TTL-expired message to the sender.

In most cases, the received MPLS packet contains only one label and the LSR responds to the sender with the TTL-expired message using the first method. If the MPLS packet contains multiple labels, the LSR uses the second method.

The MPLS VPN packets may contain only one label when they arrive at an autonomous system boundary router (ASBR) on the MPLS VPN. These devices have no IP routes to the sender, so they use the second method to reply to the TTL-expired messages.

Precautions

The **undo mpls (system view)** command deletes all configurations of the **ttl expiration pop** command.

Example

Forward ICMP packets through an LSP after the MPLS TTL expires.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] undo ttl expiration pop
```

9.1.136 ttl propagate

Function

The **ttl propagate** command sets the TTL propagate mode of MPLS packets to uniform.

The **undo ttl propagate** command sets the TTL propagate mode of MPLS packets to pipe.

By default, the TTL propagate function is enabled and the MPLS TTL processing mode is uniform.

Format

ttl propagate

undo ttl propagate

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MPLS TTL processing modes include uniform and pipe:

- Uniform

  When IP packets reach the ingress node of an MPLS network, the IP TTL decreases by one and is mapped to the MPLS TTL field. In this manner, packets are processed in the standard mode used on the MPLS network. On the egress node, the MPLS TTL decreases by one and is mapped to the IP TTL field. The traceroute output shows the path that the packets pass by.

- Pipe

  On an MPLS network, the IP TTL does not decrease by one at each hop. The traceroute output hides all the hops on the MPLS backbone network, as if the ingress node is directly connected to the egress node.

In MPLS VPN applications, the MPLS backbone network needs to be hidden to ensure network security. The pipe mode is recommended for private network packets.

Precautions

The **ttl propagate** command only take effect on LSPs that are to be set up. Before using the function on LSPs that have been set up, run the **reset mpls ldp** command to reestablish the LSPs.

Example

Set the TTL propagate mode of MPLS packets to uniform.

```
<HUAWEI> system-view
[HUAWEI] ttl propagate
```

9.1.137 ttl propagate public

Function

The **ttl propagate public** command enables IP TTL propagation for MPLS packets of the public network.

The **undo ttl propagate public** command disables IP TTL propagation for MPLS packets of the public network.

By default, IP TTL propagation for MPLS packets of the public network is enabled.

Format

ttl propagate public

undo ttl propagate public

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The **ttl propagate public** and **undo ttl propagate public** commands only take effect on LSPs that are to be set up. Before using the function on LSPs that have been set up, run the **reset mpls ldp** command to reestablish the LSPs.

Example

Enable the IP TTL propagation for MPLS packets of the public network.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] ttl propagate public
```

9.1.138 ttl propagate vpn

Function

The **ttl propagate vpn** command enables IP TTL propagation for MPLS packets of the VPN.

The **undo ttl propagate vpn** command disables IP TTL propagation for MPLS packets of the VPN.

By default, IP TTL propagation is disabled for VPN packets.

Format

ttl propagate vpn

undo ttl propagate vpn

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The **ttl propagate vpn** and **undo ttl propagate vpn** commands only take effect on LSPs that are to be set up. Before using the function on LSPs that have been set up, run the **reset mpls ldp** command to reestablish the LSPs.

Configure the IP TTL propagation consistently on all PEs. If you enable the IP TTL propagation only on some PEs, the traceroute output cannot reflect the real network situation.

Example

Enable the IP TTL propagation for MPLS packets of the VPN.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] ttl propagate vpn
```

9.1.139 undo outbound peer all

Function

The **undo outbound peer all** command deletes all outbound policies.

Format

undo outbound peer all

Parameters

None

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before MPLS LDP is used, the **outbound peer split-horizon** command needs to be executed to configure an outbound policy to control LDP LSP establishments. If multiple outbound policies have been configured, run the **undo outbound peer all** command to simultaneously delete all the outbound policies.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

Running the **undo outbound peer all** command deletes all outbound policies. Therefore, exercise caution when running this command.

Example

Delete all outbound policies.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] undo outbound peer all
```

9.1.140 undo inbound peer all

Function

The **undo inbound peer all** command deletes all inbound policies.

Format

undo inbound peer all

Parameters

None.

Views

MPLS-LDP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To delete all inbound policies in batches, run the **undo inbound peer all** command.

Before MPLS LDP is used, the **inbound peer fec** command needs to be executed to configure an inbound policy to control LDP LSP establishments. If multiple inbound policies have been configured, run the **undo inbound peer all** command to simultaneously delete all the inbound policies.

Prerequisites

MPLS LDP has been enabled globally using the **mpls ldp** command in the system view.

Precautions

Running the **undo inbound peer all** command deletes all inbound policies. Therefore, exercise caution when running this command.

Example

Delete all inbound policies.

```
<HUAWEI> system-view
[HUAWEI] mpls ldp
[HUAWEI-mpls-ldp] undo inbound peer all
```

9.2 MPLS QoS Configuration Commands

9.2.1 Command Support

Only the following switch models support MPLS QoS:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

9.2.2 diffserv-mode

Function

The **diffserv-mode** command configures a DiffServ mode for MPLS L2VPN or MPLS L3VPN labels to implement end-to-end QoS.

The **undo diffserv-mode** command restores the default DiffServ mode of an MPLS network.

By default, the uniform mode is used for MPLS L2VPN or MPLS L3VPN labels.

Format

diffserv-mode { **pipe** { **mpls-exp** *mpls-exp* | **domain** *ds-name* } | **short-pipe** [**mpls-exp** *mpls-exp*] **domain** *ds-name* | **uniform** [**domain** *ds-name*] }

undo diffserv-mode

Parameters

Parameter	Description	Value
pipe	Indicates that the DiffServ mode of an MPLS network is pipe.	-
short-pipe	Indicates that the DiffServ mode of an MPLS network is short pipe.	-
uniform	Indicates that the DiffServ mode of an MPLS network is uniform.	-
mpls-exp *mpls-exp*	Specifies the EXP priority in the private label. This parameter is valid only when the DiffServ mode on the ingress PE is set to pipe or short pipe. It is invalid on the egress PE. If a DiffServ domain is configured, the inner label specified by *mpls-exp* is preferred for the mapping. When the *mpls-exp* parameter is set to a large value, the packets have high priority and packet forwarding quality is high.	The value is an integer that ranges from 0 to 7. The default value is 0.

Parameter	Description	Value
domain *ds-name*	Indicates the name of the DiffServ domain. The default DiffServ domain name is **default**. This parameter is specified in the **diffserv domain** command.	The value is an existing DiffServ domain name.

Views

Interface view, VSI view, VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To provide QoS guarantee for VPN traffic on an MPLS VPN network, set the DiffServ mode based on actual needs.

- If you want to differentiate priorities of different services in a VPN, set the DiffServ mode to uniform. You can also set the DiffServ mode to pipe or short pipe, but you need to specify the DiffServ domain in which the mode applies.
- If you want to differentiate priorities of services in different VPNs but not priorities of services in a VPN, set the DiffServ mode to pipe or short pipe and specify EXP values in private labels.

If you do not want to change priorities carried in original packets, you are advised to set the DiffServ mode to pipe or short pipe. In uniform and pipe modes, the egress node determines the per-hop behavior (PHB) based on EXP priorities of packets. In short pipe mode, the egress node determines the PHB based on DSCP or 802.1p priorities of packets.

Precautions

Before configuring the MPLS Diff-Serv mode for IPv4 services, ensure that an IPv4 address family is configured in the VPN instance view using the **ipv4-family** command.

Before configuring the MPLS Diff-Serv mode for IPv6 services, ensure that an IPv6 address family is configured in the VPN instance view using the **ipv6-family** command.

On the ingress, all the three modes can be set. On the egress, only the short pipe mode can be set.

- If you specify the DiffServ domain in the **diffserv-mode** command, ensure that the specified DiffServ domain is already created using the **diffserv domain** command in the system view.
- Before running this command, use the **undo portswitch** command to set the working mode of the Ethernet interfaces to Layer 3 mode.

- The **diffserv-mode** command takes effect only for the new LSPs. To make the command take effect for the existing LSPs, run the **reset mpls ldp** command to reestablish LSPs.

Example

On VLANIF100, set the MPLS DiffServ mode to pipe and the value of *mpls-exp* to 3.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] diffserv-mode pipe mpls-exp 3
```

On GE0/0/1, set the MPLS DiffServ mode to pipe and the value of *mpls-exp* to 3.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] diffserv-mode pipe mpls-exp 3
```

9.2.3 mpls-exp-inbound

Function

The **mpls-exp-inbound** command maps EXP priorities of MPLS packets to PHBs and colors in a DiffServ domain on an inbound interface.

The **undo mpls-exp-inbound** command restores the default mapping.

The following table shows the default mappings from EXP priorities to PHBs and colors of MPLS packets in a DiffServ domain on an inbound interface.

Table 9-47 Default mappings from EXP priorities to PHBs and colors of MPLS packets in a DiffServ domain on an inbound interface

EXP Priority	PHB	Color
0	BE	green
1	AF1	green
2	AF2	green
3	AF3	green
4	AF4	green
5	EF	green
6	CS6	green
7	CS7	green

Format

mpls-exp-inbound *exp-value* **phb** *service-class* [*color*]

undo mpls-exp-inbound [*exp-value*]

Parameters

Parameter	Description	Value
exp-value	Specifies the EXP priority of an MPLS packet.	The value is an integer ranging from 0 to 7. A larger value indicates a higher EXP priority of MPLS packets.
service-class	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7.
color	Specifies the color of a packet.	The value can be green, yellow, or red.

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

To implement QoS scheduling on the MPLS packets that come from the upstream device, run the **mpls-exp-inbound** command to map EXP priorities of MPLS packets to PHBs and colors. After a DiffServ domain is bound to the inbound interface of packets, the QoS mechanism performs congestion management and congestion avoidance according to PHBs and colors of the packets.

Example

In the DiffServ domain **ds1**, map EXP priority 2 of MPLS packets to PHB AF1 and color incoming MPLS packets as yellow.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] mpls-exp-inbound 2 phb af1 yellow
```

9.2.4 mpls-exp-outbound

Function

The **mpls-exp-outbound** command maps PHBs and colors of MPLS packets to EXP priorities in a DiffServ domain on an outbound interface.

The **undo mpls-exp-outbound** command restores the default mapping.

The following table shows the default mappings from PHBs and colors to EXP priorities of MPLS packets in a DiffServ domain on an outbound interface.

Table 9-48 Default mappings from PHBs and colors to EXP priorities of MPLS packets in a DiffServ domain on an outbound interface

PHB	Color	EXP Priority
BE	green	0
BE	yellow	0
BE	red	0
AF1	green	1
AF1	yellow	1
AF1	red	1
AF2	green	2
AF2	yellow	2
AF2	red	2
AF3	green	3
AF3	yellow	3
AF3	red	3
AF4	green	4
AF4	yellow	4
AF4	red	4
EF	green	5
EF	yellow	5
EF	red	5
CS6	green	6
CS6	yellow	6
CS6	red	6
CS7	green	7
CS7	yellow	7
CS7	red	7

Format

mpls-exp-outbound *service-class color* **map** *exp-value*

undo mpls-exp-outbound [*service-class color*]

Parameters

Parameter	Description	Value
service-class	Specifies a PHB.	The value can be BE, AF1 to AF4, EF, CS6, or CS7.
color	Specifies the color of a packet.	The value can be green, yellow, or red.
exp-value	Specifies the EXP priority of an MPLS packet.	The value is an integer ranging from 0 to 7. A larger value indicates a higher EXP priority of the MPLS packet.

Views

DiffServ domain view

Default Level

2: Configuration level

Usage Guidelines

After QoS scheduling is performed on the MPLS packets, run the **mpls-exp-outbound** command to map the PHB and color of the MPLS packets in a DiffServ domain to the EXP priority. After the DiffServ domain is bound to the outbound interface of MPLS packets, the downstream device implements QoS scheduling according to EXP priority.

The switch can map PHBs and colors in MPLS packets to EXP priorities and 802.1p priorities on an outbound interface.

Example

In the DiffServ domain **ds1**, map the PHB AF1 of outgoing MPLS packets marked yellow to EXP priority 2.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] mpls-exp-outbound af1 yellow map 2
```

9.2.5 mpls-qos egress

Function

The **mpls-qos egress** command maps the mapping from the EXP priority of the public tunnel to the PHB/color on the egress node.

The **undo mpls-qos egress** command restores the default settings.

By default, mapping of the EXP priority of the public tunnel is performed according to the settings in the default domain.

Format

mpls-qos egress trust upstream { *ds-name* | **default** }

undo mpls-qos egress trust upstream

mpls-qos egress trust upstream none

undo mpls-qos egress trust upstream none

Parameters

Parameter	Description	Value
trust upstream	Trusts the specified DiffServ domain.	-
ds-name	Specifies the name of a DiffServ domain.	The value is an existing DiffServ domain name.
default	Specifies the DiffServ domain as a default domain.	-
none	Indicates that the system does not perform EXP priority mapping in the public network tunnel, and sets the EXP field to 0 in the public network tunnel.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement certain QoS functions on an MPLS network, the device needs to determine the packet precedence according to the tunnel label of the MPLS public network. Therefore, you need to map the tunnel label to the EXP field.

Prerequisites

The specified DiffServ domain has been created using the **diffserv domain** command in the system view.

Precautions

Run the **mpls-qos egress** command before setting up the public tunnel; otherwise, you must reestablish the MPLS LDP session to make the command take effect.

If you modify the settings of the global DiffServ domain or change the DiffServ mode of the interface, VSI, or VPN instance, you must reestablish the MPLS LDP session; otherwise, the modification cannot take effect.

Example

Map the mapping from the EXP priority of the public tunnel to the PHB/color on the egress node.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] quit
[HUAWEI] mpls-qos egress trust upstream ds1
```

9.2.6 mpls-qos ingress

Function

The **mpls-qos ingress** command maps the PHB/color of packets to the EXP priority of the public tunnel on the ingress node.

The **undo mpls-qos ingress** command restores the default settings.

By default, mapping of the EXP priority of the public tunnel is performed according to the settings in the default domain.

Format

mpls-qos ingress { **use vpn-label-exp** | **trust upstream** { *ds-name* | **default** } }

undo mpls-qos ingress { **use vpn-label-exp** | **trust upstream** }

mpls-qos ingress trust upstream none

undo mpls-qos ingress trust upstream none

Parameters

Parameter	Description	Value
use vpn-label-exp	Indicates the EXP value in the inner label of a packet.	-
trust upstream	Trusts the specified DiffServ domain.	-
ds-name	Specifies the name of a DiffServ domain.	The value is an existing DiffServ domain name.

Parameter	Description	Value
default	Specifies the DiffServ domain as a default domain.	-
none	Indicates that the system does not perform EXP priority mapping in the public network tunnel, and sets the EXP field to 0 in the public network tunnel.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement certain QoS functions on an MPLS network, the device needs to determine the packet precedence according to the tunnel label of the MPLS public network. Therefore, you need to map the tunnel label to the EXP field. You can specify **use vpn-label-exp**.

Prerequisites

The specified DiffServ domain has been created using the **diffserv domain** command in the system view.

Precautions

Run the **mpls-qos ingress** command before setting up the public tunnel; otherwise, you must reestablish the MPLS LDP session to make the command take effect.

Example

Map the PHB/color of packets to the EXP priority of the public tunnel on the ingress node.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] quit
[HUAWEI] mpls-qos ingress trust upstream ds1
```

System Response

None

9.2.7 mpls-qos transit

Function

The **mpls-qos transit** command performs the priority mapping based on the EXP priority of the public tunnel on the transit node.

The **undo mpls-qos transit** command restores the default settings.

By default, mapping of the EXP priority of the public tunnel is performed according to the settings in the default domain.

Format

mpls-qos transit trust upstream { *ds-name* | **default** }

undo mpls-qos transit trust upstream

mpls-qos transit trust upstream none

undo mpls-qos transit trust upstream none

Parameters

Parameter	Description	Value
trust upstream	Trusts the specified DiffServ domain.	-
ds-name	Specifies the name of a DiffServ domain.	The value is an existing DiffServ domain name.
default	Specifies the DiffServ domain as a default domain.	-
none	Indicates that the system does not perform EXP priority mapping in the public network tunnel, and sets the EXP field to 0 in the public network tunnel.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To implement certain QoS functions on an MPLS network, the device needs to determine the packet precedence according to the tunnel label of the MPLS public network. Therefore, you need to map the tunnel label to the EXP field.

Prerequisites

The specified DiffServ domain has been created using the **diffserv domain** command in the system view.

Precautions

Run before setting up the public tunnel; otherwise, you must reestablish the MPLS LDP session to make the command take effect.

If you modify the settings of the global DiffServ domain or change the DiffServ mode of the interface, VSI, or VPN instance, you must reestablish the MPLS LDP session; otherwise, the modification cannot take effect.

Example

Perform the priority mapping based on the EXP priority of the public tunnel on the transit node.

```
<HUAWEI> system-view
[HUAWEI] diffserv domain ds1
[HUAWEI-dsdomain-ds1] quit
[HUAWEI] mpls-qos transit trust upstream ds1
```

9.3 MPLS TE Configuration Commands

9.3.1 Command Support

Only the following switch models support MPLS TE:

S5731-S, S5731-H, S5731S-H, S5732-H, S6720-EI, S6720S-EI, S6730-S, S6730S-H, and S6730-H

9.3.2 add hop

Function

The **add hop** command adds a specified node on an MPLS TE explicit path.

Format

add hop *ip-address1* [**include** [[**loose** | **strict**] | [**incoming** | **outgoing**]] * | **exclude**] { **after** | **before** } *ip-address2*

Parameters

Parameter	Description	Value
ip-address1	Specifies the IP address of the added node.	The value is in dotted decimal notation.

Parameter	Description	Value
include [[**loose** | **strict**] | [**incoming** | **outgoing**]] *	Specifies the node with an IP address *ip-address1* on the explicit path. - **strict**: indicates that the node is added in **strict** mode. The node of *ip-address1* is directly connected to the node of *ip-address2*. - **loose**: indicates that the node is added in **loose** mode. The node of *ip-address1* may not be directly connected to the node of *ip-address2*. - **incoming**: indicates that the *ip-address1* is the IP address of an inbound interface of a new-added node. - **outgoing**: indicates that the *ip-address1* is the IP address of an outbound interface of a new-added node.	By default, an explicit path is added in **include strict** mode.
exclude	Excludes the node of *ip-address1* from the explicit path.	-
after	Indicates that the node of *ip-address1* is added after the node of *ip-address2*.	-
before	Indicates that the node of *ip-address1* is added before the node of *ip-address2*.	-
ip-address2	Specifies the IP address of an interface or the Router ID of a node on the explicit path.	The value is in dotted decimal notation.

Views

Explicit path view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following commands are used to adjust nodes on a created explicit path:

- The **add hop** command is used to add a node to the explicit path.
- The **modify hop** command is used to delete a node from the explicit path and replace the node with a specified node.
- The **delete hop** command is used to delete a node from the explicit path.

Prerequisites

The **next hop** command must have been run to specify a next-hop IP address before the **add hop** command is run.

Follow-up Procedure

Run the **display explicit-path** command to view information about the explicit path.

Precautions

A node can be added to an explicit path using the **add hop** command only when the following conditions are met:

- *ip-address2* is the IP address of a node that exists on the explicit path.
- If an explicit path over which a TE tunnel has been established is modified, the make-before-break mechanism is triggered, and a CR-LSP is reestablished without traffic loss.

Example

Exclude the next hop of 10.2.2.2 after 10.1.1.1 from the explicit path named **p1**.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] quit
[HUAWEI] explicit-path p1
[HUAWEI-explicit-path-p1] next hop 10.1.1.1
[HUAWEI-explicit-path-p1] add hop 10.2.2.2 exclude after 10.1.1.1
```

9.3.3 affinity property

Function

The **affinity property** command configures the affinity property for a CR-LSP attribute template.

The **undo affinity property** command deletes the affinity property from a CR-LSP attribute template.

By default, no affinity property for a CR-LSP attribute template is configured.

Format

affinity property *affinity-value* [**mask** *mask-value*]

undo affinity property

Parameters

Parameter	Description	Value
affinity-value	Specifies the value of the affinity property.	The value ranges from 0x0 to 0xFFFFFFFF, in hexadecimal format. By default, the affinity value is 0.

Parameter	Description	Value
mask *mask-value*	Specifies the mask value of an affinity property. Then an operation is performed between the mask value and the affinity property value, and the result indicates the bits of the affinity property to be checked.	The value ranges from 0x0 to 0xFFFFFFFF, in hexadecimal format. By default, the value is 0.

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

Affinity property and masks determine the link properties that should be checked by a device.

Example

Set the affinity property to 123 and the mask to fff in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] affinity property 123 mask fff
```

9.3.4 bandwidth (LSP attribute view)

Function

The **bandwidth** command configures the bandwidth in the CR-LSP attribute template.

The **undo bandwidth** command deletes the bandwidth in the CR-LSP attribute template.

By default, no bandwidth in the CR-LSP attribute template is configured.

Format

bandwidth { **ct0** *ct0-bandwidth* | **ct1** *ct1-bandwidth* }

undo bandwidth { **all** | **ct0** | **ct1** }

Parameters

Parameter	Description	Value
ct0 *ct0-bandwidth*	Specifies the bandwidth of an LSP of CT0.	The value is an integer that ranges from 1 to 4000000000, in kbit/s. By default, the bandwidth is 0 kbit/s.
ct1 *ct1-bandwidth*	Specifies the bandwidth of an LSP of CT1.	The value is an integer that ranges from 1 to 4000000000, in kbit/s. By default, the bandwidth is 0 kbit/s.
all	Deletes the bandwidth configured for the LSP of each CT.	-

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

The **undo bandwidth** command can be used to delete the bandwidth of all CTs or a specified CT:

- **undo bandwidth all**: deletes all configured bandwidth.
- **undo bandwidth** { **ct0** | **ct1** }: deletes the bandwidth of the specified CT configured on the current TE tunnel.

Example

Configure the bandwidth of an LSP of CT0 as 20 kbit/s in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] bandwidth ct0 20
```

9.3.5 bfd bind mpls-te

Function

The **bfd bind mpls-te** command configures BFD to monitor TE tunnels, or the primary or backup LSP bound to a TE tunnel.

The **undo bfd** command deletes a specified BFD session.

By default, no TE tunnel applies BFD.

Format

bfd *cfg-name* **bind mpls-te interface tunnel** *interface-number* [**te-lsp** [**backup**]]

undo bfd *cfg-name*

Parameters

Parameter	Description	Value
cfg-name	Specifies the BFD configuration name.	The value is a string of 1 to 15 case-insensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
interface tunnel *interface-number*	Specifies the interface number of the TE tunnel bound to a BFD session.	-
te-lsp [**backup**]	Indicates that BFD monitors the LSP bound to the TE tunnel. ● If **backup** is not selected, BFD monitors the primary LSP bound to the TE tunnel. ● If **backup** is selected, BFD monitors the backup LSP bound to the TE tunnel.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **bfd bind mpls-te** command to configure BFD to monitor TE tunnels, or the primary or backup LSP bound to a TE tunnel.

Prerequisites

Before configuring BFD to monitor TE tunnels, the following tasks must have been completed:

- BFD has been enabled globally using the **bfd** command.
- An MPLS TE tunnel interface has been configured.

Precautions

BFD can monitor a TE tunnel and the primary or backup LSP bound to the TE tunnel.

- If BFD is configured to monitor the primary or backup LSP bound to a TE tunnel, a BFD session cannot be created if the LSP status is Down.
- If the tunnel status is Down when BFD is configured to monitor a TE tunnel, the BFD session can still be created, but its status is Down.

  Multiple LSPs can be bound to a TE tunnel. When BFD detects the tunnel, the BFD session will go Down only if all LSPs bound to the TE tunnel fail.

Example

Configure BFD to detect the primary LSP bound to the TE tunnel.

```
<HUAWEI> system-view
[HUAWEI] bfd 1to4rsvp bind mpls-te interface Tunnel 1 te-lsp
[HUAWEI-bfd-lsp-session-1to4rsvp]
```

Configure BFD to detect the backup LSP bound to the TE tunnel.

```
<HUAWEI> system-view
[HUAWEI] bfd 1to4backup bind mpls-te interface Tunnel 1 te-lsp backup
[HUAWEI-bfd-lsp-session-1to4backup]
```

9.3.6 bypass-attributes

Function

The **bypass-attributes** command configures bypass CR-LSP attributes in a CR-LSP attribute template.

The **undo bypass-attributes** command deletes bypass CR-LSP attributes from a CR-LSP attribute template.

By default, no bypass CR-LSP attributes are configured.

Format

bypass-attributes { **bandwidth** *bandwidth* | **priority** *setup_priority_value* [*hold_priority_value*] }*

undo bypass-attributes

Parameters

Parameter	Description	Value
bandwidth *bandwidth*	Specifies the bandwidth value assigned to a bypass CR-LSP. **NOTE** The function of bandwidth value assigned to a bypass CR-LSP does not take effect on the devices.	An integer ranging from 1 to 4000000000, in kbit/s. By default, the bandwidth is 0 kbit/s.
priority *setup_priority_value*	Specifies the setup priority of a bypass CR-LSP.	An integer ranging from 0 to 7. The smaller the value, the higher the priority. By default, the setup priority is 7.
hold_priority_value	Specifies the holding priority of the bypass CR-LSP.	An integer ranging from 0 to 7. The smaller the value, the higher the priority. By default, the holding priority is 7.

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

To configure the **bypass-attributes** command in the CR-LSP attribute template, note the following preconditions:

- The **fast-reroute bandwidth** command must be configured in the CR-LSP attribute template, and the bandwidth of the bypass CR-LSP must be less than or equal to that of the primary CR-LSP.
- The bandwidth of the bypass CR-LSP must be less than or equal to that of the CR-LSP attribute template.
- The values of the setup and holding priority of the CR-LSP attribute template must be less than or equal to those of the bypass CR-LSP.

Example

Configure the bypass CR-LSP attributes in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] fast-reroute bandwidth
[HUAWEI-lsp-attribute-lsp-attribute-name] bypass-attributes bandwidth 30 priority 5 5
```

9.3.7 commit (LSP attribute view)

Function

The **commit** command commits the configurations of the CR-LSP attribute template.

Format

commit

Parameters

None

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

When the CR-LSP attribute template is modified, if the commands that conflict with the CR-LSP attribute template are configured on a tunnel interface, the configurations of the CR-LSP attribute template cannot be committed.

When the CR-LSP attribute template is applied by a tunnel, you can modify the tunnel attributes by modifying the configurations of the CR-LSP attribute template. Different modifications in the CR-LSP attribute template have different impacts on the setup of the tunnel. If the priorities of the CR-LSP attribute template are modified, Break-Before-Make (BBM) is performed on the tunnel. If the Make-Before-Break (MBB) attribute of the CR-LSP attribute template is modified, MBB may be performed on the tunnel.

Example

Configure the CR-LSP attribute template and commit relevant configurations.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] hop-limit 15
[HUAWEI-lsp-attribute-lsp-attribute-name] commit
```

9.3.8 delete hop

Function

The **delete hop** command deletes a specified node from an MPLS TE explicit path.

Format

delete hop *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of an interface on a node.	In dotted decimal notation.

Views

Explicit path view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following commands are used to adjust nodes on a created explicit path:

- The **add hop** command is used to add a node to the explicit path.
- The **modify hop** command is used to delete a node from the explicit path and replace the node with a specified node.
- The **delete hop** command is used to delete a node from the explicit path.

Follow-up Procedure

Run the **display explicit-path** command to view information about the explicit path.

Precautions

A node can be deleted from an explicit path using the **delete hop** command only when the following conditions are met:

- The node must exist on the explicit path
- If an explicit path over which a TE tunnel has been established is modified, the make-before-break mechanism is triggered, and a CR-LSP is reestablished without traffic loss.

Example

Delete the node of 10.10.10.10 from the MPLS TE explicit path.

```
<HUAWEI> system-view
[HUAWEI] explicit-path p1
[HUAWEI-explicit-path-p1] list hop
 Path Name : p1         Path Status : Enabled
 1       2.2.2.2            Strict       Include
 2       10.10.10.10        Strict       Include
 3       10.20.20.20        Strict       Include
[HUAWEI-explicit-path-p1] delete hop 10.10.10.10
```

```
[HUAWEI-explicit-path-p1] list hop
 Path Name : p1         Path Status : Enabled
 1       2.2.2.2           Strict       Include
 2       10.20.20.20        Strict       Include
```

9.3.9 display default-parameter mpls rsvp-te

Function

The **display default-parameter mpls rsvp-te** command displays the default parameters of MPLS RSVP-TE.

Format

display default-parameter mpls rsvp-te

Parameters

None

```

Table 9-49 Description of the display default-parameter mpls rsvp-te command output

Item	Description
Resv Confirmation Request	Whether the request for reservation confirmation is enabled.
RSVP Hello Extension	Whether the Hello extension is enabled.
GR Capability	RSVP GR capability.
GR Basic-Restart-Time	Basic RSVP GR time.
Hello Interval	Interval of Hello message.
Max Times Of Hello Misses	Maximum number of Hello messages that consecutively fail to be received.
Path/Resv Message Refresh Interval	Interval for refreshing Path or Resv messages.
Path/Resv Message Refresh Retry Times	Interval for retrying refreshing Path or Resv messages.
Challenge Retransmission Interval	Interval for resending Challenge messages.
Max Times Of Challenge Lost	Maximum number of Challenge messages that consecutively fail to be received.
Soft Preemption Timeout	The timeout of soft preemption
SRefresh Feature	Whether Srefresh is enabled.
Authentication Feature	Whether authentication is enabled.
BFD Feature	Whether BFD is enabled.
Hello Feature	Whether the Hello feature is enabled.
BFD Min-Tx	Actual interval for sending BFD packets.
BFD Min-Rx	Actual interval for receiving BFD packets.
BFD Detect-Multi	Actual local BFD detection multiplier.
MPLS MTU	Actual MTU value used for MPLS forwarding.
SRefresh Interval	Srefresh interval.
SRefresh Retransmission Interval	Srefresh retransmission interval.

Item	Description
SRefresh Retransmission Increment Value	Increment value of Srefresh retransmission.
Authentication Life Time	Authentication lifetime.

9.3.10 display default-parameter mpls te cspf

Function

The **display default-parameter mpls te cspf** command displays the default CSPF configurations.

Format

display default-parameter mpls te cspf

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the default configurations of CSPF, run the **display default-parameter mpls te cspf** command.

Example

Display the default CSPF configurations.

```
<HUAWEI> display default-parameter mpls te cspf
----------------------------------------------
        CSPF Default Configuration
----------------------------------------------
        Preferred-IGP : OSPF
        Failed-link Interval(Sec): 10
```

Table 9-50 Description of the display default-parameter mpls te cspf command output

Item	Description
Preferred-IGP	The IGP type whose database is in CSPF TEDB and that will be preferred for path calculation.
Failed-link Interval(Sec)	The default value of the failed link timer.

9.3.11 display default-parameter mpls te management

Function

The **display default-parameter mpls te management** command displays the default configurations of the MPLS TE management module.

Format

display default-parameter mpls te management

Parameters

None

Views

All views

```

Table 9-51 Description of the display default-parameter mpls te management command output

Item	Description
DS-TE MODE	DS-TE mode: • IETF: indicates DS-TE in IETF mode. • NON-IETF: indicates DS-TE in non-IETF mode.
Bandwidth constraint model	Bandwidth Constraints model: • RDM: indicates the Russian Dolls Model. • MAM: indicates the Maximum Allocation Model. • Extended MAM: indicates the extended Maximum Allocation Model.

Item	Description
Switch-delay time(ms)	Delay time before switching TE traffic from the primary CR-LSP to the modified CR-LSP in milliseconds.
Delete-delay time(ms)	Delay before deleting the primary CR-LSP after TE traffic is switched to the modified CR-LSP, in milliseconds.
Auto-bandwidth timer(sec)	Time interval at which the output rate of each tunnel configured with automatic bandwidth adjustment is sampled, in seconds.
FRR timer(sec)	FRR switching time, in seconds.
Path metric-type	Link metric type for path selection for tunnels.
Tie-breaking	Rule for selecting a route to the destination if multiple routes of equal cost are available.
Administrative group value	Administrative-group attribute.
TE metric value	TE metric of a link.
Bandwidth change thresholds up	Upper threshold of the bandwidth of an MPLS TE tunnel to be flooded.
Bandwidth change thresholds down	Lower threshold of the bandwidth of an MPLS TE tunnel to be flooded.
Retry timer(sec)	Time interval between attempts to establish a tunnel, in seconds.
Set priority	Setup priority.
Hold priority	Holding priority.
Default signal protocol	Signaling protocol used to set up an LSP.
Default resv-style	Resource reservation style.
Default classtype	Class type.
Reoptimization frequency(sec)	Time interval between attempts of re-optimization, in seconds.
Auto-bandwidth adjustment frequency(sec)	Time interval between attempts of automatic bandwidth adjustment, in seconds.
Auto-bandwidth max-bw	Maximum bandwidth allowed by automatic bandwidth adjustment.
Auto-bandwidth min-bw	Minimum bandwidth allowed by automatic bandwidth adjustment.
Auto-bandwidth threshold	Indicates the threshold of the difference between the new and existing bandwidth. The value is expressed in percentage.

Item	Description
Hop-limit	Maximum number of hops.
Diffserv-mode	DiffServ mode.
Default type	Default type.
TE-Class ID	TE-class ID. The value is an integer that ranges from 0 to 7.
Class Type	Service type. When the TE-class is not configured, "--" is displayed.
Priority	Preemption priority of a tunnel. The value is an integer that ranges from 0 to 7. The smaller the value, the higher tunnel preemption priority.

9.3.12 display explicit-path

Function

The **display explicit-path** command displays information about an explicit path and the tunnels using it.

Format

display explicit-path [[**name**] *path-name*] [**tunnel-interface** | **lsp-attribute** | **verbose**]

Parameters

Parameter	Description	Value
name	Displays information about the specified explicit path.	-
path-name	Specifies the explicit path name.	The value is an existing explicit path name.
tunnel-interface	Displays information about the interface of the tunnel that uses the explicit path.	-
lsp-attribute	Displays information about the LSP attribute template that uses the explicit path.	-
verbose	Displays detailed information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no path name is specified, information about all explicit paths is displayed.

Example

Display detailed information about the explicit path named p1.

```
<HUAWEI> display explicit-path p1 verbose
Path Name : p1          Path Status : Enabled
 1      1.1.1.1          Strict      Include
 2      2.2.2.2          Strict      Exclude
 3      3.3.3.3          Loose        Include            Outgoing
 4      4.4.4.4          Strict      Include            Incoming
 List of p2p tunnels using this path:
     Tunnel1
 Number of p2p tunnels using this path: 1
 List of lsp-attributes referring this path:
     a1
 Number of lsp-attributes referring this path: 1
```

Table 9-52 Description of the display explicit-path verbose command output

Item	Description
Path Name	Name of an explicit path.
Path Status	Status of an explicit path. ● Enabled ● Disabled
Strict	The address is a strict next hop. The address is the ingress address or the address of the node that is connected directly to the previous node.
Loose	The address is a loose next hop.
Include	The explicit path contains the node of this IP address.
Exclude	The explicit path does not contain the node of this IP address.

Item	Description
Incoming or Outgoing	Type of an interface to which the IP address belongs: ● Incoming ● Outgoing If this field is not displayed, the IP address belongs to either an outbound interface or an inbound interface.
List of p2p tunnels using this path	List of tunnels using the path.
Number of p2p tunnels using this path	Number of tunnels using the path.
List of lsp-attributes referring this path	List of CR-LSP attribute templates using the path.
Number of lsp-attributes referring this path	Number of CR-LSP attribute templates using the path.

9.3.13 display lsp-attribute

Function

The **display lsp-attribute** command displays the configurations of the CR-LSP attribute template and the tunnels using it.

Format

display lsp-attribute [**name** *lsp-attribute-name*] [**tunnel-interface** | **verbose**]

Parameters

Parameter	Description	Value
name *lsp-attribute-name*	Specifies the name of the CR-LSP attribute template.	The value is an existing CR-LSP attribute template name.
tunnel-interface	Displays information about the interface of the tunnel that uses the explicit path.	-
verbose	Displays detailed information about the CR-LSP attribute template, including information about the tunnels using it.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the name of the CR-LSP attribute template is not specified, information about all CR-LSP attribute templates is displayed in the command output.

Example

Display information about the tunnel-interface using the attribute templates of lspattr1.

```
<HUAWEI> display lsp-attribute name lspattr1 tunnel-interface
lsp-attribute Name : lspattr1
explicit-path 2
commit
List of tunnels using this lsp-attribute:
    Tunnel1                        Tunnel2
Number of tunnels using this lsp-attribute: 2
```

Display detailed information about all CR-LSP attribute templates.

```
<HUAWEI> display lsp-attribute verbose

lsp-attribute Name : lsp-attribute-name11
bandwidth ct0 100
explicit-path path-name
affinity property 2 mask 2
priority 4
hop-limit 20
record-route label
fast-reroute bandwidth
bypass-attributes bandwidth 10 priority 4
commit
List of tunnels using this lsp-attribute:
    Tunnel1                      Tunnel2
Number of tunnels using this lsp-attribute: 2
```

Table 9-53 Description of the display lsp-attribute verbose command output

Item	Description
lsp-attribute Name	Name of a CR-LSP attribute template. To set the name of a CR-LSP attribute template, run the **lsp-attribute** command.
bandwidth ct0 100	Bandwidth of the LSP of each CT configured in the CR-LSP attribute template. To set the bandwidth of the LSP of each CT configured in the CR-LSP attribute template, run the **bandwidth** command.

Item	Description
explicit-path path-name	Explicit path in the CR-LSP attribute template. To set the explicit path in the CR-LSP attribute template, run the **explicit-path** command.
affinity property 2 mask 2	Affinity property and affinity mask in a CR-LSP attribute template. To set the affinity property and affinity mask in a CR-LSP attribute template, run the **affinity property** command.
priority 4	Setup and holding priorities in a CR-LSP attribute template. To set the setup and holding priorities in a CR-LSP attribute template, run the **priority** command.
hop-limit 20	Hop limit in a CR-LSP attribute template. To set the hop limit in a CR-LSP attribute template, run the **hop-limit** command.
record-route label	Route and label storing function that is enabled in the CR-LSP attribute template. To set the route and label storing function, run the **record-route** command.
fast-reroute bandwidth	FRR enabled and bandwidth protection configured in a CR-LSP attribute template. To set the FRR and bandwidth protection in a CR-LSP attribute template, run the **fast-reroute** command.
bypass-attributes bandwidth 10 priority 4	Bypass tunnel attributes in a CR-LSP attribute template. To set the bypass tunnel attributes in a CR-LSP attribute template, run the **bypass-attributes** command.
commit	Committing configurations of a CR-LSP attribute template. To set the committing configurations of a CR-LSP attribute template, run the **commit** command.

Item	Description
List of tunnels using this lsp-attribute	List of tunnels that use a CR-LSP attribute template.
Number of tunnels using this lsp-attribute	Number of tunnels that use a CR-LSP attribute template.

9.3.14 display mpls aps statistics global

Function

The **display mpls aps statistics global** command displays statistics about MPLS TE tunnel protection group.

Format

display mpls aps statistics global

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After MPLS TE tunnel protection groups are configured, this command can be used to view statistics about these MPLS TE tunnel protection groups.

Example

Display statistics about MPLS TE tunnel protection groups.

```
<HUAWEI> display mpls aps statistics global
  Max APS Instance Num                   :  10240
  Created APS Instance Num               :  2
```

Table 9-54 Description of the **display mpls aps statistics global** command output

Item	Description
Max APS Instance Num	Maximum number of supported APS instances

Item	Description
Created APS Instance Num	Number of created MPLS TE tunnel protection groups

9.3.15 display mpls lsp attribute

Function

The **display mpls lsp attribute** command displays information about the local bypass LSP attributes.

Format

display mpls lsp attribute { **bypass-inuse** { **exists-not-used** | **inuse** | **not-exists** } | **bypass-tunnel** *tunnel-name* }

Parameters

Parameter	Description	Value
bypass-inuse	Displays the attribute of the bypass LSPs in use.	-
exists-not-used	Displays the attributes of the existing bypass LSPs that are not in use.	-
inuse	Displays the attribute of the bypass LSPs in use.	-
not-exists	Displays the attributes of the bypass LSPs that are not in use.	-
bypass-tunnel	Displays the attribute of the specified bypass tunnel.	-
tunnel-name	Specifies the name of the bypass tunnel.	The value is an existing tunnel name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mpls lsp attribute** command to view information about attributes of local bypass LSPs in the TE FRR scenarios.

Example

Display information about attributes of the existing bypass LSPs that are not in use.

```
<HUAWEI> display mpls lsp attribute bypass-inuse exists-not-used
-------------------------------------------------------------------------------
                 LSP Information: RSVP LSP
-------------------------------------------------------------------------------

 Bed-State           :  ---
 Bed-LastNotifyValue :  ---
 Bed-LastNotifyLspId :  ---
```

Table 9-55 Description of the display mpls lsp attribute command output

Item	Description
No	Sequence number of an LSP.
SessionID	Session ID of a CR-LSP.
IngressLsrID	Ingress LSR ID of a CR-LSP.
LocalLspID	Local LSP ID of a CR-LSP.
Tunnel-Interface	Tunnel interface.
Fec	Forwarding Equivalence Class, which is destination address of an LSP.
TunnelTableIndex	Index of a tunnel table.
Nexthop	IP address of the next hop of an LSP.
In-Label	Value of an incoming label.
Out-Label	Value of an outgoing label.
In-Interface	Name of an incoming interface.
Out-Interface	Name of an outgoing interface.

Item	Description
LspIndex	Index number of an LSP, which uniquely identifies an LSP that is established using a specified protocol.
Token	LSP token, which guides the packet forwarding.
LsrType	Role of an LSR on an LSP: ● Ingress ● Transit ● Egress
Mpls-Mtu	Maximum transmission unit (MTU) of an interface of an LSP.
TimeStamp	Time elapsed since an LSP was set up.
Bfd-State	BFD status.
CBfd-Event	BFD-reported error code event received on the ingress of an RSVP LSP.
Bed-State	Error code status received on the ingress of an RSVP LSP.
Bed-LastNotifyValue	Event of association relationship related to error codes informed on the egress of an RSVP LSP.
Bed-LastNotifyLspId	ID of a reverse LSP when an event of association relationship related to error codes is informed on the egress of an RSVP LSP.

9.3.16 display mpls rsvp-te

Function

The **display mpls rsvp-te** command displays the RSVP-TE configurations.

Format

display mpls rsvp-te

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When configuring a dynamic MPLS TE tunnel, you can run the **display mpls rsvp-te** command to view RSVP-TE configurations.

Example

Display information about RSVP-TE.

```
<HUAWEI> display mpls rsvp-te
 LSR ID: 1.1.1.9
 RSVP-TE Function Capability: Enable
 Resv Confirmation Request: DISABLE
 RSVP Hello Extension: ENABLE
 Hello interval: 3 sec         Max Hello misses: 3
 Path and Resv message refresh interval: 30 sec
 Path and Resv message refresh retries count: 3
 Blockade Multiplier: 4
 Graceful-Restart Capability: GR-Support GR-Self
 Restart Time:  90000 Millisecond
 Recovery Time: 0 Millisecond
 Bfd Enabled: DISABLE                  Bfd Min-Tx: 1000
 Bfd Min-Rx: 1000                      Bfd Detect-Multi: 3
 Soft Preemption Timeout: 30 sec
```

Table 9-56 Description of the display mpls rsvp-te command output

Item	Description
LSR ID	LSR ID in the format X.X.X.X.
RSVP-TE Function Capability	Whether RSVP-TE is enabled. To enable the RSVP-TE function, run the **mpls rsvp-te** command.
Resv Confirmation Request	Whether reservation confirmation is requested. To enable the reservation confirmation mechanism, run the **mpls rsvp-te resvconfirm** command.
RSVP Hello Extension	Whether the RSVP Hello extension is enabled. To enable the RSVP Hello extension, run the **mpls rsvp-te hello** command.
Hello interval	The interval at which Hello messages are sent, in seconds. To specify the interval, run the **mpls rsvp-te timer hello** command.
Max Hello misses	Maximum number of times for the consecutively lost Hello messages. To specify the maximum number, run the **mpls rsvp-te hello-lost** command.
Path and Resv message refresh interval	Time interval at which the Path and Resv messages are refreshed, in seconds. To specify the interval, run the **mpls rsvp-te timer refresh** command.

Item	Description
Path and Resv message refresh retries count	Number of retry times allowed for refreshing the Path and Resv messages. To specify the number, run the **mpls rsvp-te keep-multiplier** command.
Blockade Multiplier	Multiplier for keeping the blocked state.
Graceful-Restart Capability	RSVP GR capability of a device: ● GR-Support GR-Self: indicates that the RSVP GR on the local node is enabled and the RSVP GR of the neighbor is supported. ● GR-Self: indicates that the RSVP GR is enabled only on the local node. ● GR-Support: indicates that the RSVP GR of the neighbor is supported. ● DISABLE: indicates that the RSVP GR is disabled. To enable the RSVP GR capability, run the **mpls rsvp-te hello support-peer-gr** command or**mpls rsvp-te hello full-gr** command.
Restart Time	Start time of the GR process, in milliseconds. It is displayed only after the command **mpls rsvp-te hello basic-restart-time** is run.
Recovery Time	Time spent on recovering all LSPs, in milliseconds. It is displayed only after the command **mpls rsvp-te hello basic-restart-time** is run.
Bfd Enabled	Whether the BFD for RSVP is enabled globally in the MPLS view: ● ENABLE: indicates that BFD for RSVP is globally enabled in the MPLS view. ● DISABLE: indicates that BFD for RSVP is globally disabled in the MPLS view. To enable the BFD for RSVP function, run the **mpls rsvp-te bfd all-interfaces enable** command.
Bfd Min-Tx	Local interval at which BFD packets are sent, in milliseconds. To specify the interval, run the **mpls rsvp-te bfd all-interfaces** command.

Item	Description
Bfd Min-Rx	Local interval at which BFD packets are received, in milliseconds. To specify the interval, run the **mpls rsvp-te bfd all-interfaces** command.
Bfd Detect-Multi	Local BFD detection multiplier. To specify the multiplier, run the **mpls rsvp-te bfd all-interfaces** command.
Soft Preemption Timeout	Timeout period of soft preemption.

9.3.17 display mpls rsvp-te bfd session

Function

The **display mpls rsvp-te bfd session** command displays information about the BFD session for RSVP.

Format

display mpls rsvp-te bfd session { **all** | **interface** *interface-type interface-number* | **peer** *ip-address* } [**verbose**]

Parameters

Parameter	Description	Value
all	Displays information about all the BFD sessions for RSVP.	-
interface *interface-type interface-number*	Displays information about the BFD session for RSVP on the specified interface.	-
peer *ip-address*	Displays information about the BFD session for RSVP of the specified peer.	The value is in dotted decimal notation.
verbose	Displays detailed information about a BFD session for RSVP.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the information about the BFD session for RSVP, run the **display mpls rsvp-te bfd session** command.

Example

Display information about a BFD session for RSVP.

```
<HUAWEI> display mpls rsvp-te bfd session all
Total Nbrs/Rsvp triggered sessions : 1/1
--------------------------------------------------------------------
Local    Remote   Local       Peer        Interface    Session
Discr    Discr    Addr        Addr        Name         State
--------------------------------------------------------------------
8192     8192     10.1.1.1    10.1.1.2    VLANIF100    UP
```

Display detailed information about a BFD session for RSVP.

```
<HUAWEI> display mpls rsvp-te bfd session all verbose
Total Nbrs/Rsvp triggered sessions : 1/1
--------------------------------------------------------------------
  Local Discriminator     :  8192
  Remote Discriminator    :  8192
  Local Address           :  10.1.1.1
  Peer Address            :  10.1.1.2
  Interface Name          :  VLANIF100
  ActTx                   :  1000
  ActRx                   :  1000
  ActMulti                :  3
  Session State           :  UP
```

Table 9-57 Description of the display mpls rsvp-te bfd session command output

Item	Description
Total Nbrs/Rsvp triggered sessions	Number of BFD neighbors or RSVP-triggered sessions in the system or interface view.
Local Discr/Local Discriminator	Local discriminator of a BFD session. The value 0 indicates an invalid discriminator. To specify a local discriminator of a BFD session, run the **discriminator** command.
Remote Discr/ Remote Discriminator	Remote discriminator of a BFD session. The value 0 indicates an invalid discriminator. To specify a remote discriminator of a BFD session, run the **discriminator** command.
Local Addr/Local Address	IP address of the local node in a BFD session.
Peer Addr/Peer Address	IP address of the peer in a BFD session.
Interface Name	Outgoing interface of a BFD session.

Item	Description
ActTx/ActRx/ActMulti	Parameters of a BFD session: To specify parameters of a BFD session, run the **mpls rsvp-te bfd all-interfaces** command. ● ActTx: indicates the actual interval at which BFD packets are sent, in milliseconds. ● ActRx: indicates the actual interval at which BFD packets are received, in milliseconds. ● ActMulti: indicates the actual local detection multiplier. The default value is 3.
Session State	Status of a BFD session: ● UP: indicates that the BFD session is Up. ● DOWN: indicates that the BFD session is Down. ● NONE: indicates that no BFD session is created. ● ADMIN DOWN: indicates that the administrator manually closes the BFD session. ● INITIAL: indicates the BFD session is in the Initial state.

9.3.18 display mpls rsvp-te established

Function

The **display mpls rsvp-te established** command displays information about RSVP resource reservation based on an interface, and about the RSVP-TE LSPs that pass through the interface.

Format

display mpls rsvp-te established [**interface** *interface-type interface-number peer-ip-address*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Parameter	Description	Value
peer-ip-address	Specifies the IP address of an interface on the RSVP peer connected to the local device.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If an interface is specified, information about the establishment of the RSVP-TE LSP on this interface is displayed.

Example

Display information about the establishment of the RSVP-TE LSPs of all interfaces.

```
<HUAWEI> display mpls rsvp-te established
Interface: Outgoing-Interface at the Egress
 Token Bucket Rate: 0.00            Peak Data Rate: 0.00
 Tunnel Addr: 10.1.1.9              Ingress LSR ID: 10.3.3.9
 Local LSP ID: 4                    Session Tunnel ID: 301
 Next Hop Addr:  -----
 Upstream Label: 3

 Token Bucket Rate: 0.00            Peak Data Rate: 0.00
 Tunnel Addr: 10.1.1.9              Ingress LSR ID: 10.3.3.9
 Local LSP ID: 4                    Session Tunnel ID: 300
 Next Hop Addr:  -----
 Upstream Label: 3

 Token Bucket Rate: 0.00            Peak Data Rate: 0.00
 Tunnel Addr: 10.3.3.9              Ingress LSR ID: 10.1.1.9
 Local LSP ID: 3                    Session Tunnel ID: 300
 Next Hop Addr: 172.16.1.2
 Upstream Label: NULL               Downstream Label: 1040

 Token Bucket Rate: 0.00            Peak Data Rate: 0.00
 Tunnel Addr: 10.3.3.9              Ingress LSR ID: 10.1.1.9
 Local LSP ID: 2                    Session Tunnel ID: 301
 Next Hop Addr: 172.16.1.2
 Upstream Label: NULL               Downstream Label: 1038
```

Table 9-58 Description of the display mpls rsvp-te established command output

Item	Description
Interface: Outgoing-Interface at the Egress	Information about RSVP resource reservation based on the outgoing interface on the egress node and about the RSVP LSPs that pass through the interface.
Token Bucket Rate	Token bucket rate, in byte/s.
Peak Data Rate	Peak data rate, in byte/s.
Tunnel Addr	Tunnel address in the format X.X.X.X.
Ingress LSR ID	LSR ID on the ingress in the format X.X.X.X.
Local LSP ID	Local LSP ID.
Session Tunnel ID	Tunnel ID.
Next Hop Addr	Next-hop address in the format X.X.X.X.
Upstream Label	Value of an incoming label.
Downstream Label	Value of an outgoing label.

9.3.19 display mpls rsvp-te graceful-restart

Function

The **display mpls rsvp-te graceful-restart** command displays the status of RSVP GR.

Format

display mpls rsvp-te graceful-restart

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After completing the RSVP GR configuration, you can run the **display mpls rsvp-te graceful-restart** command to view the RSVP-TE GR status.

Example

Display the status of RSVP-TE GR.

```
<HUAWEI> display mpls rsvp-te graceful-restart
Display Mpls Rsvp te graceful restart information
 LSR ID: 1.1.1.9
 Graceful-Restart Capability:   GR-Self GR-Support
 Restart Time:  90000 Milli Second
 Recovery Time: 0 Milli Second
 GR Status:  Gracefully Restart Not going on
 Number of Restarting neighbors: 0
 Number of LSPs recovered: 0
 Received Gr Path message count: 0
 Send Gr Path message count: 0
 Received RecoveryPath message count: 0
 Send RecoveryPath message count: 0
```

Table 9-59 Description of the display mpls rsvp-te graceful-restart command output

Item	Description
LSR ID	LSR ID.
Graceful-Restart Capability	RSVP GR capability of a device.
Restart Time	Restart time for a device, in milliseconds. To set the restart time, run the **mpls rsvp-te hello basic-restart-time** command.
Recovery Time	Time spent on recovering all LSPs, in milliseconds. To set the recovery time, run the **mpls rsvp-te hello basic-restart-time** command.
GR Status	RSVP GR status of the local device: ● Gracefully Restart Not going on: indicates that the protocol is not entering the GR process. ● Gracefully Restart on going restarting: indicates that the protocol has entered the GR process. ● Gracefully Restart on going recovery: indicates that the configurations are being restored.
Number of Restarting neighbors	Number of supporting nodes.
Number of LSPs recovered	Number of recovered LSPs.
Received Gr Path message count	Number of Path messages received by restarting nodes.

Item	Description
Send Gr Path message count	Number of Path messages sent by supporting nodes.
Received RecoveryPath message count	Number of Recovery Path messages received by restarting nodes.
Send RecoveryPath message count	Number of Recovery Path messages sent by supporting nodes.

9.3.20 display mpls rsvp-te graceful-restart peer

Function

The **display mpls rsvp-te graceful-restart peer** command displays the status of RSVP GR on a neighbor.

Format

display mpls rsvp-te graceful-restart peer [{ **interface** *interface-type interface-number* | **node-id** } [*ip-address*]]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the RSVP GR status of a neighbor on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
node-id	Displays the RSVP GR status of a manually-configured neighbor.	-
ip-address	Specifies the IP addresses of a neighbor.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the RSVP-TE GR status of a specified RSVP neighbor, run the **display mpls rsvp-te graceful-restart peer** command.

Example

Display the RSVP-TE GR status of the neighbor.

```
<HUAWEI> display mpls rsvp-te graceful-restart peer
 Neighbor on Interface Vlanif100
 Neighbor Addr: 172.16.1.2             Last Attribute: Added Usually
 SrcInstance: 0x7C832B3D               NbrSrcInstance: 0x6A48E0F5
 Neighbor Capability:
                  Can Do Self GR
                  Can Support GR
 GR Status:          Normal
 Restart Time:  90000 Millisecond
 Recovery Time: 0 Millisecond
 Stored GR message number: 0
 PSB Count: 0                          RSB Count: 1
 Total to be Recover PSB Count: 0      Recovered PSB Count: 0
 Total to be Recover RSB Count: 0      Recovered RSB Count: 0
 P2MP PSB Count: 0                     P2MP RSB Count: 0
 Total to be Recover P2MP PSB Count: 0      Recovered P2MP PSB Count: 0
 Total to be Recover P2MP RSB Count: 0      Recovered P2MP RSB Count: 0
```

Table 9-60 Description of the display mpls rsvp-te graceful-restart peer command output

Item	Description
Neighbor Addr	IP address of a neighbor.
Last Attribute	Neighbor attribute: ● Added Usually: indicates the neighbor is discovered based on an interface. ● Added by Node-Id: indicates the neighbor is discovered based on the configured node ID. ● To be deleted: indicates the neighbor that is to be deleted because of the Hello timeout. ● Add by Frr: indicates an FRR neighbor.
SrcInstance	Source instance.
NbrSrcInstance	Source instance of a neighbor.

Item	Description
Neighbor Capability	GR capability of a neighbor: - Can Do Self GR: indicates that the neighbor can perform GR. - Can Support GR: indicates that the neighbor has the capability of supporting GR. - Can Transmit Recovery Path Messages: indicates that the neighbor can send Recovery Path messages. - No Gr capabilities: indicates that the neighbor does not have the capability of supporting GR.
GR Status	GR status of a neighbor: - Normal: indicates that the neighbor does not perform GR. - Supporting: indicates that the neighbor is supporting the local node of performing GR. - Restarting: indicates that the neighbor is supporting the local node of the restart.
Restart Time	Restart time of a neighbor, in milliseconds.
Recovery Time	Recovery time of a neighbor, in milliseconds.
Stored GR message number	Number of GR messages stored on the supporting node.
PSB Count	Number of PSBs.
RSB Count	Number of RSBs.
Total to be Recover PSB Count	Total number of the PSBs to be recovered.
Recovered PSB Count	Number of the recovered PSBs.
Total to be Recover RSB Count	Total number of the RSBs to be recovered.
Recovered RSB Count	Number of recovered RSBs.
P2MP PSB Count	Number of P2MP PSBs
P2MP RSB Count	Number of P2MP RSBs
Total to be Recover P2MP PSB Count	Number of P2MP PSBs to be restored after the GR process is complete
Recovered P2MP PSB Count	Number of P2MP PSBs that have been restored after the GR process is complete
Total to be Recover P2MP RSB Count	Number of P2MP RSBs to be restored after the GR process is complete

Item	Description
Recovered P2MP RSB Count	Number of P2MP RSBs that have been restored after the GR process is complete

9.3.21 display mpls rsvp-te interface

Function

The **display mpls rsvp-te interface** command displays the RSVP-TE configurations on an interface.

Format

display mpls rsvp-te interface [*interface-type interface-number*]

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the interface type and number. • *interface-type* specifies the interface type. • *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If the type and number of an interface is not specified, the **display mpls rsvp-te interface** command displays the RSVP-TE information of all RSVP TE-enabled interfaces.

Example

Display information about RSVP-TE of a specified interface.

```
<HUAWEI> display mpls rsvp-te interface vlanif 100
Interface: Vlanif100
 Interface Address: 11.11.11.11
 Interface state: UP                  Interface Index: 0x4
 Total-BW: 0                        Used-BW: 0
 Hello configured: NO                 Num of Neighbors: 0
 SRefresh feature: DISABLE             SRefresh Interval: 30 sec
 Mpls Mtu: 1500                      Retransmit Interval: 5000 msec
```

```
Increment Value: 1
Authentication: DISABLE
Bfd Enabled: DISABLE              Bfd Min-Tx: 400
Bfd Min-Rx: 300                 Bfd Detect-Multi: 4
```

Table 9-61 Description of the display mpls rsvp-te interface command output

Item	Description
Interface	Name of a tunnel interface.
Interface Address	IP address of an interface.
Interface state	Interface status: - UP - DOWN
Interface Index	Index of an interface.
Total-BW	Total available bandwidth of an interface, in kbit/s.
Used-BW	Total bandwidth of an interface in use, in kbit/s.
Hello configured	Whether the Hello feature is configured on an interface: - YES: indicates that the Hello feature is configured. - NO: indicates that the Hello feature is not configured.
Num of Neighbors	Number of neighbor devices of the local node.
SRefresh feature	Whether the Srefresh feature is enabled. To enable the Srefresh feature, run the **mpls rsvp-te srefresh** command in the interface view.
SRefresh Interval	Value of the Srefresh timer, in seconds. To specify the value of the Srefresh timer, run the **mpls rsvp-te timer refresh** command.
Mpls Mtu	MTU value used in MPLS forwarding.
Retransmit Interval	Value of the Retransmit timer, in milliseconds. To specify the value of the Retransmit timer, run the **mpls rsvp-te timer retransmission** command.
Increment Value	Retransmission increment. To specify the retransmission increment, run the **mpls rsvp-te timer retransmission** command.

Item	Description
Authentication	Whether the authentication function is enabled: ● ENABLE: indicates that the authentication function is enabled. ● DISABLE: indicates that the authentication function is disabled. To enable the authentication function, run the **mpls rsvp-te authentication** command.
Bfd Enabled	Whether BFD for RSVP is enabled on the interface: ● ENABLE: indicates that BFD for RSVP is enabled on the interface. ● DISABLE: indicates that BFD for RSVP is not enabled on the interface. To enable BFD for RSVP, run the **mpls rsvp-te bfd enable** command.
Bfd Min-Tx	Local interval at which BFD packets are sent, in milliseconds. To specify the local minimum interval at which BFD packets are sent, run the **mpls rsvp-te bfd** command.
Bfd Min-Rx	Local interval at which BFD packets are received, in milliseconds. To specify the local minimum interval at which BFD packets are received, run the **mpls rsvp-te bfd** command.
Bfd Detect-Multi	Local BFD detection multiplier. To specify the local BFD detection multiplier, run the **mpls rsvp-te bfd** command.

9.3.22 display mpls rsvp-te peer

Function

The **display mpls rsvp-te peer** command displays information about RSVP-TE neighbor devices on an RSVP-TE-enabled interface.

Format

display mpls rsvp-te peer [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about RSVP-TE of a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no interface is specified, information about RSVP-TE neighbors of all interfaces is displayed.

Example

Display information about RSVP-TE neighbors of all interfaces.

```
<HUAWEI> display mpls rsvp-te peer
 Remote Node id Neighbor
 Neighbor Addr:  -----
 SrcInstance: 0x3A76A0FA              NbrSrcInstance: 0x0
 PSB Count: 2                    RSB Count: 2
 Hello Type Sent: REQ
 SRefresh Enable: NO
 Last valid seq # rcvd: NULL

Interface: Vlanif10
 Neighbor Addr: 172.16.1.2
 SrcInstance: 0x3A76A0FA              NbrSrcInstance: 0x22A6B5C2
 PSB Count: 2                    RSB Count: 2
 Hello Type Sent: REQ              Neighbor Hello Extension: ENABLE
 SRefresh Enable: NO
 Last valid seq # rcvd: NULL
```

Table 9-62 Description of the display mpls rsvp-te peer command output

Item	Description
Neighbor Addr	Neighboring device address.
SrcInstance	Source instance.
NbrSrcInstance	Source instance of a neighbor device.
PSB Count	Number of Path State Blocks (PSBs).
RSB Count	Number of Reservation State Blocks (RSBs).

Item	Description
Hello Type Sent	Type of Hello message sent to the neighbor device: - REQ - ACK - NONE
Neighbor Hello Extension	Whether the Hello extension feature of the neighboring device is enabled.
SRefresh Enable	Whether the Srefresh mechanism is enabled: - YES - NO
Last valid seq # rcvd	Serial number of the valid RSVP message last received.

9.3.23 display mpls rsvp-te psb-content

Function

The **display mpls rsvp-te psb-content** command displays information about an RSVP TE Path State Block (PSB).

Format

display mpls rsvp-te psb-content [*ingress-lsr-id tunnel-id lsp-id*]

Parameters

Parameter	Description	Value
ingress-lsr-id	Specifies the LSR ID of the ingress.	The value is in dotted decimal notation.
tunnel-id	Specifies the tunnel ID.	The value is an integer that ranges from 0 to 65535.
lsp-id	Specifies the LSP ID.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no parameter is specified, information about all RSVP-TE PSBs is displayed.

Example

Display information about the PSB.

```
<HUAWEI> display mpls rsvp-te psb-content 10.1.1.9 100 7

Table 9-63 Description of the display mpls rsvp-te psb-content command output

Item	Description
Tunnel Addr	Tunnel address in the format X.X.X.X.
Exist time	Duration that an LSP has been established.
Tunnel ExtID	Tunnel extended ID.
Session ID	RSVP session ID

Item	Description
Ingress LSR ID	Ingress address in the format X.X.X.X.
Local LSP ID	Local LSP ID.
Previous Hop	Previous-hop address in the format X.X.X.X.
Next Hop	Next-hop address in the format X.X.X.X.
Incoming / Outgoing Interface	Incoming or outgoing interface through which a tunnel passes on the local device.
InLabel	Value of an incoming label.
OutLabel	Value of an outgoing label.
Send Message ID	ID of the sent refresh reduction message.
Recv Message ID	ID of the received refresh reduction message.
Refresh Timer	Refresh timer.
Cleanup Timer	Timeout timer.
Session Attribute	Attribute of an RSVP session.
SetupPrio	Setup priority of an RSVP session.
HoldPrio	Holding priority of an RSVP session.
SessionAttrib	RSVP session attributes, such as resource reservation style.
LSP Type	Type of LSP.
FRR Flag	State of MPLS TE FRR
Local RRO Flag	Flag bit of the local RRO.
ERO Information	Information about the Explicit Route Object (ERO).
L-Type	Types of the explicit route.
ERO-IPAddr	Explicit route address.
ERO-PrefixLen	Explicit route prefix length.
RRO Information	Information about the Record Route Object (RRO).
RRO-CType	RRO of the C type, IPv4 or label.
IPAddress	IP address of a record route.
PrefixLen	Prefix length of a recorded route.
Flag	Flag bit of a recorded route.

Item	Description
SenderTspec Information	Information about the traffic specification of the sender.
Token bucket rate	Token bucket rate, in byte/s.
Token bucket size	Token bucket size.
Peak data rate	Peak data rate, in byte/s.
Minimum policed unit	Minimum policed unit.
Maximum packet size	Maximum packet size.
Path Message arrive on	Incoming interfaces and previous-hop addresses of messages.
Path Message sent to NHOP	Next-hop addresses and outgoing interfaces of messages.
Resource Reservation OK	Ready state of resource reservation that is displayed only when the resource reserved flag is set.
LSP Statistics Information	Statistics of LSPs.
SendPacketCounter	Number of sent packets.
RecvPacketCounter	Number of received packets.
SendPathCounter	Number of sent Path messages.
RecvPathCounter	Number of received Path messages.
SendResvCounter	Number of sent Resv messages.
RecvResvCounter	Number of received Resv messages.

9.3.24 display mpls rsvp-te request

Function

The **display mpls rsvp-te request** command displays information about the RSVP-TE request messages on interfaces.

Format

display mpls rsvp-te request [**interface** *interface-type interface-number peer-ip-address*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about RSVP TE request messages on a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
peer-ip-address	Specifies the IP address of a neighbor device.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no interface name is specified, the command displays information about the RSVP-TE request information of all RSVP-TE-enabled interfaces.

Example

Display information about RSVP-TE of a specified interface.

```
<HUAWEI> display mpls rsvp-te request interface vlanif 10 172.16.1.1
Interface: Vlanif10
 Tunnel Addr: 10.2.2.9              Ingress LSR ID: 10.1.1.9
 Local LSP ID: 0                   Session Tunnel ID: 100
 NextHopAddr:  -----
 SessionAttrib: Label Recording desired. SE Style desired.
 Token bucket rate: 0.00             Token bucket size: 1000.00
 Out Interface:  -----
```

Table 9-64 Description of the display mpls rsvp-te request command output

Item	Description
Interface	Name of the interface that is enabled with RSVP-TE.
Tunnel Addr	Tunnel destination address in the format X.X.X.X.
Ingress LSR ID	LSR ID of the ingress node in the format X.X.X.X.

Item	Description
Local LSP ID	Local identifier of an LSP.
Session Tunnel ID	Tunnel ID
NextHopAddr	Next-hop address in the format X.X.X.X.
SessionAttrib	Session attribute: ● Local protection desired ● Label record desired ● Resource reservation style
Token bucket rate	Token bucket rate.
Token bucket size	Token bucket size.
Out Interface	Outgoing interface of an LSP.

9.3.25 display mpls rsvp-te reservation

Function

The **display mpls rsvp-te reservation** command displays RSVP-TE resource reservation information of an interface enabled with RSVP-TE.

Format

display mpls rsvp-te reservation [**interface** *interface-type interface-number peer-ip-address*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays the RSVP-TE reservation information of the interface that is not in stale state. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
peer-ip-address	Specifies the IP address of an RSVP-TE neighbor device.	-

Views

 Local LSP ID: 2                   Session Tunnel ID: 301
 Upstream Label: NULL
 Token bucket rate: 0.00           Token bucket size: 1000.00
```

Table 9-65 Description of the display mpls rsvp-te reservation command output

Item	Description
Interface	Name of the interface that is enabled with RSVP-TE
Tunnel Addr	Tunnel destination address in the format X.X.X.X.
Ingress LSR ID	LSR ID of the ingress node in the format X.X.X.X.
Local LSP ID	Local identifier of an LSP.
Session Tunnel ID	Tunnel ID.
Upstream Label	Incoming label.
Token bucket rate	Token bucket rate.
Token bucket size	Token bucket size.

9.3.26 display mpls rsvp-te rsb-content

Function

The **display mpls rsvp-te rsb-content** command displays information about the RSVP TE Reserve State Block (RSB).

Format

display mpls rsvp-te rsb-content [*ingress-lsr-id tunnel-id lsp-id*]

Parameters

Parameter	Description	Value
ingress-lsr-id	Specifies the ingress LSR ID.	The value is in dotted decimal notation.
tunnel-id	Specifies the tunnel ID.	The value is an integer that ranges from 0 to 65535.
lsp-id	Specifies the LSP ID.	The value is an integer that ranges from 0 to 65535.

Views

Resv Message arrive on Vlanif100 from NHOP 172.16.1.2
```

Table 9-66 Description of the display mpls rsvp-te rsb-content command output

Item	Description
Tunnel Addr	Tunnel destination address in the format X.X.X.X.
Session Tunnel ID	Tunnel ID.
Tunnel ExtID	Tunnel extension ID (ingress LSR ID) in the format X.X.X.X.
Next Hop	Next-hop address in the format X.X.X.X.
Reservation Style	Reservation style: ● SE ● FF
Reservation Incoming Interface	Incoming interface for the reservation message.
Reservation Interface	Name of the interface on which bandwidth is reserved.
Message ID	ID of the Refresh Reduction message.
Filter Spec Information	Filtering conditions.
The filter number	Total number of filters.
Ingress LSR ID	LSR ID of the ingress node in the format X.X.X.X.
Local LSP ID	Local identifier of an LSP.
OutLabel	Outgoing label.
Cleanup Timer	Timeout timer.
RRO Information	Information about the RRO.

Item	Description
RRO-CType	Class type in the RRO: - IPv4 - Label
RRO-IPAddress	IP address in the RRO, in the format X.X.X.X.
RRO-IPPrefixLen	Length of the route prefix in the RRO.
RRO-Label	Label information in the RRO
FlowSpec Information	Traffic information including flow specifications.
Token bucket rate	Token bucket rate, in byte/s.
Token bucket size	Token bucket size.
Peak data rate	Peak data rate, in byte/s.
Minimum policed unit	Minimum policed unit.
Maximum packet size	Maximum packet size.
Bandwidth guarantees	Bandwidth guarantee.
Delay guarantees	Delay guarantee.
Qos Service	QoS guarantee/control.
Resv Message	Reservation message received on an interface.

9.3.27 display mpls rsvp-te sender

Function

The **display mpls rsvp-te sender** command displays information about an RSVP-TE enabled interface as an RSVP-TE sender.

Format

display mpls rsvp-te sender [**interface** *interface-type interface-number peer-ip-address*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of the interface receiving Path messages. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
peer-ip-address	Specifies the IP address of the outgoing interface on the previous hop sending Path messages.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If no interface name is specified, the command displays the information about all RSVP-TE enabled interfaces as RSVP-TE senders.

Example

Display information about all RSVP-TE enabled interfaces as RSVP-TE senders.

```
<HUAWEI> display mpls rsvp-te sender
Interface: Incoming-Interface at the Ingress
 Tunnel Addr: 10.3.3.9              Ingress LSR ID: 10.1.1.9
 Local LSP ID: 3                  Session Tunnel ID: 300
 Session Name: Tunnel1
 Previous Hop Address:  -----
 Token bucket rate: 0.00           Token bucket size: 1000.00

 Tunnel Addr: 10.1.1.9              Ingress LSR ID: 10.3.3.9
 Local LSP ID: 4                  Session Tunnel ID: 300
 Session Name: Tunnel1
 Previous Hop Address: 172.16.1.2
 Token bucket rate: 0.00           Token bucket size: 1000.00
```

Table 9-67 Description of the display mpls rsvp-te sender command output

Item	Description
Tunnel Addr	Tunnel destination address in the format X.X.X.X.
Ingress LSR ID	LSR ID of the ingress node in the format X.X.X.X.
Local LSP ID	Local LSP ID.

Item	Description
Session Tunnel ID	Tunnel ID.
Session Name	Name of a session.
Previous Hop Address	Previous-hop address in the format X.X.X.X.
Token bucket rate	Token bucket rate.
Token bucket size	Token bucket size.
Interface: Incoming-Interface at the Ingress	Information about the RSB functioning as the ingress on the local node.

9.3.28 display mpls rsvp-te session

Function

The **display mpls rsvp-te session** command displays all information about any specified RSVP session.

Format

display mpls rsvp-te session *ingress-lsr-id tunnel-id egress-lsr-id*

Parameters

Parameter	Description	Value
ingress-lsr-id	Specifies the ingress LSR ID.	The value is in dotted decimal notation.
tunnel-id	Specifies the tunnel ID.	The value is an integer that ranges from 0 to 65535.
egress-lsr-id	Specifies the egress LSR ID.	The value is in dotted decimal notation.

Table 9-68 Description of the display mpls rsvp-te session command output

Item	Description
The PSB Content	Contents of the PSB.
Tunnel Addr	Tunnel destination address in the format X.X.X.X.
Exist time	Time elapsed since the PSB is created.
Tunnel ExtID	Tunnel extension ID (ingress LSR ID) in the format X.X.X.X.
Session ID/ Session Tunnel ID	Tunnel ID.
Ingress LSR ID	LSR ID of the ingress node in the format X.X.X.X.
Local LSP ID	Local LSP ID.
Previous Hop	Previous-hop address in the format X.X.X.X.
Next Hop	Next-hop address in the format X.X.X.X.
Incoming / Outgoing Interface	Name of the incoming or outgoing interface.
InLabel	Value of an incoming label.
OutLabel	Value of an outgoing label.
Send Message ID	ID of the sent refresh reduction message.
Recv Message ID	ID of the received refresh reduction message.
Refresh Timer	ID of the Refresh timer.
Cleanup Timer	ID of the Cleanup timer.
Session Attribute	Attribute of a session.
SetupPrio	Setup priority of a session.

Item	Description
HoldPrio	Holding priority of a session.
SessionAttrib	Session attributes, including required local protection, bandwidth protection, node protection, label record, and reservation style.
LSP Type	Type of an LSP.
FRR Flag	Flag bit of FRR: - No protection: indicates no FRR protection. - PLR in use: provides protection on the Point of Local Repair. - MP in use: provides protection on the Merge Point. - Under protecting: provides FRR protection.
Local RRO Flag	Flag bit of the local RRO.
ERO Information	Information about the Explicit Route Object (ERO).
L-Type	Types of the explicit route: - ERHOP_STRICT - ERHOP_LOOSE
ERO-IPAddr	Explicit route address.
ERO-PrefixLen	Explicit route prefix length.
RRO Information	Information about the Record Route Object (RRO).
RRO-CType	Class C routes, including IPv4 or IPv6 addresses and labels recorded.
RRO-IPAddress	IPv4 or IPv6 address of the recorded route.
RRO-IPPrefixLen	Prefix length of a recorded route.
RRO-Label	Label information in the RRO.
SenderTspec Information	Information about the traffic specification of the sender.
Token bucket rate	Token bucket rate, in byte/s.
Token bucket size	Token bucket size.
Peak data rate	Peak data rate, in byte/s.

Item	Description
Minimum policed unit	Minimum policed unit.
Maximum packet size	Maximum packet size, in bytes.
Path Message arrive on	Pre-hop addresses and incoming interfaces of messages.
Path Message sent to	Next-hop addresses and outgoing interfaces of messages.
Resource Reservation OK	Displayed only when the resource reservation flag is set.
LSP Statistics Information	Statistics of LSPs.
SendPacketCounter	Number of sent packets.
RecvPacketCounter	Number of received packets.
SendPathCounter	Number of sent Path messages.
RecvPathCounter	Number of received Path messages.
SendResvCounter	Number of sent Resv messages.
RecvResvCounter	Number of received Resv messages.
The RSB Content	Number of Reservation State Blocks (RSBs).
Reservation Style	Reservation style: ● SE: Shared Explicit Style ● FF: Fixed-Filter Style
Reservation Incoming Interface	Incoming interface for the reservation message.
Reservation Interface	Name of the interface on which bandwidth is reserved.
Message ID	Message ID locally allocated, used in the Srefresh feature and reliability.
Filter Spec Information	Filtering conditions.
The filter number	Total number of filters.
FlowSpec Information	Information about flow specifications.
Bandwidth guarantees	Bandwidth guarantee.
Delay guarantees	Delay guarantee.
Qos Service is Controlled	QoS guarantee.
Resv Message arrive on	Incoming interfaces and previous-hop addresses of messages.

9.3.29 display mpls rsvp-te statistics

Function

The **display mpls rsvp-te statistics** command displays statistics on RSVP-TE.

Format

display mpls rsvp-te statistics { **global** | **interface** [*interface-type interface-number*] }

Parameters

Parameter	Description	Value
global	Displays the global statistics on RSVP-TE.	-
interface	Displays statistics on RSVP-TE on all interface that enabled RSVP-TE function.	-
interface-type interface-number	Displays statistics on RSVP-TE on a specified interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the statistics on RSVP-TE, run the **display mpls rsvp-te statistics** command.

Example

Display the global RSVP-TE statistics.

```
<HUAWEI> display mpls rsvp-te statistics global
 LSR ID: 10.1.1.1                    LSP Count: 0

Table 9-69 Description of the display mpls rsvp-te statistics command output

Item	Description
LSR ID	Local LSR ID.
PSB Count	Number of PSBs.
RSB Count	Number of RSBs.
RFSB Count	Number of RFSBs.
LSP Count	Number of LSPs established through RSVP TE.
Total Statistics Information	Total statistics information.
PSB CleanupTimeOutCounter	Number of times that the PSB is reset after the timer expires.
RSB CleanupTimeOutCounter	Number of times that the RSB is reset after the timer expires.
SendPacketCounter	Number of sent packets.
RecPacketCounter	Number of received packets.
SendCreatePathCounter	Number of sent CreatePath messages.
RecCreatePathCounter	Number of received CreatePath messages.
SendRefreshPathCounter	Number of sent RefreshPath messages.
RecRefreshPathCounter	Number of received RefreshPath messages.
SendCreateResvCounter	Number of sent CreateResv messages.
RecCreateResvCounter	Number of received CreateResv messages.
SendRefreshResvCounter	Number of sent RefreshResv messages.
RecRefreshResvCounter	Number of received RefreshResv messages.
SendResvConfCounter	Number of sent ResvConf messages.

Item	Description
RecResvConfCounter	Number of received ResvConf messages.
SendHelloCounter	Number of sent Hello messages.
RecHelloCounter	Number of received Hello messages.
SendAckCounter	Number of sent Ack messages.
RecAckCounter	Number of received Ack messages.
SendPathErrCounter	Number of sent PathErr messages.
RecPathErrCounter	Number of received PathErr messages.
SendResvErrCounter	Number of sent ResvErr messages.
RecResvErrCounter	Number of received ResvErr messages.
SendPathTearCounter	Number of sent PathTear messages.
RecPathTearCounter	Number of received PathTear messages.
SendResvTearCounter	Number of sent ResvTear messages.
RecResvTearCounter	Number of received ResvTear messages.
SendSrefreshCounter	Number of sent Srefresh messages.
RecSrefreshCounter	Number of received Srefresh messages.
SendAckMsgCounter	Number of sent Msg_ID_ACK messages.
RecAckMsgCounter	Number of received Msg_ID_ACK messages.
SendChallengeMsgCounter	Number of sent Challenge messages.
RecChallengeMsgCounter	Number of received Challenge messages.
SendResponseMsgCounter	Number of sent Response messages.
RecResponseMsgCounter	Number of received Response messages.
SendErrMsgCounter	Number of sent Msg_ID_NACK messages.
RecErrMsgCounter	Number of received Msg_ID_NACK messages.
SendRecoveryPathMsgCounter	Number of sent Recovery Path messages.
RecRecoveryPathMsgCounter	Number of received Recovery Path messages.
SendGRPathMsgCounter	Number of sent GR Path messages.
RecGRPathMsgCounter	Number of received GR Path messages.
ResourceReqFaultCounter	Number of failed attempts to request resources.

Item	Description
RecGRPathMsgFromLSPM-Counter	Number of GR Path messages received from the LSPM module.
Bfd neighbor count	Number of upstream or downstream BFD peers through which at least one LSP in the Up state passes.
Bfd session count	Number of BFD sessions.

9.3.30 display mpls rsvp-te statistics fast-reroute

Function

The **display mpls rsvp-te statistics fast-reroute** command displays the CR-LSP statistics on the local node serving as a Point of Local Repair (PLR) or Merge Point (MP).

Format

display mpls rsvp-te statistics fast-reroute

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

This command can be used to check the following information:

- Number of CR-LSPs in the PLR Available state
- Number of CR-LSPs in the PLR Inuse state
- Number of CR-LSPs in the MP Available state
- Number of CR-LSPs in the MP Inuse state

Example

Display CR-LSP statistics information on the local node serving as PLR or MP.

```
<HUAWEI> display mpls rsvp-te statistics fast-reroute
FRR statistics information:
 PLR AvailLsps: 0                 PLR InuseLsps: 0
 MP AvailLsps: 0                  MP InuseLsps: 0
```

Table 9-70 Description of the display mpls rsvp-te statistics fast-reroute command output

Item	Description
PLR AvailLsps	Number of CR-LSPs whose local node is the PLR in the PLR Available state (the CR-LSPs are bound to the bypass tunnel but FRR does not occur on the PLR).
PLR InuseLsps	Number of CR-LSPs whose local node is the PLR in the PLR Inuse state.
MP AvailLsps	Number of CR-LSPs whose local node is the MP in the MP Available state (the CR-LSPs are bound to the bypass tunnel but FRR does not occur on the MP).
MP InuseLsps	Number of CR-LSPs whose local node is the MP in the MP Inuse state.

9.3.31 display mpls static-cr-lsp

Function

The **display mpls static-cr-lsp** command displays information about a static CR-LSP.

Format

display mpls static-cr-lsp [*lsp-name*] [{ **include** | **exclude** } *ip-address mask-length*] [**verbose**]

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of an LSP.	The value is an existing LSP name.
exclude	Displays information about the CR-LSPs without specified destination IP addresses.	-
include	Displays information about the CR-LSPs of specified destination IP addresses.	-
ip-address	Specifies the destination IP address.	The value is in dotted decimal notation.
mask-length	Specifies the mask length of a destination address.	The value is an integer that ranges from 0 to 32.

Parameter	Description	Value
verbose	Displays detailed information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the information about static CR-LSPs, run the **display mpls static-cr-lsp** command.

Example

Display brief information about static CR-LSPs.

```
<HUAWEI> display mpls static-cr-lsp
TOTAL         : 2     STATIC CRLSP(S)
UP            : 2     STATIC CRLSP(S)
DOWN          : 0     STATIC CRLSP(S)
Name            FEC               I/O Label    I/O If           Status
Tunnel1       3.3.3.3/32        NULL/20      -/Vlanif10         Up
Tunnel2       -/-               130/NULL     Vlanif10/-         Up
```

Table 9-71 Description of the display mpls static-cr-lsp command output

Item	Description
TOTAL	Total number of static CR-LSPs.
UP	Number of the static CR-LSPs in the Up state.
DOWN	Number of the static CR-LSPs in the DOWN state.
Name	Name of a static CR-LSP.
FEC	Destination IP address and mask length.
I/O Label	Incoming and outgoing labels.
I/O If	Incoming and outgoing interfaces.
Status	Current status of a CR-LSP.

Display detailed information about static CR-LSPs.

```
<HUAWEI> display mpls static-cr-lsp verbose
No             : 1
LSP-Name       : tunnel1
```

```
LSR-Type       : Transit
FEC            : -/-
In-Label       : 20
Out-Label      : 30
In-Interface   : Vlanif10
Out-Interface  : Vlanif20
NextHop        : 10.1.3.2
Lsp Status     : Up
```

Table 9-72 Description of the display mpls static-cr-lsp verbose command output

Item	Description
No	Sequence number of a static CR-LSP.
LSP-Name	Name of a static CR-LSP.
LSR-Type	Type of a static CR-LSP: ● Ingress ● Transit ● Egress
FEC	Destination address and mask length. "-/-" is displayed for the transit node and egress node.
In-Label	Value of an incoming label.
Out-Label	Value of an outgoing label.
In-Interface	Incoming interface.
Out-Interface	Outgoing interface.
NextHop	Next-hop address in the format X.X.X.X.
Lsp Status	Status of a static CR-LSP: ● Up: indicates that the static CR-LSP is successfully established. ● Down: indicates that the static CR-LSP fails to be established.

9.3.32 display mpls stale-interface

Function

The **display mpls stale-interface** command displays information about MPLS interfaces in the Stale state.

Format

display mpls stale-interface [*interface-index*] [**verbose**]

Parameters

Parameter	Description	Value
interface-index	Specifies the index of a specified stale interface.	The value is a hexadecimal integer ranging from 1 to FFFFFFFE.
verbose	Displays detailed information about an interface, for example, whether FRR is configured. If FRR is configured, information about the bound tunnels is also displayed.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The outbound interface of the primary tunnel protected by TE FRR becomes a stale interface in one of the following situations:

MPLS is disabled on the interface when the primary tunnel is in the FRR In-used state.

The **display mpls stale-interface** command displays information about the stale interfaces.

Run the **display mpls stale-interface** command without specifying a parameter to view the index of a stale interface.

Example

Display information about all MPLS interfaces in the Stale state.

```
<HUAWEI> display mpls stale-interface
Stale-Interface       Status    TE Attr   LSP Count  CRLSP Count Effective MTU
0x81a                 Up        Dis       0          1           1500
```

Table 9-73 Description of the display mpls stale-interface command output

Item	Description
Stale-Interface	Index of an MPLS interface in the Stale state.
Status	Status of the stale interface. ● Up ● Down

Item	Description
TE Attr	Whether MPLS TE is enabled on an interface: ● Dis: MPLS TE is not enabled on the interface. ● En: MPLS TE is enabled on the interface.
LSP Count	Number of LSPs on an interface.
CRLSP Count	Number of CR-LSPs on an interface.
Effective MTU	MTU value used in the MPLS forwarding. ● If the MPLS MTU is not set, the interface MTU takes effect. ● If the MPLS MTU is set, the smaller one between the MPLS MTU and the interface MTU takes effect.

Display detailed information about all MPLS interfaces in the Stale state.

```
<HUAWEI> display mpls stale-interface verbose
No                    :  1
Interface             :  0x81a
Status                :  Up
TE Attribute          :  Disable
Static LSPCount       :  0
Static CR-LSPCount    :  0
LDP LSPCount          :  0
RSVP LSPCount         :  1
MPLS MTU              :  -
Interface MTU         :  -
Effective MTU         :  1500
TE FRR                :  Enable
Manual Bypass         :  Tun1
Interface State       :  Stale
```

Table 9-74 Description of the display mpls stale-interface verbose command output

Item	Description
No	Serial number.
Interface	Index of an MPLS interface in the Stale state.
Status	Status of the stale interface, which is the Up state in this example.
TE Attribute	Whether MPLS TE is enabled on the interface: ● Disable: MPLS TE is disabled. ● Enable: MPLS TE is enabled.
Static LSPCount	Number of static LSPs created on the interface.
Static CR-LSPCount	Number of static CR-LSPs created on the interface.
LDP LSPCount	Number of LDP LSPs created on the interface.

Item	Description
RSVP LSPCount	Number of RSVP-TE LSPs created on the interface.
MPLS MTU	MPLS MTU set using the **mpls mtu** command. When the interface is in the Stale state, a hyphen (-) is displayed.
Interface MTU	MTU configured on the interface. To set the MTU, run the **mtu** command.
Effective MTU	MTU value used in the MPLS forwarding. ● If the MPLS MTU is not set, the interface MTU takes effect. ● If the MPLS MTU is set, the smaller one between the MPLS MTU and the interface MTU takes effect.
TE FRR	Whether MPLS TE is enabled on the interface: ● Disable: No bypass tunnel is set up in manual FRR mode to protect the interface. ● Enable: A bypass tunnel is set up in manual FRR mode to protect the interface.
Manual Bypass	Name of a bypass tunnel set up in manual FRR mode.
Interface State	Interface status. Stale indicates that the interface is to be deleted.

9.3.33 display mpls te cspf destination

Function

The **display mpls te cspf destination** command helps you check whether the specified path is available or not. You can specify relevant parameters in the command to set constraint conditions.

Format

display mpls te cspf destination *ip-address* [**affinity** *properties* [**mask** *mask-value*] | **bandwidth** { **ct0** *ct0-bandwidth* | **ct1** *ct1-bandwidth* } * | **explicit-path** *path-name* | **hop-limit** *hop-limit-number* | **metric-type** { **igp** | **te** } | **priority** *setup-priority* | **srlg-strict** *exclude-path-name* | **tie-breaking** { **random** | **most-fill** | **least-fill** }] * [**hot-standby** [**explicit-path** *path-name* | **overlap-path** | **affinity** *properties* [**mask** *mask-value*] | **hop-limit** *hop-limit-number* | **srlg** { **preferred** | **strict** }] *]

Parameters

Parameter	Description	Value
destination *ip-address*	Specifies the destination IP address of an MPLS TE tunnel.	The value is in dotted decimal notation.
affinity *properties*	Specifies the affinity property of an MPLS TE tunnel.	The value is a hexadecimal number that ranges from 0 to FFFFFFFF.
mask *mask-value*	Specifies the value of the affinity property mask.	The value is a hexadecimal number that ranges from 0 to FFFFFFFF.
bandwidth	Specifies the required bandwidth of an MPLS TE tunnel.	-
ct0 *ct0-bandwidth* | **ct1** *ct1-bandwidth*	Specifies the bandwidth values of CR-LSPs of CT0 to CT1.	The value is an integer that ranges from 1 to 4000000000.
explicit-path *path-name*	Specifies the explicit path of an MPLS TE tunnel.	The value is an existing explicit path name.
hop-limit *hop-limit-number*	Specifies the maximum number of hops on an MPLS TE tunnel.	The value is an integer that ranges from 1 to 32. By default, the maximum number of hops is 32.
metric-type	Specifies the metric type for the CSPF calculation.	-
igp	Specifies the metric type as IGP.	-
te	Specifies the metric type as TE.	-
priority *setup-priority*	Specifies the setup priority of an MPLS TE tunnel.	The value is an integer that ranges from 0 to 7.
srlg-strict *exclude-path-name*	Specifies the path of a specified SRLG.	The value is an existing explicit path name.

Parameter	Description	Value
tie-breaking	Configures a tie-breaking mode for CSPF.	-
random	Configures the random mode.	-
most-fill	Configures the most-fill mode, meaning the path with the highest ratio of used bandwidth to maximum reservable bandwidth is selected.	-
least-fill	Configures the least-fill mode, meaning the path with the lowest ratio of used bandwidth to the maximum capacity of reservable bandwidth is selected.	-
hot-standby	Configures hot-standby path excluding primary path.	-
overlap-path	Specifies that if a completely disjoint path is not available, a maximally disjoint path should be computed for the Hot-standby.	-
srlg preferred	Specifies that the SRLG attribute is an optional constraint used by CSPF to calculate the path for the hot-standby CR-LSP. If CSPF fails to calculate the path for the hot-standby CR-LSP based on the SRLG attribute, CSPF recalculates the path, regardless of the SRLG attribute.	-
srlg strict	Specifies that the SRLG attribute is a required constraint used by CSPF to calculate the path for the hot-standby CR-LSP. The links of the hot-standby CR-LSP and the primary CR-LSP cannot be in the same SRLG.	-

Usage Guidelines

Prerequisites

Before running this command, the CSPF function must have been enabled by using the **mpls te cspf** command.

Precautions

When this command is run, the device uses CSPF to check whether there is a path satisfying the specified constraints. If such a path exists, its information is displayed; otherwise, the display is empty.

Example

Display the path with the destination address being 10.3.3.9 by performing the CSPF calculation.

```
<HUAWEI> display mpls te cspf destination 10.3.3.9
Path for the given constraints is:
10.1.1.9            Include      LSR-ID
172.16.1.1           Include
172.16.1.2           Include
10.2.2.9            Include      LSR-ID
172.17.1.1           Include
172.17.1.2           Include
10.3.3.9            Include      LSR-ID
The total metrics of the calculated path is :   2
```

Display the explicit path named path1 with the destination address being 10.3.3.9 by performing the CSPF calculation.

```
<HUAWEI> display mpls te cspf destination 10.3.3.9 explicit-path path1
Path for the given constraints is:
10.1.1.9            Include      LSR-ID
172.16.1.1           Include
172.16.1.2           Include
10.2.2.9            Include      LSR-ID
172.17.1.1           Include
172.17.1.2           Include
10.3.3.9            Include      LSR-ID
The total metrics of the calculated path is :   2
```

Display the hot standby path with the destination address being 10.3.3.9 by performing the CSPF calculation.

```
<HUAWEI> display mpls te cspf destination 10.3.3.9 hot-standby
Path for the given constraints is:
10.1.1.9            Include      LSR-ID
172.16.1.1           Include
172.16.1.2           Include
10.2.2.9            Include      LSR-ID
172.17.1.1           Include
172.17.1.2           Include
10.3.3.9            Include      LSR-ID
The total metrics of the calculated path is :   2

Hot-standby path for the given constraints is:
10.1.1.9            Include      LSR-ID
172.19.1.1           Include
```

```
172.19.1.2                Include
10.6.6.9                Include        LSR-ID
172.20.1.1                Include
172.20.1.2                Include
10.3.3.9                Include        LSR-ID
Complete disjoint path computed and the total metrics of the calculated path is :    2
```

Display the hot standby path with the destination address being 10.4.4.9 and partial overlapping by performing the CSPF calculation.

```
<HUAWEI> display mpls te cspf destination 10.4.4.9 hot-standby overlap-path
Main path for the given constraints is:
10.1.1.9                Include        LSR-ID
172.16.1.1                Include
172.16.1.2                Include
10.2.2.9                Include        LSR-ID
172.17.1.1                Include
172.17.1.2                Include
10.3.3.9                Include        LSR-ID
172.18.1.1                Include
172.18.1.2                Include
10.4.4.9                Include        LSR-ID
The total metrics of the calculated path is :   3

Hot-standby path for the given constraints is:
10.1.1.9                Include        LSR-ID
172.21.1.1                Include
172.21.1.2                Include
10.6.6.9                Include        LSR-ID
172.22.1.1                Include
172.22.1.2                Include
10.3.3.9                Include        LSR-ID
172.18.1.1                Include
172.18.1.2                Include
10.4.4.9                Include        LSR-ID
Partial Overlap path computed and the total metrics of the calculated path is :
   3
```

Table 9-75 Description of the display mpls te cspf destination command output

Item	Description
Path for the given constraints is	Path calculated by CSPF. If * is displayed, it indicates the node does not exist on the explicit path calculated by CSPF. If * is not displayed, it indicates that the node exists on the path calculated by CSPF.
10.1.1.9 Include LSR-ID	Path information. 10.1.1.9 is the next hop address, Include is the node name, and LSR-ID indicates that the LSR ID is used as the address.
The total metrics of the calculated path is	Calculated metric value of a path.
Main path for the given constraints is	Path for the main request, when both main and hot-standby are requested.
Hot-standby path for the given constraints is	Path calculated by CSPF for the hot-standby.

Item	Description
Complete disjoint path computed and the total metrics of the calculated path is	CSPF has calculated complete disjoint path from main path for hot-standby.
Partial Overlap path computed and the total metrics of the calculated path is	CSPF has calculated partial overlap path from main path for hot-standby.

9.3.34 display mpls te cspf tedb

Function

The **display mpls te cspf tedb** command displays the CSPF TEBD information based on specified conditions.

Format

display mpls te cspf tedb { **all** | **area** { *area-id* | *area-id-ip* } | **interface** *ip-address* | **network-lsa** | **node** [*router-id*] | **srlg** *srlg-number* | **overload-node** }

Parameters

Parameter	Description	Value
all	Displays information about all TEDB nodes.	-
area *area-id*	Specifies the ID of an area.	For an OSPF area, the value is an integer that ranges from 0 to 4294967295. For an IS-IS area, the value is 1 or 2.
area *area-id-ip*	Specifies the ID of an area in IP address format.	For an OSPF area, the value is in dotted decimal notation.
interface *ip-address*	Specifies the IP address of an interface	The value is in dotted decimal notation.
network-lsa	Displays information about all network LSAs.	-
node	Displays information about a node.	-
router-id	Specifies the router ID.	The value is in dotted decimal notation.
srlg *srlg-number*	Specifies the SRLG number.	The value is an integer that ranges from 0 to 4294967295.
overload-node	Displays information of all the overload-nodes.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the CSPF TEBD information, run the **display mpls te cspf tedb** command.

Example

Display information about network LSAs in a TEDB.

```
<HUAWEI> display mpls te cspf tedb network-lsa
Maximum Network LSA Supported    : 512
Current Total Network LSA Number : 6

Table 9-79 Description of the display mpls te cspf tedb node command output

Item	Description
Router ID	Router ID in the format X.X.X.X.
IGP Type	IGP type: - OSPF - IS-IS
Process ID	IGP Process ID.

Item	Description
MPLS-TE Link Count	Number of MPLS TE link.
OSPF Router ID	OSPF Route ID.
ISIS System ID	IS-IS system ID.
Interface IP Address	Interface IP address.
DR Address	DR address.
DR ISIS System ID	IS-IS system ID of the DR.
IGP Area	IGP area.
Link Type	Link type.
Link Status	Link status.
Link [x]	Link information, with "x" being the link number.
IGP Metric	IGP metric of a link.
TE Metric	TE metric of a link.
Color	Color of a link.
Maximum Link Bandwidth	Maximum bandwidth of a link.
Maximum Reservable Bandwidth	Maximum capacity of reserved bandwidth for a link.
Bandwidth Allocation Model	Bandwidth allocation model.
Bandwidth Constraints	Bandwidth constraints.
Local Overbooking Multiplier	Local overbooking multiplier.
BC	Bandwidth constraints.
LOM	Local overbooking multiplier.
BW Unreserved	Unreserved bandwidth for LSPs.
Class ID: [x]:	Class 0 to Class 7.

Display information about overloaded nodes in a TEDB.

```
<HUAWEI> display mpls te cspf tedb overload-node

IGP	IGP type: ● OSPF ● IS-IS
Process-ID	IGP Process ID.
Area	Area to which a device belongs.
IGP_ID	● OSPF router ID of a neighbor device. ● IS-IS system ID of a neighbor device.

9.3.35 display mpls te hot-standby state

Function

The **display mpls te hot-standby state** command displays the hot-standby status of all tunnels or a specified tunnel.

Format

display mpls te hot-standby state { **all** [**verbose**] | **interface tunnel** *interface-number* }

Parameters

Parameter	Description	Value
all	Displays the status of all hot-standby tunnels.	-
verbose	Displays detailed information about hot-standby tunnels.	-
interface tunnel *interface-number*	Displays the status of a specified hot-standby tunnel.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When running the **display mpls te hot-standby state** command, note the following issues:

- The command displays the status of only hot-standby TE tunnels.
- If a tunnel interface is deleted or traffic switches from the tunnel to an ordinary backup tunnel, no command output is displayed.

Example

Display the hot-standby status of Tunnel 1.

```
<HUAWEI> display mpls te hot-standby state interface tunnel 1
(s): same path
----------------------------------------------------------------------
Verbose information about the Tunnel1 hot-standby state
----------------------------------------------------------------------
session id                  : 300
main LSP token              : 0x9
hot-standby LSP token       : 0x0
HSB switch result           : Primary LSP
HSB switch reason           : -
WTR config time             : 10s
WTR remain time             : -
using overlapped path       : -
```

Table 9-81 Description of the display mpls te hot-standby state command output

Item	Description
session id	Session ID, which is the configured tunnel ID.
main LSP token	Index of the primary CR-LSP.
hot-standby LSP token	Index of the hot-standby CR-LSP.
HSB switch result	Result of a switchover: - Primary LSP: indicates that data is switched to the primary CR-LSP. - Hot-standby LSP: indicates that data is switched to the hot-standby CR-LSP. - Ordinary LSP: indicates that data is switched to the ordinary CR-LSP. - Best-Effort LSP: indicates that data is switched to the best-effort path.
HSB switch reason	Reason why traffic is switched to the hot-standby LSP.

Item	Description
WTR config time	WTR time. If a primary CR-LSP recovers from a fault, the system waits for a period of time, or the WTR time, to switch data from the hot-standby CR-LSP or best-effort path to the primary LSP.
WTR remain time	WTR remain time.
using overlapped path	Whether the path of the primary tunnel and the path of the backup tunnel overlap: ● yes: indicates that they overlap. ● no: indicates that they do not overlap. ● -: indicates that the system does not check whether they overlap.

Display the hot-standby status of all hot-standby tunnels.

```
<HUAWEI> display mpls te hot-standby state all
(s): same path
------------------------------------------------------------------------------
No.        tunnel name         session id      switch result        overlap
------------------------------------------------------------------------------
1          Tunnel1             3               Best-Effort LSP      -
2          Tunnel2             9               Primary LSP          -
```

Table 9-82 Description of the display mpls te hot-standby state all command output

Item	Description
No.	Sequence number.
tunnel name	Name of a tunnel.
session id	Session ID, which is the configured tunnel ID.
switch result	Result of a switchover: ● Primary LSP: indicates that data is switched to the primary CR-LSP. ● Hot-standby LSP: indicates that data is switched to the hot-standby CR-LSP. ● Ordinary LSP: indicates that data is switched to the ordinary CR-LSP. ● Best-Effort LSP: indicates that data is switched to the best-effort path.

Item	Description
overlap	Whether the primary path overlaps the hot-standby path: - yes: They share one or multiple links. - no: They do not share links. - -: Their paths cannot be compared. - yse(s): They overlap each other.

9.3.36 display mpls te link-administration admission-control

Function

The **display mpls te link-administration admission-control** command displays CR-LSP information received by all links, including bandwidth and priority.

Format

display mpls te link-administration admission-control [**interface** *interface-type interface-number* | **stale-interface** *interface-index*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about admission control of a specified interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-
stale-interface *interface-index*	Displays information about admission control of a stale interface. *interface-index* specifies the index of the stale interface.	The value is a hexadecimal integer that ranges from 1 to FFFFFFFE.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display mpls stale-interface** command without specifying any parameter to view the index of a stale interface.

Example

Display information about the admission control of all MPLS TE links.

```
<HUAWEI> display mpls te link-administration admission-control
LspID                    In/Out IF                    S/H Prio CT BW(kbps)
10.3.3.9:300:4             Vlanif10 / ---                 7 /7     -  -
```

Display information about admission control of a stale interface.

```
<HUAWEI> display mpls te link-administration admission-control stale-interface 18000106
LspID                    In/Out IF              S/H Prio  CT        BW (kbps)
10.1.1.1:600:1          --- / 0x18000106           0 /0      0         0
```

Table 9-83 Description of the display mpls te link-administration admission-control command output

Item	Description
LspID	LSP ID, uniquely identified in the form of <Ingress-LSR-ID:Tunnel-ID:Local-LSP-ID>.
In/Out IF	Incoming and outgoing interfaces.
S/H Prio	Setup and holding priorities. Setup priority: An integer ranging from 0 to 7. The smaller the value, the higher the priority. Holding priority: An integer ranging from 0 to 7. The smaller the value, the higher the priority.
CT	Class type.
BW	Bandwidth.

9.3.37 display mpls te link-administration bandwidth-allocation

Function

The **display mpls te link-administration bandwidth-allocation** command displays information about bandwidth allocation of a specified MPLS TE interface or all MPLS TE interfaces.

Format

display mpls te link-administration bandwidth-allocation [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Displays information about bandwidth allocation of a specified interface. - *interface-type*: indicates the interface type. - *interface-number*: indicates the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the information about bandwidth allocation of the MPLS TE interfaces, run the **display mpls te link-administration bandwidth-allocation** command.

Example

Display information about the bandwidth allocation of all MPLS TE interfaces.

```
<HUAWEI> display mpls te link-administration bandwidth-allocation

```

Table 9-84 Description of the display mpls te link-administration bandwidth-allocation command output

Item	Description
Link ID	MPLS TE interface number.
Bandwidth Constraint Model	Bandwidth Constraints Model used by a TE tunnel: ● RDM: Russian Dolls Model ● MAM: Maximum Allocation Model ● Extended MAM: Extended Maximum Allocation Model
Physical Link Bandwidth(Kbits/sec)	Indicates the capacity of bandwidth for a physical link.

Item	Description
Maximum Link Reservable Bandwidth(Kbits/sec)	Maximum capacity of reserved bandwidth for a link. To set the maximum capacity of reserved bandwidth for a link, run the **mpls te bandwidth max-reservable-bandwidth** command.
Reservable Bandwidth BCi(0≤i≤7) (Kbits/sec)	Bandwidth that is reserved for BCi. To set the bandwidth that is reserved for BCi, run the **mpls te bandwidth** command.
Downstream Bandwidth (Kbits/ sec)	Bandwidth of an outgoing interface.
IPUpdown Link Status	IP link status of an interface: ● UP: IP link is available. ● DOWN: IP link is unavailable.
PhysicalUpdown Link Status	Physical link status of an interface: ● UP: The physical link is available. ● DOWN: The physical link is unavailable.
GracefulUpdown Link Status	Graceful link status of an interface: ● UP: The graceful link is available. ● DOWN: The graceful link is unavailable.
TE-CLASS	TE class.
CT	Class type.
PRIORITY	Preemption priority of an MPLS TE tunnel. To set the preemption priority of an MPLS TE tunnel, run the **mpls te priority** command.
BW RESERVED (Kbit/sec)	Reserved bandwidth for LSPs of the CT.
BW AVAILABLE (Kbit/sec)	Available bandwidth for LSPs of the CT.
DOWNSTREAM RSVPLSPNODE COUNT	Number of downstream RSVP LSP nodes.

9.3.38 display mpls te link-administration srlg-information

Function

The **display mpls te link-administration srlg-information** command displays SRLG(s) to which the interface belongs.

Format

display mpls te link-administration srlg-information [**interface** *interface-type interface-number*]

Parameters

Parameter	Description	Value
interface *interface-type interface-number*	Specifies the type and number of an interface. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring the SRLG in the interface view, you can run the **display mpls te link-administration srlg-information** command to check the configuration.

Example

Display the SLRG(s) to which VLANIF100 belongs to.

```
<HUAWEI> display mpls te link-administration srlg-information interface vlanif100

 SRLGs on Vlanif100 :
            2             3             9
```

Table 9-85 Description of the display mpls te link-administration srlg-information command output

Item	Description
SRLGs on Vlanif100	SRLG number to which an interface belongs.

9.3.39 display mpls te protection binding protect-tunnel

Function

The **display mpls te protection binding protect-tunnel** command displays the tunnel protection relationship.

Format

display mpls te protection binding protect-tunnel { *tunnel-id* | **interface tunnel** *interface-number* }

Parameters

Parameter	Description	Value
tunnel-id	Displays information about the protection relationship related to a protection tunnel (that is, a backup tunnel) with a specified ID.	The value is an integer that ranges from 1 to 10000.
tunnel *interface-number*	Displays information about the protection relationship related to the specified tunnel interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the tunnel protection relationship, run the **display mpls te protection binding protect-tunnel** command.

Example

Display the protection relationship related to the protection tunnel with the ID of 10.

```
<HUAWEI> display mpls te protection binding protect-tunnel 10
------------------------------------------------------------------------
Binding information of( tunnel id:  10 )
------------------------------------------------------------------------
    Protect-tunnel id                    :10
    Protect-tunnel name                  :Tunnel1
    Maximum number of bound work-tunnels :16
    Currently bound work-tunnels         :Total( 1 )
                                         :Tunnel2
```

Table 9-86 Description of the display mpls te protection binding protect-tunnel command output

Item	Description
Protect-tunnel id	ID of a protection tunnel (the backup tunnel).
Protect-tunnel name	Name of a protection tunnel (the interface name).

Item	Description
Maximum number of bound work-tunnels	Maximum number of tunnels that a protection tunnel can protect.
Currently bound work-tunnels	Information about the working tunnel to which a protection tunnel is currently bound, including the quantity and list.

9.3.40 display mpls te protection tunnel

Function

The **display mpls te protection tunnel** command displays information about a specified tunnel and its tunnel protection group.

Format

display mpls te protection tunnel { **all** | *tunnel-id* | **interface tunnel** *interface-number* } [**verbose**]

Parameters

Parameter	Description	Value
all	Displays information about all tunnel protection groups.	-
tunnel-id	Specifies the ID of a working tunnel or its protection tunnel.	The value is an integer that ranges from 1 to 10000.
interface	Displays information about tunnel protection groups on an interface.	-
tunnel *interface-number*	Specifies the name of a working tunnel or its protection tunnel.	-
verbose	Displays detailed information.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display mpls te protection tunnel** command can be used to display information about a specified tunnel protection group. The following parameters can be specified to display various types of information:

- If the ID or tunnel interface of the working tunnel is specified, information about the working tunnel and its protection tunnel is displayed.
- If the ID or tunnel interface of a protection tunnel is specified, information about the protection tunnel and all its protected working tunnels is displayed.

Example

Display information about a working tunnel with the tunnel ID of 100 and its protection tunnel.

```
<HUAWEI> display mpls te protection tunnel 100
------------------------------------------------------------------------
No. Work-tunnel status  /id  Protect-tunnel status /id    Switch-Result
------------------------------------------------------------------------
1          in defect   /100       non-defect     /300  protect-tunnel
```

Table 9-87 Description of the display mpls te protection tunnel command output

Item	Description
No.	Sequence number of a tunnel protection group.
Work-tunnel status /id	Status and ID of a working tunnel. The tunnel status can be: ● non-defect: The tunnel functions properly. ● in defect: The tunnel fails.
Protect-tunnel status /id	Status and ID of a protection tunnel. The tunnel status can be: ● non-defect: The tunnel functions properly. ● in defect: The tunnel fails.
Switch-Result	Switching result: ● work-tunnel: Traffic switches to the working tunnel. ● protect-tunnel: Traffic switches to the protection tunnel.

Display detailed information about working tunnels and their protection tunnels.

```
<HUAWEI> display mpls te protection tunnel all verbose
----------------------------------------------------------------
Verbose information about the No.1 protection-group
----------------------------------------------------------------
Work-tunnel id                    : 1
Protect-tunnel id                 : 2
```

```

Local state                              : no request
Far end request                          : no request
```

Table 9-88 Description of the display mpls te protection tunnel all verbose command output

Item	Description
Work-tunnel id	ID of the working tunnel.
Protect-tunnel id	ID of the protection tunnel.
Work-tunnel name	Tunnel interface name of the working tunnel.
Protect-tunnel name	Tunnel interface name of the protection tunnel.
Work-tunnel reverse-lsp	Name of the reverse CR-LSP in the working tunnel.
Protect-tunnel reverse-lsp	Name of the reverse CR-LSP in the protection tunnel.
Bridge type	Bridge mode.
Switch type	Switch mode.
Switch result	Switching result: ● work-tunnel: Traffic switches to the working tunnel. ● protect-tunnel: Traffic switches to the protection tunnel.
Tunnel using Best-Effort	Whether a best-effort path is used as a protection tunnel.
Tunnel using Ordinary	Whether an ordinary backup tunnel is used as a protection tunnel.

Item	Description
Work-tunnel frr in use	Whether the working tunnel is in the FRR in-use state.
Work-tunnel defect state	Working tunnel status: - non-defect: The working tunnel functions properly. - in defect: The working tunnel fails.
Protect-tunnel defect state	Protection tunnel status: - non-defect: The protection tunnel functions properly. - in defect: The protection tunnel fails.
Work-tunnel forward-lsp defect state	Status of the forward CR-LSP in the working tunnel: - non-defect: The forward CR-LSP functions properly. - in defect: The forward CR-LSP fails.
Protect-tunnel forward-lsp defect state	Status of the forward CR-LSP in the protection tunnel: - non-defect: The forward CR-LSP functions properly. - in defect: The forward CR-LSP fails.
Work-tunnel reverse-lsp defect state	Status of the reverse CR-LSP in the working tunnel: - non-defect: The reverse CR-LSP functions properly. - in defect: The reverse CR-LSP fails.
Protect-tunnel reverse-lsp defect state	Status of the reverse CR-LSP in the protection tunnel: - non-defect: The reverse CR-LSP functions properly. - in defect: The reverse CR-LSP fails.
HoldOff config time	Switching delay time. To set the switching delay time, run the **mpls te protection tunnel** command.
HoldOff remain time	Remain time of switching delay time.
WTR config time	Wait-to-restore time. To set the wait-to-restore time, run the **mpls te protection tunnel** command.
WTR remain time	Remain time of wait-to-restore time.

Item	Description
Mode	Switchback mode: ● revertive: supports a switchback. ● non-revertive: does not support a switchback. To set the switchback mode, run the **mpls te protection tunnel** command.
Using same path	Whether a path of the working tunnel and a path of the protection tunnel overlap: ● yes: The two tunnels have an overlapped path. ● no: The two tunnels do not have an overlapped path. ● -: Undetected.
Local state	Switching mode on the local end: ● signal fail for protection ● no request
Far end request	Switching mode on the remote end.

9.3.41 display mpls te session-entry

Function

The **display mpls te session-entry** command displays detailed information about LSP sessions of tunnels.

Format

display mpls te session-entry [*ingress-lsr-id tunnel-id egress-lsr-id*]

Parameters

Parameter	Description	Value
ingress-lsr-id	Specifies the LSR ID of the ingress.	In dotted decimal notation.
tunnel-id	Specifies the ID of a tunnel.	The value is an integer that ranges from 0 to 65535.
egress-lsr-id	Specifies the LSR ID of the egress.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view detailed information about LSP sessions of tunnels, run the **display mpls te session-entry** command.

Example

Display detailed information about LSP sessions of a tunnel.

```
<HUAWEI> display mpls te session-entry

 Ingress-ID               :  1.1.1.9
 Tunnel-ID                :  300
 Egress-ID                :  3.3.3.9
 Crlsp num                :  1
 First TunnelTable index  :  4
 LSP No.     :  1
 LSP ID      :  1.1.1.9:300:6
 In/Out IF   :  -/Vlanif10
 Bandwidth(Kbit/sec):
   CT0 : 500        CT1 : 0
```

Table 9-89 Description of the display mpls te session-entry command output

Item	Description
Ingress-ID	LSR ID of the ingress.
Tunnel-ID	Tunnel ID, which is the session ID.
Egress-ID	LSR ID of the egress.
Crlsp num	Number of CR-LSPs of the session entry.
First TunnelTable index	Index of the first CR-LSP of the session entry.
LSP No.	Sequence number of a CR-LSP.
LSP ID	LSP ID, uniquely identified in the form of <Ingress-LSR-ID:Tunnel-ID:Local-LSP-ID>.
In/Out IF	Incoming and outgoing interface through which the CR-LSP passes on the local node.
Bandwidth(Kbit/sec)	Bandwidth, in kbit/s.
CT0	Bandwidth value of CR-LSPs of CT0.
CT1	Bandwidth value of CR-LSPs of CT1.

9.3.42 display mpls te srlg

Function

The **display mpls te srlg** command displays the Shared Risk Link Group (SRLG) configurations and the interfaces that belong to it.

Format

display mpls te srlg { *srlg-number* | **all** }

Parameters

Parameter	Description	Value
srlg-number	Specifies the number of the SRLG to which an interface belongs.	The value is an integer that ranges from 0 to 4294967295.
all	Displays information about all SRLGs on the node and the interfaces that belong to the SRLG groups.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the configuring the SRLG on an interface, you can run the **display mpls te srlg** command to check the configuration.

The **display mpls te srlg** command displays the following information:

- Maximum of SRLGs that a node can support
- Number of SRLGs that are configured on the node
- Member interfaces of each SRLG

Example

Display information about all SRLGs on the node.

```
<HUAWEI> display mpls te srlg all
Total SRLG supported : 1024
Total SRLG configured : 1
SRLG  239:            Vlanif30
```

Table 9-90 Description of the display mpls te srlg all command output

Item	Description
Total SRLG supported	Total SRLGs supported.
Total SRLG configured	Total SRLGs configured.
SRLG	Shared risk link group. To set the shared risk link group, run the **mpls te srlg** command.

9.3.43 display mpls te tunnel-interface

Function

The **display mpls te tunnel-interface** command displays information about tunnel interfaces on the local LSR.

Format

display mpls te tunnel-interface [**tunnel** *interface-number* | **auto-bypass-tunnel** [*tunnel-name*]]

Parameters

Parameter	Description	Value
tunnel *interface-number*	Specifies the number of a tunnel interface on the local LSR.	-
auto-bypass-tunnel *tunnel-name*	Specifies the name of an MPLS TE tunnel. If the *tunnel-name* parameter is configured, information about the specified Auto bypass tunnel is displayed. If this parameter is not configured, information about all Auto bypass tunnels is displayed.	The value is an existing tunnel name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If you do not specify any parameters, information about all tunnel interfaces is displayed.

Example

Display information about Tunnel 1.

```
<HUAWEI> display mpls te tunnel-interface tunnel 1
    ----------------------------------------------------------------
                            Tunnel1
    ----------------------------------------------------------------
    Tunnel State Desc   :  GRACEFUL SWITCH
    Active LSP          :  Best-Effort LSP
    Traffic Switch      :  Best-Effort LSP -> Ordinary LSP
    Session ID          :  50
    Ingress LSR ID      :  1.1.1.1          Egress LSR ID:  2.2.2.2
    Admin State         :  UP               Oper State   :  UP
    Primary LSP State      : DOWN
      Main LSP State       : SETTING UP
    Hot-Standby LSP State  : UP
      Main LSP State       : READY              LSP ID  : 32799
      Modify LSP State     : SETTING UP
    Ordinary LSP State     : UP
      Main LSP State       : READY              LSP ID  : 32782
    Best-Effort LSP State  : UP
      Main LSP State       : READY              LSP ID  : 32780
```

Table 9-91 Description of the display mpls te tunnel-interface command output

Item	Description
Tunnel State Desc	Tunnel status: - UP: indicates that the tunnel is successfully set up. - DOWN: indicates that the tunnel fails to be set up. - GRACEFUL SWITCH: indicates that the tunnels are switched through GR. - GRACEFUL DELETE: indicates that during the GR process a type of LSP is deleted.
Active LSP	Type of CR-LSP in use: - Primary LSP: indicates the primary CR-LSP. - Hot-Standby LSP: indicates the hot-standby CR-LSP. - Ordinary LSP: indicates the ordinary backup CR-LSP. - Best-Effort LSP: indicates the best-effort path.
Traffic Switch	Traffic switching status.
Session ID	Session ID of a CR-LSP.
Ingress LSR ID	LSR ID of the ingress.
Egress LSR ID	LSR ID of the egress.
Admin State	Administrative status.
Oper State	Operating status.

Item	Description
Primary LSP State	Status of a primary CR-LSP: - UP: indicates that the primary CR-LSP is successfully set up. - DOWN: indicates that no primary CR-LSP is set up. - GRACEFUL SWITCH: indicates that the primary CR-LSP is being switched to the Modified CR-LSP. - GRACEFUL DELETE: indicates that during the GR process, the primary CR-LSP is deleted.
Main LSP State	Status of the primary CR-LSP: - READY: indicates that the primary CR-LSP is successfully set up. - SETTING UP: indicates that the primary CR-LSP is being set up.
Hot-Standby LSP State	Status of a hot-standby CR-LSP: - UP: indicates that a hot-standby CR-LSP is successfully set up. - DOWN: indicates that no hot-standby CR-LSP is set up. - GRACEFUL SWITCH: indicates that the primary CR-LSP is being switched to the Modified CR-LSP. - GRACEFUL DELETE: indicates that during the GR process, the primary CR-LSP is deleted.
Modify LSP State	Status of a modified CR-LSP: - READY: indicates that the Modified CR-LSP is successfully set up. - SETTING UP: indicates that the Modified CR-LSP is being set up.
Ordinary LSP State	Status of an ordinary backup CR-LSP: - UP: indicates that the ordinary backup CR-LSP is successfully set up. - DOWN: indicates that no ordinary backup CR-LSP is set up. - GRACEFUL SWITCH: indicates that the main CR-LSP is being switched to the modified CR-LSP. - GRACEFUL DELETE: indicates that during the GR process, the main CR-LSP is deleted.

Item	Description
Best-Effort LSP State	Status of a best-effort path: - UP: indicates that the best-effort path is successfully set up. - DOWN: indicates that no best-effort path is set up. - GRACEFUL SWITCH: indicates that the main CR-LSP is being switched to the Modified CR-LSP. - GRACEFUL DELETE: indicates that during the GR process, the main CR-LSP is deleted.
LSP ID	LSP ID.

9.3.44 display mpls te tunnel-interface failed

Function

The **display mpls te tunnel-interface failed** command displays the MPLS TE tunnels that fail to be set up or that are being set up.

Format

display mpls te tunnel-interface failed

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After configuring multiple MPLS TE tunnels, you can use the **display mpls te tunnel-interface failed** command to check whether there are any tunnels that fail to be set up or are still being set up.

Example

Display the MPLS TE tunnels that fail to be set up or that are being set up.

```
<HUAWEI> display mpls te tunnel-interface failed
  Tunnel name       SessionId       State Desc
  ----------------------------------------------------------
  Tunnel1          39              DOWN
```

Table 9-92 Description of the display mpls te tunnel-interface failed command output

Item	Description
Tunnel name	Name of a tunnel interface.
SessionId	Session ID, which is the tunnel ID.
State Desc	Description of the tunnel status: ● UP: The tunnel is in Up state. ● DOWN: The tunnel is in Down state.

9.3.45 display mpls te tunnel-interface last-error

Function

The **display mpls te tunnel-interface last-error** command displays the last errors of a tunnel interface on the local node.

Format

display mpls te tunnel-interface last-error [*tunnel-name*]

Parameters

Parameter	Description	Value
tunnel-name	Displays the last errors of a specified tunnel interface.	The value is an existing tunnel name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display mpls te tunnel-interface last-error** command on the ingress to view the error of a local node or the error carried in an RSVP PathErr message sent by a downstream node. The errors can be as follows:

- CSPF computation fails.
- RSVP times out.

- One or more LSPs are deleted during RSVP GR smooth.
- One or more LSPs are deleted during RSVP aging.
- RSVP GR fails to be triggered.

Precautions

The **display mpls te tunnel-interface last-error** command shows the last 20 recorded errors of each TE tunnel and LSP on which the errors occur, including errors about the primary CR-LSP, modified LSP, and backup CR-LSP.

If an RSVP PathErr message sent by a downstream node carries the error information, the ErroInfo field in the command output shows the IP address of the faulty downstream node and the cause of the error. If an error occurs on the ingress, the command output only shows the cause of the error.

Example

Display information about the last errors of Tunnel1.

```
<HUAWEI> display mpls te tunnel-interface last-error Tunnel1
  Tunnel name: Tunnel1

    Error No.  : 1
    LSP Type   : Hot-Standby LSP             LSP ID     : 10.1.1.9:300:32776
    Error Code : 0x3e8                   Occur Time : 2013/01/07 14:42:23+00:00

```

Table 9-93 Description of the display mpls te tunnel-interface last-error command output

Item	Description
Tunnel name	Name of an MPLS TE tunnel.
Error No	Number of errors.
LSP Type	Type of LSP: ● Modified LSP: indicates the LSP which is in modified state. ● Primary LSP: indicates the primary LSP. ● Backup LSP: indicates the backup LSP. ● Hot-Standby LSP: indicates the hot-standby LSP.
LSP ID	LSP ID, uniquely identified in the form of Ingress-LSR-ID:Tunnel-ID:Local-LSP-ID.
Error Code	Returned code, which specifies a unique type of error. The value is an integer in hexadecimal notation. For specific error information, see the **Error Info** field.
Occur Time	Time when an error occurred.
Error Info	Error description.
error node	Node on which an error occurs.
error lsrid	LSR ID of the node on which an error occurred.
Routing Problem	Error information carried in a received RSVP PathErr message: No route available toward destination: indicates that no route to the destination address of the tunnel is available. Bad EXPLICIT_ROUTE object: indicates that an unknown EXPLICIT_ROUTE object is received. bad strict node: indicates that a certain node cannot be found on the strict explicit path.
Cspf failed to calculate a path for Tunnel	CSPF computation failure.

9.3.46 display mpls te tunnel-interface lsp-constraint

Function

The **display mpls te tunnel-interface lsp-constraint** command displays information about the CR-LSP attribute template on an MPLS TE tunnel interface.

Format

display mpls te tunnel-interface lsp-constraint [**tunnel** *interface-number*]

Parameters

Parameter	Description	Value
tunnel *interface-number*	Specifies information about the CR-LSP attribute template on a specified MPLS TE tunnel interface.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the information about the CR-LSP attribute template on an MPLS TE tunnel interface, run the **display mpls te tunnel-interface lsp-constraint** command.

Example

Display information about the CR-LSP attribute template on all MPLS TE tunnel interfaces.

```
<HUAWEI> display mpls te tunnel-interface lsp-constraint
    Tunnel Name                      :  Tunnel1
    Primary-lsp-constraint Name      :  p1
    Hotstandby-lsp-constraint Number:  2
    Hotstandby-lsp-constraint Name  :  p1
    Ordinary-lsp-constraint Number  :  2
    Ordinary-lsp-constraint Name     :  p1
```

Table 9-94 Description of the display mpls te tunnel-interface lsp-constraint command output

Item	Description
Tunnel Name	Name of a tunnel.

Item	Description
Primary-lsp-constraint Name	Name of a CR-LSP attribute template.
Hotstandby-lsp-constraint Number	Number of the hot-standby CR-LSP attribute template, which indicates the sequence in which the template is used. To set the number of the hot-standby CR-LSP attribute template, run the **mpls te hotstandby-lsp-constraint** command.
Hotstandby-lsp-constraint Name	Name of a hot-standby CR-LSP attribute template. To set the name of a hot-standby CR-LSP attribute template, run the **mpls te hotstandby-lsp-constraint** command.
Ordinary-lsp-constraint Number	Number of the ordinary CR-LSP attribute template, which indicates the sequence in which the template is used. To set the number of the ordinary CR-LSP attribute template, run the **mpls te ordinary-lsp-constraint** command.
Ordinary-lsp-constraint Name	Name of an ordinary CR-LSP attribute template. To set the name of an ordinary CR-LSP attribute template, run the **mpls te ordinary-lsp-constraint** command.

9.3.47 display mpls te tunnel-interface traffic-state

Function

The **display mpls te tunnel-interface traffic-state** command displays information about the traffic on the tunnel interface of the local LSR.

Format

display mpls te tunnel-interface traffic-state [*tunnel-name*]

Parameters

Parameter	Description	Value
tunnel-name	Specifies a tunnel name.	The value is an existing tunnel name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To check the traffic protection mode, traffic state, and traffic switchover reasons of a tunnel interface on a local LSR, run the **display mpls te tunnel-interface traffic-state** command.

Example

Display information about the traffic on the tunnel interface of the local LSR.

```
<HUAWEI> display mpls te tunnel-interface traffic-state
 Protect Config: HSB - Hot-Standby,       OBK - Ordinary Backup
                 FRR - Fast Reroute,      BBK - Best-Effort Backup
                 PS  - Protection Switch

 -------------------------------------------------------------------------------
 Tunnel Interface    Protect Config   Traffic State          Switch Reason
 -------------------------------------------------------------------------------
 Tunnel1           OBK             Primary LSP           --
 Tunnel2           HSB             Primary LSP           Signal Fail
```

Table 9-95 Description of the display mpls te tunnel-interface traffic-state command output

Item	Description
Tunnel Interface	Tunnel interface name.
Protect Config	Protection modes. The protection modes are displayed using short names. If two protection modes are performed, both the two protection modes are displayed. ● HSB: indicates the hot standby. ● OBK: indicates ordinary backup. ● BBK: indicates the best-effort path. ● FRR: indicates FRR. ● PS: indicates the tunnel protection group.

Item	Description
Traffic State	Traffic protection state, including the following types: - Hot-Standby LSP: Traffic is switched to the hot-standby LSP. - Primary LSP FRR In Use: Traffic is on the primary LSP that is in the FRR in use state. - Best-Effort LSP: Traffic is on the best-effort LSP. - Ordinary LSP: Traffic is on the ordinary backup LSP. - Protection Tunnel: Traffic is on the protection tunnel. - Primary LSP: Traffic is on the primary LSP, and no switchover is performed.
Switch Reason	Reason why traffic is not on the primary LSP. If the traffic is on the primary LSP, or the traffic is on the primary LSP which is in the FRR in use state, this field is not displayed. If multiple reasons exist, only one reason with the highest priority is displayed. Following are the reasons listed in descending order of priorities: - Manual Command: The user uses a command to enable a switchover. - Signal Fail: The signaling protocol or detection protocol is Down. - Signal Degrade: The detection protocol signal degrades. This field is also displayed when bit errors occur. - Wait To Restore (WTR): The system waits for the WTR period to elapse and then switches traffic back to the primary LSP. - Do Not Revertive: Traffic is not switched back to the primary LSP even if the primary LSP recovers.

9.3.48 display mpls te tunnel

Function

The **display mpls te tunnel** command displays information about an MPLS TE tunnel.

Format

display mpls te tunnel [**destination** *ip-address*] [**lsp-id** *ingress-lsr-id session-id local-lsp-id*] [**lsr-role** { **all** | **egress** | **ingress** | **remote** | **transit** }] [**name** *tunnel-*

name] [{ **incoming-interface** | **interface** | **outgoing-interface** } *interface-type interface-number*] [**verbose**]

display mpls te tunnel { **stale-incoming-interface** | **stale-interface** | **stale-outgoing-interface** } *interface-index* [**verbose**]

Parameters

Parameter	Description	Value
destination *ip-address*	Displays information about an MPLS TE tunnel with a specified destination address.	-
lsp-id	Displays information about an MPLS TE tunnel with a specified LSP ID.	-
ingress-lsr-id	Specifies the LSR ID of the ingress.	The value is in dotted decimal notation.
session-id	Specifies the ID of a session.	The value is an integer that ranges from 0 to 65535.
local-lsp-id	Specifies the local LSP ID.	The value is an integer that ranges from 0 to 65535.
lsr-role	Displays information about an MPLS TE tunnel according to the specified role of the local LSR.	-
all	Displays information of all MPLS TE tunnels.	-
egress	Displays information about an MPLS TE tunnel with the local LSR as the egress.	-
ingress	Displays information about an MPLS TE tunnel with the local LSR as the ingress.	-
remote	Displays information about an MPLS TE tunnel with the local LSR as the egress or the transit node.	-

Parameter	Description	Value
transit	Displays information about an MPLS TE tunnel with the local LSR as a transit node.	-
name *tunnel-name*	Displays the MPLS TE tunnel whose name is specified.	*tunnel-name* must be the name of an existing tunnel and its format, including the upper and lower casing, and blank spaces, must be consistent with that of the configuration file. For example, when the tunnel interface in a configuration file is named "interface Tunnel1", the tunnel name to be specified must also be Tunnel1. "tunnel1" or "Tunnel 1" is incorrect.
incoming-interface *interface-type interface-number*	Displays information about all MPLS TE tunnels with a specified incoming interface.	-
interface *interface-type interface-number*	Displays information about all MPLS TE tunnels with an outgoing or incoming interface of the specified type and number.	-
outgoing-interface *interface-type interface-number*	Displays information about all MPLS TE tunnels with a specified outgoing interface.	-
verbose	Displays detailed information.	-
stale-incoming-interface	Displays information about MPLS TE tunnels with a specified incoming interface in the stale state.	-
stale-interface	Displays information about MPLS TE tunnels on an interface in the stale state.	-

Parameter	Description	Value
stale-outgoing-interface	Displays information about MPLS TE tunnels with a specified outgoing interface in the stale state.	-
interface-index	Specifies the index of a specified stale interface.	The value is a hexadecimal integer that ranges from 1 to FFFFFFFE.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When **verbose** is configured, the command output varies with the signaling protocol used by the MPLS TE tunnel.

Example

Display information about an MPLS TE tunnel.

```
<HUAWEI> display mpls te tunnel
-------------------------------------------------------------------------------
Ingress LsrId    Destination      LSPID   In/Out Label     R  Tunnel-name
-------------------------------------------------------------------------------
10.1.1.9         10.3.3.9         6       --/1027          I  Tunnel1
```

Table 9-96 Description of the display mpls te tunnel command output

Item	Description
Ingress LsrId	Ingress LSR ID.
Destination	Destination IP address.
LSPID	LSP ID of the ingress.
In/Out Label	Incoming and outgoing labels.
R	LSR role: • I: Ingress • T: Transit • E: Egress
Tunnel-name	Tunnel name.

Display information about the MPLS TE tunnel with the ingress IP address being 10.1.1.9 and the LSP ID being 1.

```
<HUAWEI> display mpls te tunnel lsp-id 10.1.1.9 1 1
------------------------------------------------------------------------------
Ingress LsrId    Destination      LSPID  In/Out Label     R  Tunnel-name
------------------------------------------------------------------------------
10.1.1.9         10.2.2.9         1      --/3             I  Tunnel1
```

Display detailed information about an MPLS TE tunnel.

```
<HUAWEI> display mpls te tunnel verbose

Table 9-97 Description of the display mpls te tunnel verbose command output

Item	Description
No	Number of an MPLS TE tunnel.
Tunnel-Name	Name of an MPLS TE tunnel.
Tunnel Interface Name	Interface name of an MPLS TE tunnel.
TunnelIndex	Index of an MPLS TE tunnel.
LSP Index	Index of an LSP.
Session ID	Session ID, which is the tunnel ID.
LSP ID	LSP ID.
LSR Role	Role of the LSR: ● Ingress: indicates the node is the ingress of the tunnel. ● Egress: indicates the node is the egress of the tunnel. ● Transit: indicates the node is the transit of the tunnel.
LSP Type	Type of an LSP: ● Primary: indicates the primary CR-LSP. ● Hot-Standby: indicates the hot-standby CR-LSP. ● Ordinary: indicates the ordinary backup CR-LSP. ● Best-Effort: indicates the best-effort path.
Ingress LSR ID	LSR ID of the ingress.
Egress LSR ID	LSR ID of the egress.
In-Interface	Incoming interface of the LSP on the local node.
Out-Interface	Outgoing interface of the LSP on the local node.
Sign-Protocol	Tunnel protocol: ● Static: indicates Static LSP. ● Static CR: indicates Static CR-LSP. ● RSVP TE: uses RSVP TE signaling.

Item	Description
Resv Style	Style of resource reservation. For a static CR-LSP, no resource reservation style is displayed. For an RSVP-TE tunnel, shared explicit (SE) or fixed filter (FF) is displayed.
IncludeAnyAff	Valid affinity property. The default value is 0x0.
ExcludeAnyAff	Invalid affinity property. The default value is 0x0.
IncludeAllAff	The affinity property needs to be included. The default value is 0x0.
LspConstraint	Sequence number of the constraint used by an LSP.
ER-Hop Table Index	Index of an explicit routing table.
AR-Hop Table Index	Index of the actual explicit routing table.
C-Hop Table Index	Routing table index that is calculated by CSPF.
PrevTunnelIndexInSession	Index of the previous tunnel entry in the same session.
NextTunnelIndexInSession	Index of the next tunnel entry in the same session.
PSB Handle	Handle of the PSB.
Created Time	Amount of time an MPLS TE tunnel is created for.
RSVP LSP Type	LSP type. ● Primary: indicates that the LSP is a primary LSP. ● Hot-Standby: indicates that the LSP is a hot-standby LSP. **NOTE** This field is displayed as "-" because the device does not support the error code switching function.
Bandwidth Reserved Flag	Bandwidth reservation flag: ● Unreserved: indicates that no bandwidth is reserved for CTs. ● Reserved: indicates that the bandwidth is reserved for one or multiple CTs.
CT0 Bandwidth(Kbit/sec) - CT7 Bandwidth(Kbit/sec)	Value of the bandwidth that is reserved for CT0 to CT7.

Item	Description
Setup-Priority	Setup priority of an MPLS TE tunnel.
Hold-Priority	Holding priority of an MPLS TE tunnel.
Primary LSP Info	Information about the primary LSP.
TE Attribute Flag	Flag of the TE tunnel attribute.
Protected Flag	Flag of the primary tunnel of the protection group.
Bypass In Use	LSP ID of the bypass tunnel. "Not Exists" indicates that the primary tunnel is not bound to a bypass tunnel.
Bypass Tunnel Id	Tunnel ID of the bypass tunnel.
BypassTunnel	Name of the bypass tunnel.
Bypass LSP ID	LSP ID of the bypass tunnel.
FrrNextHop	Next hop of the redirect route.
ReferAutoBypassHandle	Handle of the automatic bypass tunnel.
FrrPrevTunnelTableIndex	Index value of the previous tunnel entry in FRR.
FrrNextTunnelTableIndex	Index value of the next tunnel entry in FRR.
Bypass Attribute	Attributes of a bypass tunnel. "(Not configured)" indicates that no such attribute is configured and the bypass tunnel inherits the attributes of the primary tunnel.
Setup Priority	Setup priority of a bypass tunnel.
Hold Priority	Holding priority of a bypass tunnel.
HopLimit	Maximum number of hops along a bypass tunnel.
Bandwidth	Bandwidth of a bypass tunnel.
IncludeAnyGroup	Valid affinity property of a bypass tunnel.
ExcludeAnyGroup	Invalid affinity property of a bypass tunnel.
IncludeAllGroup	The affinity property of a bypass tunnel needs to be included.
Bypass Unbound Bandwidth Info	Information about the bandwidth that is not bound to a bypass tunnel.

Item	Description
CT0 Unbound Bandwidth - CT7 Unbound Bandwidth	Bandwidth that is able to be reserved, but not for CT0 to CT7.
NextSessionTunnelIndex	Next index of a bypass tunnel entry.
PrevSessionTunnelIndex	Previous index of a bypass tunnel entry.
NextLspId	Value of the next bypass LSP ID.
PrevLspId	Value of the previous bypass LSP ID.

9.3.49 display mpls te tunnel c-hop

Function

The **display mpls te tunnel c-hop** command displays the path computation results of tunnels.

Format

display mpls te tunnel c-hop [*tunnel-name*] [**lsp-id** *ingress-lsr-id session-id lsp-id*]

Parameters

Parameter	Description	Value
tunnel-name	Displays the path computation result of the specified tunnel.	The value is an existing tunnel name.
lsp-id	Displays the path computation result of the specified tunnel based on the LSP ID.	-
ingress-lsr-id	Specifies the ingress LSR ID.	The value is in dotted decimal notation.
session-id	Specifies the session ID.	The value is an integer that ranges from 0 to 65535.
lsp-id	Specifies the LSP ID.	The value is an integer that ranges from 0 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Tunnels are established based on path computation results. When a tunnel cannot be established successfully, run the **display mpls te tunnel c-hop** command to view the path computation results for locating causes on a per-hop basis.

Example

Display the path computation result of a tunnel.

```
<HUAWEI> display mpls te tunnel c-hop
 Tunnel Interface Name : Tunnel1
 Lsp ID : 10.2.2.2 :1 :10958
 CHop Information:
  Hop 0   10.3.0.2
  Hop 1   10.3.0.3
```

Display the path computation result of the specified tunnel based on the LSP ID.

```
<HUAWEI> display mpls te tunnel c-hop lsp-id 10.2.2.2 1 10958
 Tunnel Interface Name : Tunnel1
 Lsp ID : 10.2.2.2 :1 :10958
 CHop Information:
  Hop 0   10.3.0.2
  Hop 1   10.3.0.3
```

Table 9-98 Description of the display mpls te tunnel c-hop command output

Item	Description
Tunnel Interface Name	Interface name of a tunnel.
Lsp ID	LSP ID of a tunnel, in the Ingress-Lsr-Id:Tunnel-Id:LSP-Id format.
CHop Information	Information about CSPF path computation. **Hop** specifies the IPv4 address of each hop in the path computation result.

9.3.50 display mpls te tunnel path

Function

The **display mpls te tunnel path** command displays the path of an MPLS TE tunnel.

Format

display mpls te tunnel path [[[**tunnel-name**] *tunnel-name*] [**lsp-id** *ingress-lsr-id session-id lsp-id*] | **fast-reroute** { **local-protection-available** | **local-protection-inuse** } | **lsr-role** { **ingress** | **transit** | **egress** }]

display mpls te tunnel path expanded tunnel-name *tunnel-name* [**lsp-id** *ingress-lsr-id session-id lsp-id*]

display mpls te tunnel path expanded lsp-id *ingress-lsr-id session-id lsp-id*

Parameters

Parameter	Description	Value
tunnel-name *tunnel-name*	Specifies the name of an MPLS TE tunnel. If the **mpls te signalled tunnel-name** command has been used to configure a tunnel name, this specified name is used.	The value is an existing tunnel name.
ingress-lsr-id	Specifies the LSR ID of the ingress.	The value is in dotted decimal notation.
session-id	Specifies the ID of a session.	The value is an integer that ranges from 0 to 65535.
lsp-id	Specifies the LSP ID.	The value is an integer that ranges from 0 to 65535.
fast-reroute local-protection-available	Specifies the available path for local protection of FRR.	-
fast-reroute local-protection-inuse	Specifies the path in use for local protection of FRR.	-
lsr-role { **ingress** | **transit** | **egress** }	Indicates the role of an LSR. ● **ingress**: indicates the ingress LSR. ● **transit**: indicates the transit LSR. ● **egress**: indicates the egress LSR.	-
expanded	Displays the expanded LSP path information by completing the RRO information.	-

Usage Guidelines

Usage Scenario

The **display mpls te tunnel path** command displays information about the path of an MPLS TE tunnel.

If no tunnel name is specified, information about all MPLS TE tunnels' path attributes is displayed.

When a Huawei device is interconnected with a non-Huawei device and the RRO information carried in the packet sent by the non-Huawei device is incomplete, the RRO information can be complemented using the **display mpls te tunnel path expanded** command on the Huawei device to display the information about the entire LSP path.

Precautions

The system can record and display the paths only after the **mpls te record-route** command is configured.

Example

Display information about path attributes of all MPLS TE tunnels.

```
<HUAWEI> display mpls te tunnel path
Tunnel Interface Name : Tunnel1
 Lsp ID : 10.1.1.9 :100 :34
 Hop Information
  Hop 0   172.16.1.1 Local-Protection available | node
  Hop 1   172.16.1.2  Label 1055
  Hop 2   10.2.2.9  Label 1055
  Hop 3   172.20.1.1 Local-Protection available
  Hop 4   172.20.1.2  Label 1063
  Hop 5   10.3.3.9  Label 1063
  Hop 6   172.30.1.1
  Hop 7   172.30.1.2  Label 3
  Hop 8   10.4.4.9  Label 3
```

Display path attributes of the MPLS TE tunnel with the ingress IP address being 10.1.1.9, the session ID being 300, and the LSP ID being 4.

```
<HUAWEI> display mpls te tunnel path lsp-id 10.1.1.9 300 4
 Tunnel Interface Name : Tunnel1
 Lsp ID : 10.1.1.9 :300 :4
 Hop Information
  Hop 0   172.16.1.1
  Hop 1   172.16.1.2  Label 1043
  Hop 2   10.2.2.9  Label 1043
  Hop 3   172.20.1.1
  Hop 4   172.20.1.2  Label 4
  Hop 5   10.3.3.9  Label 4
```

Display path attributes of a tunnel named **LSRAtoLSRC**.

```
<HUAWEI> display mpls te tunnel path tunnel-name LSRAtoLSRC
 Tunnel Interface Name : LSRAtoLSRC
 Lsp ID : 10.1.1.9 :1 :2
 Hop Information
  Hop 0   10.11.1.1  Local-Protection in use
  Hop 1   10.11.1.2  Label 3
  Hop 2   10.2.2.9
```

Display path attributes of a tunnel named **A2** using the command which expanded the information about the path.

```
<HUAWEI> display mpls te tunnel path expanded tunnel-name A2
 Tunnel Interface Name : A2
 Lsp ID : 10.1.1.9 :300 :4
```

```
Hop Information
 Hop 0   10.1.1.9   Local-Protection available | bandwidth
 Hop 1   172.16.1.1
 Hop 2   172.16.1.2  Label 1042
 Hop 3   10.2.2.9  Label 1042
 Hop 4   172.20.1.1
 Hop 5   172.20.1.2  Label 3
 Hop 6   10.3.3.9  Label 3
```

Table 9-99 Description of the display mpls te tunnel path command output

Item	Description
Tunnel Interface Name	Name of a tunnel interface.
Lsp ID	LSP ID on the ingress.
Hop Information	Number, IP address, and label of each hop.
Local-Protection available	Link protection provided by the bypass tunnel.
Local-Protection available | bandwidth	Bandwidth protection provided by the bypass tunnel.
Local-Protection available | node	Node protection provided by the bypass tunnel.
Local-Protection in use	The bypass tunnel in use.

9.3.51 display mpls te tunnel statistics

Function

The **display mpls te tunnel statistics** command displays the number and status of MPLS TE tunnels.

Format

display mpls te tunnel statistics

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view the number and status of MPLS TE tunnels, run the **display mpls te tunnel statistics** command.

Example

Display the number and status of MPLS TE tunnels.

```
<HUAWEI> display mpls te tunnel statistics
Ingress:    84 Tunnels     83 Up,     83 CRLSPs Up
            0 Modified,    0 In-Progress,    1 Failed
Transit:     2 Up
Egress :     3 Up
```

Table 9-100 Description of the display mpls te tunnel statistics command output

Item	Description
Ingress	Number and status of MPLS TE tunnels on the local LSR functioning as the ingress node: ● Tunnel: indicates the number of primary tunnels. ● Up: indicates the number of MPLS TE tunnels in the Up state. ● CRLSPs Up: indicates the number of CR-LSPs in the Up state. ● Modified: indicates the number of tunnels in the reestablishing state. **NOTE** The possible causes that an MPLS TE tunnel is in the Modified state are as follows: Configurations of the MPLS TE tunnel are manually modified. The MPLS TE tunnel is being re-optimized. The MPLS TE tunnel is in the FRR inuse state. The MPLS TE tunnel is in the Backup state. ● In-Progress: indicates the number of MPLS TE tunnels in the establishing process. At the moment, these tunnels do not go Up. ● Failed: indicates the number of MPLS TE tunnels in the Down state.
Transit	Number of MPLS TE tunnels, which are in the Up state, on the local LSR functioning as a transit node.
Egress	Number of MPLS TE tunnels, which are in the Up state, on the local LSR functioning as the egress node.

9.3.52 display ospf mpls-te

Function

The **display ospf mpls-te** command displays information about TE LSAs in an LSDB.

Format

display ospf [*process-id*] **mpls-te** [**area** *area-id*] [**self-originated**]

Parameters

Parameter	Description	Value
process-id	Specifies the OSPF process ID.	The value ranges from 1 to 65535.
area *area-id*	Displays information about the area with a specified ID. The value can be a decimal integer or in the IP address format.	The integer value ranges from 0 to 4294967295.
self-originated	Displays information about the self originated TE LSAs.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can view information about LSAs of a specific process or area by specifying parameters.

Example

Display information about all TE LSAs in the LSDB.

```
<HUAWEI> display ospf mpls-te
        OSPF Process 1 with Router ID 172.16.1.2

 Area ID                  : 0.0.0.0

...
```

Table 9-101 Description of the display ospf mpls-te command output

Item	Description
OSPF Process 1 with Router ID 172.16.1.2	OSPF process 1 with Router ID being 172.16.1.2.
Area ID	ID of the OSPF area enabled with TE.
Traffic Engineering LSAs of the database	TE LSAs in an LSDB.
Lsa Type	LSA type: - Opq-Link: indicates Type 9 LSAs that can only be spread on a specified interface. - Opq-Area: indicates Type 10 LSAs that can only be spread within a specified area. - Opq-As: indicates Type 11 LSAs that can be spread the same as Type 5 LSAs in the entire AS, except for the stub and NSSA areas.

Item	Description
Opaque Type	Application type of LSAs. For example, when LSAs are applied to traffic engineering, the value of the LSA type is 1. When LSAs are applied to the OSPF graceful restart, the value of the LSA type is 3.
Opaque Id	LSAs that are applied to the same application type. Opaque type and Opaque ID in an LSA header together specify the link status ID.
Advertising Router Id	Device that generates the LSA.
Lsa age	Aging time of the LSA. It is in the header of Opaque LSA, in seconds.
Length	Length of the Opaque LSA, including the LSA header, in bytes.
Lsa Options	LSA options: ● E: floods AS-external-LSAs. ● MC: forwards IP multicast packets. ● N/P: processes Type 7 LSAs. ● DC: processes required links.
LS Seq Number	LSA sequence, according to which other devices can identify the latest LSAs.
CheckSum	Checksum of LSA fields except for the LS age field.
Link Type	Link type: ● Point-to-point ● Point-to-multi-point (P2MP) ● Broadcast
Link ID	Link ID in the IP address format: ● Point-to-point: indicates the router ID of an OSPF neighbor. ● P2MP or broadcast: indicates the IP address of the DR interface.
Local Interface Address	IP address of the local interface.
Remote Interface Address	IP address of the peer interface: ● Point-to-point: indicates that the IP address of the peer is used. ● P2MP or broadcast: indicates that 0.0.0.0 is used or the IP address is omitted.
TE Metric	TE metric.

Item	Description
Maximum Bandwidth	Maximum bandwidth.
Maximum Reservable BW	Maximum capacity of reserved bandwidth.
Admin Group	Administration group.
Global Pool	Global address pool.
Unreserved BW [0] to [7]	Available bandwidth of eight levels.
Sub Pool	Sub-address pool. It is only applied to DS-TE LSAs.
Unreserved BW [8] to [15]	Available bandwidth of eight levels in the sub-address pool.
DS-TE Mode	DS-TE mode: ● Standard IETF mode ● Non-standard IETF mode
Bandwidth Constraint Model	Bandwidth Constraints model of LSAs: ● RDM ● MAM ● Extended-MAM
Bandwidth Constraints	Bandwidth constraints, which are only applied to DS-TE LSAs.
BC [0] - [7]	Eight bandwidth constraints, which are only applied to DS-TE LSAs.
Local OverBooking Multipliers	Local overbooking multiplier.
LOM [0] LOM [1]	Local overbooking multipliers for BC0 or BC1. It is applied only to DS-TE LSAs.

9.3.53 display ospf traffic-adjustment

Function

The **display ospf traffic-adjustment** command displays OSPF process-specific tunnel information relevant to traffic adjustment (through IGP shortcut and forwarding adjacency).

Format

display ospf [*process-id*] **traffic-adjustment**

Parameters

Parameter	Description	Value
process-id	Specifies the OSPF process ID. If you do not specify a process ID, information about all OSPF processes is displayed.	The value is an integer that ranges from 1 to 65535.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When you want to look up the OSPF process-specific tunnel information relevant to traffic adjustment, you can run this command.

Example

Display tunnel information, which is relevant to traffic adjustment, of OSPF process 100.

```
<HUAWEI> display ospf 100 traffic-adjustment

         OSPF Process 100 with Router ID 1.1.1.9
                 Traffic adjustment

 Interface: 1.1.1.9 (Tunnel1)
 Type: Forwarding Adjacency
 Neighbor ID: 3.3.3.9           Cost: 1
 Configuration:
  Neighbor ip address: 3.3.3.9
  Cost     :1
  Cost Type: Absolute
  Hold Time: 0
```

Table 9-102 Description of the display ospf traffic-adjustment command output

Item	Description
Interface	Name and IP address of a tunnel interface
Type	Whether a tunnel is applied to IGP shortcut or forwarding adjacency
Neighbor ID	Router ID of a neighbor device
Cost	Actual cost
Neighbor ip address	IP address of a neighbor device
Cost	Configured cost

Item	Description
Cost Type	Cost type: ● Relative: Relative cost ● Absolute: Absolute cost
Hold Time	Time elapsed since the tunnel has been created

9.3.54 enable traffic-adjustment

Function

The **enable traffic-adjustment** command enables the IGP shortcut function.

The **enable traffic-adjustment advertise** command enables the forwarding adjacency function.

The **undo enable traffic-adjustment** command disables the IGP shortcut function.

The **undo enable traffic-adjustment advertise** command disables the forwarding adjacency function.

By default, the IGP shortcut function and the forwarding adjacency function are disabled.

Format

enable traffic-adjustment [**advertise**]

undo enable traffic-adjustment [**advertise**]

Parameters

None.

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

After the configuration of a command, all TE tunnels are involved in the SPF calculation and flooding.

Example

Enable the forwarding adjacency function of the OSPF process.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] enable traffic-adjustment advertise
```

9.3.55 explicit-path

Function

The **explicit-path** command configures an explicit path of a tunnel.

The **undo explicit-path** command deletes a configured explicit path.

By default, no explicit path of a tunnel is configured.

Format

explicit-path *path-name*

undo explicit-path *path-name*

Parameters

Parameter	Description	Value
path-name	Indicates the name of an explicit path.	The value is a string of 1 to 31 case-insensitive characters, spaces not supported.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

You must enable MPLS TE before running the **explicit-path** command.

The addresses of the hops along the explicit path must be different, without loops. If a loop exists, CSPF detects the loop and fails to compute a path.

If the explicit path is in use, the **undo explicit-path** command cannot be run to delete the explicit path.

Example

Create an explicit path named path1.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] quit
[HUAWEI] explicit-path path1
[HUAWEI-explicit-path-path1] quit
```

9.3.56 explicit-path (LSP attribute view)

Function

The **explicit-path** command configures an explicit path in a CR-LSP attribute template.

The **undo explicit-path** command deletes an explicit path from a CR-LSP attribute template.

No explicit path is configured in a CR-LSP attribute template by default.

Format

explicit-path *path-name*

undo explicit-path

Parameters

Parameter	Description	Value
path-name	Specifies the name of an explicit path.	The value is an existing explicit path name.

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

To specify an explicit path in a CR-LSP attribute template, you must configure the explicit path in the system view and ensure that its hop list is not null.

Example

Configure an explicit path in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] explicit-path path-name
```

9.3.57 fast-reroute

Function

The **fast-reroute** command enables the Fast Reroute (FRR) function in a CR-LSP attribute template.

The **undo fast-reroute** command disables the FRR function in the CR-LSP attribute template.

The FRR function is disabled in the CR-LSP attribute template by default.

Format

fast-reroute [**bandwidth**]

undo fast-reroute

Parameters

Parameter	Description	Value
bandwidth	Indicates that bandwidth protection is needed during fast rerouting.	-

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

After the FRR function is enabled, the route storing function is automatically enabled. After the FRR function is disabled, the bypass tunnel configurations are automatically deleted.

Example

Enable the FRR function in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] fast-reroute
```

9.3.58 hop-limit

Function

The **hop-limit** command sets the hop limit in a CR-LSP attribute template.

The **undo hop-limit** command restores the default hop limit from a CR-LSP attribute template.

By default, the hop limit in a CR-LSP attribute template is 32.

Format

hop-limit *hop-limit*

undo hop-limit

Parameters

Parameter	Description	Value
hop-limit	Specifies the value of the hop limit.	The value is an integer that ranges from 1 to 32. The hop limit is 32 by default.

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To limit the maximum number of hops supported by each CR-LSP established using the CR-LSP attribute template, run the **hop-limit** command in the LSP attribute view. This hop limit restricts CR-LSP path selection.

Prerequisites

A CR-LSP attribute template has been created and the LSP attribute view has been entered using the **lsp-attribute** command.

Example

Set the maximum number of hops in the CR-LSP attribute template to 20.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] hop-limit 20
```

9.3.59 hotstandby-switch

Function

The **hotstandby-switch force** command forcibly switches traffic from a primary CR-LSP to a hot-standby CR-LSP.

The **hotstandby-switch clear** command disables the forcible switchover function and switches traffic from a hot-standby CR-LSP to the primary CR-LSP.

Format

hotstandby-switch { **force** | **clear** }

Parameters

None.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a hot-standby CR-LSP is established and a primary CR-LSP needs to be adjusted, run the **hotstandby-switch force** command to switch traffic forcibly to the hot-standby CR-LSP. After the primary CR-LSP has been adjusted, run the **hotstandby-switch clear** command to disable the forcible switchover function and switch traffic back to the primary CR-LSP.

Precautions

A hot-standby CR-LSP must have been established before the **hotstandby-switch force** command is used. If this command is run but no hot-standby CR-LSP is established, traffic will be dropped.

Example

Forcibly switch traffic from a primary CR-LSP to a hot-standby CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] hotstandby-switch force
```

9.3.60 list hop

Function

The **list hop** command displays information about nodes along an explicit path of an MPLS TE tunnel.

Format

list hop [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a node.	The value is in dotted decimal notation.

Views

Explicit path view

Default Level

2: Configuration level

Usage Guidelines

To view the information about nodes along an explicit path of an MPLS TE tunnel, run the **list hop** command.

Example

Display information about nodes along an explicit path of an MPLS TE tunnel.

```
<HUAWEI> system-view
[HUAWEI] explicit-path path1
[HUAWEI-explicit-path-path1] list hop
 Path Name : path1      Path Status : Enabled
 1      10.1.1.1          Strict      Include
 2      10.2.2.2          Strict      Exclude
 3      10.3.3.3          Loose       Include             Outgoing
 4      10.4.4.4          Strict      Include             Incoming
```

9.3.61 lsp-attribute

Function

The **lsp-attribute** command creates a CR-LSP attribute template and displays the LSP attribute view.

The **undo lsp-attribute** command deletes a specified CR-LSP attribute template.

By default, no CR-LSP attribute template is created.

Format

lsp-attribute *lsp-attribute-name*

undo lsp-attribute *lsp-attribute-name*

Parameters

Parameter	Description	Value
lsp-attribute-name	Specifies the name of the CR-LSP attribute template.	The value is a string of 1 to 31 case-insensitive characters, spaces not supported.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To simplify configurations of TE tunnel interfaces and enhance their flexibility, you can reference CR-LSP attribute templates to set up TE tunnels. The CR-LSP attribute template contains the attributes relevant to a TE tunnel, including the bandwidth, affinity property, explicit path, hop limit, route storing, setup priority, holding priority, FRR, and bypass tunnel attribute.

Prerequisites

Before configuring a CR-LSP attribute template, you must enable the MPLS TE function in the system view.

Precautions

When deleting a CR-LSP attribute template, ensure that the CR-LSP attribute template is not referenced by any tunnel interface.

Example

Create the CR-LSP attribute template named **lsp-attribute-name**.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name]
```

9.3.62 modify hop

Function

The **modify hop** command modifies the IP address of a hop on an explicit path.

Format

modify hop *ip-address1 ip-address2* [**include** [[**loose** | **strict**] | [**incoming** | **outgoing**]] * | **exclude**]

Parameters

Parameter	Description	Value
ip-address1 ip-address2	Changes *ip-address1* to *ip-address2* on an explicit path.	The value is in dotted decimal notation.

Parameter	Description	Value
include [[**loose** | **strict**] | [**incoming** | **outgoing**]] *	Indicates that the explicit path must pass through the modified node on the explicit path. ● **strict**: indicates the strict explicit path. The modified node must be directly connected to the previous node. ● **loose**: indicates the loose explicit path. The modified node can be not directly connected to the previous node. ● **incoming**: indicates that the *ip-address2* is the IP address of an inbound interface of the modified node. ● **outgoing**: indicates that the *ip-address2* is the IP address of an outbound interface of the modified node.	By default, a node is added to an explicit path in **include strict** mode.
exclude	Indicates that the LSP set up along an explicit path excludes the modified link or node.	-

Views

Explicit path view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The following commands are used to adjust nodes on a created explicit path:

- The **add hop** command is used to add a node to the explicit path.
- The **modify hop** command is used to delete a node from the explicit path and replace the node with a specified node.
- The **delete hop** command is used to delete a node from the explicit path.

Prerequisites

A next-hop IP address has been configured using the **next hop** command.

Follow-up Procedure

Run the **display explicit-path** command to view information about the explicit path.

Precautions

A node can be modified on an explicit path using the **modify hop** command only when the following conditions are met:

- *ip-address2* must not be a next-hop IP address of an existing node on the explicit path.
- If an explicit path over which a TE tunnel has been established is modified, the make-before-break mechanism is triggered, and a CR-LSP is reestablished without traffic loss.

Example

Modify IP address of a node along the explicit path from 10.1.1.9 to 10.2.2.9.

```
<HUAWEI> system-view
[HUAWEI] explicit-path p1
[HUAWEI-explicit-path-p1] next hop 10.1.1.9
[HUAWEI-explicit-path-p1] modify hop 10.1.1.9 10.2.2.9
```

9.3.63 mpls-te enable

Function

The **mpls-te enable** command enables the MPLS TE feature in the current OSPF area.

The **undo mpls-te** command disables the MPLS TE feature in the current OSPF area.

OSPF area does not support MPLS TE by default.

Format

mpls-te enable [**standard-complying**]

undo mpls-te

Parameters

Parameter	Description	Value
standard-complying	Accepts only LSAs in the standard format. This means that an LSA is rejected if it has more than one Top level TLV.	-

Views

OSPF area view

Default Level

2: Configuration level

Usage Guidelines

MPLS TE can only be enabled in an OSPF area after the OSPF process is enabled with the Opaque LSA function.

Example

Enable TE in OSPF area 1.

```
<HUAWEI> system-view
[HUAWEI] ospf 100
[HUAWEI-ospf-100] opaque-capability enable
[HUAWEI-ospf-100] area 1
[HUAWEI-ospf-100-area-0.0.0.1] mpls-te enable
```

9.3.64 mpls autobypass-tunnel-number threshold-alarm

Function

The **mpls autobypass-tunnel-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for Auto bypass tunnel interfaces.

The **undo mpls autobypass-tunnel-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls autobypass-tunnel-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls autobypass-tunnel-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for the proportion of configured Auto bypass tunnel interfaces to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for the proportion of configured Auto bypass tunnel interfaces to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of Auto bypass tunnel interfaces reaches a specified upper limit, new Auto bypass tunnel interfaces cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of configured Auto bypass tunnel interfaces to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls autobypass-tunnel-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of configured Auto bypass tunnel interfaces to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of configured Auto bypass tunnel interfaces to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls autobypass-tunnel-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls autobypass-tunnel-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for Auto bypass tunnel interfaces.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls autobypass-tunnel-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.65 mpls bfd-te-number threshold-alarm

Function

The **mpls bfd-te-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for dynamic BFD sessions for TE.

The **undo mpls bfd-te-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls bfd-te-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls bfd-te-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Sets the upper alarm threshold for the proportion of established dynamic BFD sessions for TE to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Sets the lower alarm threshold for the proportion of established dynamic BFD sessions for TE to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of dynamic BFD sessions for TE reaches a specified upper limit, new dynamic BFD sessions for TE cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of established dynamic BFD sessions for TE to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls bfd-te-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of established dynamic BFD sessions for TE to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of established dynamic BFD sessions for TE to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls bfd-te-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls bfd-te-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for dynamic BFD sessions for TE.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls bfd-te-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.66 mpls cspf threshold-alarm

Function

The **mpls** { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm** command sets the upper and lower alarm thresholds for the proportion of the number of existing CSPF resources of a specified type to the maximum number of CSPF resources that a device supports. The CSPF resources can be CSPF links, nodes, network LSAs, or SRLGs.

The **undo mpls** { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm** command restores the default the upper and lower alarm thresholds.

By default, the upper threshold for alarms is 80 (percent), and the lower threshold for clear alarms is 75 (percent).

Format

mpls { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm**

Parameters

Parameter	Description	Value
cspf-link-number	Indicates the upper and lower alarm thresholds of the proportion of the existing CSPF links to the maximum number of CSPF links that a device supports.	-
cspf-node-number	Indicates the upper and lower alarm thresholds of the proportion of the existing CSPF nodes to the maximum number of CSPF nodes that a device supports.	-
cspf-nlsa-number	Indicates the upper and lower alarm thresholds of the proportion of the existing CSPF network LSAs to the maximum number of CSPF network LSAs that a device supports.	-
cspf-srlg-number	Indicates the upper and lower alarm thresholds of the proportion of the existing CSPF SRLGs to the maximum number of CSPF SRLGs that a device supports.	-
upper-limit *upper-limit-value*	Specifies a percent for the upper alarm threshold.	The value is a percent integer ranging from 1 to 100. Set the value less than or equal to 95. Default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies a percent for the lower alarm threshold.	The value is a percent integer ranging from 1 to 100. *lower-limit-value* must be less than *upper-limit-value*. Default value 75 is recommended.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the following example, the alarm thresholds for CSPF links are used. If the number of CSPF links reaches the maximum number of CSPF links that a device supports, new CSPF links fail to be established. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of configured CSPF links to all supported ones reaches a specified upper alarm threshold. To enable this function, run the **mpls cspf-link-number threshold-alarm** command to set the upper and lower alarm thresholds with the following parameters configured:

- *upper-limit-value*: An alarm is generated if the proportion of the number of existing CSPF links to the maximum number reaches *upper-limit-value*.
- *lower-limit-value*: The alarm is cleared if the proportion of the number of existing CSPF links to the maximum number falls to *lower-limit-value*.

Precautions

- If the **mpls** { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- The **mpls** { **cspf-link-number** | **cspf-node-number** | **cspf-nlsa-number** | **cspf-srlg-number** } **threshold-alarm** command only configures trigger conditions for alarms and clear alarms. Although trigger conditions are met, an alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_lspm trap-name** { **hwmplsresourcethresholdexceed** | **hwmplsresourcethresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Set the upper and lower alarm thresholds to 90% and 60%, respectively, for the proportion of existing CSPF links to the maximum number of CSPF links that a device supports.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls cspf-link-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.67 mpls rsvp-lsp-number threshold-alarm

Function

The **mpls rsvp-lsp-number threshold-alarm** command configures the alarm threshold for Resource Reservation Protocol (RSVP) label switched path (LSP) usage.

The **undo mpls rsvp-lsp-number threshold-alarm** command restores the default settings.

The default upper limit of the alarm threshold for RSVP LSP usage is 80%. The default lower limit of the clear alarm threshold for RSVP LSP usage is 75%.

Format

mpls rsvp-lsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls rsvp-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls rsvp-lsp-number threshold-alarm

undo mpls rsvp-lsp-number { **ingress** | **transit** | **egress** } **threshold-alarm**

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for RSVP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for RSVP LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.
ingress	The alarm that the number of ingress RSVP LSPs reached the upper threshold is generated.	-
transit	The alarm that the number of transit RSVP LSPs reached the upper threshold is generated.	-
egress	The alarm that the number of egress RSVP LSPs reached the upper threshold is generated.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of RSVP LSPs in the system reaches a specific limit, establishing subsequent RSVP LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of RSVP LSPs reaches the specific limit. To configure the alarm threshold for RSVP LSP usage, run the **mpls rsvp-lsp-number threshold-alarm** command. The parameters in this command are described as follows:

- When the RSVP LSP usage increases to the value of *upper-limit-value*, an alarm for RSVP LSPs is generated.
- When the RSVP LSP usage falls below the value of *lower-limit-value*, a clear alarm for RSVP LSPs is generated.

If you want to set the alarm threshold for ingress RSVP LSPs, transit RSVP LSPs or egress RSVP LSPs, run **mpls rsvp-lsp-number** { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls rsvp-lsp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- This command configures the alarm threshold for RSVP LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceed** is configured, and the actual RSVP LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the lower threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual RSVP LSP usage falls below the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for RSVP LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-lsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.68 mpls rsvp-peer-number threshold-alarm

Function

The **mpls rsvp-peer-number threshold-alarm** command configures the conditions that trigger the threshold-reaching alarm and its clear alarm for RSVP neighbors.

The **undo mpls rsvp-peer-number threshold-alarm** command restores the default settings.

By default, the upper alarm threshold is 80%, and the lower alarm threshold is 75%.

Format

mpls rsvp-peer-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls rsvp-peer-number threshold-alarm

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper alarm threshold for the proportion of configured RSVP neighbors to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower alarm threshold for the proportion of configured RSVP neighbors to all supported ones.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of RSVP neighbors reaches a specified upper limit, new RSVP neighbors cannot be configured due to insufficient resources. To alert the administrator in operation and maintenance, enable a device to generate an alarm when the proportion of configured RSVP neighbors to all supported ones reaches a specified upper alarm threshold. The following parameters can be configured in the **mpls rsvp-peer-number threshold-alarm** command:

- *upper-limit-value*: upper alarm threshold. If the proportion of configured RSVP neighbors to all supported ones reaches the upper alarm threshold, an alarm can be generated.
- *lower-limit-value*: lower alarm threshold. If the proportion of configured RSVP neighbors to all supported ones falls below the lower alarm threshold, a clear alarm can be generated.

Precautions

- If the **mpls rsvp-peer-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.

- The **mpls rsvp-peer-number threshold-alarm** command only configures the trigger conditions for an alarm and its clear alarm. Although trigger conditions are met, the alarm and its clear alarm can be generated only after the **snmp-agent trap enable feature-name mpls_rsvp trap-name** { **hwrsvpteifnbrthresholdexceed** | **hwrsvpteifnbrthresholdexceedclear** } command is run to enable the device to generate an MPLS resource insufficiency alarm and its clear alarm.

Example

Configure conditions that trigger the threshold-reaching alarm and its clear alarm for RSVP neighbors.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-peer-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.69 mpls rsvp-te

Function

The **mpls rsvp-te** command enables the RSVP-TE function on an interface or globally.

The **undo mpls rsvp-te** command disables the RSVP-TE function.

RSVP-TE is disabled by default.

Format

mpls rsvp-te

undo mpls rsvp-te

Parameters

None

Views

MPLS view, VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

You must run the **mpls (system view)** and **mpls te** commands to enable MPLS and MPLS TE before running the **mpls rsvp-te** command in the MPLS view.

You must run the **mpls (interface view)** and **mpls te** commands to enable MPLS and MPLS TE before running the **mpls rsvp-te** command in the interface view.

Precautions

Before enabling the RSVP-TE function on an interface, you need to run this command in the MPLS view to enable the RSVP-TE function globally.

NOTICE

After the **undo mpls rsvp-te** command is run in the MPLS view, MPLS RSVP-TE services may be interrupted and all MPLS RSVP-TE configurations are deleted. To restore the MPLS RSVP-TE services, reconfigure these commands.

Example

Enable RSVP-TE globally.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls rsvp-te
```

Enable RSVP-TE on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
```

Enable RSVP-TE on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
```

9.3.70 mpls rsvp-te authentication

Function

The **mpls rsvp-te authentication** command run in the interface or neighbor view enables authentication and sets an authentication key.

The **undo mpls rsvp-te authentication** command run in the interface or neighbor view disables authentication.

Authentication is disabled by default.

Format

mpls rsvp-te authentication { { **cipher** | **plain** } *auth-key* | **keychain** *keychain-name* [**sha256-compatible**] }

undo mpls rsvp-te authentication

Parameters

Parameter	Description	Value
cipher	Indicates that the key is displayed in cipher text.	-
plain	Indicates that the key is displayed in plain text. **NOTICE** If **plain** is selected, the password is saved in the configuration file in plain text. In this case, users at a lower level can easily obtain the password by viewing the configuration file. This brings security risks. Therefore, it is recommended that you select **cipher** to save the password in cipher text.	-
auth-key	Specifies the password.	A string of case-sensitive characters, spaces not supported. When the key is displayed in plaintext, its length ranges from 1 to 255; when the key is displayed in MD5 cipher text, its length ranges from 20 to 392. When double quotation marks are used around the string, spaces are allowed in the string.
keychain *keychain-name*	Specifies the keychain name, which is configured by running the **keychain** command.	The value is the name of an existing keychain.
sha256-compatible	Indicates that the calculated digest includes the authentication key when the SHA-256 algorithm is used for Keychain authentication. If this parameter is not specified, the calculated digest does not include the authentication key.	-

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, RSVP-TE neighbor view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

RSVP authentication can be configured to improve network reliability and security and prevent attacks initiated using messages modified or forged by unauthorized users.

RSVP authentication can prevent the setup of an illegal RSVP neighbor relationship using the following methods and protect the local node against attacks (such as malicious reservation of a larger number of bandwidth resources):

- An unauthorized node attempts to set up an RSVP neighbor relationship with the local node.
- A remote node generates and sends forged RSVP messages to set up a neighbor relationship with the local node.

Prerequisites

The **mpls rsvp-te** command is run to enable RSVP-TE in the MPLS view and interface view.

Precautions

The **mpls rsvp-te authentication** command run in either of the following views produces a specific result:

- If this command is run in the interface view, RSVP authentication takes effect on packets received by the interface. The interface sends RSVP-TE packets all carrying authentication information that is calculated using the key of the configured authentication mode, and authenticates all received RSVP-TE packets based on the configured key.
- If this command is run in the MPLS RSVP-TE neighbor view, RSVP authentication takes effect on packets received by the local RSVP-TE neighbor. The RSVP-TE packets sending by neighbor node all carry authentication information that is calculated using the key of the configured authentication mode, and authenticates all RSVP-TE packets sending to the neighbor node based on the configured key.

Parameters are optional for configuring HMAC-MD5 or keychain authentication:

- **cipher**: indicates HMAC-MD5 authentication with the key displayed in cipher text.
- **plain**: indicates HMAC-MD5 authentication with the key displayed in plain text.
- **keychain**: indicates keychain authentication with a globally configured keychain.
  - If the **sha256-compatible** parameter is specified and the SHA-256 algorithm is used for Keychain authentication, the calculated digest includes the authentication key.
  - If the **sha256-compatible** parameter is not specified and the SHA-256 algorithm is used for Keychain authentication, the digest is calculated using only original packets.

  – If the SHA-256 algorithm is not used for Keychain authentication, the **sha256-compatible** parameter does not need to be specified.

Note that HMAC-MD5 encryption algorithm cannot ensure security. Keychain authentication is recommended.

Example

Configure keychain authentication for the peer. The referenced keychain name is **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] quit
[HUAWEI] mpls rsvp-te peer 10.0.0.1
[HUAWEI-mpls-rsvp-te-peer-10.0.0.1] mpls rsvp-te authentication keychain kc1
```

Configure keychain authentication for the peer. The referenced keychain name is **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] quit
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te authentication keychain kc1
```

Configure keychain authentication for the peer. The referenced keychain name is **kc1**.

```
<HUAWEI> system-view
[HUAWEI] keychain kc1 mode absolute
[HUAWEI-keychain-kc1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication keychain kc1
```

9.3.71 mpls rsvp-te authentication handshake

Function

The **mpls rsvp-te authentication handshake** command configures the RSVP-TE handshake mechanism.

The **undo mpls rsvp-te authentication handshake** command deletes the RSVP-TE handshake mechanism configuration.

By default, no RSVP-TE handshake mechanism is configured.

Format

mpls rsvp-te authentication handshake

undo mpls rsvp-te authentication handshake

Parameters

None

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, RSVP-TE neighbor view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Enhanced RSVP authentication can be configured to improve the system security and the capability to authenticate users in the unfavorable environment such as network congestion. Enhanced RSVP authentication functions are as follows:

- Sets the sliding window size for RSVP authentication messages.
- Configures the RSVP-TE handshake mechanism.

Traditional RSVP authentication is used to prevent an unauthorized remote node from setting up a neighbor relationship with the local node. It also prevents attacks (such as maliciously reserving a large number of bandwidth resources) initiated by a remote node after the remote node constructs pseudo RSVP messages to set up an RSVP neighbor relationship with the local node. Traditional RSVP authentication, however, cannot prevent anti-replay attacks or prevent the problem of neighbor relationship termination due to RSVP message disorder.

In an unfavorable environment, the **mpls rsvp-te authentication handshake** command can be used to configure the RSVP-TE handshake mechanism to prevent anti-replay and improve network security.

Prerequisites

The RSVP authentication function must have been enabled by running the **mpls rsvp-te authentication** { { **cipher** | **plain** } *auth-key* | **keychain** *keychain-name* [**sha256-compatible**] } command in the interface view or the MPLS RSVP-TE neighbor view.

Example

Configure the RSVP-TE handshake mechanism.

```
<HUAWEI> system-view
[HUAWEI] mpls rsvp-te peer 172.16.1.1
[HUAWEI-mpls-rsvp-te-peer-172.16.1.1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-mpls-rsvp-te-peer-172.16.1.1] mpls rsvp-te authentication handshake
```

Configure the RSVP-TE handshake mechanism.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
```

```
[HUAWEI-Vlanif100] mpls rsvp-te authentication cipher beijing123
[HUAWEI-Vlanif100] mpls rsvp-te authentication handshake
```

Configure the RSVP-TE handshake mechanism.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication handshake
```

9.3.72 mpls rsvp-te authentication lifetime

Function

The **mpls rsvp-te authentication lifetime** command sets the RSVP-TE authentication lifetime.

The **undo mpls rsvp-te authentication lifetime** command restores the default RSVP-TE authentication lifetime.

By default, the RSVP-TE authentication lifetime is 30 minutes.

Format

mpls rsvp-te authentication lifetime *lifetime*

undo mpls rsvp-te authentication lifetime

Parameters

Parameter	Description	Value
lifetime	Specifies the authentication lifetime.	The value ranges from 00:00:01 to 23:59:59 in the format of HH:MM:SS. The default value is 00:30:00.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, RSVP-TE neighbor view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The RSVP lifetime functions are as follows:

- When no CR-LSP exists between RSVP neighbors, the RSVP adjacency remains until the RSVP authentication lifetime expires. The configuration of the RSVP authentication time does not affect the status of existing CR-LSPs.
- This function can avoid continuous RSVP authentication. For example, when RSVP authentication is enabled between RTA and RTB, but the key is damaged because the RSVP messages sent from RTA to RTB are incorrect, RTB receives and discards the messages. This can cause RTA to continuously send RTB the faulty RSVP messages and RTB to continuously discard these RSVP messages. The authentication relationship between the neighbors, however, cannot be torn down. In this case, the authentication lifetime needs to be configured. When a neighbor is able to receive a valid RSVP message within the lifetime, the RSVP authentication lifetime resets. Otherwise, the authentication relationship between RSVP-TE neighbors is deleted after the authentication lifetime expires.

Prerequisites

The RSVP authentication function must have been enabled by running the **mpls rsvp-te authentication** { { **cipher** | **plain** } *auth-key* | **keychain** *keychain-name* [**sha256-compatible**] } command in the interface view or the MPLS RSVP-TE neighbor view.

Example

Set the authentication lifetime to 40 minutes.

```
<HUAWEI> system-view
[HUAWEI] mpls rsvp-te peer 10.0.0.1
[HUAWEI-mpls-rsvp-te-peer-10.0.0.1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-mpls-rsvp-te-peer-10.0.0.1] mpls rsvp-te authentication lifetime 00:40:00
```

Set the authentication lifetime to 20 minutes.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te authentication cipher beijing123
[HUAWEI-Vlanif100] mpls rsvp-te authentication lifetime 00:20:00
```

Set the authentication lifetime to 20 minutes.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication lifetime 00:20:00
```

9.3.73 mpls rsvp-te authentication window-size

Function

The **mpls rsvp-te authentication window-size** command specifies the maximum number of RSVP authentication messages that can be received out of sequence.

The **undo mpls rsvp-te authentication window-size** command restores the default configuration.

By default, the maximum number of RSVP authentication messages that can be received out of sequence is 1.

Format

mpls rsvp-te authentication window-size *window-size*

undo mpls rsvp-te authentication window-size

Parameters

Parameter	Description	Value
window-size	Specifies the size of a message window.	The value is an integer that ranges from 1 to 64. The default size is 1.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view, RSVP-TE neighbor view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Enhanced RSVP authentication can be configured to improve the system security and the capability to authenticate users in the unfavorable environment such as network congestion. Enhanced RSVP authentication functions are as follows:

- Sets the sliding window size for RSVP authentication messages.
- Configures the RSVP-TE handshake mechanism and sets the local password.

Traditional RSVP authentication is used to prevent an unauthorized remote node from setting up a neighbor relationship with the local node. It also prevents attacks (such as maliciously reserving a large number of bandwidth resources) initiated by a remote node after the remote node constructs pseudo RSVP messages to set up an RSVP neighbor relationship with the local node. Traditional RSVP authentication, however, cannot prevent anti-replay attacks or prevent the problem of neighbor relationship termination due to RSVP message disorder.

In an unfavorable environment, the **mpls rsvp-te authentication window-size** command can be used to set the maximum number of RSVP authentication messages that can be received. This setting prevents authentication termination due to RSVP message disorder.

Prerequisites

The RSVP authentication function must have been enabled by running the **mpls rsvp-te authentication** { { **cipher** | **plain** } *auth-key* | **keychain** *keychain-name*

[**sha256-compatible**] } command in the interface view or the MPLS RSVP-TE neighbor view.

Precautions

Setting the window size to a value greater than 32 is recommended. If the size of a sliding window is small, the RSVP messages may be dropped and the RSVP neighbor relationship may be terminated. If the size of a sliding window is set to 1, all the RSVP authentication messages that are received out of sequence are dropped.

Example

Set the size of the message window to 64.

```
<HUAWEI> system-view
[HUAWEI] mpls rsvp-te peer 172.16.1.1
[HUAWEI-mpls-rsvp-te-peer-172.16.1.1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-mpls-rsvp-te-peer-172.16.1.1] mpls rsvp-te authentication window-size 64
```

Set the size of the message window to 1.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te authentication cipher beijing123
[HUAWEI-Vlanif100] mpls rsvp-te authentication window-size 1
```

Set the size of the message window to 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication cipher beijing123
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te authentication window-size 1
```

9.3.74 mpls rsvp-te bfd

Function

The **mpls rsvp-te bfd** command sets parameters of a BFD session for RSVP on a specified interface.

The **undo mpls rsvp-te bfd** command restores the default configuration.

By default, no parameter of a BFD session for RSVP on a specified interface is set.

Format

mpls rsvp-te bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

undo mpls rsvp-te bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo mpls rsvp-te bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

Parameters

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-rx-interval *rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection multiplier value of a BFD session.	An integer ranging from 3 to 50. The value is 3 by default.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Actual local interval at which BFD packets are sent = MAX { Local interval at which BFD packets are sent, Remote interval at which BFD packets are received }; Actual local interval at which BFD packets are received = MAX { Remote interval at which BFD packets are sent, Local interval at which BFD packets are received }; Local detection period = Actual interval at which BFD packets are received x Remote BFD detection multiplier.

For example:

- The local sending interval is 200 ms, while the local receiving interval is 300 ms, and the detection multiplier is 4.
- The remote sending interval is 100 ms, while the remote receiving interval is 600 ms, and the detection multiplier is 5.

Then,

- The actual local sending interval is 600 ms (MAX { 200 ms, 600 ms }), while the local receiving interval is 300 ms (MAX { 100 ms, 300 ms }), and the detection period is 1500 ms (300 ms x 5).
- The actual remote sending interval is 300 ms (MAX { 100 ms, 300 ms }), while the receiving interval is 600 ms (MAX { 200 ms, 600 ms }), and the detection period is 2400 ms (600 ms x 4).

Example

Set the parameters for the BFD session on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te bfd min-tx-interval 50 detect-multiplier 5
```

Set the parameters for the BFD session on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te bfd min-tx-interval 50 detect-multiplier 5
```

9.3.75 mpls rsvp-te bfd all-interfaces

Function

The **mpls rsvp-te bfd all-interfaces** command sets session parameters on all RSVP-TE interfaces.

The **undo mpls rsvp-te bfd all-interfaces** command restores the default configuration.

By default, no session parameters on all RSVP-TE interfaces are set.

Format

mpls rsvp-te bfd all-interfaces { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

undo mpls rsvp-te bfd all-interfaces { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo mpls rsvp-te bfd all-interfaces { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

Parameters

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. ● After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. ● After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.

Parameter	Description	Value
min-rx-interval *rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection multiplier value of a BFD session.	An integer ranging from 3 to 50. The value is 3 by default.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Actual local interval at which BFD packets are sent = MAX { Local interval at which BFD packets are sent, Remote interval at which BFD packets are received }; Actual local interval at which BFD packets are received = MAX { Remote interval at which BFD packets are sent, Local interval at which BFD packets are received }; Local detection period = Actual interval at which BFD packets are received x Remote BFD detection multiplier.

For example:

- The local sending interval is 200 ms, while the local receiving interval is 300 ms, and the detection multiplier is 4.
- The remote sending interval is 100 ms, while the remote receiving interval is 600 ms, and the detection multiplier is 5.

Then,

- The actual local sending interval is 600 ms (MAX { 200 ms, 600 ms }), while the local receiving interval is 300 ms (MAX { 100 ms, 300 ms }), and the detection period is 1500 ms (300 ms x 5).
- The actual remote sending interval is 300 ms (MAX { 100 ms, 300 ms }), while the receiving interval is 600 ms (MAX { 200 ms, 600 ms }), and the detection period is 2400 ms (600 ms x 4).

Example

Set the session parameters of all RSVP-TE interfaces.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te bfd all-interfaces min-tx-interval 500 min-rx-interval 400
```

9.3.76 mpls rsvp-te bfd all-interfaces enable

Function

The **mpls rsvp-te bfd all-interfaces enable** command globally enables BFD for RSVP.

The **undo mpls rsvp-te bfd all-interfaces enable** command restores the default configuration.

By default, BFD for RSVP is disabled.

Format

mpls rsvp-te bfd all-interfaces enable

undo mpls rsvp-te bfd all-interfaces enable

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The **mpls rsvp-te bfd all-interfaces enable** command enables the capability of creating BFD sessions on all interfaces that are not blocked from BFD for RSVP.

Example

Enable BFD for RSVP globally.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te bfd all-interfaces enable
```

9.3.77 mpls rsvp-te bfd block

Function

The **mpls rsvp-te bfd block** command blocks the BFD for RSVP capability on an interface.

The **undo mpls rsvp-te bfd block** command restores the default configuration.

By default, the BFD for RSVP capability on an interface is not blocked.

Format

mpls rsvp-te bfd block

undo mpls rsvp-te bfd block

Parameters

None

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls rsvp-te bfd block** command and the **mpls rsvp-te bfd enable** command are mutually exclusive.

The **mpls rsvp-te bfd block** command is similar to the **undo mpls rsvp-te bfd enable** command. Their differences are as follows:

- When the **undo mpls rsvp-te bfd enable** command is run to disable BFD for RSVP on an RSVP interface, the interface can obtain the BFD for RSVP capability after you configure the **mpls rsvp-te bfd all-interfaces enable** command in the MPLS view.
- When the **mpls rsvp-te bfd block** command is run on an interface, the interface cannot obtain the BFD for RSVP capability even if the **mpls rsvp-te bfd all-interfaces enable** command is run in the MPLS view.

NOTE

- To enable the BFD for RSVP capability on a majority of interfaces, you can run the **mpls rsvp-te bfd block** command on a minority of interfaces that do not need to be enabled with BFD for RSVP. Then, you can run the **mpls rsvp-te bfd all-interfaces enable** command in the MPLS view to enable the BFD for RSVP capability for the desired majority.
- To enable BFD for RSVP capability on a few interfaces, you can run the **mpls rsvp-te bfd enable** command on these specific interfaces. In addition, you can run the **undo mpls rsvp-te bfd enable** command or the **mpls rsvp-te bfd block** command to disable BFD for RSVP on these interfaces.

Example

Disable BFD for RSVP on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te bfd block
```

Disable BFD for RSVP on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te bfd block
```

9.3.78 mpls rsvp-te bfd enable

Function

The **mpls rsvp-te bfd enable** command enables the BFD for RSVP capability on an interface.

The **undo mpls rsvp-te bfd enable** command restores the default configuration.

By default, the BFD for RSVP capability on an interface is disabled.

Format

mpls rsvp-te bfd enable

undo mpls rsvp-te bfd enable

Parameters

None

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls rsvp-te bfd enable** command and the **mpls rsvp-te bfd block** command are mutually exclusive. When using these commands, note the following:

- If the **undo mpls rsvp-te bfd enable** command is run to disable BFD for RSVP on an RSVP interface, the interface can still obtain the BFD for RSVP capability after you configure the **mpls rsvp-te bfd all-interfaces enable** command in the MPLS view.
- If the **mpls rsvp-te bfd block** command is run on an interface, the interface cannot obtain the BFD for RSVP capability even if the **mpls rsvp-te bfd all-interfaces enable** command is run in the MPLS view.

NOTE

- To enable the BFD for RSVP capability on a majority of interfaces, you can run the **mpls rsvp-te bfd block** command on a minority of interfaces that do not need to be enabled with BFD for RSVP. Then, you can run the **mpls rsvp-te bfd all-interfaces enable** command in the MPLS view to enable the BFD for RSVP capability for the desired majority.
- To enable BFD for RSVP capability on a few interfaces, you can run the **mpls rsvp-te bfd enable** command on these specific interfaces. In addition, you can run the **undo mpls rsvp-te bfd enable** command or the **mpls rsvp-te bfd block** command to disable BFD for RSVP on these interfaces.

Example

Enable the BFD for RSVP capability on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te bfd enable
```

Enable the BFD for RSVP capability on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te bfd enable
```

9.3.79 mpls rsvp-te challenge-lost

Function

The **mpls rsvp-te challenge-lost** command sets the maximum number of times that the authenticator allows itself to retransmit Challenge messages during RSVP authentication.

The **undo mpls rsvp-te challenge-lost** command restores the default setting.

By default, the number of times for retransmitting Challenge messages is 3.

Format

mpls rsvp-te challenge-lost *max-miss-times*

undo mpls rsvp-te challenge-lost

Parameters

Parameter	Description	Value
max-miss-times	Specifies the number of times for retransmitting Challenge messages.	The value is an integer that ranges from 1 to 10. The default value is 3.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Assume node A and node B are RSVP neighbors and they need to authenticate each other. Node A authenticates node B as follows:

- Node A sends an RSVP message carrying an Integrity object to node B.
- When node B receives the message and detects that the key ID of node A is different from that in the Integrity object, node B sends a Challenge message to node A and starts a timer determining the time interval at which the Challenge message will be periodically retransmitted, and records the number of retries.
- When node A receives the Challenge message from node B, it directly copies the Challenge object in a message and adds its Integrity object to the message to generate a Response message to be sent to node B.
- When node B receives the Response message from node A, it checks whether the Challenge object in the Response message is consistent with the local Challenge object.
  - If the Challenge objects are consistent, node B stops and resets the timer for sending Challenge messages. Then, the authentication is successful.
  - If the Challenge message timer expires before node B receives the Response message, the authentication fails.

You can run the **mpls rsvp-te challenge-lost** command to change the maximum number of times for sending Challenge messages. In addition, you can use the **mpls rsvp-te retrans-timer challenge** command to change the interval for retransmitting Challenge messages.

Example

Set the number of times for retransmitting Challenge messages to 5.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te challenge-lost 5
```

9.3.80 mpls rsvp-te fast-reroute-bandwidth compatible

Function

The **mpls rsvp-te fast-reroute-bandwidth compatible** command configures the bandwidth of FRR objects to be saved in the integer mode.

The **undo mpls rsvp-te fast-reroute-bandwidth compatible** command restores the default configuration.

By default, the bandwidth of FRR objects is saved in the float point mode.

Format

mpls rsvp-te fast-reroute-bandwidth compatible

undo mpls rsvp-te fast-reroute-bandwidth compatible

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

When Huawei devices communicate with devices from other vendors whose saving mode of the bandwidth of FRR objects is set to the integer mode, you need to run this command to set the saving mode of the bandwidth of FRR objects to the integer mode.

Example

Configure the saving mode of the bandwidth of FRR objects as the integer mode.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te fast-reroute-bandwidth compatible
```

9.3.81 mpls rsvp-te hello-lost

Function

The **mpls rsvp-te hello-lost** command sets the maximum number of times for the consecutively lost Hello messages.

The **undo mpls rsvp-te hello-lost** command restores the default configuration.

By default, a maximum of three Hello messages can be lost consecutively.

Format

mpls rsvp-te hello-lost *times*

undo mpls rsvp-te hello-lost

Parameters

Parameter	Description	Value
times	Specifies the maximum number of times for the consecutively lost Hello messages.	The value is an integer that ranges from 3 to 10. The default value is 3.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the RSVP Hello extension function is enabled, you can run this command to set the maximum number of times for the consecutively lost Hello messages. If the number of times a node does not receive Hello messages consecutively exceeds the maximum value, it is considered that the link fails.

Prerequisites

The RSVP Hello extension function has been enabled by running the **mpls rsvp-te hello** command in the MPLS view.

Example

Set the maximum number of times for the consecutively lost Hello messages to 5.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te hello
[HUAWEI-mpls] mpls rsvp-te hello-lost 5
```

9.3.82 mpls rsvp-te hello

Function

The **mpls rsvp-te hello** command enables the RSVP Hello extension function globally or on an interface.

The **undo mpls rsvp-te hello** command disables the RSVP Hello extension function globally or on an interface.

By default, the RSVP Hello extension function is disabled.

Format

mpls rsvp-te hello

undo mpls rsvp-te hello

Parameters

None

Views

MPLS view, VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The RSVP Hello extension mechanism provides fast detection on the reachability between RSVP nodes. The function increases network costs. Therefore, you need to determine whether to enable this function based on network requirements.

Prerequisites

RSVP-TE has been enabled by running the **mpls rsvp-te** command.

Precautions

The **undo mpls rsvp-te hello** command in the MPLS view disables the Hello function from all interfaces and disables GR on the local node.

You can run the **mpls rsvp-te hello** command in the MPLS view to enable the Hello function globally. After that, you can run the **mpls rsvp-te hello** command in the interface view to enable the Hello function on an interface.

The **undo mpls rsvp-te hello** command in the interface view is used to disable the Hello function on the interface. The **undo mpls rsvp-te hello** command in the MPLS view is used to disable the Hello function globally.

Example

Enable the RSVP Hello extension function globally.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te hello
```

Enable the RSVP Hello extension function on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te hello
```

Enable the RSVP Hello extension function on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te hello
```

9.3.83 mpls rsvp-te hello basic-restart-time

Function

The **mpls rsvp-te hello basic-restart-time** command changes the basic time of RSVP GR.

The **undo mpls rsvp-te hello basic-restart-time** command restores the default setting.

By default, the basic time of RSVP GR is 90 seconds.

Format

mpls rsvp-te hello basic-restart-time *basic-restart-time*

undo mpls rsvp-te hello basic-restart-time

Parameters

Parameter	Description	Value
basic-restart-time	Specifies the basic time of RSVP GR.	The value is an integer that ranges from 30 to 1200, in seconds.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

At the beginning of the AMB/SMB switchover, an RSVP-TE GR node enters a period during which the data plane can forward data but the control plane is not restored. A Restart timer starts following this phase. The restart time is relevant to the basic time, the number of ingress LSPs and the number of non-ingress LSPs. The default basic time is 90 seconds. You can use the **mpls rsvp-te hello basic-restart-time** command to change the value of the basic time.

After the Restart timer expires, the node starts a Recovery timer. The recovery time is relevant to the restart time and total number of LSPs.

Prerequisites

RSVP GR has been enabled by running the **mpls rsvp-te hello full-gr** command in the MPLS view.

Example

Set the basic time of RSVP GR to 39 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te hello basic-restart-time 39
```

9.3.84 mpls rsvp-te hello full-gr

Function

The **mpls rsvp-te hello full-gr** command enables RSVP GR and RSVP GR Helper.

The **undo mpls rsvp-te hello full-gr** command restores the default configurations.

By default, RSVP GR and RSVP GR Helper are disabled.

Format

mpls rsvp-te hello full-gr

undo mpls rsvp-te hello full-gr

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The RSVP Hello extension function has been enabled by running the **mpls rsvp-te hello** command.

Example

Enable RSVP GR and RSVP GR Helper.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te hello
[HUAWEI-mpls] mpls rsvp-te hello full-gr
```

9.3.85 mpls rsvp-te hello nodeid-session

Function

The **mpls rsvp-te hello nodeid-session** command establishes a Hello session between a PLR node and an MP node and specifies the ID of a single-hop or multi-hop node.

The **undo mpls rsvp-te hello nodeid-session** command restores the default configuration.

By default, no Hello session is established between a PLR node and an MP node.

Format

mpls rsvp-te hello nodeid-session *ip-address*

undo mpls rsvp-te hello nodeid-session [*ip-address*]

Parameters

Parameter	Description	Value
ip-address	Specifies the LSR ID of a neighbor.	The value is in dotted decimal notation.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

On a TE FRR network, to ensure the protection of the primary tunnel when FRR and RSVP GR simultaneously occur, run the **mpls rsvp-te hello nodeid-session** command to establish a Hello session between a PLR node and an MP node.

Example

Establish a Hello session between the PLR and MP along the bypass tunnel.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te hello
[HUAWEI-mpls] mpls rsvp-te hello nodeid-session 10.0.0.1
```

9.3.86 mpls rsvp-te hello support-peer-gr

Function

The **mpls rsvp-te hello support-peer-gr** command enables RSVP GR Helper.

The **undo mpls rsvp-te hello support-peer-gr** command restores the default configuration.

By default, RSVP GR Helper is disabled.

Format

mpls rsvp-te hello support-peer-gr

undo mpls rsvp-te hello support-peer-gr

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

The RSVP Hello extension function has been enabled by running the **mpls rsvp-te hello** command.

Precautions

If the **mpls rsvp-te hello full-gr** command is run on an RSVP node, this node has the capability of RSVP GR Helper. If a node is a GR supporter rather than a GR node, run the **mpls rsvp-te hello support-peer-gr** command.

To change a node from a GR node to a GR supporter, you must run the **undo mpls rsvp-te hello full-gr** command, then run the **mpls rsvp-te hello support-peer-gr** command.

Example

Enable RSVP GR Helper.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te hello
[HUAWEI-mpls] mpls rsvp-te hello support-peer-gr
```

9.3.87 mpls rsvp-te keep-multiplier

Function

The **mpls rsvp-te keep-multiplier** command sets the number of retry times allowed for RSVP Refresh messages.

The **undo mpls rsvp-te keep-multiplier** command restores the default settings.

The number of retry times allowed for RSVP Refresh messages is 3 by default.

Format

mpls rsvp-te keep-multiplier *keep-multiplier-number*

undo mpls rsvp-te keep-multiplier

Parameters

Parameter	Description	Value
keep-multiplier-number	Specifies the number of retry times allowed for RSVP Refresh messages.	The value is an integer that ranges from 3 to 255. The default value is 3.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a node does not receive any Refresh message about PSB or RSB within a specified time period, the node deletes the state. You can run this command to modify the number of retry times for Refresh messages to change of the timeout period.

Prerequisites

RSVP-TE has been enabled by running the **mpls rsvp-te** command.

Precautions

The timeout period is calculated by using the following formula:

Timeout period = (*keep-multiplier-number* + 0.5) x 1.5 x *refresh-interval*.

In the formula, *keep-multiplier-number* specifies the number of retry times allowed for RSVP Refresh messages; *refresh-interval* specifies the interval at which RSVP Refresh messages are sent. To set these two parameters, run the **mpls rsvp-te timer refresh** command.

Example

Set the number of retry times for RSVP Refresh messages to 5.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te keep-multiplier 5
```

9.3.88 mpls rsvp-te peer

Function

The **mpls rsvp-te peer** command sets up an RSVP neighbor node and displays the MPLS RSVP-TE neighbor view.

The **undo mpls rsvp-te peer** command deletes an RSVP neighbor node.

No RSVP neighbor node is set up by default.

Format

mpls rsvp-te peer *ip-address*

undo mpls rsvp-te peer *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of a neighbor interface or the LSR ID. The LSR ID is specified in the **mpls lsr-id** command.	The value is in dotted decimal notation.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

RSVP-TE has been enabled by running the **mpls rsvp-te** command in the MPLS view.

Precautions

You can run this command on two neighboring devices to configure neighbor nodes. Then you can configure these neighbors with other functions such as authentication and handshake. The command functions differ according to the values of *ip-address*.

- When *ip-address* is the LSR-ID of a neighbor, the command takes effect on an entire device.
- When *ip-address* is the IP address of a neighbor interface, the command takes effect only on the single interface.

NOTE

If a neighbor node is identified by its LSR-ID, CSPF must be enabled on two neighboring devices where RSVP authentication is required.

Example

Set up an RSVP neighbor node and displays the MPLS RSVP-TE neighbor view.

```
<HUAWEI> system-view
[HUAWEI] mpls rsvp-te peer 10.0.0.1
[HUAWEI-mpls-rsvp-te-peer-10.0.0.1]
```

9.3.89 mpls rsvp-te resv-rro

Function

The **mpls rsvp-te resv-rro** command configures record route objects (RROs) carried in Resv messages.

The **undo mpls rsvp-te resv-rro** command restores the default setting.

By default, the labels carried in the transit LSP RRO in turn are inbound interface address with upstream label, LSR ID with upstream label, and outbound interface address. The labels carried in the egress LSP RRO in turn are inbound interface address with upstream label, LSR ID with upstream label.

Format

mpls rsvp-te resv-rro transit { { **incoming** | **incoming-with-label** } | { **routerid** | **routerid-with-label** } | { **outgoing** | **outgoing-with-label** } } *

mpls rsvp-te resv-rro egress { { **incoming** | **incoming-with-label** } | { **routerid** | **routerid-with-label** } } *

undo mpls rsvp-te resv-rro transit

undo mpls rsvp-te resv-rro egress

Parameters

Parameter	Description	Value
transit	Indicates a transit node.	-
incoming	Indicates an inbound interface address.	-
incoming-with-label	Indicates an inbound interface address and upstream label.	-
routerid	Indicates an LSR ID.	-
routerid-with-label	Indicates an LSR ID and an upstream label.	-
outgoing	Indicates an outbound interface address.	-
outgoing-with-label	Indicates an outbound interface address and a downstream label.	-
egress	Indicates an egress.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Two devices of different types must have the same RRO configuration to ensure that they can communicate with each other. You can run the **mpls rsvp-te resv-rro** command to configure RROs carried in Resv messages.

Precautions

The modification takes effect only for new LSPs.

Example

Configure the transit LSP RRO to carry the following labels: LSR ID with upstream label, inbound interface address, and outbound interface address with downstream label.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te resv-rro transit routerid-with-label incoming outgoing-with-label
```

Configure the egress LSP RRO to carry the following labels: LSR ID with upstream label, and inbound interface address.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te resv-rro egress routerid-with-label incoming
```

9.3.90 mpls rsvp-te resvconfirm

Function

The **mpls rsvp-te resvconfirm** command enables the reservation confirmation mechanism on a node.

The **undo mpls rsvp-te resvconfirm** command disables the reservation confirmation mechanism.

The mechanism is disabled on a node by default.

Format

mpls rsvp-te resvconfirm

undo mpls rsvp-te resvconfirm

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The **mpls rsvp-te resvconfirm** command is configured on the egress of the TE tunnel.

Example

Enable the reservation confirmation mechanism on the local node.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te resvconfirm
```

9.3.91 mpls rsvp-te retrans-timer challenge

Function

The **mpls rsvp-te retrans-timer challenge** command configures the interval at which a Challenge message is retransmitted.

The **undo mpls rsvp-te retrans-timer challenge** command restores the default value.

The interval at which a Challenge message is retransmitted is set to 1000 milliseconds by default.

Format

mpls rsvp-te retrans-timer challenge *retransmission-interval*

undo mpls rsvp-te retrans-timer challenge

Parameters

Parameter	Description	Value
retransmission-interval	Specifies the interval at which a Challenge message is retransmitted.	An integer ranging from 500 to 10000 in milliseconds. The value is 1000 milliseconds by default.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Assume node A and node B are RSVP neighbors and they need to authenticate each other. Node A authenticates node B as follows:

- Node A sends an RSVP message carrying an Integrity object to node B.
- When node B receives the message and detects that the key ID of node A is different from that in the Integrity object, node B sends a Challenge message to node A and starts a timer determining the time interval at which the Challenge message will be periodically retransmitted, and records the number of retries.
- When node A receives the Challenge message from node B, it directly copies the Challenge object in a message and adds its Integrity object to the message to generate a Response message to be sent to node B.
- When node B receives the Response message from node A, it checks whether the Challenge object in the Response message is consistent with the local Challenge object.
  - If the Challenge objects are consistent, node B stops and resets the timer for sending Challenge messages. Then, the authentication is successful.
  - If the Challenge message timer expires before node B receives the Response message, the authentication fails.

You can run the **mpls rsvp-te challenge-lost** command to change the maximum number of attempts to send Challenge messages. In addition, you can use the

mpls rsvp-te retrans-timer challenge command to change the interval at which a Challenge message is retransmitted.

Example

Set the interval for retransmitting a Challenge message to 800 ms.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te retrans-timer challenge 800
```

9.3.92 mpls rsvp-te send-message

Function

The **mpls rsvp-te send-message** command configures the formats of objects in a sent message.

The **undo mpls rsvp-te send-message** command restores the default configuration.

By default, the formats of objects in the sent message are not configured.

Format

mpls rsvp-te send-message { **suggest-label** | **extend-class-type value-length-type** | **session-attribute without-affinity** | **down-reason** }

undo mpls rsvp-te send-message { **suggest-label** | **extend-class-type value-length-type** | **session-attribute without-affinity** | **down-reason** }

Parameters

Parameter	Description	Value
suggest-label	Indicates that an RSVP message carries the suggest-label object.	-
extend-class-type value-length-type	Indicates that the encoding format of the extend-class-type object in an RSVP message is value-length-type.	-
session-attribute without-affinity	Indicates that the session-attribute in an RSVP message does not carry the affinity attribute.	-
down-reason	Indicates that RSVP messages carry the down-reason object.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **mpls rsvp-te send-message** command controls the formats of objects in the messages sent by nodes. If required, you can use this command to adjust the transmission of messages so that downstream nodes can use the carried object format in processing.

When a Huawei device attempts to communicate with a non-Huawei device, RSVP messages sent by the non-Huawei device may not support the affinity attribute, causing a communication failure. To allow successful communication, run the **mpls rsvp-te send-message session-attribute without-affinity** command to allow the Huawei device to receive RSVP messages without the affinity attribute.

If you want an ingress to learn RSVP-TE tunnel Down causes of the transit and egress nodes, run the **mpls rsvp-te send-message down-reason** command on the transit and egress nodes, facilitating fault locating.

Precautions

The modification takes effect only for new LSPs.

Configurations of the four formats of objects in a sent message can take effect simultaneously.

Example

Include the suggest-label object from a message.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te send-message suggest-label
```

Set the encoding format of the extend-class-type object in an RSVP message to value-length-type.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te send-message extend-class-type value-length-type
```

Allow a message to carry the session-attribute object without the affinity attribute.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te send-message session-attribute without-affinity
```

Configure RSVP messages to carry the down-reason object.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls rsvp-te send-message down-reason
```

9.3.93 mpls rsvp-te srefresh

Function

The **mpls rsvp-te srefresh** command enables the summary refresh (Srefresh) function on an interface or globally.

The **undo mpls rsvp-te srefresh** command disables the Srefresh function.

The Srefresh function is disabled by default.

Format

mpls rsvp-te srefresh

undo mpls rsvp-te srefresh

Parameters

None

Views

MPLS view, VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Each RSVP session needs to generate, send, receive, and process RSVP Path messages and Resv message within the refresh period. With an increasing number of RSVP sessions, a large number of Refresh messages are generated to maintain the RSVP soft state. When an RSVP message, not an RSVP Refresh message, is dropped, reliability is deteriorated and causes delay. The Srefresh extension can solve the preceding problems. The summary refresh mechanism reduces the required number of Refresh messages and improves reliability of RSVP messages and efficiency of resource usage.

After the Srefresh function is enabled in the MPLS view, the Srefresh function is enabled globally. In addition, the interface enabled with the Srefresh function can refresh the path status and the reservation status by sending Srefresh messages, rather than Path or Resv messages.

Example

Enable the Srefresh function globally.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te srefresh
```

Enable the Srefresh function on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te srefresh
```

Enable the Srefresh function on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te srefresh
```

9.3.94 mpls rsvp-te timer hello

Function

The **mpls rsvp-te timer hello** command sets an interval at which Hello messages are sent.

The **undo mpls rsvp-te timer hello** command restores the default setting.

The interval at which Hello messages are sent is 3 seconds by default.

Format

mpls rsvp-te timer hello *interval*

undo mpls rsvp-te timer hello

Parameters

Parameter	Description	Value
interval	Specifies the interval at which Hello messages are sent.	The value is an integer that ranges from 1 to 25, in seconds. The default value is 3s.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

The RSVP Hello extension function has been enabled by running the **mpls rsvp-te hello** command in the MPLS view.

NOTE

If the interval at which Hello messages are sent is changed, the new interval can only take effect after the previous Hello timer expires.

Example

Set the interval at which Hello messages are sent to 5s.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te hello
[HUAWEI-mpls] mpls rsvp-te timer hello 5
```

9.3.95 mpls rsvp-te timer refresh

Function

The **mpls rsvp-te timer refresh** command sets an interval at which RSVP Refresh messages are sent.

The **undo mpls rsvp-te timer refresh** command restores the default setting.

The time interval is 30 seconds by default.

Format

mpls rsvp-te timer refresh *refresh-interval*

undo mpls rsvp-te timer refresh

Parameters

Parameter	Description	Value
refresh-interval	Specifies the interval at which RSVP Refresh messages are sent.	An integer ranging from 10 to 65535 in seconds.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

RSVP-TE has been enabled by running the **mpls rsvp-te** command.

NOTE

If the interval at which RSVP Refresh messages are sent is changed, the new interval can only take effect after the previous refreshing timer expires. Therefore, you are not recommended to set an excessively long refreshing interval, or frequently change a refreshing interval.

Example

Set the interval at which RSVP Refresh messages are sent to 60s.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls rsvp-te
[HUAWEI-mpls] mpls rsvp-te timer refresh 60
```

9.3.96 mpls rsvp-te timer retransmission

Function

The **mpls rsvp-te timer retransmission** command adjusts retransmission-related parameters on an interface.

The **undo mpls rsvp-te timer retransmission** command restores the default settings.

By default, the retransmission incremental is 1 and the timeout period of a retransmission timer is 5000 ms.

Format

mpls rsvp-te timer retransmission { **increment-value** *increment* | **retransmit-value** *interval* } *

undo mpls rsvp-te timer retransmission [**increment-value** [*increment*] | **retransmit-value** [*interval*]] *

Parameters

Parameter	Description	Value
increment-value *increment*	Specifies the retransmission incremental value.	The value is an integer that ranges from 1 to 10. The default value is 1.
retransmit-value *interval*	Specifies the timeout period of a retransmission timer.	The value is an integer that ranges from 500 to 5000, in milliseconds. The default value is 5000 ms.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The relationship between *increment* and *interval*: Next retransmission *interval* = Current retransmission *interval* x (1 + *increment*)

Prerequisites

The Srefresh function has been enabled by running the **mpls rsvp-te srefresh** command in the MPLS view.

Example

Set the timeout period of the retransmission timer to 500 ms and the increment to 2 on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls rsvp-te
[HUAWEI-Vlanif100] mpls rsvp-te timer retransmission retransmit-value 500 increment-value 2
```

Set the timeout period of the retransmission timer to 500 ms and the increment to 2 on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te
[HUAWEI-GigabitEthernet0/0/1] mpls rsvp-te timer retransmission retransmit-value 500 increment-value 2
```

9.3.97 mpls te

Function

The **mpls te** command enables MPLS TE.

The **undo mpls te** command disables MPLS TE.

MPLS TE is disabled by default.

Format

mpls te

undo mpls te

Parameters

None

Views

MPLS view, VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When running the **mpls te** command in the MPLS view, you can globally enable MPLS TE. When running the **mpls te** command in the interface view, you can enable MPLS TE on a specified interface. MPLS TE can only be enabled on interfaces after the function is enabled globally.

Precautions

NOTICE

When the MPLS TE is disabled in the interface view, all the CR-LSPs on the current interface change to Down.

After the **undo mpls te** command is run in the MPLS view, MPLS TE services may be interrupted and all MPLS TE configurations are deleted. To restore the MPLS TE services, reconfigure these commands.

Example

Enable MPLS TE globally.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 1.1.1.9
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
```

Enable MPLS TE on VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
```

Enable MPLS TE on GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
```

9.3.98 mpls te affinity property

Function

The **mpls te affinity property** command configures the affinity property for an MPLS TE tunnel.

The **undo mpls te affinity property** command restores the default settings.

By default, both the affinity value and the affinity mask are 0x0 for an MPLS TE tunnel.

Format

mpls te affinity property *properties* [**mask** *mask-value*] [**secondary** | **best-effort**]

undo mpls te affinity property [**secondary** | **best-effort**]

undo mpls te affinity property *properties* [**mask** *mask-value*] { **secondary** | **best-effort** }

Parameters

Parameter	Description	Value
properties	Specifies the affinity property of links that carry a tunnel.	The value is in hexadecimal notation and is of 32 bits with each bit representing an attribute. The value ranges from 0x0 to 0xFFFFFFFF. The default value is 0x0.
mask *mask-value*	Specifies the link property to be checked.	The value is in hexadecimal notation and is of 32 bits with each bit representing an attribute. The value ranges from 0x0 to 0xFFFFFFFF. The default value is 0x0.
secondary	Indicates the affinity property of a backup CR-LSP.	-
best-effort	Indicates the affinity property of the best-effort path.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Affinity property masks determine the link properties that should be checked by a device.

To ensure that a link can be used by a tunnel, for the bits that are 1 in a mask, it is required that at least one bit in the administrative group and the corresponding bit in the affinity property be 1. In addition, if the bits in the affinity property are 0, the corresponding bits in the administrative group cannot be 1.

After an affinity property for the MPLS TE tunnel is changed and the new configuration is committed, the established LSPs can be affected, and the path of the TE tunnel is recalculated.

Example

Set the affinity property of Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te affinity property a04 mask e0c
[HUAWEI-Tunnel1] mpls te commit
```

Set the affinity property of the backup CR-LSP and the best-effort path.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te backup hot-standby
[HUAWEI-Tunnel1] mpls te backup ordinary best-effort
[HUAWEI-Tunnel1] mpls te affinity property a04 mask e0c secondary

```

9.3.99 mpls te auto-bandwidth

Function

The **mpls te auto-bandwidth** command configures automatic bandwidth adjustment of a tunnel.

The **undo mpls te auto-bandwidth** command disables automatic bandwidth adjustment.

Automatic bandwidth adjustment is disabled by default.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730-H, and S6730S-H support this command.

Format

mpls te auto-bandwidth { **adjustment** [**threshold** *percent*] | **collect-bw** } [**frequency** *interval*] [**max-bw** *max-bandwidth* **min-bw** *min-bandwidth*]

undo mpls te auto-bandwidth

Parameters

Parameter	Description	Value
adjustment	Enables automatic bandwidth adjustment.	-
threshold *percent*	Specifies the threshold of the difference between the new and existing bandwidth. The value is expressed in percentage.	An integer ranging from 0 to 100. The default value is 0.
collect-bw	Collects output rate information of a tunnel without adjusting the bandwidth.	-
frequency *interval*	Specifies the time interval for automatic bandwidth adjustment.	An integer ranging from 300 to 604800 in seconds. The default value is 86400. The recommended value is not less than the interval for sampling the output rate of a tunnel specified in the **mpls te timer auto-bandwidth** command.
max-bw *max-bandwidth*	Specifies the maximum allowable bandwidth.	An integer ranging from 0 to 4000000000 in kbit/s. The default value is 4294901760.
min-bw *min-bandwidth*	Specifies the minimum allowable bandwidth.	An integer ranging from 0 to 4000000000 in kbit/s. The default value is 0.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The bandwidth of a tunnel can be set manually, but is not adaptable to changeable traffic on the tunnel. To ensure continuity of traffic, reserve enough bandwidth for the maximum volume of traffic. This provides enough bandwidth for traffic, but wastes bandwidth resources. To save bandwidth, configure automatic bandwidth adjustment by running the **mpls te auto-bandwidth** command.

After automatic bandwidth adjustment is enabled, run the **mpls te timer auto-bandwidth** command to configure periodic sampling and obtain the average bandwidth of the MPLS TE tunnel during a sampling interval. The system calculates the average bandwidth during the sampling interval and attempts to establish an MPLS TE tunnel based on the average bandwidth.

- After the MPLS TE tunnel is established, traffic switches to the new MPLS TE tunnel, and the original is deleted.
- If a new MPLS TE tunnel fails to be established, traffic is still transmitted along the original MPLS TE tunnel. The bandwidth will be adjusted after the next sampling period expires.

Configuring the parameter **threshold** controls whether the bandwidth of an MPLS TE tunnel should be adjusted. The system compares the average bandwidth D within a sampling period with the actual bandwidth C. If the percentage of the bandwidth change in comparison to the actual bandwidth is greater than the **threshold** value, that is, (|D-C|÷C)×100 > **threshold**, the system adjusts the bandwidth.

If traffic volume fluctuates on a network but the bandwidth does not need to be adjusted accordingly, set the value of **threshold** to a larger value.

Precautions

The **mpls te auto-bandwidth** command cannot be configured with the following commands on the same tunnel interface:

- **mpls te route-pinning**
- **mpls te resv-style ff**
- **mpls te bandwidth** (tunnel interface view) with the multi-CT specified

Example

Set the interval for automatic bandwidth adjustment to **1** hour.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te auto-bandwidth adjustment frequency 3600
```

9.3.100 mpls te auto-frr (MPLS view)

Function

The **mpls te auto-frr** command globally enables the TE Auto FRR function.

The **undo mpls te auto-frr** command globally disables the TE Auto FRR function.

TE Auto FRR is disabled by default.

Format

mpls te auto-frr

undo mpls te auto-frr

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can run the **mpls te auto-frr** command to globally enable the TE Auto FRR function.

Precautions

After the TE Auto FRR function is enabled globally, all MPLS TE-enabled interfaces use node protection by default.

If TE Auto FRR is enabled globally, all interfaces that are enabled with MPLS TE on the device are automatically configured with the **mpls te auto-frr default** command by default. To disable TE Auto FRR on certain interfaces, run the **mpls te auto-frr block** command on these interfaces.

Example

Enable the TE Auto FRR function.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te auto-frr
```

Disable the TE Auto FRR function.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] undo mpls te auto-frr
```

9.3.101 mpls te auto-frr (interface view)

Function

The **mpls te auto-frr** command configures the TE Auto FRR function in the interface view.

The **undo mpls te auto-frr** command restores the default configuration.

The TE Auto FRR function is disabled on an interface by default.

Format

mpls te auto-frr { **default** | **link** | **node** | **block** }

undo mpls te auto-frr { **block** | **link** | **node** }

Parameters

Parameter	Description	Value
default	Indicates that the configuration of the TE Auto FRR function in the MPLS view is used by default. Only node protection is provided.	-
link	Indicates that only link protection is provided.	-
node	Indicates that node protection is provided. When the topology does not meet the requirement to set up a bypass CR-LSP for node protection, the penultimate hop (but not other hops) on the primary CR-LSP attempts to set up a bypass CR-LSP for link protection.	-
block	Disables the TE Auto FRR function in the interface view.	-

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the TE Auto FRR function is enabled globally, all MPLS TE-enabled interfaces can use the TE Auto FRR configuration configured in the MPLS view.

To disable the TE Auto FRR function on a specified interface, you must run the **mpls te auto-frr block** command. To enable link protection on a specified interface, you must run the **mpls te auto-frr link** command.

Prerequisites

MPLS TE has been enabled by running the **mpls te** command in the interface view.

Precautions

After the **mpls te auto-frr block** command is run on an interface, the interface does not have the TE Auto FRR capability, regardless of whether TE Auto FRR is already enabled or reenabled globally.

After the command **mpls te auto-frr** is configured in the MPLS view, the device provides only node protection when you run the **mpls te auto-frr default** or **mpls te auto-frr node** command on an interface. When the topology does not meet the requirement to set up a bypass CR-LSP for node protection, the penultimate hop (but not other hops) on the primary CR-LSP attempts to set up a bypass CR-LSP for link protection.

Example

Enable TE Auto FRR that provides link protection on the interface.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te auto-frr link
```

Disable the TE Auto FRR function in the interface view.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te auto-frr block
```

Enable TE Auto FRR that provides node protection on the interface.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te auto-frr node
```

9.3.102 mpls te auto-frr reoptimization

Function

The **mpls te auto-frr reoptimization** command enables auto bypass tunnel re-optimization.

The **undo mpls te auto-frr reoptimization** command disables auto bypass tunnel re-optimization.

By default, auto bypass tunnel re-optimization is disabled.

Format

mpls te auto-frr reoptimization [**frequency** *interval*]

undo mpls te auto-frr reoptimization

Parameters

Parameter	Description	Value
frequency *interval*	Indicates the re-optimization interval. Paths are recalculated at the *interval* based on auto bypass tunnel constraints. If an optimal path to the same destination is available, the system re-optimizes the auto bypass tunnel.	The value is an integer ranging from 60 to 604800, in seconds. The default value is 3600s (one hour).

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Network changes often cause the changes in optimal paths. Run the **mpls te auto-frr reoptimization** to allow paths to be recalculated at certain intervals for an auto bypass tunnel. If an optimal path to the same destination is found due to some reasons, such as the changes in the cost, a new auto bypass tunnel will be set up over this optimal path. In this manner, network resources are optimized.

Auto bypass tunnel re-optimization can be classified into the following modes:

- Automatic re-optimization: Auto bypass tunnels are re-optimized at intervals, requiring no manual intervention. The **mpls te auto-frr reoptimization** command can be used to implement the function, and this command takes effect on the auto bypass tunnels that have been already set up successfully.
- Manual re-optimization: After the **mpls te auto-frr reoptimization** command is run, run the **mpls te reoptimization (user view)** command to re-optimize auto bypass tunnels manually.

Prerequisites

MPLS TE has been enabled using the **mpls te** command.

Example

Configure auto bypass tunnel re-optimization at 8939-second intervals.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te auto-frr reoptimization frequency 8939
```

9.3.103 mpls te backup

Function

The **mpls te backup** command specifies the backup mode of an existing tunnel.

The **undo mpls te backup** command restores the default configuration.

By default, no tunnel is backed up.

Format

mpls te backup ordinary [**best-effort**]

mpls te backup hot-standby [**mode** { **revertive** [**wtr** *interval*] | **non-revertive** } | **dynamic-bandwidth**] *

mpls te backup hot-standby wtr *interval* [**dynamic-bandwidth**]

mpls te backup hot-standby dynamic-bandwidth wtr *interval*

undo mpls te backup { **hot-standby** [**mode** { **revertive** [**wtr** [*interval*]] | **non-revertive** } | **dynamic-bandwidth**] * | **ordinary** }

Parameters

Parameter	Description	Value
ordinary	Enables the ordinary backup mode. In ordinary backup mode, an ordinary backup CR-LSP is created only after the primary CR-LSP fails.	-
hot-standby	Enables the hot-standby mode. In hot-standby mode, both the primary and backup CR-LSP are set up. If the primary CR-LSP fails, traffic is immediately switched to the hot-standby CR-LSP.	-
dynamic-bandwidth	Enables the dynamic bandwidth function for a hot-standby CR-LSP.	-
wtr *interval*	Specifies the wait-to-restore (WTR) time in hot standby.	The value is an integer that ranges from 0 to 2592000, in seconds. The default value is 10 seconds.
best-effort	Enables the best-effort path mode. When both the primary and backup CR-LSPs fail, the system triggers the establishment of a best-effort path.	-

Parameter	Description	Value
mode { **revertive** | **non-revertive** }	Specifies the revertive mode. - **revertive**: The current mode can be switched to the original mode. - **non-revertive**: The current mode cannot be switched to the original mode.	The default mode is **revertive**.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To help enhance the reliability of a CR-LSP, you are recommended to set up a backup CR-LSP to protect traffic on the primary CR-LSP.

You can select the following CR-LSP backup modes as required:

- Hot-standby mode: A hot-standby backup CR-LSP is set up over a separate path immediately after the primary CR-LSP is set up. When the CR-LSP transmitting services fails, traffic can be immediately switched to the other CR-LSP. However, additional bandwidth is needed in hot-standby mode.
- Ordinary backup mode: The system attempts to set up an ordinary backup CR-LSP over a new explicit path, only when the primary CR-LSP fails. No additional bandwidth is needed in ordinary backup mode. In the case that the primary CR-LSP fails, this mode provides a traffic switchover slower than that of the hot-standby mode.
- Best-effort path mode: When both the primary and backup CR-LSP fail, the system establishes a best-effort path. There are few constraints on the establishment of best-effort path; therefore, it is easy to set up. In best-effort path mode, packet loss is decreased, and certain QoS requirements may not be guaranteed.

Prerequisites

A tunnel ID has been configured by running the **mpls te tunnel-id** command.

Precautions

After tunnel backup is enabled, the route storing function is automatically enabled, regardless of whether the **mpls te record-route** command is run.

Tunnel backup and the function configured by running the **mpls te resv-style ff** command are mutually exclusive.

The **mpls te backup ordinary** command and the **mpls te backup ordinary best-effort** command cannot be configured together; otherwise, the previous configuration overrides the later one.

After initiating the dynamic bandwidth function for a hot-standby CR-LSP, the hot-standby CR-LSP does not occupy any bandwidth when bearing no traffic. If the primary CR-LSP fails, the system re-establishes a hot-standby CR-LSP with the expected bandwidth according to the Make-Before-Break mechanism. The new hot-standby CR-LSP now transmits traffic. The system then deletes the hot-standby CR-LSP with the bandwidth being 0 bit/s.

Example

Enable hot standby for the current CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te backup hot-standby
[HUAWEI-Tunnel1] mpls te commit
```

9.3.104 mpls te backup frr-in-use

Function

The **mpls te backup frr-in-use** command allows a device to start a bypass CR-LSP if a primary CR-LSP becomes faulty (when the primary CR-LSP is in the FRR-in-use state), and to attempt to set up a backup CR-LSP while the system is restoring the primary CR-LSP.

The **undo mpls te backup frr-in-use** command restores the default configuration.

If the primary CR-LSP is faulty, the system starts the bypass CR-LSP and attempts to restore the primary CR-LSP, but does not set up a backup CR-LSP by default.

Format

mpls te backup frr-in-use

undo mpls te backup frr-in-use

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the primary CR-LSP is faulty, the system starts the bypass CR-LSP and tries to restore the primary CR-LSP the same time it sets up a backup CR-LSP.

Prerequisites

End-to-end protection in hot standby or ordinary backup mode has been enabled by running the **mpls te backup** { **hot-standby** | **ordinary** } command, and local protection of TE FRR has been enabled by running the **mpls te fast-reroute** command.

Precautions

If only the best-effort path is configured, rather than another end-to-end protection mode, the **mpls te backup frr-in-use** command cannot take effect.

After the **mpls te backup frr-in-use** command is run and if the primary CR-LSP is faulty:

- If ordinary backup is configured, the system tries to set up a backup CR-LSP when the traffic is switched to the bypass CR-LSP and also attempts to restore the primary CR-LSP. If the backup CR-LSP is set up successfully and the primary CR-LSP is not restored, traffic is switched to the backup CR-LSP.
- If hot standby is configured and the backup CR-LSP is in the Up state, the traffic is switched to the bypass CR-LSP and then immediately to the backup CR-LSP while the system attempts to restore the primary CR-LSP.

It is recommended that ordinary backup be configured together with the **mpls te backup frr-in-use** command. This saves bandwidth resources and improves tunnel security.

Example

Configure the system to set up a backup CR-LSP the same time it starts the bypass CR-LSP and tries to restore the primary CR-LSP after the primary CR-LSP is faulty.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te backup ordinary
[HUAWEI-Tunnel1] mpls te fast-reroute
[HUAWEI-Tunnel1] mpls te backup frr-in-use
[HUAWEI-Tunnel1] mpls te commit
```

9.3.105 mpls te backup hot-standby overlap-path

Function

The **mpls te backup hot-standby overlap-path** command enables the path partially overlapping function for hot-standby CR-LSPs.

The **undo mpls te backup hot-standby overlap-path** command disables the path overlapping function for hot-standby CR-LSPs.

By default, the path partially overlapping function is disabled for hot-standby CR-LSPs.

Format

mpls te backup hot-standby overlap-path

undo mpls te backup hot-standby overlap-path

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

After the path overlapping function is configured, the path of a hot-standby CR-LSP can partially overlap the path of the primary CR-LSP when primary CR-LSP is not excluded by the system in path calculation.

Example

Enable the path overlapping function for hot-standby CR-LSPs.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te backup hot-standby
[HUAWEI-Tunnel1] mpls te backup hot-standby overlap-path
[HUAWEI-Tunnel1] mpls te commit
```

9.3.106 mpls te backup hotstandby-lsp-constraint

Function

The **mpls te backup hotstandby-lsp-constraint** command sets the WTR time for a switchback, locks an attribute template, and enables the dynamic bandwidth function for a hot-standby CR-LSP.

The **undo mpls te backup hotstandby-lsp-constraint** command restores default settings.

By default, the interval between switchbacks is 10 seconds; no attribute template is locked; the dynamic bandwidth function is disabled for a hot-standby CR-LSP.

Format

mpls te backup hotstandby-lsp-constraint { **wtr** *interval* | **lock** | **dynamic-bandwidth** | **overlap-path** }

mpls te backup hotstandby-lsp-constraint mode { **revertive** [**wtr** *interval*] | **non-revertive** }

undo mpls te backup hotstandby-lsp-constraint { **wtr** | **lock** | **dynamic-bandwidth** | **overlap-path** }

undo mpls te backup hotstandby-lsp-constraint mode { **non-revertive** | **revertive wtr** }

Parameters

Parameter	Description	Value
dynamic-bandwidth	Enables the dynamic bandwidth function for a hot-standby CR-LSP.	-
lock	Enables the function of locking a hot-standby CR-LSP attribute template.	-
wtr *interval*	Specifies the WTR time for a switchback from a hot-standby CR-LSP.	The value is an integer that ranges from 0 to 2592000, in seconds. The default value is 10 seconds.
overlap-path	Indicates that if no other path is available, the hot-standby LSP can overlap the primary LSP.	-
mode { **revertive** | **non-revertive** }	Specifies the revertive mode. ● **revertive**: The current mode can be switched to the original mode. ● **non-revertive**: The current mode cannot be switched to the original mode.	The default mode is **revertive**.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The function of locking a hot-standby CR-LSP attribute template allows the system to lock a lower-priority attribute template that has been used by an exiting hot-standby CR-LSP. The system will not attempt to use a higher-priority template to set up a new hot-standby CR-LSP.

Prerequisites

The following configurations must be completed before the **mpls te backup hotstandby-lsp-constraint** command is run:

- Run the **mpls te primary-lsp-constraint** command to use attribute templates to set up a primary CR-LSP.
- Run the **mpls te hotstandby-lsp-constraint** command to use attribute template to set up a hot-standby CR-LSP.

Precautions

This command is valid only for the hot-standby CR-LSP that is set up using a CR-LSP attribute template. If a hot-standby CR-LSP is set up without a CR-LSP attribute template, the following commands apply:

- The **mpls te backup hot-standby wtr** *interval* command is used to set the WTR time for a switchback.
- The **mpls te backup hot-standby dynamic-bandwidth** command is used to enable the dynamic bandwidth function for the hot-standby CR-LSP.
- The **mpls te backup hot-standby overlap-path** command is used to enable the path overlapping function for hot-standby CR-LSPs that are not established using attribute templates.

The dynamic bandwidth function for the hot-standby CR-LSP prevents a hot-standby CR-LSP transmitting no traffic from using bandwidth resources. If the primary CR-LSP fails, the system attempts to re-establish a new hot-standby CR-LSP with the required bandwidth determined by the Make-Before-Break mechanism. After the new hot-standby CR-LSP takes over traffic, the bandwidth of the failed hot-standby CR-LSP becomes 0 bit/s and is deleted by the system.

Example

Set the WTR time for a switchback from the hot-standby CR-LSP to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te primary-lsp-constraint lsp-attribute t1
[HUAWEI-Tunnel1] mpls te hotstandby-lsp-constraint 1 lsp-attribute t2
[HUAWEI-Tunnel1] mpls te backup hotstandby-lsp-constraint wtr 20
[HUAWEI-Tunnel1] mpls te commit
```

9.3.107 mpls te backup ordinary-lsp-constraint

Function

The **mpls te backup ordinary-lsp-constraint** command globally locks an attribute template for ordinary backup CR-LSPs.

The **undo mpls te backup ordinary-lsp-constraint** command restores the default setting.

The attribute template for ordinary backup CR-LSPs is unlocked by default.

Format

mpls te backup ordinary-lsp-constraint lock

undo mpls te backup ordinary-lsp-constraint lock

Parameters

Parameter	Description	Value
lock	Locks an attribute template for ordinary backup CR-LSPs.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Assume that an existing ordinary backup CR-LSP has been set up using a lower-priority attribute template. When the lower-priority attribute template is locked, the system does not attempt to use a higher-priority attribute template to set up a new ordinary backup CR-LSP, avoiding unnecessary traffic switchover.

Prerequisites

An ordinary backup CR-LSP has been set up using a CR-LSP attribute template by running the **mpls te ordinary-lsp-constraint** command.

Precautions

This command is valid only for an ordinary backup CR-LSP that is set up using a CR-LSP attribute template.

Example

Lock an attribute template for ordinary backup CR-LSPs.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te primary-lsp-constraint lsp-attribute t1
[HUAWEI-Tunnel1] mpls te ordinary-lsp-constraint 2 lsp-attribute t2
[HUAWEI-Tunnel1] mpls te ordinary-lsp-constraint 3 lsp-attribute t3
[HUAWEI-Tunnel1] mpls te backup ordinary-lsp-constraint lock
[HUAWEI-Tunnel1] mpls te commit
```

9.3.108 mpls te bandwidth (interface view)

Function

The **mpls te bandwidth** command sets the BC bandwidth for a link.

The **undo mpls te bandwidth** command restores the default setting.

By default, no BC bandwidth is configured for a link.

Format

mpls te bandwidth { **bc0** *bc0-bw-value* | **bc1** *bc1-bw-value* } *

undo mpls te bandwidth

Parameters

Parameter	Description	Value
bc0 *bc0-bw-value*	Specifies the bandwidth of BC0.	The value is an integer that ranges from 1 to 4000000000, in kbit/s. The default value is 1.
bc1 *bc1-bw-value*	Specifies the bandwidth of BC1.	The value is an integer that ranges from 1 to 4000000000, in kbit/s. The default value is 1.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In real-world situations, the bandwidth value is set on outbound interfaces along links of a TE tunnel that requires sufficient bandwidth.

NOTE

The configured bandwidth takes effect only during tunnel establishment and protocol negotiation, and does not limit the bandwidth for traffic forwarding.

Precautions

To change bandwidth BC values, reconfigure the **mpls te bandwidth** command. The last configured BC bandwidth value overrides the previous one.

One or more BC bandwidth values can be set in a single command in a random order.

A BC bandwidth value can be changed only to a value greater than or equal to the set one. For example, the BC0 bandwidth of 10 Mbit/s can be changed to 10 or a larger value.

Example

Set the maximum reservable bandwidth to 10000 kbit/s, the bandwidth of BC0 to 1000 kbit/s on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te bandwidth max-reservable-bandwidth 10000
[HUAWEI-Vlanif100] mpls te bandwidth bc0 1000
```

Set the maximum reservable bandwidth to 10000 kbit/s, the bandwidth of BC0 to 1000 kbit/s on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te bandwidth max-reservable-bandwidth 10000
[HUAWEI-GigabitEthernet0/0/1] mpls te bandwidth bc0 1000
```

9.3.109 mpls te bandwidth (tunnel interface view)

Function

The **mpls te bandwidth** command sets the bandwidth of an MPLS TE tunnel.

The **undo mpls te bandwidth** command restores the default settings.

By default, the bandwidth of an MPLS TE tunnel is not set.

Format

mpls te bandwidth { **ct0** *ct0-bw-value* | **ct1** *ct1-bw-value* }

undo mpls te bandwidth { **all** | **ct0** [*ct0-bw-value*] | **ct1** [*ct1-bw-value*] }

Parameters

Parameter	Description	Value
ct0 *ct0-bw-value*	Specifies the bandwidth reserved for a TE tunnel of CT0.	*ct0-bw-value* is an integer that ranges from 1 to 4000000000, in kbit/s.
ct1 *ct1-bw-value*	Specifies the bandwidth reserved for a TE tunnel of CT1.	*ct1-bw-value* is an integer that ranges from 1 to 4000000000, in kbit/s.
all	Deletes bandwidth for all CTs.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

NOTE

The configured bandwidth takes effect only during tunnel establishment and protocol negotiation, and does not limit the bandwidth for traffic forwarding.

The **undo mpls te bandwidth** command is used to restore the default settings of all CTs or specified CTs:

- **undo mpls te bandwidth all**: deletes all configured bandwidth.
- **undo mpls te bandwidth** { **ct0** | **ct1** }: deletes the bandwidth of the specified CT configured on the current TE tunnel.

Example

Set the bandwidth required by Tunnel1. The bandwidth of CT0 is 2000 kbit/s.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] quit

[HUAWEI-Tunnel1] mpls te commit
```

9.3.110 mpls te bandwidth change thresholds

Function

The **mpls te bandwidth change thresholds** command sets the percentage threshold of the physical link bandwidth used by an MPLS TE tunnel for flooding link information.

The **undo mpls te bandwidth change thresholds** command restores the default settings.

If the ratio of the reserved (or released) bandwidth for a tunnel to the remaining bandwidth in a Traffic Engineering Database (TEDB) is equal to or greater than 10%, an IGP floods link information and CSPF updates the TEDB by default.

Format

mpls te bandwidth change thresholds { **down** | **up** } *percent*

undo mpls te bandwidth change thresholds { **down** | **up** }

Parameters

Parameter	Description	Value
down	Indicates the flooding threshold of the bandwidth used by an MPLS TE tunnel. If the ratio of the bandwidth used by an MPLS TE tunnel to the remaining link bandwidth in a TEDB is equal to or greater than the threshold, an IGP floods link information and CSPF updates the TEDB.	-
up	Indicates the flooding threshold of the bandwidth released by an MPLS TE tunnel. If the ratio of the bandwidth released by an MPLS TE tunnel to the remaining link bandwidth in a TEDB is equal to or greater than the threshold, an IGP floods link information and CSPF updates the TEDB.	-
percent	Specifies the threshold as a percentage.	The value is an integer that ranges from 0 to 100. The default value is 10.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

When the bandwidth changes slightly, flooding the bandwidth wastes network resources. For example, the bandwidth of a link is 100 Mbit/s. During the creation of 100 TE tunnels each with the bandwidth being 1 Mbit/s, the bandwidth of all TE tunnels needs to be flooded 100 times. If the flooding threshold is set to 10%, the first nine tunnels are created without flooding. When the tenth tunnel is created, the 10 Mbit/s bandwidth that is used by the preceding 10 tunnels is flooded. The tunnels from the eleventh tunnel to the eighteenth are created without flooding. When the nineteenth tunnel is created, the bandwidth is flooded, and so on.

Example

On VLANIF100, when the link bandwidth reserved for the MPLS TE tunnel exceeds 10% of the overall bandwidth or the bandwidth released by the MPLS TE tunnel exceeds 25% of the overall bandwidth, the link information is flooded.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te bandwidth change thresholds up 25
[HUAWEI-Vlanif100] mpls te bandwidth change thresholds down 10
```

On GE0/0/1, when the link bandwidth released by the MPLS TE tunnel exceeds 25% of the overall bandwidth, the link information is flooded.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te bandwidth change thresholds up 25
```

9.3.111 mpls te bandwidth max-reservable-bandwidth

Function

The **mpls te bandwidth max-reservable-bandwidth** command sets or modifies the maximum reservable bandwidth of a link.

The **undo mpls te bandwidth max-reservable-bandwidth** command restores the default configuration.

The maximum reservable bandwidth of a link is not configured by default.

Format

mpls te bandwidth max-reservable-bandwidth *bw-value*

undo mpls te bandwidth max-reservable-bandwidth

Parameters

Parameter	Description	Value
bw-value	Specifies the maximum reservable bandwidth of a link.	The value is an integer that ranges from 0 to 4000000000, in kbit/s. The default value is 0.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

In practical applications, the **mpls te bandwidth max-reservable-bandwidth** command can be configured for a TE tunnel on an outgoing interface of the link through which the tunnel passes.

NOTE

The configured bandwidth takes effect only during tunnel establishment and protocol negotiation, and does not limit the bandwidth for traffic forwarding.

Example

Set the maximum reservable bandwidth of the link to 10000 kbit/s on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te bandwidth max-reservable-bandwidth 10000
```

Set the maximum reservable bandwidth of the link to 10000 kbit/s on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te bandwidth max-reservable-bandwidth 10000
```

9.3.112 mpls te bfd

Function

The **mpls te bfd** command sets the parameters of a BFD session for TE.

The **undo mpls te bfd** command restores the default configuration.

By default, no parameters of a BFD session for TE are set.

Format

mpls te bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

undo mpls te bfd { **min-tx-interval** | **min-rx-interval** | **detect-multiplier** } *

undo mpls te bfd { **min-tx-interval** *tx-interval* | **min-rx-interval** *rx-interval* | **detect-multiplier** *multiplier* } *

Parameters

Parameter	Description	Value
min-tx-interval *tx-interval*	Specifies the interval at which BFD packets are sent.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
min-rx-interval *rx-interval*	Specifies the interval at which BFD packets are received.	The value is an integer that ranges from 100 to 1000, in milliseconds. - After the **set service-mode enhanced** command is configured on the S5731-S, S5731-H and S5731S-H, the value ranges from 3 to 1000. - After the **set service-mode enhanced-bfd** command is configured on the S5732-H, S6730-S, S6730-H, and S6730S-H, the value ranges from 3 to 1000.
detect-multiplier *multiplier*	Specifies the local detection multiplier value of a BFD session.	An integer ranging from 3 to 50. The value is 3 by default.

Views

MPLS view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

If **min-tx-interval** *tx-interval* configured on the local end is different from **min-rx-interval** *rx-interval* configured on the peer, the larger value is used as the actual session parameter.

The used **detect-multiplier** *multiplier* is the value set on the peer.

If the **mpls te bfd** command is configured in the MPLS view, it takes effect globally. If the command is configured in the tunnel interface view, it only takes effect on the current tunnel interface, and the parameters of the BFD session for TE set in the MPLS view are overridden.

Example

Set the parameters of the BFD session.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te bfd min-tx-interval 200 detect-multiplier 5
[HUAWEI-Tunnel1] mpls te commit
```

9.3.113 mpls te bfd block

Function

The **mpls te bfd block** command blocks the BFD capability on a specified tunnel interface of a CR-LSP.

The **undo mpls te bfd block** command restores the default configuration.

The BFD capability is not blocked on a tunnel interface by default.

Format

mpls te bfd block

undo mpls te bfd block

Parameters

None.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te bfd block** command and the **mpls te bfd enable** command are mutually exclusive.

The differences between the **mpls te bfd block** command and the **undo mpls te bfd enable** command in the tunnel interface view are as follows:

- When the **undo mpls te bfd enable** command is run on a tunnel interface, the interface can still obtain the BFD for TE capability after you configure the **mpls te bfd enable** command in the MPLS view.
- When the **mpls te bfd block** command is run on a tunnel interface, the interface cannot obtain the BFD for TE capability even if the **mpls te bfd enable** command is run in the MPLS view.

NOTE

To enable the BFD for TE capability on a majority of interfaces, you can run the **mpls te bfd block** command on a minority of interfaces that do not need to be enabled with BFD for TE. Then, you can run the **mpls te bfd enable** command in the MPLS view to enable the BFD for TE capability on the other interfaces.

To enable BFD for TE capability on a few interfaces, you can run the **mpls te bfd enable** command on these interfaces. After, you can run the **undo mpls te bfd enable** command or the **mpls te bfd block** command to disable BFD for TE from these interfaces.

Example

Block the BFD capability on Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te bfd block
[HUAWEI-Tunnel1] mpls te commit
```

9.3.114 mpls te bfd enable

Function

The **mpls te bfd enable** command enables BFD for TE.

The **undo mpls te bfd enable** command restores the default configuration.

BFD for TE is disabled by default.

Format

mpls te bfd enable

undo mpls te bfd enable

Parameters

None.

Views

MPLS view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

If the **mpls te bfd enable** command is configured in the MPLS view, all TE tunnel interfaces are enabled with BFD for TE, except those configured with the **mpls te bfd block** command, blocking BFD for TE.

If this command is configured in the tunnel interface view, it only takes effect on the single tunnel interface.

The differences between the **undo mpls te bfd enable** command and the **mpls te bfd block** command configured in the tunnel interface view are as follows:

- When the **undo mpls te bfd enable** command is run on a tunnel interface, the interface can still obtain the BFD for TE capability after you configure the **mpls te bfd enable** command in the MPLS view.
- When the **mpls te bfd block** command is run on a tunnel interface, the interface cannot obtain the BFD for TE capability even if the **mpls te bfd enable** command is run in the MPLS view.

NOTE

- To enable the BFD for TE capability on a majority of interfaces, you can run the **mpls te bfd block** command on a minority of interfaces that do not need to be enabled with BFD for TE. Then, you can run the **mpls te bfd enable** command in the MPLS view to enable the BFD for TE capability for the other interfaces.
- To enable BFD for TE capability on a few interfaces, you can run the **mpls te bfd enable** command on these interfaces. After, you can run the **undo mpls te bfd enable** command or the **mpls te bfd block** command to disable BFD for TE from these interfaces.

Example

Enable BFD for TE globally.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te bfd enable
```

Enable BFD for TE on the tunnel interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te bfd enable
[HUAWEI-Tunnel1] mpls te commit
```

9.3.115 mpls te bypass-attributes

Function

The **mpls te bypass-attributes** command configures the bypass tunnel attributes in the MPLS TE Auto FRR feature.

The **undo mpls te bypass-attributes** command restores the default settings.

By default, no bypass tunnel attributes in the MPLS TE Auto FRR feature are configured.

Format

mpls te bypass-attributes [**bandwidth** *bandwidth*] [**priority** *setup-priority* [*hold-priority*]]

undo mpls te bypass-attributes

Parameters

Parameter	Description	Value
bandwidth *bandwidth*	Specifies the bandwidth.	The value is an integer that ranges from 1 to 4000000000, in kbit/s.
setup-priority	Specifies the setup priority.	The value is an integer that ranges from 0 to 7. The smaller the value, the higher the priority. The value is 7 by default.
hold-priority	Specifies the holding priority.	The value is an integer that ranges from 0 to 7. The smaller the value, the higher the priority. The value is 7 by default.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Prerequisites

Before running the **mpls te bypass-attributes** command, you must run the **mpls te fast-reroute bandwidth** command to enable FRR function. The bandwidth of a bypass tunnel cannot be greater than that of the primary tunnel.

Precautions

The setup priority of a bypass tunnel cannot be higher than the holding priority. Both cannot be higher than the priorities of the primary tunnel.

On the same TE tunnel interface, the **mpls te bypass-attributes** command cannot be configured together with the **mpls te bandwidth (tunnel interface view)** command.

Example

Set the bandwidth of the bypass tunnel to 2048 kbit/s, the setup priority to 3, and the holding priority to 3.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 1.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te bandwidth ct0 10000
[HUAWEI-Tunnel1] mpls te priority 3 3
[HUAWEI-Tunnel1] mpls te fast-reroute bandwidth
[HUAWEI-Tunnel1] mpls te bypass-attributes bandwidth 2048 priority 3 3
[HUAWEI-Tunnel1] mpls te commit
```

9.3.116 mpls te bypass-tunnel

Function

The **mpls te bypass-tunnel** command specifies the bypass tunnel for MPLS TE Auto FRR.

The **undo mpls te bypass-tunnel** command deletes the bypass tunnel configuration.

By default, no bypass tunnel for MPLS TE Auto FRR is specified.

Format

mpls te bypass-tunnel

undo mpls te bypass-tunnel

Parameters

None.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The total bandwidth of LSPs protected by the bypass tunnel is not more than the bandwidth of the primary tunnel. When multiple bypass tunnels exist, the system selects a single bypass tunnel through the best-fit algorithm.

If global Srefresh or RSVP GR needs to be enabled on the bypass PLR and MP node, configure the MPLS LSR ID of the destination peer FRR MP node as the destination address of the bypass tunnel.

NOTE

The **mpls te bypass-tunnel** command cannot be configured simultaneously with the following commands on the same tunnel interface:

- **mpls te fast-reroute**
- **mpls te backup**
- **mpls te protection tunnel**

Example

Configure the bypass tunnel on Tunnel1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te bypass-tunnel
[HUAWEI-Tunnel1] mpls te commit
```

9.3.117 mpls te commit

Function

The **mpls te commit** command commits the tunnel configurations to the system for processing.

Format

mpls te commit

Parameters

None.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The configurations of an MPLS TE tunnel can only take effect after the **mpls te commit** command is run. The destination and tunnel ID must be configured;

otherwise, the commitment fails, and you need to configure both of them and then commit the configuration again. If the MPLS TE configuration changes, you must run the **mpls te commit** command to validate the modification.

NOTE

Each time the MPLS TE tunnel configuration is changed, the **mpls te commit** command must be run to make the modification take effect. If this command is not run, the changed configuration can be saved in the configuration file but cannot take effect.

Example

Configure an MPLS TE tunnel and then commit the configuration.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 10.2.2.9
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te commit
```

9.3.118 mpls te cspf

Function

The **mpls te cspf** command enables CSPF.

The **undo mpls te cspf** command disables CSPF.

CSPF is disabled by default.

Format

mpls te cspf

undo mpls te cspf

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

You must enable MPLS TE in the MPLS view before enabling CSPF.

CSPF provides a mechanism for selecting a path in an MPLS domain. You must enable CSPF before configuring CSPF functions.

Example

Enable CSPF.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te cspf
```

9.3.119 mpls te cspf disable

Function

The **mpls te cspf disable** command disables CSPF calculation when an LSP is being established in a TE tunnel.

The **undo mpls te cspf disable** command enables CSPF calculation when an LSP is being established in a TE tunnel.

By default, CSPF calculation is enabled when an LSP is being established in a TE tunnel.

Format

mpls te cspf disable

undo mpls te cspf disable

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After CSPF is enabled globally, CSPF calculation is triggered each time an LSP is being established in a TE tunnel. In the inter-AS VPN-OptionC scenario, no IGP is configured between two ASs, causing the TEDB to fail to be generated. As a result, CSPF calculation fails to be performed, and inter-area TE tunnels fail to be set up. Run the **mpls te cspf disable** command on the configured TE tunnel interface to disable CSPF calculation in the TE tunnel, and set up inter-area TE tunnels using direct routes or static routes.

Precautions

After the **mpls te cspf disable** command is run, CR-LSP selection functions, such as hop limit, CSPF tie-breaking, and SRLG, will become invalid.

Example

Disable CSPF calculation when an LSP is being established in a TE tunnel.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te cspf disable
[HUAWEI-Tunnel1] mpls te commit
```

9.3.120 mpls te cspf preferred-igp

Function

The **mpls te cspf preferred-igp** command specifies a preferred IGP for the CSPF calculation.

The **undo mpls te cspf preferred-igp** command restores the default settings.

The TEDB generated by OSPF is preferred by default.

Format

mpls te cspf preferred-igp { **isis** [*isis-process-id* [**level-1** | **level-2**]] | **ospf** [*ospf-process-id* [**area** { *area-id-1* | *area-id-2* }]] }

undo mpls te cspf preferred-igp

Parameters

Parameter	Description	Value
isis	Indicates that the TEDB generated by IS-IS is preferred.	-
isis-process-id	Specifies the process ID.	The value is an integer that ranges from 1 to 65535.
level-1	Indicates that the TEDB generated by a Level-1 IS-IS device is preferred.	-
level-2	Indicates that the TEDB generated by a Level-2 IS-IS device is preferred.	-
ospf	Indicates that the TEDB generated by OSPF is preferred.	-
ospf-process-id	Specifies the ID of an OSPF process.	The value is an integer that ranges from 1 to 65535.
area *area-id-1*	Specifies a preferred OSPF area configured in number format.	The value is an integer that ranges from 0 to 4294967295.
area *area-id-2*	Specifies a preferred OSPF area configured in IP address format.	The value is in dotted decimal notation.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When selecting a path, CSPF prefers the TEDB generated by OSPF to calculate a CR-LSP by default. When the OSPF TEDB can be used to calculate a path, the IS-IS TEDB is not used. If the calculation based on the OSPF TEDB fails, recalculation based on the IS-IS TEDB is performed.

You can run the **mpls te cspf preferred-igp** command to configure CSPF to prefer the TEDB generated by IS-IS when calculating a CR-LSR. In this case, the OSPF TEDB is only used to calculate a path when the path calculation based on the IS-IS TEDB fails.

Prerequisites

CSPF has been enabled using the **mpls te cspf** command.

Example

Configure CSPF to prefer the TEDB generated by OSPF when calculating a CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te cspf
[HUAWEI-mpls] mpls te cspf preferred-igp ospf
```

9.3.121 mpls te cspf timer failed-link

Function

The **mpls te cspf timer failed-link** command sets the timeout period of a failed-link timer.

The **undo mpls te cspf timer failed-link** command restores the default setting.

By default, the timeout period of the failed-link timer is 10 seconds.

Format

mpls te cspf timer failed-link *interval*

undo mpls te cspf timer failed-link

Parameters

Parameter	Description	Value
interval	Specifies the timeout period of a failed-link timer.	The value is an integer that ranges from 1 to 300, in seconds. The default value is 10.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A failed-link timer starts when a link goes Down.

- If an IGP deletes or modifies the link before the timer expires, CSPF is informed of the change. Then CSPF updates the link in the Traffic Engineering DataBase (TEDB) and terminates the timer.
- If IGP does not delete the link after the timer expires, the link goes Up.

Prerequisites

The CSPF function has been enabled by running the **mpls te cspf** command.

Example

Set the timeout period of the failed-link timer to 50 seconds.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te cspf
[HUAWEI-mpls] mpls te cspf timer failed-link 50
```

9.3.122 mpls te fast-reroute

Function

The **mpls te fast-reroute** command enables FRR.

The **undo mpls te fast-reroute** command disables FRR.

By default, FRR is disabled.

Format

mpls te fast-reroute [**bandwidth**]

undo mpls te fast-reroute

Parameters

Parameter	Description	Value
bandwidth	Indicates that bandwidth protection is needed.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

When FRR is enabled on a tunnel interface, the record route flag is automatically set as "record reroute with label", irrespective of the configuration of the **mpls te record-route label** command.

You must disable FRR If run the **mpls te record-route** or **undo mpls te record-route** command.

NOTE

- The **mpls te fast-reroute** command and the **mpls te resv-style ff** command cannot be configured together.
- The **mpls te fast-reroute** command and the **mpls te bypass-tunnel** command cannot be configured on the same tunnel interface.
- The **mpls te fast-reroute** command and the **mpls te protected-interface** command cannot be configured on the same tunnel interface.
- The **mpls te fast-reroute** command and the **mpls te protection tunnel** command cannot be configured for the protection tunnel in a tunnel protection group, whereas these two commands can be configured on the interface of the primary tunnel in the tunnel protection group.

Example

Enable FRR on Tunnel1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] mpls te fast-reroute
[HUAWEI-Tunnel1] mpls te commit
```

9.3.123 mpls te hop-limit

Function

The **mpls te hop-limit** command limits the maximum number of hops of a CR-LSP.

The **undo mpls te hop-limit** command restores the default setting.

By default, the maximum number of hops of a CR-LSP is 32.

Format

mpls te hop-limit *hop-limit-value* [**best-effort** | **secondary**]

undo mpls te hop-limit [**best-effort** | **secondary**]

undo mpls te hop-limit *hop-limit-value* { **secondary** | **best-effort** }

Parameters

Parameter	Description	Value
hop-limit-value	Specifies the value of the hop limit.	The value is an integer that ranges from 1 to 32. The default value is 32.
best-effort	Indicates the hop limit of a best-effort path.	-
secondary	Indicates the hop limit of a backup CR-LSP.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

After a CR-LSP is configured with a hop limit, the hop limit acts as one of routing conditions such as the link bandwidth and affinity property when the CR-LSP is created. After the hop limit is set, the number of hops of a CR-LSP cannot exceed this limit.

Example

Set the maximum number of hops of the primary CR-LSP, bypass CR-LSP, and best-effort path in hot-standby to 10.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te hop-limit 10
[HUAWEI-Tunnel1] mpls te hop-limit 10 secondary
[HUAWEI-Tunnel1] mpls te hop-limit 10 best-effort
[HUAWEI-Tunnel1] mpls te commit
```

9.3.124 mpls te hotstandby-lsp-constraint

Function

The **mpls te hotstandby-lsp-constraint** command allows you to use a CR-LSP attribute template to set up a hot-standby CR-LSP.

The **undo mpls te hotstandby-lsp-constraint** command deletes the used CR-LSP attribute template.

No CR-LSP attribute template is used to set up a hot-standby CR-LSP by default.

Format

mpls te hotstandby-lsp-constraint *number* { **dynamic** | **lsp-attribute** *lsp-attribute-name* }

undo mpls te hotstandby-lsp-constraint *number*

Parameters

Parameter	Description	Value
number	Specifies the number of a CR-LSP attribute template. It indicates the sequence of using each CR-LSP attribute template to set up a hot-standby CR-LSPs. The CR-LSP attribute templates are used in ascending order of their number.	The value is an integer ranging from 1 to 3.
dynamic	Indicates that when a hot-standby CR-LSP is being set up, it is assigned the same bandwidth and priority as the primary CR-LSP, but specified with a different path from the primary LSP.	-
lsp-attribute *lsp-attribute-name*	Specifies the name of a CR-LSP attribute template.	The value is an existing CR-LSP attribute template name.

2: Configuration level

Usage Guidelines

A maximum number of three CR-LSP attribute templates can be configured to set up hot-standby CR-LSPs. The hot-standby CR-LSPs must be consistent with the primary CR-LSP in the following attributes:

- Setup priority
- Holding priority
- Bandwidth type

In each of the three CR-LSP attribute template types corresponding to the primary CR-LSP, the hot-standby CR-LSP, and the ordinary backup CR-LSP respectively, only one attribute template can be specified with the **dynamic** parameter.

The parameter *number* is used to number each CR-LSP attribute template, which indicates the sequence of using each CR-LSP attribute template to set up a hot-standby CR-LSP. To set up a hot-standby CR-LSP, the system attempts to apply each CR-LSP attribute template by the template number in ascending order until a hot-standby CR-LSP is successfully up.

NOTE

- Before configuring the **mpls te hotstandby-lsp-constraint** command, you must run the **mpls te primary-lsp-constraint** command to use a CR-LSP attribute template to set up a primary CR-LSP.
- When the **mpls te hotstandby-lsp-constraint** command is configured to help set up a hot-standby CR-LSP, the **record-route** function is automatically enabled.

Example

Use the attribute template named t2 to set up a hot-standby CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te primary-lsp-constraint lsp-attribute t1
[HUAWEI-Tunnel1] mpls te hotstandby-lsp-constraint 1 lsp-attribute t2
[HUAWEI-Tunnel1] mpls te commit
```

9.3.125 mpls te igp advertise

Function

The **mpls te igp advertise** command configures forwarding adjacency to take an MPLS TE tunnel as a virtual link and advertise the virtual link to an IGP network.

The **undo mpls te igp advertise** command restores the default configuration.

By default, forwarding adjacency to take an MPLS TE tunnel as a virtual link and advertise the virtual link to an IGP network is disabled.

Format

mpls te igp advertise [**hold-time** *interval*]

undo mpls te igp advertise

Parameters

Parameter	Description	Value
hold-time *interval*	Specifies the interval between the time when a TE tunnel goes Down and when the network is notified of the change.	The value is an integer that ranges from 0 to 4294967295 in milliseconds. The default value is 0.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te igp advertise** command and the **mpls te igp shortcut** command cannot be configured simultaneously.

Example

Configure the forwarding adjacency and use the default hold time.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te igp advertise
[HUAWEI-Tunnel1] mpls te commit
```

9.3.126 mpls te igp metric

Function

The **mpls te igp metric** command specifies the MPLS TE tunnel metric for the SPF calculation in IGP shortcut or forwarding adjacency mode.

The **undo mpls te igp metric** command restores the default settings.

The TE tunnel metric is equal to the IGP metric of the TE tunnel by default.

Format

mpls te igp metric { **absolute** *absolute-value* | **relative** *relative-value* }

undo mpls te igp metric

Parameters

Parameter	Description	Value
absolute *absolute-value*	Specifies the absolute metric mode.	The value is an integer that ranges from 1 to 65535.
relative *relative-value*	Specifies the relative metric mode, indicating the offset value between the MPLS TE metric and the IGP metric.	The value is an integer that ranges from -10 to 10. The default value is 0.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IGP uses an auto route related to a CR-LSP in a TE tunnel that functions as a logical link to calculate a path. The tunnel interface is used as an outbound interface in the auto route. An auto route can work in IGP shortcut or forwarding adjacency mode. You can set a metric for a TE tunnel in either mode.

When specifying the metric for a TE tunnel in IGP shortcut mode, pay attention to the following points:

- If the **absolute** parameter is used, the metric of the TE tunnel is the set metric.
- If the **relative** parameter is used, the metric of the TE tunnel is the sum of the metric of the corresponding IGP path and relative metric.

A proper IGP metric for the TE tunnel in forwarding adjacency mode can ensure that the LSP be advertised and used correctly. For example, the metric of a TE tunnel should be less than the metric of an IGP route.

Precautions

When specifying an IGP metric for a TE tunnel in forwarding adjacency mode, select the **absolute** parameter if the IGP protocol is IS-IS.

Example

Set the MPLS TE tunnel metric to the IGP metric minus 1 in the SPF calculation.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te igp metric relative -1
[HUAWEI-Tunnel1] mpls te commit
```

9.3.127 mpls te igp shortcut

Function

The **mpls te igp shortcut** command configures an IGP to use MPLS TE tunnels in the Up state for performing the enhanced SPF calculation.

The **undo mpls te igp shortcut** command restores the default configuration.

By default, an IGP does not use MPLS TE tunnels for performing the enhanced SPF calculation.

Format

mpls te igp shortcut [**isis** | **ospf**]

undo mpls te igp shortcut

Parameters

Parameter	Description	Value
isis	Indicates the IS-IS protocol.	-
ospf	Indicates the OSPF protocol.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te igp shortcut** command and the **mpls e igp advertise** command cannot be configured simultaneously.

Example

Configure OSPF or IS-IS to use Tunnel 1 in the enhanced SPF calculation if this tunnel is Up.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te igp shortcut
[HUAWEI-Tunnel1] mpls te commit
```

9.3.128 mpls te link administrative group

Function

The **mpls te link administrative group** command sets the value of the administrative-group attribute for an interface.

The **undo mpls te link administrative group** command restores the default setting.

The default administrative-group attribute is 0x0.

Format

mpls te link administrative group *value*

undo mpls te link administrative group

Parameters

Parameter	Description	Value
value	Specifies the link attributes compared with affinity bits during the selection of a path.	The value is in hexadecimal notation and is of 32 bits with each bit representing an attribute. The value ranges from 0x0 to 0xFFFFFFFF.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

After being advertised globally, interface attributes can work as a standard for the ingress of a tunnel to select a path.

The modification on the administrative-group attributes takes effect only on the LSPs created after the modification and does not affect the established LSPs.

The **mpls te link administrative group** command can be run on the outgoing interface of the link through which a TE tunnel passes.

Example

Set the administrative-group attribute to 0x0101 on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
```

```
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te link administrative group 101
```

Set the administrative-group attribute to 0x0101 on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te link administrative group 101
```

9.3.129 mpls te loop-detection

Function

The **mpls te loop-detection** command enables the loop detection function while a tunnel is being set up.

The **undo mpls te loop-detection** command disables this function.

The loop detection function is disabled by default.

Format

mpls te loop-detection

undo mpls te loop-detection

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

To prevent loops, you can run the **mpls te loop-detection** command on the ingress of the MPLS TE tunnel to enable the loop detection function.

Example

Enable the loop detection when an MPLS TE tunnel is being set up.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te loop-detection
[HUAWEI-Tunnel1] mpls te commit
```

9.3.130 mpls te metric

Function

The **mpls te metric** command configures the TE metric value of a link.

The **undo mpls te metric** command restores the default configuration.

The IGP metric value of a link is used as the TE metric value by default.

Format

mpls te metric *value*

undo mpls te metric

Parameters

Parameter	Description	Value
metric *value*	Specifies the TE metric of a link.	An integer ranging from 1 to 16777215.

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

If the IGP is OSPF and the current device is a stub router, the **mpls te metric** command does not take effect.

Example

Set the TE metric of the link to 20 on interface VLANIF100.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te metric 20
```

Set the TE metric of the link to 20 on interface GE0/0/1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te metric 20
```

9.3.131 mpls te ordinary-lsp-constraint

Function

The **mpls te ordinary-lsp-constraint** command allows you to use a CR-LSP attribute template to set up an ordinary backup CR-LSP.

The **undo mpls te ordinary-lsp-constraint** command deletes a used CR-LSP attribute template.

No CR-LSP attribute template is used to set up an ordinary backup CR-LSP by default.

Format

mpls te ordinary-lsp-constraint *number* { **dynamic** | **lsp-attribute** *lsp-attribute-name* }

undo mpls te ordinary-lsp-constraint *number*

Parameters

Parameter	Description	Value
number	Specifies the number of a CR-LSP attribute template. The CR-LSP attribute templates are used to set up ordinary backup CR-LSPs in sequence of ascending number.	An integer ranging from 1 to 3.
dynamic	Indicates that when an ordinary backup CR-LSP is being set up, it is assigned the same bandwidth and priority as the primary CR-LSP.	-
lsp-attribute *lsp-attribute-name*	Specifies the name of a CR-LSP attribute template.	It is a string of 1 to 31 characters.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

A maximum number of three CR-LSP attribute templates can be configured to set up an ordinary backup CR-LSP. The ordinary backup CR-LSPs must be consistent with the primary CR-LSP in the following attributes:

- Setup priority

- Holding priority
- Bandwidth type

Among the three CR-LSP attribute templates corresponding to a primary CR-LSP and ordinary backup CR-LSP, only one CR-LSP attribute template can be specified with the **dynamic** parameter.

The parameter *number* is used to number each CR-LSP attribute template. The CR-LSP attribute templates are each applied by the system in sequence of ascending number until an ordinary backup CR-LSP is set up.

NOTE

- Before running the **mpls te ordinary-lsp-constraint** command, you must run the **mpls te primary-lsp-constraint** command to use a CR-LSP attribute template to set up a primary CR-LSP.
- When the **mpls te ordinary-lsp-constraint** command is run to help set up an ordinary backup CR-LSP, the **record route** function is automatically enabled.

Example

Use the attribute template named t3 to set up an ordinary backup CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te primary-lsp-constraint lsp-attribute t1
[HUAWEI-Tunnel1] mpls te ordinary-lsp-constraint 1 lsp-attribute t3
[HUAWEI-Tunnel1] mpls te commit
```

9.3.132 mpls te path explicit-path

Function

The **mpls te path explicit-path** command configures an explicit path for a tunnel.

The **undo mpls te path** command deletes a configured explicit path.

By default, no explicit path for a tunnel is configured.

Format

mpls te path explicit-path *path-name* [**secondary**]

undo mpls te path [**secondary**]

undo mpls te path explicit-path *path-name* **secondary**

Parameters

Parameter	Description	Value
path-name	Specifies the name of the explicit path for a tunnel.	The value is an existing explicit path name.

Parameter	Description	Value
secondary	Indicates that the explicit path is configured for a backup tunnel. The parameter is applied only to configuring a backup CR-LSP using the **mpls te backup** command.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te path explicit-path** command can be run successfully only after an explicit path is set up by running the **explicit-path** command in the system view, and the nodes on the path are specified.

Example

Apply the explicit path named path1 to Tunnel1.

```
<HUAWEI> system-view
[HUAWEI] explicit-path path1
[HUAWEI-explicit-path-path1] next hop 10.2.2.9
[HUAWEI-explicit-path-path1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te path explicit-path path1
[HUAWEI-Tunnel1] mpls te commit
```

9.3.133 mpls te path metric-type

Function

The **mpls te path metric-type** command specifies a link metric type used to select a path for a tunnel without any metric type.

The **undo mpls te path metric-type** command restores the default settings.

The TE metric is used to select a path for a tunnel by default.

Format

mpls te path metric-type { **igp** | **te** }

undo mpls te path metric-type

Parameters

Parameter	Description	Value
igp	Indicates that the IGP metric is used.	-
te	Indicates that the TE metric is used.	-

Views

MPLS view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

If the **mpls te path metric-type** command is not configured in the tunnel interface view, the metric type set in the MPLS view is used. Otherwise, the metric type set in the tunnel interface view will be used.

Example

Adopt the IGP metric that is used to select a path for the tunnel that is not configured with any metric type.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te path metric-type igp
```

Adopt the TE metric that is used to select a path for Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te path metric-type te
[HUAWEI-Tunnel1] mpls te commit
```

9.3.134 mpls te path-selection overload

Function

The **mpls te path-selection overload** command associates CR-LSP establishment with the IS-IS overload setting. This association allows CSPF to calculate paths excluding overloaded IS-IS nodes.

The **undo mpls te path-selection** command restores the default configuration.

By default, CR-LSP establishment is not associated with the IS-IS overload setting.

Format

mpls te path-selection overload

undo mpls te path-selection

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An administrator can run the **set-overload** command to mark a node overloaded if the node is transmitting a large number of services or its CPU is overburdened. If there are overloaded nodes on an MPLS TE network, associate CR-LSP establishment with the IS-IS overload setting to ensure that CR-LSPs are established over paths excluding overloaded nodes. This configuration prevents overloaded nodes from being further burdened and improves CR-LSP reliability.

Prerequisites

The route record has been enabled using the **mpls te record-route** command.

Precautions

The **mpls te path-selection overload** command has the following influences on the CR-LSP establishment:

- CSPF recalculates paths excluding overloaded nodes for established CR-LSPs.

  NOTE

  Traffic travels through an existing CR-LSP before a new CR-LSP is established. After the new CR-LSP is established, traffic is switched to the new CR-LSP and the original CR-LSP is deleted. This traffic switchover is performed based on the Make-Before-Break mechanism. Traffic is not dropped during the switchover.

- CSPF calculates paths excluding overloaded nodes for new CR-LSPs.

This command does not take effect on bypass tunnels.

If the ingress or egress is marked overloaded, the **mpls te path-selection overload** command does not take effect. The established CR-LSPs associated with the ingress or egress will not be reestablished and new CR-LSPs associated with the ingress or egress will also not be established.

If a TE LSP uses the local device as a transit node before the **set-overload** command is run, the TE LSP is not torn down and re-established and still uses the local device as a transit node after the **set-overload** command is run; if the local device is restarted after the command is run and fast convergence is not configured on the ingress of the RSVP-LSP, TE LSP forwarding fails, and services are affected. Therefore, the **mpls te path-selection overload** command needs to be run on the ingress of the RSVP-LSP before the device is restarted.

Example

Associate CR-LSP establishment with the IS-IS overload setting.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te path-selection overload
```

9.3.135 mpls te primary-lsp-constraint

Function

The **mpls te primary-lsp-constraint** command allows you to use a CR-LSP attribute template to set up a primary CR-LSP.

The **undo mpls te primary-lsp-constraint** command restores the default configuration.

No CR-LSP attribute template is used to set up a primary CR-LSP by default.

Format

mpls te primary-lsp-constraint { **dynamic** | **lsp-attribute** *lsp-attribute-name* }

undo mpls te primary-lsp-constraint

Parameters

Parameter	Description	Value
dynamic	Indicates that when a CR-LSP attribute template is used to set up a primary CR-LSP, all attributes in the attribute template use the default values.	-
lsp-attribute *lsp-attribute-name*	Specifies the name of a CR-LSP attribute template.	The value is an existing CR-LSP attribute template name.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

A CR-LSP attribute template already configured with the bandwidth and priority can be referenced to set up CR-LSPs in batches, greatly simplifying configurations of CR-LSPs.

If the TE attribute configured in the tunnel interface view and that configured through a CR-LSP attribute template coexist, the former takes precedence over the latter.

Example

Use the attribute template named **t1** to set up a primary CR-LSP.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te primary-lsp-constraint lsp-attribute t1
[HUAWEI-Tunnel1] mpls te commit
```

9.3.136 mpls te priority

Function

The **mpls te priority** command configures the setup priority and holding priority for an MPLS TE tunnel.

The **undo mpls te priority** command restores the default settings.

The default setup and holding priority for an MPLS TE tunnel are both 7.

Format

mpls te priority *setup-priority* [*hold-priority*]

undo mpls te priority

Parameters

Parameter	Description	Value
setup-priority	Specifies the setup priority.	The value is an integer that ranges from 0 to 7. The smaller the value, the higher the priority.
hold-priority	Specifies the holding priority.	The value is an integer that ranges from 0 to 7. The smaller the value, the higher the priority. Its value is the same as the setup priority by default.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If bandwidth resources on a link cannot satisfy the requirements for establishing all CR-LSPs, you can specify the setup and holding priorities for certain CR-LSPs. In this manner, the CR-LSPs with higher priorities can be established by preempting bandwidth resources of CR-LSPs with lower priorities before transmitting certain user services.

Priorities of a CR-LSP consist of the setup priority and holding priority, representing the preemption relationship between a CR-LSP to be established and an established CR-LSP. If the setup priority of a CR-LSP to be established is higher than the holding priority of an established CR-LSP, the CR-LSP to be established can preempt the bandwidth resources of the established one.

The default setup and holding priorities of CR-LSPs are 7, the lowest priority value. Default priorities take effect on all CR-LSPs if no priorities are specified. These CR-LSPs with the default priorities are at the risk of being preempted by those with higher priorities.

Precautions

During the planning of a network, it is recommended that the setup and holding priorities of all CR-LSPs be strictly planned. To preferentially transmit services over a CR-LSP, you can set the higher setup and holding priorities for the CR-LSP, preventing unwanted bandwidth preemption. The same setup and holding priorities are set for CR-LSPs which are transmitting services with the same priority, also preventing bandwidth preemption.

In addition, on one TE tunnel, its setup priority must be less than or equal to its holding priority. This ensures that CR-LSPs in the tunnel can be successfully set up, and prevents CR-LSP flapping caused by bandwidth preemption between CR-LSPs.

NOTICE

After the priorities of an existing CR-LSP have been changed, the existing CR-LSP will be deleted and a new one will be established. Therefore, back up CR-LSPs with lower priorities before setting higher priorities for a certain CR-LSP.

Example

Set the setup priority and the holding priority to 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te priority 1
[HUAWEI-Tunnel1] mpls te commit
```

9.3.137 mpls te protected-interface

Function

The **mpls te protected-interface** command specifies an interface to be protected by a bypass tunnel.

The **undo mpls te protected-interface** command delete an interface protected by a bypass tunnel.

By default, no interface to be protected by a bypass tunnel is specified.

Format

mpls te protected-interface *interface-type interface-number*

undo mpls te protected-interface *interface-type interface-number*

Parameters

Parameter	Description	Value
interface-type interface-number	Specifies the type and number of the interface to be protected. - *interface-type* specifies the interface type. - *interface-number* specifies the interface number.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te protected-interface** command must be configured together with the **mpls te bypass-tunnel** command on the same tunnel interface. Otherwise, the configured **mpls te protected-interface** command cannot take effect.

Currently, a bypass tunnel can protect up to six interfaces that must be enabled with MPLS TE.

NOTE

If a tunnel interface is configured with the **mpls te protected-interface** command, it cannot be configured with the **mpls te backup** or **mpls te fast-reroute** command.

Example

Use Tunnel 1 as a bypass tunnel of VLANIF 100.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te protected-interface vlanif 100
[HUAWEI-Tunnel1] mpls te commit
```

9.3.138 mpls te protect-switch

Function

The **mpls te protect-switch** command configures the manual switching mode for a specified tunnel.

The **mpls te protect-switch clear** and **undo mpls te protect-switch** commands delete the manual switching mode for a specified tunnel.

By default, no manual switching mode for a specified tunnel is configured.

Format

mpls te protect-switch { **force** | **lock** | **manual** }

mpls te protect-switch clear

undo mpls te protect-switch

Parameters

Parameter	Description	Value
force	Forcibly directs traffic to a protection tunnel.	-
lock	Locks traffic in the working tunnel. Being locked, traffic cannot be switched to a protection tunnel even if the working tunnel fails.	-
manual	Enables manual switching.	-
clear	Deletes the switching request manually configured on the current tunnel.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an LSP fault is detected, traffic switching is automatically triggered in a tunnel protection group. Alternatively, run the **mpls te protect-switch** command to trigger traffic switching.

MPLS OAM supports multiple traffic switching modes. These switching modes are prioritized. A newly configured switching mode takes effect only if its priority is higher than that of the existing switching mode.

The traffic switching modes are prioritized in descending order when the protection tunnel is Up:

- Force switching mode: has the highest priority. If force switching is configured, traffic is forced to switch to a protection tunnel and does not switch back even if the working tunnel recovers. Both the **mpls te protect-switch force** command and the **mpls te protect-switch lock** command can trigger force switching, but force switching triggered by the latter command has a higher priority.

- Signal failure mode: automatically triggers traffic switching if an LSP fault is detected.
- Manual switching mode: manually switches traffic to a protection tunnel.
- WTR mode: switches traffic back to a working tunnel after the WTR time expires. Although the WTR time is set, if a command is run to manually switch traffic, traffic will be switched immediately before the WTR time expires.

If a new local or remote request has a higher priority than an existing request manually configured using the **mpls te protect-switch** command, the APS state machine is changed, and the manual switching command is deleted. In the **mpls te protect-switch** command, the **force** and **manual** parameters, except the **lock** parameter, configure lower priority requests. After the **mpls te protect-switch** command with **force** or **manual** configured is run, the command is lost after a device is restarted. This situation is normal, in compliance with Recommendation G.8131.

Prerequisites

A tunnel protection group has been created by running the **mpls te protection tunnel** command.

Follow-up Procedure

The **mpls te protect-switch clear** command can be used to cancel force or manual switching.

Example

Switch traffic to the protection tunnel manually on Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te protect-switch manual
```

Delete the traffic switching to the protection tunnel on Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] mpls te protect-switch clear
```

9.3.139 mpls te protection tunnel

Function

The **mpls te protection tunnel** command creates a tunnel protection group by binding a configured protection tunnel to a primary tunnel.

The **undo mpls te protection tunnel** command deletes the binding between the protection tunnel and the primary tunnel.

By default, no protection tunnel group is created.

Format

mpls te protection tunnel *tunnel-id* [**holdoff** *holdoff-time*] [**mode** { **non-revertive** | **revertive** [**wtr** *wtr-time*] }]

undo mpls te protection tunnel

Parameters

Parameter	Description	Value
tunnel-id	Specifies the ID of a protection tunnel.	The value is an integer that ranges from 1 to 10000.
holdoff *holdoff-time*	Specifies the delay time. When a fault on a primary tunnel is detected, the switchover is performed after the delay time expires.	The value is an integer that ranges from 0 to 100 with the step of 100 milliseconds. The maximum delay time is 10 seconds. By default, the value is 10, indicating that the switchover is performed immediately after a fault on the primary tunnel is detected.
mode	Specifies the revertive mode. ● **non-revertive**: The current mode cannot be switched to the original mode. ● **revertive**: The current mode can be switched to the original mode.	By default, the revertive mode is used.
wtr *wtr-time*	Specifies the WTR time for the switchback. When a primary tunnel recovers from a fault, the switchback is performed after the WRT time expires.	The value is an integer that ranges from 0 to 60, with the increment of 30 seconds. By default, the value is 24, that is, 12 minutes.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

In addition to configuring a tunnel protection group to protect a working tunnel, you can configure TE FRR on the working tunnel. In this manner, the working tunnel can work under dual protection. The protection tunnel, however, cannot function as the working tunnel that is protected by another tunnel. In addition, the protection tunnel cannot be enabled with TE FRR.

After creating a protection tunnel in the tunnel interface view, you must run the **mpls te commit** command to commit the configuration.

NOTE

Tunnel protection group and TE FRR cannot be configured simultaneously on the ingress of a primary tunnel.

Example

Configure a protection tunnel for Tunnel1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te protection tunnel 239 holdoff 100 mode revertive wtr 30
[HUAWEI-Tunnel1] mpls te commit
```

9.3.140 mpls te record-route

Function

The **mpls te record-route** command enables the system to record routes and labels during tunnel establishment.

The **undo mpls te record-route** command configures the system not to record routes and labels during tunnel establishment.

By default, the system does not record routes and labels during tunnel establishment.

Format

mpls te record-route [**label**]

undo mpls te record-route

Parameters

Parameter	Description	Value
label	Indicates that a label is also recorded when the system records a route.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If an MPLS TE tunnel is not established over an explicit path, the system does not record detailed path information. In this case, to view detailed path information about the tunnel, run this command on a tunnel interface. After the configuration, RROs are carried in Path and Resv messages and record the IP address of each hop along the tunnel. In addition, the keyword **label** can be configured to record the label of each hop along the tunnel.

Precautions

After the **mpls te record-route** command is configured and the MPLS TE tunnel is established, the **display mpls te tunnel path** command can be run to display detailed path information about the tunnel.

Do not run the **mpls te record-route** command on a large-scale network. On such a network, a large number of hops exist along a tunnel. Running this command allows the Path and Resv messages to carry RROs that record the IP address of each hop along the tunnel. As a result, the Path or Resv message will be oversized, lowering the system performance.

NOTE

After the **mpls te fast-reroute**, **mpls te backup**, or **mpls te bypass-tunnel** command has been configured on a tunnel interface, the route record function is automatically enabled.

Example

Enable the system to record routes and labels during tunnel establishment.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te record-route label
[HUAWEI-Tunnel1] mpls te commit
```

9.3.141 mpls te reoptimization (user view)

Function

The **mpls te reoptimization** command immediately triggers re-optimization for an MPLS TE tunnel.

Format

mpls te reoptimization [**tunnel** *interface-number*]

Parameters

Parameter	Description	Value
tunnel *interface-number*	Specifies a tunnel that needs immediate re-optimization.	-

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The manual re-optimization function is used in either of the following situations:

- After the network topology is modified manually, a new optimal path will be calculated. The new optimal path needs to be immediately used by the TE tunnel.
- TE tunnels need to be immediately optimized in batches, optimizing resources of these TE tunnels in time.

If you run the **mpls te reoptimization** command without specifying the **tunnel** *interface-number* parameter, all TE tunnels are optimized. If you run the **mpls te reoptimization** command and specify the **tunnel** *interface-number* parameter, the specified TE tunnels are optimized.

Re-optimization of a TE tunnel can be performed in either of the following modes:

- Automatic re-optimization: means that the TE tunnel is periodically optimized, saving manpower. To enable automatic re-optimization, run the **mpls te reoptimization (tunnel interface view)** command in the tunnel interface view. In addition, this command takes effect only on an established TE tunnel.
- Manual re-optimization: means that the TE tunnel is immediately optimized. To immediately optimize the TE tunnel, run the **mpls te reoptimization** command in the user view.

Precautions

- If the re-optimization function is configured after an explicit path is configured and a new path fails to meet the explicit path constraints, the re-optimization function will not take effect.
- After a TE tunnel is configured with the re-optimization function, the tie-breaking in most-fill mode will not be supported.
- The **mpls te reoptimization** command cannot be run together with the following commands:
  - **mpls te route-pinning**
  - **mpls te resv-style ff**

Example

Immediately re-optimize all the TE tunnels on the local device.

```
<HUAWEI> mpls te reoptimization
```

9.3.142 mpls te reoptimization (tunnel interface view)

Function

The **mpls te reoptimization** command enables automatic re-optimization for a TE tunnel.

The **undo mpls te reoptimization** command restores the default setting.

By default, automatic re-optimization for a TE tunnel is disabled.

Format

mpls te reoptimization [**frequency** *interval*]

undo mpls te reoptimization

Parameters

Parameter	Description	Value
frequency *interval*	Specifies the interval for re-optimization. The system calculates the path for a TE tunnel based on constraints at the intervals of *interval*. If a better path to the same destination is calculated, the TE tunnel will be re-established over the better path.	The value is an integer that ranges from 60 to 604800, in seconds. By default, the interval is 3600 seconds.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a better path is calculated, to allow a TE tunnel to be automatically re-established over the better path, the **mpls te reoptimization** command needs to be run in the tunnel interface view. In this manner, after a better path to the same destination has been calculated for a certain reason such as the change of the cost, the TE tunnel can be automatically re-established, optimizing the resources on the network.

Re-optimization of a TE tunnel can be performed in either of the following modes:

- Automatic re-optimization: means that the TE tunnel is periodically optimized, saving manpower. To enable automatic re-optimization, run the **mpls te reoptimization** command in the tunnel interface view. In addition, this command takes effect only on an established TE tunnel.
- Manual re-optimization: means that the TE tunnel is immediately optimized. To immediately optimize the TE tunnel, run the **mpls te reoptimization** command in the user view.

Prerequisites

CSPF has been enabled by running the **mpls te cspf** command.

Precautions

- If the re-optimization function is configured after an explicit path is configured and a new path fails to meet the explicit path constraints, the re-optimization function will not take effect.
- After a TE tunnel is configured with the re-optimization function, the tie-breaking in most-fill mode will not be supported.
- The **mpls te reoptimization** command cannot be run together with the following commands:
  - **mpls te route-pinning**
  - **mpls te resv-style ff**

Example

Enable periodic re-optimization for a TE tunnel named Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te reoptimization frequency 43200
[HUAWEI-Tunnel1] mpls te commit
```

9.3.143 mpls te resv-style

Function

The **mpls te resv-style** command specifies a reservation style.

The **undo mpls te resv-style** command restores the default setting.

The default reservation style is SE.

Format

mpls te resv-style { **ff** | **se** }

undo mpls te resv-style

Parameters

Parameter	Description	Value
ff	Indicates the style of fixed filter.	-
se	Indicates the style of shared explicit.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

RSVP-TE only supports two resources reservation styles: FF and SE.

NOTE

The **mpls te resv-style ff** command cannot be configured simultaneously with the following commands: **mpls te fast-reroute**, **mpls te backup**, and **mpls te reoptimization (tunnel interface view)**.

Example

Set up a CR-LSP with the resource reservation style being FF.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te signal-protocol rsvp-te
[HUAWEI-Tunnel1] mpls te resv-style ff
[HUAWEI-Tunnel1] mpls te commit
```

9.3.144 mpls te route-pinning

Function

The **mpls te route-pinning** command enables the route pinning function.

The **undo mpls te route-pinning** command disables this function.

Route pinning is disabled by default.

Format

mpls te route-pinning

undo mpls te route-pinning

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

The **mpls te route-pinning** command cannot be configured simultaneously the **mpls te reoptimization (tunnel interface view)** command.

Example

Enable route pinning function.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te route-pinning
[HUAWEI-Tunnel1] mpls te commit
```

9.3.145 mpls te signal-protocol

Function

The **mpls te signal-protocol** command specifies a signaling protocol to set up an LSP.

The **undo mpls te signal-protocol** command deletes the signaling protocol to set up an LSP.

The default signaling protocol used to set up an LSP is RSVP-TE.

Format

mpls te signal-protocol { **cr-static** | **rsvp-te** | **static** }

undo mpls te signal-protocol { **cr-static** | **static** }

Parameters

Parameter	Description	Value
cr-static	Uses static CR-LSPs to establish TE tunnels.	-
rsvp-te	Uses RSVP-TE as the signaling protocol.	-
static	Uses static LSPs to establish TE tunnels.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

When configuring MPLS TE, you can run this command to specify a signaling protocol to set up a tunnel.

- When configuring a static MPLS TE tunnel, the signaling protocol used is **cr-static**.
- When configuring a dynamic MPLS TE tunnel, the signaling protocol used is **rsvp-te**.

Example

Use RSVP-TE as the signaling protocol for MPLS TE.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te signal-protocol rsvp-te
[HUAWEI-Tunnel1] mpls te commit
```

9.3.146 mpls te signaling-delay-trigger enable

Function

The **mpls te signaling-delay-trigger enable** command enables the RSVP signaling delay-trigger function.

The **undo mpls te signaling-delay-trigger enable** command disables the RSVP signaling delay-trigger function.

The RSVP signaling delay-trigger function is disabled by default.

Format

mpls te signaling-delay-trigger enable

undo mpls te signaling-delay-trigger enable

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a fault occurs on an MPLS network and a large number of RSVP CR-LSPs need to be re-established, a large amount of system resources may be required. In this case, after the RSVP signaling delay-trigger function is configured, the interval between re-establishments of a CR-LSP is prolonged so that system resources are saved.

Prerequisites

Before running the **mpls te signaling-delay-trigger enable** command, the **mpls te** command must be run in the MPLS view.

Precautions

Use caution when configuring the RSVP signaling delay-trigger function because it causes the delay of CR-LSP convergence. The default settings are recommended.

Example

Enable the RSVP signaling delay-trigger function.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te signaling-delay-trigger enable
```

9.3.147 mpls te signalled tunnel-name

Function

The **mpls te signalled tunnel-name** command configures the name of a TE tunnel.

The **undo mpls te signalled tunnel-name** command deletes the configured name of the TE tunnel.

By default, the name of a TE tunnel is not configured.

Format

mpls te signalled tunnel-name *tunnel-name*

undo mpls te signalled tunnel-name

Parameters

Parameter	Description	Value
tunnel-name	Specifies the name of a TE tunnel.	A string of 1 to 63 case-sensitive characters, spaces or slashes (/) not supported. The initial character must be an underscore (_) or an English letter, not a digit.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

A tunnel interface name is used as a tunnel name by default, for example, Tunnel1. Alternatively, if you want to customize a name for a TE tunnel, the **mpls te signalled tunnel-name** command can be used to configure a TE tunnel name. For example, a TE tunnel from LSR A to LSR C is named LSRAtoLSRC.

Prerequisites

MPLS TE has been enabled using the **mpls te** command.

Precautions

A TE tunnel name must be unique on an entire device.

If a TE tunnel name is specified, RSVP signaling messages will carry the specified name. If a configured TE tunnel name is deleted or no TE tunnel name is specified, RSVP signaling messages will carry the TE tunnel interface name as the TE tunnel name.

The **mpls te signalled tunnel-name** command or its undo form takes effect on a TE tunnel established using only RSVP signaling, not a static route.

Example

Name a TE tunnel **LSRAtoLSRC**.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te signalled tunnel-name LSRAtoLSRC
[HUAWEI-Tunnel1] mpls te commit
```

9.3.148 mpls te srlg

Function

The **mpls te srlg** command configures an interface as an SRLG member.

The **undo mpls te srlg** command deletes an interface from an SRLG.

No interface is added to any SRLG by default.

Format

mpls te srlg *srlg-number*

undo mpls te srlg { *srlg-number* | **all** }

Parameters

Parameter	Description	Value
srlg-number	Specifies the number of the SRLG to which an interface belongs.	The value is an integer that ranges from 0 to 4294967295.
all	Indicates that all SRLG configurations are deleted from an interface.	-

Views

VLANIF interface view, GE interface view, XGE interface view, MultiGE interface view, 25GE interface view, 40GE interface view, 100GE interface view, Eth-trunk interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The SRLG, like the bandwidth and affinity property, is a constraint in path calculation. If SRLG is configured for links, an IGP floods the TE link information along with the SRLG membership information to all devices in an IGP area. The SRLG membership information is also added into the TEDB.

Prerequisites

Before running the **mpls te srlg** command, the **mpls te** command must be run in the interface view.

Precautions

If SRLG is configured for links and the **mpls te srlg path-calculation** command is configured on the ingress of the primary tunnel, when calculating the path of a bypass tunnel or a hot-standby tunnel, CSPF determines whether the SRLG attribute is used as a constraint according to the configured SRLG calculation mode.

One interface can join multiple SRLGs.

Example

Add VLANIF100 to SRLG 1 and SRLG 2.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 100
[HUAWEI-Vlanif100] mpls
[HUAWEI-Vlanif100] mpls te
[HUAWEI-Vlanif100] mpls te srlg 1
[HUAWEI-Vlanif100] mpls te srlg 2
```

Add GE0/0/1 to SRLG 1.

```
<HUAWEI> system-view
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] mpls
[HUAWEI-GigabitEthernet0/0/1] mpls te
[HUAWEI-GigabitEthernet0/0/1] mpls te srlg 1
```

9.3.149 mpls te srlg path-calculation

Function

The **mpls te srlg path-calculation** command configures an SRLG-based path calculation mode.

The **undo mpls te srlg path-calculation** command deletes an SRLG-based path calculation mode.

By default, when calculating a path, CSPF does not consider an SRLG constraint or check whether the primary CR-LSP and a Bypass CR-LSP or a hot-standby CR-LSP are in the same SRLG.

Format

mpls te srlg path-calculation [**strict** | **preferred**]

undo mpls te srlg path-calculation

Parameters

Parameter	Description	Value
strict	Indicates that CSPF must calculate a bypass CR-LSP or a hot-standby CR-LSP according to the SRLG attribute. The link that the primary path uses and the link that the bypass CR-LSP or hot-standby CR-LSP uses cannot be in the same SRLG. **NOTE** After you specify this parameter, all the links on the primary CR-LSP regardless of whether the SRLG attribute is configured cannot be used for calculation of the bypass or hot-standby CR-LSP. However, nodes on the primary CR-LSP can be used in CSPF calculation.	-
preferred	Indicates that CSPF prefers the SRLG attribute the first time it calculates a Bypass CR-LSP or hot-standby CR-LSP. If the initial calculation fails, the CSPF does not use the SRLG attribute as a constraint. **NOTE** If no path calculation mode is specified in the **mpls te srlg path-calculation** command, SRLG-based path calculation is performed in preferred mode by default.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the TE FRR or hot standby scenario, to enable CSPF to calculate a path for a Bypass CR-LSP or a hot-standby CR-LSP based on the SRLG attribute, you must run the **mpls te srlg path-calculation** command on the ingress of the tunnel.

The SRLG, like the bandwidth and affinity property, is a constraint in path calculation. If SRLG is configured for links and the **mpls te srlg path-calculation** command is configured on the ingress of the primary CR-LSP, when calculating the path of a Bypass CR-LSP or a hot-standby tunnel, CSPF determines whether the SRLG attribute is used as a constraint according to the configured SRLG calculation mode.

Precautions

If **strict** is configured, CSPF always considers SRLG as a constraint.

If **preferred** is configured, the first time that CSPF calculates a path is according to the SRLG attribute. If the calculation fails, CSPF tries to calculate again without considering SRLG.

Example

Enable path calculation in **strict** mode.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te srlg path-calculation strict
```

9.3.150 mpls te switch-delay

Function

The **mpls te switch-delay** command sets the switching and deletion delays for a TE tunnel.

The **undo mpls te switch-delay** command restores the default settings.

By default, the switching delay is 5000 milliseconds and the deletion delay is 7000 milliseconds.

Format

mpls te switch-delay *switch-time* **delete-delay** *delete-time*

undo mpls te switch-delay *switch-time* **delete-delay** *delete-time*

Parameters

Parameter	Description	Value
switch-delay *switch-time*	Specifies the time period that the TE traffic is switched from the primary CR-LSP to the Modified CR-LSP.	The value is an integer that ranges from 0 to 600000, in milliseconds. The default value is 5000.
delete-delay *delete-time*	Specifies the delay for deleting the primary CR-LSP after the TE traffic is switched to a Modified CR-LSP.	The value is an integer that ranges from 0 to 600000, in milliseconds. The default value is 7000.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MPLS TE uses the Make-Before-Break mechanism. When the attributes of an MPLS TE tunnel such as bandwidth and path change, a new CR-LSP with new attributes, also called Modified CR-LSP, must be established.

On the same modified CR-LSP, when a downstream LSR is too busy but the upstream LSR is not as busy, the Modified CR-LSP may go Up earlier on the upstream LSR than on the downstream LSR. The upstream LSR switches traffic to the Modified CR-LSP but the Modified CR-LSP is not Up on the downstream LSR. This causes a momentary traffic interruption. You can set a suitable switching delay time to avoid the traffic interruption.

If a modified CR-LSP fails, the failed node sends PathErr messages to its upstream LSRs and deletes the Modified CR-LSP, and traffic should be switched back to the primary CR-LSP. In applications, when detecting the fault, the upstream LSRs of the failed node are too occupied to forward the PathErr messages. This causes a traffic interruption on the failed node because the primary CR-LSP is deleted on the failed node. You can set a suitable deletion delay time to prevent the traffic interruption.

NOTE

In a VPLS over MPLS TE scenario, you can configure TE FRR to improve network reliability. TE FRR protects links and nodes on an MPLS TE tunnel. If a link or node fails, TE FRR rapidly switches traffic to the protection path. However, traffic loss may occur during a traffic switchback if the delay for deleting the TE FRR protection path is too short. To prevent this situation, run the **delete-delay** *delete-time* command to configure an appropriate delay based on the number of VSIs on the MPLS TE tunnel:

- 30s if there are 2001 to 4000 VSIs
- 20s if there are 1001 to 2000 VSIs
- 10s if there are 501 to 1000 VSIs
- 7s if there are 1 to 500 VSIs

Prerequisites

MPLS TE has been enabled globally by running the **mpls te** command.

Example

Set the switching delay of the TE tunnel to 3000 milliseconds and the deletion delay of the TE tunnel to 8000 milliseconds.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te switch-delay 3000 delete-delay 8000
```

9.3.151 mpls te tie-breaking

Function

The **mpls te tie-breaking** command configures a rule for selecting a route among multiple available equal-cost routes to the destination.

The **undo mpls te tie-breaking** command restores the default settings.

By default, tie-breaking policy is random.

Format

mpls te tie-breaking { **least-fill** | **most-fill** | **random** }

undo mpls te tie-breaking

Parameters

Parameter	Description	Value
least-fill	Selects the route with the smallest ratio of the occupied bandwidth to the maximum reservable bandwidth.	-
most-fill	Selects the route with the largest ratio of the occupied bandwidth to the maximum reservable bandwidth.	-
random	Selects a route randomly.	-

Views

MPLS view, tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The route is selected based on the ratio of the occupied available bandwidth to the maximum reservable bandwidth. If **least-fill** is configured, the route with the smallest ratio is selected; if **most-fill** is configured, the route with the largest ratio is selected.

Prerequisites

MPLS TE has been enabled by running the **mpls te** command.

Precautions

Note that the link is selected according to a ratio through the tie-breaking mechanism. In the case that the ratios are the same when the reservable bandwidth is not used or the same reservable bandwidth is used on the links, the first found link is used regardless of whether **least-fill** or **most-fill** is configured.

NOTE

A tunnel prefers the route-selecting rule configured in the local tunnel interface view. If no rule is configured in the tunnel interface view, the rule configured in the MPLS view is used.

Example

Select the path with the smallest ratio of the occupied bandwidth to the maximum reservable bandwidth.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te tie-breaking least-fill
[HUAWEI-Tunnel1] mpls te commit
```

Select the path with the smallest ratio of the occupied bandwidth to the maximum reservable bandwidth.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te tie-breaking least-fill
```

9.3.152 mpls te timer auto-bandwidth

Function

The **mpls te timer auto-bandwidth** command enables automatic bandwidth adjustment and samples the output rate for tunnels.

The **undo mpls te timer auto-bandwidth** command disables automatic bandwidth adjustment.

By default, automatic bandwidth adjustment is not enabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730-H, and S6730S-H support this command.

Format

mpls te timer auto-bandwidth [*interval*]

undo mpls te timer auto-bandwidth

Parameters

Parameter	Description	Value
interval	Specifies the interval for sampling the output rate of each tunnel configured with automatic bandwidth adjustment.	The value is an integer that ranges from 1 to 604800 in seconds. The default value is 300 seconds, and is a recommended value.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Before a sampling interval is changed, the **undo mpls te timer auto-bandwidth** command must be run. Then the **mpls te timer auto-bandwidth** command is run to set an interval.

Example

Sample the output rate of the MPLS TE tunnel every 10 minutes.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] mpls te timer auto-bandwidth 600
```

9.3.153 mpls te timer fast-reroute

Function

The **mpls te timer fast-reroute** command sets the interval at which the binding between a bypass CR-LSP and a primary CR-LSP is refreshed.

The **undo mpls te timer fast-reroute** command restores the default configuration.

By default, the time weight used to calculate the interval is 300. And the actual interval at which the binding between a bypass CR-LSP and a primary LSP is refreshed depends on device performance and the maximum number of LSPs that can be established on the device.

Format

mpls te timer fast-reroute [*weight*]

undo mpls te timer fast-reroute

Parameters

Parameter	Description	Value
weight	Specifies the weight value used to calculate the interval at which the binding between a bypass CR-LSP and a primary LSP is refreshed.	The value is an integer that ranges from 0 to 604800. **NOTE** If *weight* is not specified, the default weight value is 300.

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After TE FRR is configured, a PLR refreshes the binding between a bypass CR-LSP and a primary CR-LSP at a specified interval. The PLR searches for the optimal bypass CR-LSP and binds it to a primary CR-LSP. To set the interval at which the binding between a bypass CR-LSP and a primary CR-LSP is refreshed, run the **mpls te timer fast-reroute** command.

The PLR calculates the interval using the value of *weight*. And the actual interval depends on device performance and the maximum number of LSPs that can be established on the device

Prerequisites

RSVP-TE has been enabled by running the **mpls rsvp-te** command in the MPLS view.

Example

Set the weight of the interval at which binding between a bypass CR-LSP and a primary LSP is refreshed to **120**.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls te timer fast-reroute 120
```

9.3.154 mpls te timer retry

Function

The **mpls te timer retry** command sets the interval for re-establishing a tunnel.

The **undo mpls te timer retry** command restores the default setting.

The default interval is 30 seconds.

Format

mpls te timer retry *interval*

undo mpls te timer retry [*interval*]

Parameters

Parameter	Description	Value
interval	Specifies the interval for resetting up tunnels.	The value is an integer that ranges from 10 to 65535, in seconds. The default value is 30 seconds.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a TE tunnel has been established, the TE tunnel is kept Up by periodically sending a Path message from the local node to its neighbor and receiving a Resv message from the neighbor. If no Resv message is received after the specified interval at which a tunnel is re-established, the local node considers the tunnel Down and reattempts to establish the tunnel. You can run this command to modify the interval for re-establishing a tunnel.

Precautions

A rather smaller interval imposes heavy burden of message processing on the system, causing network flapping; a rather large interval deteriorates the efficiency of RSVP CR-LSP convergence. Therefore, the default interval, 30 seconds, is recommended.

Example

Set the interval for setting up tunnels to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te timer retry 20
[HUAWEI-Tunnel1] mpls te commit
```

9.3.155 mpls te tunnel-id

Function

The **mpls te tunnel-id** command specifies the ID for a tunnel.

Format

mpls te tunnel-id *tunnel-id*

Parameters

Parameter	Description	Value
tunnel-id	Specifies the ID for a tunnel.	The value is an integer that ranges from 1 to 10000.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The ID for a tunnel is a number that uniquely identifies an MPLS TE tunnel to facilitate tunnel planning and management.

Prerequisites

MPLS TE has been configured as the tunnel protocol using the **tunnel-protocol mpls te** command in the tunnel interface view.

Precautions

A tunnel ID must be set for a tunnel; otherwise, the tunnel fails to be established.

Example

Create a tunnel interface, configure MPLS TE as a tunnel protocol, set the tunnel ID to 100, and assign a tunnel destination address 2.2.2.2 to the interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te tunnel-id 100
[HUAWEI-Tunnel1] destination 2.2.2.2
[HUAWEI-Tunnel1] mpls te commit
```

9.3.156 mpls total-crlsp-number threshold-alarm

Function

The **mpls total-crlsp-number threshold-alarm** command configures the alarm threshold for total constraint-based routed label switched path (CR-LSP) usage.

The **undo mpls total-crlsp-number threshold-alarm** command restores the default settings.

The default upper limit of the alarm threshold for total CR-LSP usage is 80%. The default lower limit of the clear alarm threshold for total CR-LSP usage is 75%.

Format

mpls total-crlsp-number threshold-alarm upper-limit *upper-limit-value* **lower-limit** *lower-limit-value*

mpls total-crlsp-number { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*

undo mpls total-crlsp-number threshold-alarm

undo mpls total-crlsp-number { **ingress** | **transit** | **egress** } **threshold-alarm**

Parameters

Parameter	Description	Value
upper-limit *upper-limit-value*	Specifies the upper limit of the alarm threshold for total CR-LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. Using a value larger than 95 is not recommended. Using the default value 80 is recommended.
lower-limit *lower-limit-value*	Specifies the lower limit of the clear alarm threshold for total CR-LSP usage.	The value is an integer ranging from 1 to 100, represented in percentage. The value must be smaller than the value of *upper-limit-value*. Using the default value 75 is recommended.
ingress	Specifies the alarm threshold for total ingress CR-LSPs.	-
transit	Specifies the alarm threshold for total transit CR-LSPs.	-
egress	Specifies the alarm threshold for total egress CR-LSPs.	-

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the number of total CR-LSPs (including static CR-LSPs and Resource Reservation Protocol (RSVP) LSPs) in the system reaches a specific limit, establishing subsequent CR-LSPs may fail because of insufficient resources. To facilitate user operation and maintenance, enable an alarm to be generated when the number of total CR-LSPs reaches the specific limit. To configure the alarm threshold for total CR-LSP usage, run the **mpls total-crlsp-number threshold-alarm** command. The parameters in this command are described as follows:

- When the total CR-LSP usage increases to the value of *upper-limit-value*, an alarm for total CR-LSPs is generated.
- When the total CR-LSP usage falls below the value of *lower-limit-value*, a clear alarm for total CR-LSPs is generated.

If you want to set the alarm threshold for total ingress CR-LSPs, total transit CR-LSPs or total egress CR-LSPs, run **mpls total-crlsp-number** { **ingress** | **transit** | **egress** } **threshold-alarm upper-limit** *upper-limit-value* **lower-limit** *lower-limit-value*.

Precautions

- If the **mpls total-crlsp-number threshold-alarm** command is run more than once, the latest configuration overrides the previous one.
- This command configures the alarm threshold for total CR-LSP usage. The alarm that the number of LSPs exceeded the upper threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceed** is configured, and the actual total CR-LSP usage reaches the upper limit of the alarm threshold. The alarm that the number of LSPs fell below the lower threshold is generated only when the command **snmp-agent trap enable feature-name mpls_lspm trap-name hwmplslspthresholdexceedclear** is configured, and the actual total CR-LSP usage falls below the lower limit of the clear alarm threshold.

Example

Configure the upper limit and the lower limit of the alarm threshold for total CR-LSP usage.

```
<HUAWEI> system-view
[HUAWEI] mpls
[HUAWEI-mpls] mpls total-crlsp-number threshold-alarm upper-limit 90 lower-limit 60
```

9.3.157 next hop

Function

The **next hop** command specifies the next-hop address on an explicit path, and creates an MPLS TE tunnel through nodes in the order in which they are configured.

The **undo next hop** command restores the default configuration.

By default, no next-hop address on an explicit path is specified.

Format

next hop *ip-address* [**include** [[**loose** | **strict**] | [**incoming** | **outgoing**]] * | **exclude**]

undo next hop *ip-address*

Parameters

Parameter	Description	Value
ip-address	Specifies the next-hop IP address on an explicit path.	The value is in dotted decimal notation.
include [[**loose** | **strict**] | [**incoming** | **outgoing**]] *	Specifies the IP address of a node included on an explicit path. - **strict**: indicates that the node is added in **strict** mode. The node of *ip-address* is directly connected to the previous hop. - **loose**: indicates that the node is added in **loose** mode. The node of *ip-address* may not be directly connected to the previous hop. - **incoming**: indicates that the *ip-address1* is the IP address of an inbound interface of a next-hop node. - **outgoing**: indicates that the *ip-address1* is the IP address of an outbound interface of a next-hop node.	By default, a node is added to an explicit path in **include strict** mode.
exclude	Excludes the IP address from an explicit path.	-

Views

Explicit path view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **next hop** command is used to plan nodes for an explicit path.

Precautions

The **include strict** parameter is used by default, meaning the tunnel must pass through a specified node.

Example

Exclude the IP address 10.0.0.125 from the MPLS TE explicit path.

```
<HUAWEI> system-view
[HUAWEI] explicit-path p1
[HUAWEI-explicit-path-p1] next hop 10.0.0.125 exclude
```

9.3.158 notify neighbor-down

Function

The **notify neighbor-down** command configures a BFD session to notify the upper layer protocol when the BFD session detects a neighbor Down event.

The **undo notify neighbor-down** command restores the default configuration.

By default, when the BFD detection time expires or a BFD session detects a neighbor Down event, the BFD session notifies the upper layer protocol.

Format

notify neighbor-down

undo notify neighbor-down

Parameters

None

Views

BFD-LSP session view

Default Level

2: Configuration level

Usage Guidelines

In most cases, when you use a BFD session to detect link faults, the BFD session notifies the upper layer protocol of a link fault in the following scenarios:

- When the BFD detection time expires, the BFD session notifies the upper layer protocol. BFD sessions must be configured on both ends. If the BFD session on the local end does not receive any BFD packets from the remote end within the detection time, the BFD session on the local end concludes that the link fails and notifies the upper layer protocol of the link fault.
- When a BFD session detects a neighbor Down event, the BFD session notifies the upper layer protocol. If the BFD session on the local end detects a neighbor Down event within the detection time, the BFD session on the local end directly notifies the upper layer protocol of the neighbor Down event.

When you use a BFD session to detect faults on an LSP, you need only be concerned about whether a fault occurs on the link from the local end to remote end. In this situation, run the **notify neighbor-down** command to configure the BFD session to notify the upper layer protocol only when the BFD session detects a neighbor Down event. This configuration prevents the BFD session from notifying the upper layer protocol when the BFD detection time expires and ensures that services are not interrupted.

Example

Configure the BFD session to notify the upper layer protocol when the BFD session detects a neighbor Down event.

```
<HUAWEI> system-view
[HUAWEI] bfd atob bind ldp-lsp peer-ip 10.1.2.1 nexthop 10.1.1.2 interface vlanif 100
[HUAWEI-bfd-lsp-session-atob] discriminator local 1
[HUAWEI-bfd-lsp-session-atob] discriminator remote 2
[HUAWEI-bfd-lsp-session-atob] notify neighbor-down
[HUAWEI-bfd-lsp-session-atob] commit
```

9.3.159 opaque-capability enable

Function

The **opaque-capability enable** command enables the Opaque-LSA capability so that an OSPF process can generate Opaque LSAs and receive Opaque LSAs from neighbors.

The **undo opaque-capability** command disables the Opaque-LSA capability.

By default, the Opaque-LSA capability is disabled.

Format

opaque-capability enable

undo opaque-capability

Parameters

None

Views

OSPF view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Opaque LSAs provide a generic mechanism for OSPF extension:

- OSPF supports GR using Type 9 LSAs.
- OSPF supports TE using Type 10 LSAs.

Before configuring OSPF GR or OSPF TE, you must enable opaque LSA capability running the **opaque-capability enable** command.

Configuration Impact

Enabling or disabling the opaque LSA function may delete and re-establish all sessions and instances.

Example

Enable OSPF opaque-lsa.

```
<HUAWEI> system-view
[HUAWEI] ospf
[HUAWEI-ospf-1] opaque-capability enable
```

9.3.160 priority

Function

The **priority** command sets the setup priority and holding priority in a CR-LSP attribute template.

The **undo priority** command restores the default setup priority and holding priority in a CR-LSP attribute template.

The default setup and holding priority for a CR-LSP attribute template are both 7.

Format

priority *setup_priority_value* [*hold_priority_value*]

undo priority

Parameters

Parameter	Description	Value
setup_priority_value	Specifies the setup priority value in a CR-LSP attribute template.	An integer ranging from 0 to 7. The smaller the value, the higher the priority. The default setup priority is 7.
hold_priority_value	Specifies the holding priority value in a CR-LSP attribute template.	An integer ranging from 0 to 7. The smaller the value, the higher the priority. The default holding priority is 7.

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

When configuring the **priority** command in the LSP attribute view, ensure that the setup priority is greater than or equal to the holding priority.

Example

Set both the setup priority and holding priority to 4 in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] priority 4 4
```

9.3.161 record-route

Function

The **record-route** command enables the system to record routes in a CR-LSP attribute template.

The **undo record-route** command configures the system not to record routes in a CR-LSP attribute template.

The system does not record routes in a CR-LSP attribute template.

Format

record-route [**label**]

undo record-route

Parameters

Parameter	Description	Value
label	Indicates that a label is also recorded when the system records a route.	-

Views

LSP attribute view

Default Level

2: Configuration level

Usage Guidelines

If the FRR function is enabled in a CR-LSP attribute template, the route storing function cannot be disabled.

Example

Enable the system to record routes in the CR-LSP attribute template.

```
<HUAWEI> system-view
[HUAWEI] lsp-attribute lsp-attribute-name
[HUAWEI-lsp-attribute-lsp-attribute-name] record-route
```

9.3.162 reset mpls rsvp-te

Function

The **reset mpls rsvp-te** command resets RSVP-TE process.

Format

reset mpls rsvp-te

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

You can delete and re-establish a CR-LSP by running the **reset mpls rsvp-te** command. This command is used to verify the working process of RSVP-TE in special cases. Generally, this command is not needed.

NOTE

If this command is run in an attempt to restart RSVP-TE and the interval at which RSVP-TE is restarted is small, the attempt fails. The interval varies according to the number of LSPs. The more the LSPs are established, the longer the interval is. The interval can be set to 30, 60, 90, or 120, in seconds.

Example

Reset RSVP-TE.

```
<HUAWEI> reset mpls rsvp-te
Warning: The MPLS RSVP-TE services will be reset. Continue? [Y/N]:y
```

9.3.163 reset mpls rsvp-te statistics

Function

The **reset mpls rsvp-te statistics** command clears the operational statistics on RSVP-TE.

Format

reset mpls rsvp-te statistics { **global** | **interface** [*interface-type interface-number*] }

Parameters

Parameter	Description	Value
global	Clears the global operational statistics on RSVP-TE.	-
interface	Clears the operational statistics on RSVP-TE on the interface.	-
interface-type interface-number	Clears the operational statistics on RSVP-TE on the specifies interface. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	If no type or number of an interface is specified, statistics about all RSVP-TE interfaces are cleared.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

When you run this command to clear the running information about RSVP-TE, the system displays the statistics from after the previous information is cleared.

Example

Clear the global operational statistics on RSVP-TE.

```
<HUAWEI> reset mpls rsvp-te statistics global
```

9.3.164 reset mpls stale-interface

Function

The **reset mpls stale-interface** command deletes information about MPLS interfaces in the Stale state.

Format

reset mpls stale-interface [*interface-index*]

Parameters

Parameter	Description	Value
interface-index	Specifies the index of a specified stale interface.	A hexadecimal integer ranging from 1 to FFFFFFFE.

Views

User view

Default Level

3: Management level

Usage Guidelines

If the configuration of an interface is deleted, or MPLS is disabled on an interface, the interface status becomes Stale. Run the **reset mpls stale-interface** command to delete information about a stale interface.

Run the **display mpls stale-interface** command without specifying a parameter to view the index of a stale interface.

Example

Delete information about a specified stale interface.

```
<HUAWEI> reset mpls stale-interface 9d
```

Delete information about all stale interfaces.

```
<HUAWEI> reset mpls stale-interface
```

9.3.165 reset mpls te auto-bandwidth adjustment timers

Function

The **reset mpls te auto-bandwidth adjustment timers** command initializes automatic bandwidth adjustment.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730-H, and S6730S-H support this command.

Format

reset mpls te auto-bandwidth adjustment timers

Parameters

None

Views

User view

Default Level

3: Management level

Usage Guidelines

After the automatic bandwidth adjustment function runs for a certain period of time, to delete the running information and re-collect information, run the **reset mpls te auto-bandwidth adjustment timers** command in the user view. You do not need to delete this function or reconfigure it.

After the **reset mpls te auto-bandwidth adjustment timers** command is run, the device deletes information about the sampled traffic rate on the outbound interface and resets the automatic bandwidth adjustment timer.

Example

Initialize automatic bandwidth adjustment for MPLS TE tunnels.

```
<HUAWEI> reset mpls te auto-bandwidth adjustment timers
```

9.3.166 reset mpls te auto-frr

Function

The **reset mpls te auto-frr** command resets a specified auto bypass tunnel.

NOTE

After the Auto FRR function is enabled, you can use this command to recreate a bypass tunnel.

Format

reset mpls te auto-frr { **lsp-id** *ingress-lsr-id tunnel-id* | **name** *bypass-tunnel-name* }

Parameters

Parameter	Description	Value
lsp-id	Specifies the ID of an LSP.	-
ingress-lsr-id	Specifies the LSR ID of the ingress.	The value is in dotted decimal notation.
tunnel-id	Specifies the ID of a tunnel.	The value is an integer and its ranges from 0 to 65535.

Parameter	Description	Value
name *bypass-tunnel-name*	Specifies the name of a bypass tunnel.	The value is a string of 1 to 63 characters.

Views

User view

Default Level

3: Management level

Usage Guidelines

To immediately recreate a specified auto bypass tunnel, run the **reset mpls te auto-frr** command.

Example

Reset the bypass tunnel with the ingress address being 1.1.1.1 and the tunnel ID being 10.

```
<HUAWEI> reset mpls te auto-frr lsp-id 1.1.1.1 10
```

9.3.167 reset mpls te tunnel-interface tunnel

Function

The **reset mpls te tunnel-interface tunnel** command resets a TE tunnel interface and re-establishes a TE tunnel.

Format

reset mpls te tunnel-interface tunnel *interface-number*

Parameters

Parameter	Description	Value
tunnel *interface-number*	Specifies the number of a TE tunnel.	-

Views

User view

Default Level

3: Management level

Usage Guidelines

To validate the configurations of an MPLS TE tunnel, you can run the **mpls te commit** command in the tunnel interface view, and then run the **reset mpls te tunnel-interface tunnel** command in the user view.

If you do not run the **mpls te commit** command after modifying the configuration of a TE tunnel in the tunnel interface view, the system prompts a fault after the **reset mpls te tunnel-interface tunnel** command is run.

Example

Reset Tunnel 1.

```
<HUAWEI> reset mpls te tunnel-interface tunnel 1
```

9.3.168 static-cr-lsp egress

Function

The **static-cr-lsp egress** command configures a static CR-LSP on the egress LSR.

The **undo static-cr-lsp egress** command deletes a static CR-LSP from the egress LSR.

By default, no static CR-LSP on the egress LSR is configured.

Format

static-cr-lsp egress *lsp-name* [**incoming-interface** *interface-type interface-number*] **in-label** *in-label*

undo static-cr-lsp egress *lsp-name*

Parameters

Parameter	Description	Value
lsp-name	Specifies the name of a CR-LSP.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
incoming-interface *interface-type interface-number*	Specifies the type and number of an inbound interface.	-
in-label *in-label*	Specifies the value of an incoming label.	The value is an integer that ranges from 16 to 1023.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When configuring the egress of the CR-LSP, you can run the command **static-cr-lsp egress**. Before setting up an MPLS TE tunnel through a static CR-LSP, configure a static route or an IGP to ensure connectivity between LSRs, and enable basic MPLS and MPLS TE functions. After setting up a static CR-LSP, you can run the **display mpls static-cr-lsp** command to ensure that the static CR-LSP is established successfully.

To modify the value of **incoming-interface** *interface-type interface-number* and **in-label** *in-label*, run the **static-cr-lsp egress** command to set a new value. There is no need to run the **undo static-cr-lsp egress** command before changing a configured value.

Example

Configure the static CR-LSP named tunnel34 with the inbound interface being VLANIF100, and the incoming label being 233 on the egress LSR.

```
<HUAWEI> system-view
[HUAWEI] static-cr-lsp egress tunnel34 incoming-interface vlanif 100 in-label 233
```

9.3.169 static-cr-lsp ingress

Function

The **static-cr-lsp ingress** command configures a static CR-LSP on the ingress LSR.

The **undo static-cr-lsp ingress** command deletes a static CR-LSP from the ingress LSR.

By default, no static CR-LSP on the ingress LSR is configured.

Format

static-cr-lsp ingress { **tunnel-interface tunnel** *interface-number* | *tunnel-name* } **destination** *destination-address* { **nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number* } * **out-label** *out-label* [**bandwidth** [**ct0** | **ct1**] *bandwidth*]

undo static-cr-lsp ingress { **tunnel-interface tunnel** *interface-number* | *tunnel-name* }

Parameters

Parameter	Description	Value
tunnel-interface tunnel *interface-number*	Specifies the tunnel interface of a static CR-LSP. *interface-number* indicates the tunnel interface number.	-
tunnel-name	Specifies the name of a CR-LSP.	The name is a string of 1 to 19 case-sensitive characters, spaces and abbreviation not supported. If you use the **interface Tunnel 1** command to create a tunnel interface for a static CR-LSP, the tunnel name in the **static-cr-lsp ingress** command must be formatted as "Tunnel1", otherwise, the tunnel cannot be created. There is no such a limit for the transit node and egress node.
destination *destination-address*	Specifies the destination IP address of a static CR-LSP.	The value is in dotted decimal notation.
nexthop *next-hop-address*	Specifies the next-hop IP address of a static CR-LSP.	The value is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Specifies the type and number of an outgoing interface. This parameter is only applicable to a P2P link.	-
out-label *out-label*	Specifies the value of an outgoing label.	The value is an integer that ranges from 16 to 1048575.
bandwidth [**ct0** | **ct1**] *bandwidth*	Specifies the bandwidth values of CR-LSPs of CT0 to CT1.	The value is an integer that ranges from 0 to 4000000000, in kbit/s. The default value is 0.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Run this command on the ingress node to configure a static CR-LSP.

Before setting up an MPLS TE tunnel through a static CR-LSP, configure a static route or an IGP to ensure connectivity between LSRs, and enable basic MPLS and MPLS TE functions. After setting up a static CR-LSP, you can run the **display mpls static-cr-lsp** command to ensure that the static CR-LSP is established successfully.

Precautions

To modify parameters including **destination** *destination-address*, **nexthop** *next-hop-address*, **outgoing-interface** *interface-type interface-number*, and **out-label** *out-label*, run the **static-cr-lsp ingress** command to set a new value. There is no need to run the **undo static-cr-lsp ingress** command before changing a configured value.

When configuring a static CR-LSP ensure that the route of the static CR-LSP exactly matches the routing information. For example:

- If you specify a next hop when configuring a static CR-LSP, specify a next hop when configuring a static IP route. If you do not specify a next hop, the static LSP cannot be set up. For example:

```
[HUAWEI] ip route-static 10.1.3.0 24 10.1.1.2
[HUAWEI] static-cr-lsp ingress Tunnel1 destination 10.1.3.1 nexthop 10.1.1.2 out-label 237
```

- If a dynamic routing protocol applies to the link between LSRs, the next-hop IP address along the LSP must be the same as the IP address of the next hop in the routing table.

NOTE

The configured bandwidth takes effect only during tunnel establishment and protocol negotiation, and does not limit the bandwidth for traffic forwarding.

Example

Configure the static CR-LSP named Tunnel1, with the destination IP address being 10.1.3.1, the next-hop address being 10.1.1.2, the outgoing label being 237.

```
<HUAWEI> system-view
[HUAWEI] static-cr-lsp ingress Tunnel1 destination 10.1.3.1 nexthop 10.1.1.2 out-label 237
```

9.3.170 static-cr-lsp transit

Function

The **static-cr-lsp transit** command configures a static CR-LSP on a transit LSR.

The **undo static-cr-lsp transit** command deletes a static CR-LSP from the transit LSR.

By default, no static CR-LSP on a transit LSR is configured.

Format

static-cr-lsp transit *lsp-name* [**incoming-interface** *interface-type interface-number*] **in-label** *in-label* { **nexthop** *next-hop-address* | **outgoing-interface** *interface-type interface-number* } * **out-label** *out-label* [**bandwidth** [**ct0** | **ct1**] *bandwidth*] [**description** *description*]

undo static-cr-lsp transit *lsp-name*

Parameters

Parameter	Description	Value
lsp-name	Specifies the CR-LSP name.	The value is a string of 1 to 19 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
incoming-interface *interface-type interface-number*	Specifies the incoming interface of the CR-LSP. ● *interface-type* specifies the interface type. ● *interface-number* specifies the interface number.	-
in-label *in-label*	Specifies the value of an incoming label.	The value is an integer that ranges from 16 to 1023.
nexthop *next-hop-address*	Specifies the next-hop address.	The value is in dotted decimal notation.
outgoing-interface *interface-type interface-number*	Specifies the name of an outgoing interface.	-
out-label *out-label*	Specifies the value of an outgoing label.	The value is an integer that ranges from 16 to 1048575.
bandwidth [**ct0** | **ct1**] *bandwidth*	Specifies the bandwidth values of CR-LSPs of CT0 to CT1.	The value is an integer that ranges from 0 to 4000000000, in kbit/s. The default value is 0.
description *description*	Specifies the description information.	The value is a string of 1 to 63 case-sensitive characters with spaces.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Before setting up an MPLS TE tunnel through a static CR-LSP, configure a static route or an IGP to ensure connectivity between LSRs, and enable basic MPLS and MPLS TE functions. After setting up a static CR-LSP, you can run the **display mpls static-cr-lsp** command to ensure that the static CR-LSP is established successfully.

To modify parameters including **incoming-interface** *interface-type interface-number*, **in-label** *in-label*, **nexthop** *next-hop-address*, **outgoing-interface** *interface-type interface-number*, and **out-label** *out-label*, run the **static-cr-lsp transit** command to set a new value for each parameter. There is no need to run the **undo static-cr-lsp transit** command before modifying a value.

NOTE

The configured bandwidth takes effect only during tunnel establishment and protocol negotiation, and does not limit the bandwidth for traffic forwarding.

Example

Configure the static CR-LSP named tunnel39 with the incoming interface being VLANIF100, the incoming label being 123, the outgoing interface being VLANIF200, the outgoing label as 253.

```
<HUAWEI> system-view
[HUAWEI] static-cr-lsp transit tunnel39 incoming-interface vlanif 100 in-label 123 outgoing-interface
vlanif 200 out-label 253
```

9.3.171 statistic enable (MPLS TE tunnel interface view)

Function

The **statistic enable** command enables MPLS TE traffic statistics collection.

The **undo statistic enable** command disables MPLS TE traffic statistics collection.

By default, MPLS TE traffic statistics collection is disabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

statistic enable

undo statistic enable

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To view MPLS TE traffic statistics collected in the outbound direction of an interface, run the **statistic enable** command in the tunnel interface view to enable MPLS TE traffic statistics collection first. After a period of time, run the **display interface tunnel** or **display counters interface** command to view the MPLS TE traffic statistics.

Prerequisites

The tunneling protocol of the tunnel interface has been set to MPLS TE using the **tunnel-protocol mpls te** command in the tunnel interface view.

Precautions

MPLS TE traffic statistics collection is supported only in the outbound direction of a tunnel interface.

Example

Enable MPLS TE traffic statistics collection on Tunnel1.

```
<HUAWEI> system-view
[HUAWEI] mpls lsr-id 10.1.1.1
[HUAWEI] mpls
[HUAWEI-mpls] mpls te
[HUAWEI-mpls] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] statistic enable
```

9.3.172 traffic-eng

Function

The **traffic-eng** command enables TE features on a specified level for an IS-IS process.

The **undo traffic-eng** command restores the default settings.

By default, TE features are disabled for an IS-IS process.

Format

traffic-eng [**level-1** | **level-2** | **level-1-2**]

undo traffic-eng [**level-1** | **level-2** | **level-1-2**]

Parameters

Parameter	Description	Value
level-1	Enables IS-IS TE on Level-1.	-
level-2	Enables IS-IS TE on Level-2.	-
level-1-2	Enables IS-IS TE on Level-1-2. **NOTE** If no level is specified, TE is enabled on Level-1-2.	-

Views

IS-IS view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When you deploy MPLS TE on the MPLS backbone network where IS-IS is used to advertise routes, run this command to enable TE features on a specified level for an IS-IS process.

Prerequisites

The **cost-style** command has been executed to set the cost type of IS-IS packets to wide, compatible, or wide-compatible.

Precautions

The IS-IS level in this command must be the same as that on the MPLS backbone network.

Example

Enable TE on level-2 for IS-IS process 1.

```
<HUAWEI> system-view
[HUAWEI] isis 1
[HUAWEI-isis-1] cost-style compatible
[HUAWEI-isis-1] traffic-eng level-2
```

9.3.173 undo mpls te srlg all-config

Function

The **undo mpls te srlg all-config** command deletes the member interfaces of all SRLGs on an MPLS TE node.

Format

undo mpls te srlg all-config

Parameters

None

Views

MPLS view

Default Level

2: Configuration level

Usage Guidelines

If an MPLS TE node is configured with the **undo mpls te srlg all-config** command, the **mpls te srlg** command is deleted from all the interfaces of an MPLS TE node, while the **mpls te srlg path-calculation** command configured in the MPLS view is not deleted.

Example

Delete the SRLG configuration from all the interfaces of the MPLS TE node.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] mpls te srlg 1
[HUAWEI-Vlanif10] mpls te srlg 2
[HUAWEI-Vlanif10] quit
[HUAWEI] interface vlanif 20
[HUAWEI-Vlanif20] mpls te srlg 1
[HUAWEI-Vlanif20] mpls te srlg 2
[HUAWEI-Vlanif20] quit
[HUAWEI] mpls
[HUAWEI-mpls] undo mpls te srlg all-config
```

10 VPN Configuration Commands

10.1 GRE Configuration Commands

10.1.1 Command Support

Only the following switch models support GRE:

S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S

10.1.2 description (tunnel interface view)

Function

The **description** command sets the description of the current tunnel interface.

The **undo description** command deletes the description of the current tunnel interface.

By default, a tunnel interface does not have a description.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of a tunnel interface.	The value is a string of 1 to 242 case-sensitive characters, with spaces supported.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

After using the **interface tunnel** command to create a tunnel interface, you can run the **description** command to configure a description of the tunnel interface to facilitate later query.

To check the description of a tunnel interface, run the **display this interface** command in the tunnel interface view or the **display interface tunnel** command.

Example

Configure the description of Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] description This is a tunnel from 10.1.1.1 to 10.2.2.2
```

Delete the description of Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] undo description
```

10.1.3 destination

Function

The **destination** command specifies the destination IP address of a tunnel interface.

The **undo destination** command deletes the destination IP address of a tunnel interface.

By default, no destination address is configured.

Format

destination [**vpn-instance** *vpn-instance-name*] *dest-ip-address*

undo destination

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance that the destination address of a tunnel belongs to. When the tunnel interface uses GRE, you can specify **vpn-instance** *vpn-instance-name*.	The value is the name of an existing VPN instance.
dest-ip-address	Specifies the destination IP address of a tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **destination** command to specify the destination IP address for the tunnel interface.

When using the **destination** command on a PE to specify the destination address of a GRE tunnel bound for a CE, you need to set **vpn-instance** *vpn-instance-name* in the command to specify the name of the VPN instance to which the destination address belongs.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the destination address of the local tunnel interface is the source address of the remote tunnel interface, and the source address of the local tunnel interface is the destination address of the remote tunnel interface.

Example

Establish a manual IPv6 over IPv4 tunnel between VLANIF 10 at 10.1.1.1 on switch HUAWEI1 and VLANIF 20 at 10.2.1.1 on switch HUAWEI2.

```
<HUAWEI1> system-view
[HUAWEI1] interface tunnel 1
[HUAWEI1-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI1-Tunnel1] source 10.1.1.1
[HUAWEI1-Tunnel1] destination 10.2.1.1
<HUAWEI2> system-view
[HUAWEI2] interface tunnel 1
[HUAWEI2-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI2-Tunnel1] source 10.2.1.1
[HUAWEI2-Tunnel1] destination 10.1.1.1
```

Set the destination address of the GRE tunnel Tunnel1 to 10.1.1.1 that belongs to vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] quit
[HUAWEI-vpn-instance-vpn1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] destination vpn-instance vpn1 10.1.1.1
```

10.1.4 display interface tunnel

Function

The **display interface tunnel** command displays details of the tunnel interface.

Format

display interface tunnel [*interface-number* | **main**]

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface. If this parameter is not specified, the command displays information about all tunnel interfaces.	The value must be the number a tunnel interface that has been created.

Parameter	Description	Value
main	Displays status and traffic statistics about main interface. The interface has no sub-interfaces. Status and traffic statistics about the interface are displayed whether you specify the main parameter or not.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

To check status of tunnels or diagnose the fault in these tunnels, run the **display interface tunnel** command. You can run this command to obtain tunnel interface information when configuring tunnels or when locating the fault on these tunnels.

Prerequisites

Before run **display interface tunnel**, please ensure that tunnel interface has been created using the **interface tunnel** command.

Example

Display the details of the tunnel interface.

```
<HUAWEI> display interface tunnel 1
Tunnel1 current state : UP
Line protocol current state : UP
Last line protocol up time : 2012-11-16 19:16:33 UTC+08:00
Description:
Route Port,The Maximum Transmit Unit is 1500
Internet Address is 10.3.1.2/24
Encapsulation is TUNNEL, loopback not set
Tunnel source 10.2.1.2 (Vlanif1234), destination 10.2.1.1
Tunnel protocol/transport GRE/IP, key disabled
keepalive enable period 5 retry-times 3
Checksumming of packets disabled
Current system time: 2012-11-16 19:17:39+08:00
Last 300 seconds input rate 16 bits/sec, 0 packets/sec
Last 300 seconds output rate 0 bits/sec, 0 packets/sec
Input:  5 packets, 650 bytes
Output:  0 packets, 0 bytes
    Input bandwidth utilization  :    0%
    Output bandwidth utilization :    0%
```

Table 10-1 Description of the display interface tunnel command output

Item	Description
Tunnel1 current state	Physical layer status of the tunnel interface: - UP: The interface is in normal state. - Administratively DOWN: The network administrator executes the **shutdown** command on the interface. After a tunnel interface is created, its physical layer status is Up.
Line protocol current state	Link protocol status: - UP: The link layer protocol of the tunnel interface works normally. - Down: The link layer protocol of the tunnel interface is abnormal.
Last line protocol up time	Last time the link layer protocol of the tunnel interface goes UP. **NOTE** This field is displayed only when the link layer protocol status of the tunnel interface is UP.
Description	Description of the tunnel interface.
Route Port	Indicates the Layer 3 interface.
The Maximum Transmit Unit is 1500	MTU of tunnel interfaces, which is 1500 bytes by default. Any packet larger than the MTU is fragmented before being sent. If non-fragmentation is configured, the packet is discarded.
Internet Address is 10.3.1.2/24	IP address of the tunnel interface is 10.3.1.2. The mask is 24 bits, that is, 255.255.255.0.
Encapsulation is TUNNEL,	Encapsulation type of packets on a tunnel interface. Packet encapsulation protects a whole IP packet.
loopback not set	The tunnel interface does not support a loopback test.
Tunnel source 10.2.1.2 (Vlanif1234)	The source address of the tunnel is 10.2.1.2. That is, the IP address of the VLANIF 1234 interface sending packets at the source side is 10.2.1.2.
destination 10.2.1.1	Destination address of the tunnel.

Item	Description
Tunnel protocol/ transport GRE/IP, key disabled	The tunnel encapsulation protocol is the GRE protocol, and the transport protocol is the IP protocol. Encapsulation protocol types of a tunnel are as follows: ● GRE: indicates Generic Routing Encapsulation. ● MPLS: encapsulates packets into MPLS packets. ● IPv6 over IPv4: encapsulates IPv6 packets into IPv4 packets. ● IPv4 over IPv6: encapsulates IPv4 packets into IPv6 packets. ● none: indicates no encapsulation. This is the default mode of the tunnel interface. key disabled: the key word recognition function of GRE is not enabled.
keepalive enable period 5 retry-times 3	The keepalive function of GRE.
Checksumming of packets disabled	The check sum function of GRE is not enabled.
Current system time	Current system time. If the time zone is configured and the daylight saving time is used, the time is in YYYY/MM/DD HH:MM:SS UTC±HH:MM DST format.
Last 300 seconds input rate	Incoming packet rate (bits per second and packets per second) within the last 300 seconds.
Last 300 seconds output rate	Outgoing packet rate (bits per second and packets per second) within the last 300 seconds.
Input	Total number of received packets.
Output	Total number of sent packets.
Input bandwidth utilization : --	Input bandwidth usage.
Output bandwidth utilization : --	Output bandwidth usage.

10.1.5 display keepalive packets count

Function

The **display keepalive packets count** command displays the number of Keepalive packets and Keepalive response packets sent and received by the local GRE tunnel interface.

Format

display keepalive packets count

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When a tunnel is a GRE tunnel, you can enable the Keepalive function to check the link connectivity. If the function is disabled, service packets are continuously forwarded through this tunnel interface when the link fails, resulting in a tunnel black hole and loss of service data.

The **display keepalive packets count** command allows you to view the number of Keepalive packets and Keepalive response packets sent and received through the GRE tunnel interface.

Prerequisites

1. The tunnel interface view has been displayed using the **interface tunnel** command.
2. The tunnel type has been set to GRE using the **tunnel-protocol gre** command.
3. The Keepalive function has been enabled for the GRE tunnel using the **keepalive** command.

Follow-up Procedure

Run the **reset keepalive packets count** command to reset the Keepalive packet statistics.

Example

View the Keepalive packet statistics of GRE tunnel interface 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] keepalive
[HUAWEI-Tunnel1] display keepalive packets count
Send 10 keepalive packets to peers, Receive 10 keepalive response packets from
peers
Receive 8 keepalive packets from peers, Send 8 keepalive response packets to
peers.
```

Table 10-2 Description of the display keepalive packets count command output

Item	Description
Send 10 keepalive packets to peers	Ten Keepalive packets are sent to the remote end.
Receive 10 keepalive response packets from peers	Ten Keepalive response packets are received from the remote end.
Receive 8 keepalive packets from peers	Eight Keepalive packets are received from the remote end.
Send 8 keepalive response packets to peers	Eight Keepalive response packets are sent to the remote end.

10.1.6 display tunnel-info

Function

The **display tunnel-info** command displays the tunnel information.

Format

display tunnel-info { **tunnel-id** *tunnel-id* | **all** | **statistics** [**slots**] }

Parameters

Parameter	Description	Value
tunnel-id *tunnel-id*	Specifies the tunnel ID. If the specified ID does not exist, the system prompts errors.	A hexadecimal integer ranging from 1 to FFFFFFFE.
all	Displays information about all the tunnels.	-
statistics	Displays statistics about all tunnels.	-
slots	Displays tunnel statistics in the order of slots.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display tunnel-info all** command displays existing tunnel IDs, tunnel types, destination IP addresses, and Token information about all tunnels.

The **display tunnel-info tunnel-id** *tunnel-id* command displays detailed information about a tunnel when you only know the tunnel ID.

The **display tunnel-info statistics** command displays the number of tunnels configured on the switch.

Example

View information about the tunnel.

```
<HUAWEI> display tunnel-info tunnel-id 2
Tunnel ID:                  0x2
Tunnel Token:                 2
Type:                      cr lsp
Destination:                 1.1.1.1
Out Slot:                   0
Instance ID:                 0
Interface:                  Tunnel1
Sub Tunnel ID:                0x0
<HUAWEI> display tunnel-info tunnel-id 3
Tunnel ID:                  0x3
Tunnel Token:                 3
Type:                      lsp
Destination:                 10.20.10.10
Out Slot:                   0
Instance ID:                 0
Out Interface:                Vlanif1024
Out Label:                   3
Next Hop:                   10.24.10.200
Lsp Index:                  2048
<HUAWEI> display tunnel-info tunnel-id 10006
Tunnel ID:                  0x10006
Tunnel Token:                 2
Type:                      lsp
Destination:                 6.6.6.6
Out Slot:                   0
Instance ID:                 0
Out Interface:                Vlanif15
Lsp Index:                  0
SubTunnel Type:                L2VPN QoS Token
```

Table 10-3 Description of the **display tunnel-info tunnel-id** command output

Item	Description
Tunnel ID	Tunnel ID in hexadecimal notation that is assigned by the system.
Tunnel Token	Token value used for MPLS forwarding that is a part of tunnel ID and is assigned by the system.
Type	Type of a tunnel, such as GRE, MPLS LSP, or CR-LSP. The command output varies according to the tunnel type.
Destination	Destination IP address of the tunnel.

Item	Description
Out Slot	Number of the slot that is used when the switch sends packets.
Instance ID	VPN instance ID (0 indicates that a tunnel is a public network tunnel).
Interface	Local tunnel interface.
Sub Tunnel ID	Sub-tunnel ID of VPN QoS in hexadecimal notation that is automatically assigned by the system.
Out Label	Out label value.
Next Hop	Next hop.
Lsp Index	LSP index, which is allocated by MPLS.
Out Interface	Local outbound interface of the tunnel.
SubTunnel Type	Types of tokens of sub-tunnels: ● LDP LSP over TE QoS Token ● LDP LSP QoS Token ● BGP LSP over TE QoS Token ● BGP LSP QoS Token ● Static LSP QoS Token ● CR-LSP over TE QoS Token ● L2VPN over TE QoS Token ● L2VPN QoS Token This field is displayed only for sub-tunnels.

Display all tunnel information.

```
<HUAWEI> display tunnel-info all
 * -> Allocated VC Token
Tunnel ID            Type                Destination          Token
----------------------------------------------------------------------
0x10006              lsp                 10.2.1.1             6
```

Display tunnel statistics.

```
<HUAWEI> display tunnel-info statistics
LSP/32bit LSP :                         0/0
GRE :                                   2
CRLSP :                                 0
LOCAL IFNET :                           0
MPLS LOCAL IFNET :                      0
VPN QOS LSP :                           0
Reserved :                              0
Vxlan :                                 0
```

Table 10-4 Description of the **display tunnel-info statistics** command output

Item	Description
LSP/32bit LSP	Number of LSP tunnels created in the system view/Number of LSP tunnels triggered by the route of host with the 32-bit mask address.
GRE	Number of tunnel IDs allocated to the GRE tunnels.
CRLSP	Number of tunnel IDs allocated to the CR-LSP tunnels.
LOCAL IFNET	Number of tunnels used by the VPN internal module.
MPLS LOCAL IFNET	Number of tunnels used by the MPLS internal module.
VPN QOS LSP	Number of the tunnel ID allocated to the LSP used in VPN QoS.
Reserved	Number of the tunnel ID allocated to the product.
Vxlan	Number of tunnel IDs allocated to the Vxlan tunnels.

Display tunnel statistics in the order of slots.

```
<HUAWEI> display tunnel-info statistics slots
------------------------------------------------------------------
Slot        LSP     CR      GRE     LCL     MPLS-L  VPN     VXLAN
Num                 LSP             IFNET   IFNET   QOS
------------------------------------------------------------------
0           0       0       0       0       0       0       0
Logic Slot: 0                      Total:  0
```

Table 10-5 Description of the display tunnel-info statistics slots command output

Item	Description
Slot Num	Slot number used by the device to send packets.
LSP	Total LSP tunnels set up by the device.
CR LSP	Number of CR-LSPs created on the device.
GRE	Number of GRE tunnels created on the device.
LCL IFNET	Number of tunnels used by the VPN module.
MPLS-L IFNET	Number of tunnels used by the MPLS module.
VPN QOS	Number of tunnels used for VPN QoS.
VXLAN	Number of VXLAN tunnels created on the device.

10.1.7 gre key

Function

The **gre key** command sets the key number of a GRE tunnel.

The **undo gre key** command deletes the key number of a GRE tunnel.

By default, the GRE key number is not configured.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this command.

Format

gre key { **plain** *key-number* | [**cipher**] *plain-cipher-text* }

undo gre key

Parameters

Parameter	Description	Value
plain *key-number*	Specifies a plaintext key. **NOTICE** If **plain** is selected, the key is saved in the configuration file in plain text. This brings security risks. It is recommended that you select **cipher** to save the key in cipher text.	The value is an integer that ranges from 0 to 4294967295.
[**cipher**] *plain-cipher-text*	Specifies that a ciphertext key is displayed.	You can specify a plaintext key (integer) ranging from 0 to 4294967295 or a ciphertext key of 32 or 48 characters.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure key numbers for both ends of a GRE tunnel to improve GRE tunnel security. This security mechanism ensures that a device accepts only packets sent from the valid tunnel interface and discards invalid packets.

Prerequisites

The tunnel interface view has been displayed using the **interface tunnel** command.

The tunnel type has been set to GRE using the **tunnel-protocol gre** command.

Precautions

Packets pass authentication only when the key numbers set on both ends of the tunnel are consistent. Otherwise, the packets are discarded.

When you run the **gre key** command several times, the latest configuration overrides the previous configurations.

Example

Configure the GRE key number for the ends of a tunnel is 123.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] gre key cipher 123
```

10.1.8 interface tunnel

Function

The **interface tunnel** command creates a tunnel interface.

The **undo interface tunnel** command deletes the configured tunnel interface.

By default, no tunnel interface is configured.

Format

interface tunnel *interface-number*

undo interface tunnel *interface-number*

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface.	The value is an integer that ranges from 0 to 2047 .

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To forward data over a tunnel, ensure that the tunnel has been created. The system supports the following types of tunnels:

- LSP (Static LSP, BGP LSP, LDP LSP)
- MPLS TE
- GRE
- IPv6 over IPv4
- IPv4 over IPv6

You must use the **interface tunnel** command to create a tunnel interface when creating a tunnel except for LSP tunnels.

Precautions

Tunnel interface numbers are valid on the local device only. You can configure different numbers for the tunnel interfaces on the two ends.

Follow-up Procedure

After a tunnel interface is created, you need to configure an IP address and encapsulation type for the tunnel interface.

To save IP addresses, run the **ip address unnumbered** command to configure the tunnel interface to borrow an IP address of another interface.

The **tunnel-protocol** command configures an encapsulation protocol for the tunnel interface. Then basic configurations are performed based on the encapsulation protocol:

- On an MPLS TE tunnel, run the **destination**, **mpls te tunnel-id**, **mpls te signal-protocol**, and **mpls te commit** commands.
- On the GRE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, run the **source** and **destination** commands.

Example

Create a tunnel interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1]
```

10.1.9 keepalive

Function

The **keepalive** command enables the Keepalive function of GRE tunnels.

The **undo keepalive** command disables the Keepalive function of GRE tunnels.

By default, the Keepalive function of a GRE tunnel is disabled.

Format

keepalive [**period** *period* [**retry-times** *retry-times*]]

undo keepalive

Parameters

Parameter	Description	Value
period *period*	Specifies the interval for sending Keepalive packets.	The value is an integer that ranges from 1 to 32767, in seconds. The default value is 5 seconds.
retry-times *retry-times*	Specifies the parameter of the unreachable counter.	The value is an integer that ranges from 1 to 255. The default value is 3.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before you configure a tunnel policy and set the VPN tunnel type to GRE, you need to enable the Keepalive function. After Keepalive is enabled, the VPN cannot choose a tunnel with an unreachable remote end, preventing data loss.

When Keepalive is disabled on a local end, the tunnel interface status of the local end might be Up even if the remote end is unreachable. After Keepalive is enabled on the local end, the tunnel interface status of the local end changes to Down if the remote end is unreachable. Therefore, when the remote end is unreachable, the VPN cannot choose the GRE tunnel, preventing data loss.

The Keepalive function takes effect uni-directionally. To enable the Keepalive function on both ends of a tunnel, run the **keepalive** command on each end of the tunnel. The Keepalive configuration takes effect on one end even if the function is disabled on the other end. However, it is recommended that you enable the Keepalive function on both ends.

After the Keepalive function is enabled on a GRE tunnel, the tunnel periodically sends Keepalive packets. The unreachable counter increases by one each time a packet is sent. If no response packet is received when the value of the counter reaches the value of *retry-times*, the remote end is considered unreachable.

Prerequisites

The **keepalive** command can be used only when the encapsulation mode has been set to GRE on an interface.

Precautions

When you run the **keepalive** command several times, the latest configuration overrides the previous configurations.

When the VPN instance to which a GRE tunnel interface is bound is not the specified destination VPN instance, the **keepalive** command cannot be used to check GRE tunnel connectivity. If this command is used in this situation, the Keepalive function cannot be implemented.

Follow-up Procedure

Run the **display keepalive packets count** command to display the number of Keepalive packets and Keepalive response packets sent and received by the local GRE tunnel interface.

Example

Enable the Keepalive function for the GRE tunnel using default parameters.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] keepalive
```

Enable the Keepalive function for the GRE tunnel, and set the interval for sending Keepalive packets to 12 seconds and **retry-times** to 4.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] keepalive period 12 retry-times 4
```

10.1.10 map interface virtual-ethernet

Function

The **map interface virtual-ethernet** command binds an L2VE interface to a tunnel interface.

The **undo map interface virtual-ethernet** command deletes the binding relationship between a tunnel interface and a specified VE interface.

The **undo map** command deletes the binding relationship between a tunnel interface and all VE interfaces.

By default, no L2VE interface is bound to a tunnel interface.

NOTE

Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support this function.

Format

map interface virtual-ethernet *ve-number*

undo map interface virtual-ethernet *ve-number*

undo map

Parameters

Parameter	Description	Value
ve-number	Specifies the number of a VE interface.	The VE interface number must already exist.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Customers want to use GRE to transparently transmit Ethernet packets over networks of a different network layer protocol, such as the IPv4 network. You can configure Ethernet over GRE to achieve this purpose. Run the **map interface virtual-ethernet** command in the tunnel interface view to bind a VE interface to a tunnel interface. After the binding, the tunnel interface can transparently transmit Ethernet packets over the GRE tunnel.

Prerequisites

- A VE interface has been created by using the **interface virtual-ethernet** *ve-number* command, and the VE interface has been changed from Layer 3 mode to Layer 2 mode by using the **portswitch** command.
- The tunnel protocol of a tunnel interface has been set to GRE by using the **tunnel-protocol gre** command in the tunnel interface view.

Precautions

NOTE

- If a VLANIF interface has been created for a VLAN, this VLAN cannot be specified for a VE interface. If a VLAN has been specified for a VE interface, no VLANIF interface can be created for this VLAN.
- One tunnel interface can be bound with two VE interfaces, but one VE interface can be bound to only one tunnel interface.
- Only VE interfaces of the Trunk type can be bound to a tunnel interface.
- A tunnel interface bound with a VE interface does not support the IPv6 protocol stack. A VE interface cannot be bound to a tunnel interface enabled with the IPv6 protocol stack.
- To prevent loops, packets transmitted through an Ethernet over GRE tunnel cannot be sent to a GRE tunnel again.
- Ensure that the VE interfaces at both ends of a GRE tunnel are added to the same VLAN. Otherwise, the VE interfaces will learn MAC addresses not in the VLANs to which the VE interfaces belong, and these MAC addresses cannot be deleted using the **undo mac-address** command. Run the **undo mac-address** [*mac-address*] [**vlan** *vlan-id*] command to delete a specific MAC address or delete MAC addresses by VLAN ID, or wait until the MAC addresses automatically age out.
- When configuring Ethernet over GRE, ensure that routes can recurse to GRE tunnels. Otherwise, packets cannot be encapsulated using Ethernet over GRE.

Example

Bind Virtual-Ethernet 0/0/1 to Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface virtual-ethernet 0/0/1
[HUAWEI-Virtual-Ethernet0/0/1] portswitch
[HUAWEI-Virtual-Ethernet0/0/1] port link-type trunk
[HUAWEI-Virtual-Ethernet0/0/1] undo port trunk allow-pass vlan 1
[HUAWEI-Virtual-Ethernet0/0/1] port trunk allow-pass vlan 10
[HUAWEI-Virtual-Ethernet0/0/1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] map interface virtual-ethernet 0/0/1
```

10.1.11 reset keepalive packets count

Function

The **reset keepalive packets count** command clears the statistics on Keepalive packets sent and received by a GRE tunnel interface.

Format

reset keepalive packets count

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After the Keepalive function is enabled on a GRE tunnel, the VPN cannot choose a tunnel with an unreachable remote end, preventing data loss. You can run the **display keepalive packets count** command to view the statistics on Keepalive packets and Keepalive response packets sent and received by the GRE tunnel interface, and the running status of the GRE tunnel.

The **reset keepalive packets count** command resets the statistics of Keepalive packets and Keepalive response packets sent and received by the GRE tunnel interface. You can monitor the running status of the GRE tunnel.

Precautions

The cleared packet statistics cannot be restored. Exercise caution when you run the command.

Example

Reset the Keepalive packet statistics of GRE tunnel interface 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] reset keepalive packets count
 Info: Succeeded in resetting tunnel keepalive packets count.
```

10.1.12 source

Function

The **source** command configures the source address or source interface of the tunnel.

The **undo source** command deletes the configured source address or source interface.

The source address and source interface of a tunnel are not specified by default.

Format

source { *source-ip-address* | *interface-type interface-number* }

undo source

Parameters

Parameter	Description	Value
source-ip-address	Specifies the source address of a tunnel interface. If a tunnel interface works in IPv4-IPv6 mode, specify an IPv6 address as the source address of the tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.
interface-type interface-number	Specifies the type and the number of the source interface of the tunnel. The following types of interfaces are often used: VLANIF and loopback.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **source** command to specify the source IP address for the tunnel interface.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the source address of the local tunnel interface is the destination address of the remote tunnel interface, and the destination address of the local tunnel interface is the source address of the remote tunnel interface.

Example

Set the tunnel type of Tunnel1 to IPv6 over IPv4 of manual mode and configure the source IP address of Tunnel1 as 10.1.1.1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI-Tunnel1] source 10.1.1.1
```

Configure Tunnel1 of GRE and use Loopback1 address as the interface address.

```
<HUAWEI> system-view
[HUAWEI] interface Loopback 1
[HUAWEI-LoopBack1] ip address 10.2.1.1 32
[HUAWEI-LoopBack1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] source loopback 1
```

10.1.13 statistic enable (Tunnel interface view)

Function

The **statistic enable** command enables traffic statistics collection on a Tunnel interface.

The **undo statistic enable** command disables traffic statistics collection on a Tunnel interface.

By default, traffic statistics collection is disabled on a Tunnel interface.

Format

statistic enable { **both** | **inbound** | **outbound** }

undo statistic enable { **both** | **inbound** | **outbound** }

Parameters

Parameter	Description	Value
both	Enables traffic statistics collection for incoming and outgoing traffic.	-
inbound	Enables incoming traffic statistics collection.	-
outbound	Enables outgoing traffic statistics collection.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To check the network status or locate network faults, you can use the **statistic enable** command to enable traffic statistics collection on Tunnel interfaces. The device then collect traffic statistics on the Tunnel interfaces.

Prerequisites

The protocol type of the tunnel interface has been configured using the **tunnel-protocol** command.

Precautions

After running the **statistic enable** command on an interface, you can run the **display interface tunnel** command to view the traffic statistics on the interface. The traffic statistics help you diagnose the fault of a tunnel.

Example

Enable incoming traffic statistics collection on a Tunnel interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] statistic enable inbound
```

10.1.14 tunnel-protocol

Function

The **tunnel-protocol** command configures the tunnel protocol on a tunnel interface.

The **undo tunnel-protocol** command restores the tunnel protocol to the default configuration.

By default, no tunnel protocol is used on a tunnel interface.

Format

tunnel-protocol { **gre** | **ipv6-ipv4** [**6to4** | **isatap**] | **ipv4-ipv6** | **mpls te** | **none** }

undo tunnel-protocol

Parameters

Parameter	Description	Value
gre	Indicate that the GRE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameters.	-
ipv4-ipv6	Indicate that the IPv4 to IPv6 tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6730-H, S6730S-H, S6730-S, and S6730S-S support the parameter.	-
ipv6-ipv4 [**6to4** | **isatap**]	Configure the tunnel protocol of the tunnel interface as ipv6-ipv4: ● **ipv6-ipv4**: use a manual IPv6 over IPv4 tunnel ● **ipv6-ipv4 6to4** : using 6to4 tunnel ● **ipv6-ipv4 isatap** : using isatap tunnel **NOTE** Only the S5720I-SI, S5735-S, S500, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support these parameter.	-
mpls te	Indicate that the MPLS TE tunnel protocol is configured on a tunnel interface. **NOTE** Only the S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6720-EI, S6720S-EI, S6730-H, S6730-S, S6730S-S, and S6730S-H support the parameter.	-
none	Indicate that no tunnel protocol is configured on a tunnel interface.	-

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After creating a tunnel interface using the **interface tunnel** command, run the **tunnel-protocol** command to configure the tunnel encapsulation mode for the tunnel interface.

The following tunnel encapsulation modes are available:

- GRE: encapsulates packets of some network layer protocols such as IP or IPX to enable these encapsulated packets to be transmitted on networks running other protocols such as IP.
- IPv4-IPv6: creates tunnels on the IPv6 networks to connect IPv4 isolated sites so that IPv4 isolated sites can access other IPv4 networks through the IPv6 public network.
- IPv6-IPv4: creates tunnels on the IPv4 networks to connect IPv6 isolated sites so that IPv6 packets can be transmitted on IPv4 networks.
- MPLS TE: integrates the MPLS technology with traffic engineering. It can reserve resources by setting up LSP tunnels for a specified path in an attempt to avoid network congestion and balance network traffic.

Precautions

- The **none** mode indicates the initial configuration, that is, no tunnel encapsulation mode is configured. In practice, you must select another tunnel encapsulation mode.
- You must configure the tunnel encapsulation mode before setting the source IP address or other parameters for a tunnel interface. Changing the encapsulation mode of a tunnel interface deletes other parameters of the tunnel interface.

Example

Set the tunnel encapsulation mode of Tunnel2 to GRE.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 2
[HUAWEI-Tunnel2] tunnel-protocol gre
```

10.2 IPSec Configuration Commands (IPSec Encryption)

10.2.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

10.2.2 ah authentication-algorithm

Function

The **ah authentication-algorithm** command configures the authentication algorithm for AH.

The **undo ah authentication-algorithm** command restores the default authentication algorithm for AH.

By default, AH uses the Secure Hash Algorithm-256 (SHA2-256) authentication algorithm.

Format

ah authentication-algorithm { **sha1** | **sha2-256** }

undo ah authentication-algorithm

Parameters

Parameter	Description	Value
sha1	Specifies Secure Hash Algorithm-1 (SHA-1) as the authentication algorithm. SHA-1 generates a 160-bit message summary based on a message of less than 2^{64} bits.	-
sha2-256	Specifies SHA2-256 as the authentication algorithm. SHA2-256 generates a 256-bit message summary based on a message of less than 2^{64} bits.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPSec can use AH to authenticate packets, preventing packets from being intercepted or modified, you can run the **ah authentication-algorithm** command to configure the authentication algorithm for AH.

Prerequisite

The protocol of this IPSec proposal has been configured to AH using the **transform** command.

Precautions

The authentication algorithms on both IPSec peers must be identical.

The system software does not support the **md5** parameter. To use the **md5** parameter, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the **sha2-256** parameter.

For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Configure the IPSec proposal **prop1** to use the AH protocol, and specify SHA2-256 as the authentication algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform ah
[HUAWEI-ipsec-proposal-prop1] ah authentication-algorithm sha2-256
```

10.2.3 display ipsec proposal

Function

The **display ipsec proposal** command displays IPSec proposal information.

Format

display ipsec proposal [**name** *proposal-name*]

Parameters

Parameter	Description	Value
name *proposal-name*	Specifies the name of an IPSec proposal.	The value is an existing name of an IPSec proposal.

Views

All views

Default Level

1: Monitoring Level

Usage Guidelines

After IPSec is configured, when valid packets are dropped between IPSec peers, you can run the **display ipsec proposal** command to check whether the IPSec proposal configurations on both IPSec peers are identical.

IPSec ensures security using the IPSec proposal. You can run the **display ipsec proposal** command to view the following information:

- Name of the IPSec proposal

- Encapsulation mode defined in the IPSec proposal
- Security protocol defined in the IPSec proposal
- Authentication and encryption algorithms defined in the IPSec proposal

Example

Display information about all IPSec proposals.

```
<HUAWEI> display ipsec proposal
  Total IP security proposal number: 1

  IP security proposal name: proposal1
    encapsulation mode: transport
    transform: esp-new
    ESP protocol: authentication SHA2-HMAC-256, encryption AES-192
```

Table 10-6 Description of the **display ipsec proposal** command output

Item	Description
Total IP security proposal number	Number of IPSec proposals created.
IP security proposal name	Name of an IPSec proposal. To configure an IPSec proposal, run the **ipsec proposal** command.
encapsulation mode	IPSec encapsulation mode: - transport - tunnel To configure an encapsulation mode, run the **encapsulation-mode** command.
transform	Security protocol defined in the security proposal: - esp-new: ESP - ah-new: AH To configure a security protocol, run the **transform** command.
ESP protocol	The authentication algorithm and encryption algorithm used by the ESP protocol. To configure the authentication algorithm and encryption algorithm, run the **esp authentication-algorithm** and **esp encryption-algorithm** command separately.
AH protocol	To configure an authentication algorithm used by the AH protocol, run the **ah authentication-algorithm** command.

10.2.4 display ipsec sa

Function

The **display ipsec sa** command displays information about a Security Association (SA).

Format

display ipsec sa [**name** *sa-name*] [**brief**]

Parameters

Parameter	Description	Value
name *sa-name*	Specifies the SA name.	The value is an existing SA name.
brief	Displays brief information of the SA, such as the SA name and the Security Parameter Index (SPI) value.	-

Views

All views

Default Level

1: Monitoring Level

Usage Guidelines

Usage Scenario

You can run the **display ipsec sa** command to check whether the SA configurations for outgoing packets on the local end are identical with those for incoming packets on the peer end. The **display ipsec sa** command output displays the following information:

- SA name
- Security proposal applied to the SA
- Number of times the SA is applied
- SA configurations for incoming Authentication Header (AH) packets
- SA configurations for outgoing AH packets
- SA configurations for incoming Encapsulating Security Payload (ESP) packets
- SA configurations for outgoing ESP packets

Example

Display configurations of the SA.

```
<HUAWEI> display ipsec sa
  IP security association name: sa1
  Number of references: 0
    proposal name: prop1
    inbound AH setting:
      AH spi:
      AH string-key:
      AH authentication hex key: %^%#0D_@HS5002;U1AR{t$3W:H188Ghs~N'_r`Y&R<j70V5-,r-NF(z!
92N)oSNA%^%#
    inbound ESP setting:
      ESP spi:
      ESP string-key:
      ESP encryption hex key: %^%#A*v9(B!U3U%*HL%Rod;%|G}F;B3[5%q#VMTG#9EP%^%#
      ESP authentication hex key: %^%#w_eeVg;FD3ybX!(2&P2ecMN%'JMGWXm^bR#qcUNKj_3AGrb@#
\B4(Vn5cYC%^%#
    outbound AH setting:
      AH spi:
      AH string-key:
      AH authentication hex key: %^%#jp!o1aA7qD^qMN&yI4M8nG_(~~O.{8;tyqI3%o5M4&L@G]rJw/
au]r'm=j^9%^%#
    outbound ESP setting:
      ESP spi:
      ESP string-key:
      ESP encryption hex key: %^%#".dAYkLlqV_o-'SI0.":&<M';66l4UGMEjB9Cl\S%^%#
      ESP authentication hex key: %^%#Nkz8Z-sF*Pw3clT]@_F9B4:8>RIwc'r#sCJl0N[;{drLI|
%uU5lVUWQkY3p1%^%#
```

Table 10-7 Description of the **display ipsec sa** command output

Item	Description
IP security association name	SA name
Number of references	Number of times the SA is applied
proposal name	Security proposal applied to the SA
inbound AH setting	SA configurations for incoming AH packets
AH spi	SPI for AH
AH string-key	Authentication key for AH in the string format displayed in cipher text
AH authentication hex key	Authentication key for AH in cipher text
inbound ESP setting	SA configurations for incoming ESP packets
ESP spi	SPI for ESP
ESP string-key	Authentication key for ESP in the string format displayed in cipher text
ESP encryption hex key	Encryption key for ESP in cipher format

Item	Description
ESP authentication hex key	Authentication key for ESP in cipher text
outbound AH setting	SA configurations for outgoing AH packets
outbound ESP setting	SA configurations for outgoing ESP packets

10.2.5 display ipsec statistics

Function

The **display ipsec statistics** command displays the statistics about packets processed by IPSec.

Format

display ipsec statistics [**sa-name** *sa-name* **slot** *slot-number*]

Parameters

Parameter	Description	Value
sa-name *sa-name*	Specifies the IPSec Security Association (SA) name.	The value is an existing SA name.
slot *slot-number*	Displays the IPSec SA statistics of the specified slot.	The value is an integer, and the value range depends on the device configuration.

Views

All views

Default Level

1: Monitoring Level

Usage Guidelines

Usage Scenario

After IPSec protection is configured for a routing protocol, you can run the **display ipsec statistics** command to view information about transmitted packets and dropped packets. The details are as follows:

- Number of received and sent packets
- Number of received and sent bytes
- Number of dropped incoming and outgoing packets
- Detailed information about dropped packets

Example

Display statistics about packets processed by IPSec.

```
<HUAWEI> display ipsec statistics
 IPv6 security packet statistics:
   input/output security packets: 0/0
   input/output security bytes: 0/0
   input/output dropped security packets: 0/0
   dropped security packet detail:
     memory process problem: 0
     can't find SA: 0
     queue is full: 0
     authentication is failed: 0
     wrong length: 0
     replay packet: 0
     too long packet: 0
     invalid SA: 0
     policy deny: 0
 the normal packet statistics:
   input/output dropped normal packets: 0/0
 IPv4 security packet statistics:
   input/output security packets: 0/0
   input/output security bytes: 0/0
   input/output dropped security packets: 0/0
   dropped security packet detail:
     memory process problem: 0
     can't find SA: 0
     queue is full: 0
     authentication is failed: 0
     wrong length: 0
     replay packet: 0
     too long packet: 0
     invalid SA: 0
     policy deny: 0
 the normal packet statistics:
   input/output dropped normal packets: 0/0
```

Table 10-8 Description of the **display ipsec statistics** command output

Item	Description
IPv6 security packet statistics	Statistics on IPv6 security packets.
IPv4 security packet statistics	Statistics on IPv4 security packets.
input/output security packets	Indicates the number of received and sent packets.
input/output security bytes	Indicates the number of received and sent bytes.
input/output dropped security packets	Indicates the number of dropped incoming and outgoing packets.

Item	Description
dropped security packet detail	Detailed information about dropped packets.
memory process problem	Indicates the number of packets that are dropped due to a memory fault.
can't find SA	Indicates the number of packets that are dropped because no SA is found.
queue is full	Indicates the number of packets that are dropped because the queue is full.
authentication is failed	Indicates the number of packets that are dropped due to authentication failure.
wrong length	Indicates the number of packets that are dropped due to a packet length fault.
replay packet	Indicates the number of packets that are dropped due to repeated transmission.
too long packet	Indicates the number of packets that are dropped due to excess packet length.
invalid SA	Indicates the number of packets that are dropped due to an invalid SA.
policy deny	Indicates the number of packets that are dropped due to a deny action in the policy.
the normal packet statistics	Statistics about normal packets.
input/output dropped normal packets	Indicates the number of received/sent normal packets that are dropped.

10.2.6 encapsulation-mode

Function

The **encapsulation-mode** command sets the encapsulation mode for IP packets.

The **undo encapsulation-mode** command restores the default encapsulation mode for IP packets.

By default, the encapsulation mode is set to **tunnel**.

Format

encapsulation-mode { **transport** | **tunnel** }

undo encapsulation-mode

Parameters

Parameter	Description	Value
transport	Sets the encapsulation mode to **transport**.	-
tunnel	Sets the encapsulation mode to **tunnel**.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can configure Authentication Header (AH) or Encapsulating Security Payload (ESP) to ensure security based on data confidentiality. If AH is configured, an AH header is generated; if ESP is configured, an ESP header, an ESP tail, and an ESP authentication field are generated. Two encapsulation modes are available for IPSec: transport and tunnel.

- The transport mode is applicable to a scenario in which two hosts, or a host and a security gateway, are communicating with each other. In transport mode, the two devices encrypting and decrypting packets must be the original packet sender and the final receiver, respectively.
- The tunnel mode is generally applied to a scenario in which two security gateways are communicating with each other. The packets that are encrypted on the local security gateway can be decrypted only on the peer security gateway. Therefore, an IP packet must be encapsulated using the tunnel mode and an IP header embed. After arriving at the peer security gateway, the IP packet can be decrypted.

Precautions

The encapsulation modes on both IPSec peers must be identical.

Example

Set the encapsulation mode to **transport** in the security proposal named **prop2**.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop2
[HUAWEI-ipsec-proposal-prop2] encapsulation-mode transport
```

10.2.7 esp authentication-algorithm

Function

The **esp authentication-algorithm** command configures the authentication algorithm for ESP.

The **undo esp authentication-algorithm** command cancels the authentication algorithm for ESP.

By default, ESP uses the Secure Hash Algorithm-256 (SHA2-256) authentication algorithm.

Format

esp authentication-algorithm { **sha1** | **sha2-256** }

undo esp authentication-algorithm

Parameters

Parameter	Description	Value
sha1	Specifies Secure Hash Algorithm-1 (SHA-1) as the authentication algorithm. SHA-1 generates a 160-bit message summary based on a message of less than 2^{64} bits.	-
sha2-256	Specifies SHA2-256 as the authentication algorithm. SHA2-256 generates a 256-bit message summary based on a message of less than 2^{64} bits.	-

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPSec can use ESP protocol to authenticate and encrypt packets, preventing packets from being intercepted or modified, you can run the **esp authentication-algorithm** command to configure the authentication algorithm for ESP.

Prerequisite

The protocol of this IPSec proposal has been configured to ESP using the **transform** command.

Precautions

The authentication algorithms on both IPSec peers must be identical.

The authentication algorithm and encryption algorithm cannot be both set to **NULL** for ESP.

The system software does not support the **md5** parameter. To use the **md5** parameter, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the **sha2-256** parameter.

For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Configure the IPSec proposal **prop1** to use the ESP protocol, and specify SHA2-256 as the authentication algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform esp
[HUAWEI-ipsec-proposal-prop1] esp authentication-algorithm sha2-256
```

10.2.8 esp encryption-algorithm

Function

The **esp encryption-algorithm** command configures the encryption algorithm for ESP protocol.

The **undo esp encryption-algorithm** command cancels the encryption algorithm for ESP protocol.

By default, ESP protocol uses the Advanced Encryption Standard-256 (AES-256) encryption algorithm.

Format

esp encryption-algorithm { **3des** | **aes** [**128** | **192** | **256**] }

undo esp encryption-algorithm

Parameters

Parameter	Description	Value
3des	Indicates that ESP uses 3DES algorithm to encrypt packets.	-

Parameter	Description	Value
aes	Indicates that ESP uses Advanced Encryption Standard (AES) algorithm in CBC mode to encrypt packets. By default, If 128, 192 and 256 are not configured, AES 128 bits algorithm is used for ESP to encrypt packets.	-
128	Indicates that ESP uses AES 128 bits algorithm to encrypt packets.	-
192	Indicates that ESP uses AES 192 bits algorithm to encrypt packets.	-
256	Indicates that ESP uses AES 256 bits algorithm to encrypt packets.	-

Usage Guidelines

Usage Scenario

IPSec can use ESP protocol to authenticate and encrypt packets, preventing packets from being intercepted or modified, you can run the **esp encryption-algorithm** command to configure the encryption algorithm for ESP protocol.

Prerequisite

The protocol of this IPSec proposal has been configured to ESP using the **transform** command.

Precautions

The encryption algorithms on both IPSec peers must be identical.

The authentication algorithm and encryption algorithm cannot be both set to **NULL** for ESP.

The system software does not support the **des** parameter. To use the **des** parameter, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify the **aes** [**128** | **192** | **256**] parameter.

For details about how to install the WEAKEA plug-in, see WEAKEA Configuration.

Example

Configure the IPSec proposal **prop1** to use the ESP protocol, and specify AES-128 as the encryption algorithm.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform esp
[HUAWEI-ipsec-proposal-prop1] esp encryption-algorithm aes 128
```

10.2.9 ipsec proposal

Function

The **ipsec proposal** command creates an IPSec proposal and displays the IPSec proposal view.

The **undo ipsec proposal** command deletes an IPSec proposal.

By default, no IPSec proposal is configured.

Format

ipsec proposal *proposal-name*

undo ipsec proposal *proposal-name*

Parameters

Parameter	Description	Value
proposal-name	Specifies the name of an IPSec proposal.	The value is a string of 1 to 15 case-insensitive characters without question marks (?) or spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An IPSec proposal, part of an IPSec SA, defines security parameters for IPSec SA negotiation, including the security protocol, encryption and authentication algorithms, and encapsulation mode.

Follow-up Procedure

Run the **proposal** command to reference the IPSec proposal in an IPSec SA.

Precautions

Both ends of an IPSec tunnel must be configured with the same parameters.

You cannot delete the security proposal applied on a Security Association (SA). However, you can apply the same proposal on different SA's. To delete a security proposal, run the **undo proposal** command to remove a security proposal from the SA.

Example

Create an IPSec proposal **newprop1**.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal newprop1
[HUAWEI-ipsec-proposal-newprop1]
```

10.2.10 ipsec sa

Function

The **ipsec sa** command creates an SA and displays the SA view.

The **undo ipsec sa** command deletes an SA.

By default, no SA is created.

Format

ipsec sa *sa-name*

undo ipsec sa *sa-name*

Parameters

Parameter	Description	Value
sa-name	Specifies the name of an SA.	The value is a string of 1 to 15 case-insensitive characters without question marks (?) or spaces. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

IPSec uses an SA to ensure security during data transmission. When configuring IPSec, run the **ipsec sa** command to create an SA and configure SA parameters.

Follow-up Procedure

Run the **proposal** command to import a security proposal; run the **sa spi** command to configure the SPI; run the **sa string-key** or **sa authentication-hex** command to configure the authentication key.

Precautions

An SA is unidirectional. Incoming packets and outgoing packets are processed by different SAs.

An SA can be configured with only one security protocol.

Example

Create an SA.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1]
```

10.2.11 proposal

Function

The **proposal** command applies a security proposal to a Security Association (SA).

The **undo proposal** command removes a security proposal from an SA.

By default, no security proposal is created.

Format

proposal *proposal-name*

undo proposal

Parameters

Parameter	Description	Value
proposal-name	Specifies the name of an IPSec proposal.	The value is an existing IPSec proposal name.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

An SA defines a protection policy, and a security proposal defines a protection method. Data protection can be implemented only after a security proposal is applied to an SA.

Prerequisite

The **ipsec proposal** command has been run to create a security proposal before the **proposal** command is run. If no security proposal has been created, an error message will be displayed when the **proposal** command is run.

Before running the **proposal** command, it needs to set the encapsulation mode to transport.

Precautions

After the **proposal** command is run, the security proposal is applied to an SA and cannot be deleted.

Example

Create an IPSec proposal **prop1** and configure it to use the default parameters. Then reference the IPSec proposal in IPSec SA **sa1**.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop1
[HUAWEI-ipsec-proposal-prop1] transform ah
[HUAWEI-ipsec-proposal-prop1] encapsulation-mode transport
[HUAWEI-ipsec-proposal-prop1] quit
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1] proposal prop1
```

10.2.12 reset ipsec statistics

Function

The **reset ipsec statistics** command clears statistics about packets processed by IPSec.

Format

reset ipsec statistics [**sa-name** *sa-name* **slot** *slot-number*]

Parameters

Parameter	Description	Value
sa-name *sa-name*	Specifies the IPSec Security Association (SA) name.	The value is an existing SA name.
slot *slot-number*	Displays the IPSec SA statistics of the specified slot.	The value is an integer, and the value range depends on the device configuration.

Views

User view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Before collecting statistics about packets processed by IPSec in a specified length of time, you can run the **reset ipsec statistics** command to clear the original statistics.

Follow-up Procedure

Run the **display ipsec statistics** command to check statistics about packets processed by IPSec.

Precautions

The statistics cannot be restored after being cleared. Therefore, confirm the action before running this command.

Example

Clear statistics about packets processed by IPSec.

```
<HUAWEI> reset ipsec statistics
```

10.2.13 sa authentication-hex

Function

The **sa authentication-hex** command sets an authentication in hexadecimal format or cipher text for Security Associations (SAs).

The **undo sa authentication-hex** command deletes an authentication key from SAs.

By default, no authentication key is created.

Format

sa authentication-hex { **inbound** | **outbound** } { **ah** | **esp** } [**cipher**] { *hex-plain-key* | *hex-cipher-key* }

undo sa authentication-hex { **inbound** | **outbound** } { **ah** | **esp** }

Parameters

Parameter	Description	Value
inbound	Specifies SA parameters for incoming packets.	-
outbound	Specifies SA parameters for outgoing packets.	-
ah	Specifies SA parameters for Authentication Header (AH). If the security proposal applied to an SA uses AH, **ah** must be configured in the **sa authentication-hex** command.	-
esp	Specifies SA parameters for Encapsulating Security Payload (ESP). If the security proposal applied to an SA uses ESP, **esp** must be configured in the **sa authentication-hex** command.	-
cipher	Indicates the cipher text used for authentication.	-
hex-plain-key	Sets the authentication password to be in plaintext format.	The value is in hexadecimal notation. ● If authentication algorithm Message Digest 5 (MD5) is used, the length of the key is 16 bytes. ● If authentication algorithm Secure Hash Algorithm-1 (SHA-1) is used, the length of the key is 20 bytes. ● If authentication algorithm SHA2-256 is used, the length of the key is 32 bytes.

Parameter	Description	Value
hex-cipher-key	Sets the authentication password to be in ciphertext format.	The value is a string of case-insensitive characters, spaces not supported. ● If authentication algorithm MD5 is used, the length of the key is 68. ● If authentication algorithm SHA-1 is used, the length of the key is 88. ● If authentication algorithm SHA2-256 is used, the length of the key is 108.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

AH and ESP can use either MD5, SHA-1, or SHA-256 that require an authentication key in the string or hexadecimal format. If an authentication key in the hexadecimal format is required, run the **sa authentication-hex** command. The MD5 and SHA-1 algorithms are not recommended because they cannot meet your security defense requirements.

Precautions

Set parameters for both **inbound** and **outbound** SAs.

SA parameters on both IPSec peers must be identical. The authentication key for incoming packets on the local end must be identical with that for outgoing packets on the peer end and vice versa.

The authentication key can be in the hexadecimal or string format. To configure an authentication key in the string format, run the **sa string-key** command. If multiple authentication keys are configured, the latest one takes effect. The formats of authentication keys on both IPSec peers must be identical. If an authentication key in the string format is configured on one end and an authentication key in the hexadecimal format on another end, the two ends cannot communicate.

Example

In an IPSec SA, set the authentication key of the inbound SA to 112233445566778899aabbccddeeff00, and the authentication key of the

outbound SA to aabbccddeeff001100aabbccddeeff00. The authentication key is displayed in cipher text.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1] sa authentication-hex inbound ah cipher 112233445566778899aabbccddeeff00
[HUAWEI-ipsec-sa-sa1] sa authentication-hex outbound ah cipher aabbccddeeff001100aabbccddeeff00
```

10.2.14 sa encryption-hex

Function

The **sa encryption-hex** command configures an encryption key for manual Security Association (SA) in hexadecimal format.

The **undo sa encryption-hex** command deletes an encryption key for manual SA configured in hexadecimal format.

By default, no encryption key is created.

Format

sa encryption-hex { **inbound** | **outbound** } **esp** [**cipher**] { *hex-plain-key* | *hex-cipher-key* }

undo sa encryption-hex { **inbound** | **outbound** } **esp**

Parameters

Parameter	Description	Value
inbound	Specifies SA parameters for incoming packets.	-
outbound	Specifies SA parameters for outgoing packets.	-
esp	Specifies SA parameters for Encapsulating Security Payload (ESP). If the security proposal applied to an SA uses ESP, **esp** must be configured in the **sa encryption-hex** command.	-
cipher	Indicates the ciphertext used for encryption.	-

Parameter	Description	Value
hex-plain-key	Sets the authentication password to be in plaintext format.	The value is in hexadecimal notation. ● If encryption algorithm Data Encryption Standard (DES) is used, the length of the key is 8 bytes. ● If encryption algorithm Triple Data Encryption Standard (3DES) is used, the length of the key is 24 bytes. ● If encryption algorithm Advanced Encryption Standard 128 (AES-128) is used, the length of the key is 16 bytes. ● If encryption algorithm AES-192 is used, the length of the key is 24 bytes. ● If encryption algorithm AES-256 is used, the length of the key is 32 bytes.
hex-cipher-key	Sets the authentication password to be in ciphertext format.	The value is a string of case-insensitive characters, spaces not supported. ● If encryption algorithm DES is used, the length of the key is 48. ● If encryption algorithm 3DES is used, the length of the key is 88. ● If encryption algorithm AES-128 is used, the length of the key is 68. ● If encryption algorithm AES-192 is used, the length of the key is 88. ● If encryption algorithm AES-256 is used, the length of the key is 108.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

ESP security protocol support encryption of IP packets. The algorithm used for encryption/decryption is either DES, 3DES or AES. These algorithms need a key either in hexadecimal format to operate. The hexadecimal key to be used for encryption is configured using the **sa encryption-hex** command.

NOTICE

- The DES and 3DES algorithms have security risks; therefore, you are advised to use AES algorithm preferentially.
- If **sa encryption-hex** command is configured, then the encryption key configured using **sa string-key** command is deleted automatically.

Example

In an IPSec SA, set the encryption key of the inbound SA to 0x1234567890abcdef, and the encryption key of the outbound SA to 0xabcdefabcdef1234. The encryption key is displayed in cipher text.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1] sa encryption-hex inbound esp cipher 1234567890abcdef
[HUAWEI-ipsec-sa-sa1] sa encryption-hex outbound esp cipher abcdefabcdef1234
```

10.2.15 sa spi

Function

The **sa spi** command configures the Security Parameter Index (SPI) for a Security Association (SA).

The **undo sa spi** command deletes the SPI from an SA.

By default, no SPI is configured.

Format

sa spi { **inbound** | **outbound** } { **ah** | **esp** } *spi-number*

undo sa spi { **inbound** | **outbound** } { **ah** | **esp** }

Parameters

Parameter	Description	Value
inbound	Specifies SA parameters for incoming packets.	-
outbound	Specifies SA parameters for outgoing packets.	-
ah	Specifies SA parameters for Authentication Header (AH). If the security proposal applied to an SA uses AH, **ah** must be configured in the **sa spi** command.	-

Parameter	Description	Value
esp	Specifies SA parameters for Encapsulating Security Payload (ESP). If the security proposal applied to an SA uses ESP, **esp** must be configured in the **sa spi** command.	-
spi-number	Specifies the SPI.	The value is an integer ranging from 256 to 4294967295.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

SPI uniquely identifies an SA. When an SPI is configured for an SA, the SPI is carried in each sent packet. The receiver checks the packet authenticity based on the SPI. When the **ipsec sa** *sa-name* command is used to create an SA, run the **sa spi** command to configure the SPI.

Precautions

Set parameters for both **inbound** and **outbound** SAs.

The SPI for incoming packets on the local end must be identical with that for outgoing packets on the peer end and vice versa.

Example

In an IPSec SA, set the SPI of the inbound SA to 10000 and the SPI of the outbound SA to 20000.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1] sa spi inbound ah 10000
[HUAWEI-ipsec-sa-sa1] sa spi outbound ah 20000
```

10.2.16 sa string-key

Function

The **sa string-key** command configures an authentication key in the string format.

The **undo sa string-key** command deletes an authentication key from Security Associations (SAs).

By default, no authentication key is created.

Format

sa string-key { **inbound** | **outbound** } { **ah** | **esp** } [**cipher**] *string-cipher-key*

undo sa string-key { **inbound** | **outbound** } { **ah** | **esp** }

Parameters

Parameter	Description	Value
inbound	Specifies SA parameters for incoming packets.	-
outbound	Specifies SA parameters for outgoing packets.	-
ah	Specifies SA parameters for Authentication Header (AH). If the security proposal applied to an SA uses AH, **ah** must be configured in the **sa string-key** command.	-
esp	Specifies SA parameters for Encapsulating Security Payload (ESP). If the security proposal applied to an SA uses ESP, **esp** must be configured in the **sa string-key** command.	-
cipher	Indicates the cipher text used for authentication.	-
string-cipher-key	Specifies the cipher text key.	The value is a string of case-sensitive characters that can be letters or digits. The authentication password can be a string of 1 to 127 characters in plain text or a string of 20 to 392 characters in encrypted text. Except the question mark (?) and space. However, when quotation marks (") are used around the string, spaces are allowed in the string.

Views

SA view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

AH and ESP can use either Message Digest 5 (MD5), Secure Hash Algorithm 1 (SHA-1) or SHA-256, that require an authentication key in the string or hexadecimal format. If an authentication key in the string format is required, run the **sa string-key** command. The MD5 and SHA-1 algorithms are not recommended because they cannot meet your security defense requirements.

Precautions

Set parameters for both **inbound** and **outbound** SAs.

SA parameters on both IPSec peers must be identical. The authentication key for incoming packets on the local end must be identical with that for outgoing packets on the peer end and vice versa.

The authentication key can be in the hexadecimal or string format. To configure an authentication key in the hexadecimal format, run the **sa authentication-hex** command. If multiple authentication keys are configured, the latest one takes effect. The formats of authentication keys on both IPSec peers must be identical. If an authentication key in the string format is configured on one end and an authentication key in the hexadecimal format on another end, the two ends cannot communicate.

Example

In an IPSec SA, set the authentication key of the inbound SA to abcdef, and the authentication key of the outbound SA to efcdab. The authentication key is displayed in cipher text.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa sa1
[HUAWEI-ipsec-sa-sa1] sa string-key inbound ah cipher abcdef
[HUAWEI-ipsec-sa-sa1] sa string-key outbound ah cipher efcdab
```

10.2.17 transform

Function

The **transform** command configures the security protocol in a security proposal.

The **undo transform** command restores the default security protocol.

By default, the Encapsulating Security Payload (ESP) protocol is used, as defined in RFC.

Format

transform { **ah** | **esp** }

undo transform

Parameters

Parameter	Description	Value
ah	Configures Authentication Header (AH) as the security protocol.	-
esp	Configures ESP as the security protocol.	-

Views

IPSec proposal view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

- When AH is specified, AH only authenticates packets.

  When AH is specified, by default, AH uses the SHA-256 authentication algorithm.
- When ESP is specified, ESP can encrypt/authenticate, or encrypt and authenticate packets.

  When ESP is specified, ESP uses the SHA-256 authentication algorithm, the AES-256 encryption algorithm.

AH prevents data tampering but cannot prevent data interception, so it applies only to the transmission of non-confidential data. ESP provides authentication service inferior to that of AH, but it can encrypt packet payloads.

Follow-up Procedure

Configure the authentication algorithm for AH when AH is used.

Configure the authentication and encryption algorithms for ESP when ESP is used.

Precautions

When multiple security proposals are configured, the latest configuration takes effect, and the default authentication and encryption algorithms will be restored.

The IPSec proposals configured on both ends of an IPSec tunnel must use the same security tunnel.

Example

Configure AH for the security proposal named **prop**.

```
<HUAWEI> system-view
[HUAWEI] ipsec proposal prop
[HUAWEI-ipsec-proposal-prop] transform ah
```

10.3 IPSec Configuration Commands (IPSec Efficient VPN)

10.3.1 Command Support

Commands provided in this section and all the parameters in the commands are supported by all switch models (except the S5731-L and S5731S-L), unless otherwise specified. For details, see specific commands.

10.3.2 anti-replay window

Function

The **anti-replay window** command sets the anti-replay window size for an IPSec tunnel.

The **undo anti-replay window** command restores the default anti-replay window size of an IPSec tunnel.

By default, the anti-replay window size of a single IPSec tunnel is not set. The global value is used.

Format

anti-replay window *window-size*

undo anti-replay window

Parameters

Parameter	Description	Value
window-size	Specifies the anti-replay window size of an IPSec tunnel.	The value can be 32, 64, 128, 256, 512, or 1024, in bits.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Configuration Impact

You may need to change the anti-replay window size for an IPSec tunnel in some situations. For example, if QoS is performed for packets passing an IPSec tunnel, sequence numbers of service data packets may be different from those in common data packets. As a result, these service data packets are dropped as replay attack packets. To prevent such packets from being dropped incorrectly, you can disable the anti-replay function or increase the anti-replay window size for the IPSec tunnel.

Prerequisites

The anti-replay function is enabled for the IPSec tunnel. By default, the anti-replay function is enabled (through the **ipsec anti-reply enable** command).

Precautions

When both **anti-replay window** and **ipsec anti-replay window** are configured, the **anti-replay window** configuration takes effect. When **anti-replay window** is not configured, the **ipsec anti-replay window** configuration takes effect.

Example

Set the IPSec anti-replay window size to 128 bits.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] anti-replay window 128
```

10.3.3 dh

Function

The **dh** command specifies a Diffie-Hellman (DH) group used for IKE negotiation.

The **undo dh** command restores the default DH group for IKE negotiation.

By default, group14 is used for IKE negotiation.

Format

dh { **group14** | **group19** | **group20** | **group21** }

undo dh

Parameters

Parameter	Description	Value
group14	Uses the 2048-bit DH group in IKE negotiation phase 1.	-
group19	Uses the 256-bit Elliptic Curve Groups modulo a Prime (ECP) DH group in IKE negotiation phase 1.	-
group20	Uses the 384-bit Elliptic Curve Groups modulo a Prime (ECP) DH group in IKE negotiation phase 1.	-

Parameter	Description	Value
group21	Uses the 521-bit Elliptic Curve Groups modulo a Prime (ECP) DH group in IKE negotiation phase 1.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The DH algorithm is a public key algorithm. Two communicating parties calculate a shared key based on data exchanged between them, without transmitting the key. A third party (such as a hacker) cannot calculate the actual key even if it obtains all exchanged data for key calculation.

Precautions

- Both ends of an IPSec tunnel must be configured with the same DH group. Otherwise, the negotiation fails.
- The security level order of the DH groups is: **group21** > **group20** > **group19** > **group14**.
- The system software does not support the **group1**, **group2**, and **group5** parameters. To use these DH groups, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify other DH groups.

  For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Example

Specify the 2048-bit DH group for the IPSec Efficient VPN policy.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] dh group14
```

10.3.4 display ike error-info

Function

The **display ike error-info** command displays information about IPSec tunnel negotiation failures using IKE.

Format

display ike error-info [**verbose**] [**peer** *remote-address*]

Parameters

Parameter	Description	Value
verbose	Displays details about IPSec tunnel negotiation failures using IKE.	-
peer *remote-address*	Displays information about IPSec tunnel negotiation failures using IKE with a specified remote IP address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output contains information of the latest 200 IPSec tunnel negotiation failures using IKE.

Example

Display information about IPSec tunnel negotiation failures using IKE.

```
<HUAWEI> display ike error-info

  current info Num :2
  Ike error information:
  current ike Error-info number :2
  ---------------------------------------------------------------------------
  peer       port      error-reason               version     error-time
  ---------------------------------------------------------------------------
  10.1.1.1   500       phase1 proposal mismatch     v1         2013-08-26 13:42:37
  10.1.1.1   500       phase1 proposal mismatch     v1         2013-08-26 13:08:45
  ---------------------------------------------------------------------------
```

Display details about IPSec tunnel negotiation failures using IKE.

```
<HUAWEI> display ike error-info verbose

  current info Num :1
  Ike error information:
  current ike Error-info number :1
---------------------------------------------------------------------------
Peer       : 10.1.1.1
Port       : 500
version    : v1

Detail     : phase1 proposal mismatch
Error-time : 2013-08-26 12:02:37
---------------------------------------------------------------------------
```

Table 10-9 Description of the **display ike error-info** command output

Item	Description
current info Num	Current information number.
Ike error information	Information about IPSec tunnel negotiation failures using IKE.
current ike Error-info number	Number of IPSec tunnel negotiation failures using IKE.
peer or Peer	Peer IP address.
port or Port	Peer UDP port number.

Item	Description
error-reason or Reason	Causes for IPSec tunnel negotiation failures using IKE: ● phase1 proposal mismatch: IKE proposal parameters of the two ends do not match. ● phase2 proposal or pfs mismatch: IPSec proposal parameters, pfs algorithm, or security ACL of the two ends do not match. ● responder dh mismatch: The DH algorithm of the responder does not match. ● initiator dh mismatch: The DH algorithm of the initiator does not match. ● encapsulation mode mismatch: The encapsulation mode does not match. ● flow or peer mismatch: The security ACL or IKE peer address of the two ends does not match. ● version mismatch: The IKE version number of the two ends does not match. ● peer address mismatch: The IKE peer address of the two ends does not match. ● config ID mismatch: The IKE peer of the specified ID is not found. ● exchange mode mismatch: The negotiation mode of the two ends does not match. ● authentication fail: Identity authentication fails. ● construct local ID fail: The local ID fails to be constructed. ● rekey no find old sa: The old SA is not found during re-negotiation. ● rekey fail: The old SA is going offline during re-negotiation. ● first packet limited: The rate of the first packet is limited. ● unsupported version: The IKE version number is not supported. ● malformed message: Malformed message. ● malformed payload: Malformed payload. ● critical drop: Unidentified critical payload. ● cookie mismatch: Cookie mismatch. ● invalid cookie: Invalid cookie. ● invalid length: Invalid packet length. ● unknown exchange type: Unknown negotiation mode. ● uncritical drop: Unidentified non-critical payload. ● local address mismatch: The local IP address in IKE negotiation and interface IP address do not match.

Item	Description
	- dynamic peers number reaches limitation: The number of IKE peers reaches the upper limit. - ipsec tunnel number reaches limitation: The number of IPSec tunnels reaches the upper limit. - no policy applied on interface: No policy is applied to an interface. - nat detection fail: NAT detailed failed. - fragment packet limit: Fragment packets exceed the limit. - fragment packet reassemble timeout: Fragment packet reassembly times out. - max transmit reached: Tunnel negotiation fails after the number of IKE packet retransmissions reaches the maximum value. - no valid local cert: No valid CA/local certificate exists.
version	IKE version.
Error-time/error-time	Time of IPSec tunnel negotiation failures using IKE.

Item	Description
Detail	Details about IPSec tunnel negotiation failures using IKE. ● phase1 proposal mismatch: IKE proposal parameters of the two ends do not match. ● phase2 proposal or pfs mismatch: IPSec proposal parameters, pfs algorithm, or security ACL of the two ends do not match. ● responder dh mismatch: The DH algorithm of the responder does not match. ● initiator dh mismatch: The DH algorithm of the initiator does not match. ● encapsulation mode mismatch: The encapsulation mode does not match. ● flow or peer mismatch: The security ACL or IKE peer address of the two ends does not match. ● version mismatch: The IKE version number of the two ends does not match. ● peer address mismatch: The IKE peer address of the two ends does not match. ● config ID mismatch: The IKE peer of the specified ID is not found. ● exchange mode mismatch: The negotiation mode of the two ends does not match. ● authentication fail: Identity authentication fails. ● construct local ID fail: The local ID fails to be constructed. ● rekey no find old sa: The old SA is not found during re-negotiation. ● rekey fail: The old SA is going offline during re-negotiation. ● first packet limited: The rate of the first packet is limited. ● unsupported version: The IKE version number is not supported. ● malformed message: Malformed message. ● malformed payload: Malformed payload. ● critical drop: Unidentified critical payload. ● cookie mismatch: Cookie mismatch. ● invalid cookie: Invalid cookie. ● invalid length: Invalid packet length. ● unknown exchange type: Unknown negotiation mode. ● uncritical drop: Unidentified non-critical payload. ● local address mismatch: The local IP address in IKE negotiation and interface IP address do not match.

Item	Description
	● dynamic peers number reaches limitation: The number of IKE peers reaches the upper limit. ● ipsec tunnel number reaches limitation: The number of IPSec tunnels reaches the upper limit. ● no policy applied on interface: No policy is applied to an interface. ● nat detection fail: NAT detailed failed. ● fragment packet limit: Fragment packets exceed the limit. ● fragment packet reassemble timeout: Fragment packet reassembly times out. ● max transmit reached: Tunnel negotiation fails after the number of IKE packet retransmissions reaches the maximum value. ● no valid local cert: No valid CA/local certificate exists. ● receive phase1 proposal mismatch: The received IKE proposal parameters do not match the local parameters. ● receive phase2 proposal mismatch: The received IPSec proposal parameters do not match the local parameters. ● phase2 proposal mismatch: IPSec proposal parameters on both ends do not match. ● receive flow or peer mismatch: The received security ACL or IKE peer address does not match the local one. ● (peer local or tunnel local or interface) address mismatch: The peer's local IP address, local tunnel IP address or interface IP address does not match the local one. ● remote auth method mismatch: The peer authentication method does not match. ● proc auth payload fail(pre-share-key): Failed to process the authentication payload during pre-shared key authentication. ● recv peer auth fail notification: An authentication failure notification from the peer end is received. ● recv peer auth fail notification(pre-share-key): An authentication failure notification from the peer end is received during pre-shared key authentication. ● proc and auth ID payload fail(pre-share-key): The peer ID fails to be authenticated during pre-shared key authentication.

10.3.5 display ike global config

Function

The **display ike global config** command displays global IKE configurations.

Format

display ike global config

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view global IKE configurations, such as the local name used in IKE negotiation, interval for sending heartbeat packets, timeout interval of heartbeat packets, and interval for sending NAT keepalive packets.

Example

Display global IKE configurations.

```
<HUAWEI> display ike global config
IKE Global Config:
----------------------------------------------------------------
  IKE local-name                     : huawei
  IKE heartbeat-timer interval      : 30
  IKE heartbeat-timer timeout       : 100
  IKE nat-keepalive-timer interval : 52   IKEv1 phase1-phase2 sa dependent : enable   IKE
DSCP                          : -   IKEv2 initial-contact             : enable   IKEv2 delete old child-sa         : enable
----------------------------------------------------------------
```

Table 10-10 Description of the **display ike global config** command output

Item	Description
IKE Global Config	Global IKE configurations.
IKE local-name	Local peer name used in IKE negotiation. This parameter can be configured using the **ike local-name** command. If the **ike local-name** command is not run, the device name configured using the **sysname** command is used for IKE negotiation.

Item	Description
IKE heartbeat-timer interval	Interval (in seconds) at which a device sends heartbeat packets through an IKE SA. This parameter is configured using the **ike heartbeat-timer interval** command.
IKE heartbeat-timer timeout	Timeout period (in seconds) of sending heartbeat packets through an IKE SA. This parameter is configured using the **ike heartbeat-timer timeout** command.
IKE nat-keepalive-timer interval	Interval (in seconds) at which a device sends NAT keepalive packets through an IKE SA. This parameter is configured using the **ike nat-keepalive-timer interval** command.
IKEv1 phase1-phase2 sa dependent	Dependency between an IPSec SA and an IKE SA during IKEv1 negotiation is enabled. ● enable ● disable This function is configured using the **ikev1 phase1-phase2 sa dependent** command.
IKE DSCP	Global DSCP value of IKE packets. This parameter can be configured using the **ike dscp** command.
IKEv2 initial-contact	Whether the first IKE_AUTH request message carries the INITIAL_CONTACT notification payload. ● enable ● disable This function is configured using the **ikev2 initial-contact enable** command.
IKEv2 delete old child-sa	Whether to enable the function of instructing the peer device to delete the old child SA: ● enable ● disable This function is configured using the **ikev2 delete old child-sa enable** command.

10.3.6 display ike offline-info

Function

The **display ike offline-info** command displays information about deleted IPSec tunnels established through IKE negotiation.

Format

display ike offline-info [**peer** *remote-address*]

Parameters

Parameter	Description	Value
peer *remote-address*	Displays information about deleted IPSec tunnels with a specified remote IP address and established through IKE negotiation.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The command output contains the possible causes and time of the latest 200 IPSec tunnel deletions.

Example

Display information about deleted IPSec tunnels established through IKE negotiation.

```
<HUAWEI> display ike offline-info

  Current info Num :2
  Ike offline information:
---------------------------------------------------------------------------
  peer              offline-reason              version     offline-time
---------------------------------------------------------------------------
  2.1.1.2           dpd timeout                  v2         2017-02-18 02:12:39
  2.1.1.2           dpd timeout                  v2         2017-02-18 01:17:06
---------------------------------------------------------------------------
```

Table 10-11 Description of the **display ike offline-info** command output

Item	Description
Current info Num	Current number of information records.
Ike offline information	Information about IPSec tunnels established through IKE negotiation have been deleted.
peer	Peer IP address of a deleted IPSec tunnel.

Item	Description
offline-reason	Causes for deletion of IPSec tunnels established through IKE negotiation: ● dpd timeout: Dead peer detection (DPD) times out. ● peer request: The remote end has sent a message, asking the local end to tear down the tunnel. ● config modify or manual offline: An SA is deleted due to configuration modification or an SA is manually deleted. ● phase1 hard expiry: Hard lifetime expires in phase 1 (no new SA negotiation success message is received). ● phase2 hard expiry: Hard lifetime expires in phase 2. ● heartbeat timeout: heartbeat detection times out. ● modecfg address soft expiry: The IP address lease applied by the remote end from the server expires. ● re-auth timeout: An SA is deleted due to reauthentication timeout. ● aaa cut user: The AAA module disconnects users. ● hard expiry triggered by port mismatch: A hard timeout occurs due to mismatch NAT port number. ● spi conflict: An SPI conflict occurs. ● phase1 sa replace: The new IKE SA replaces the old IKE SA. ● phase2 sa replace: The new IPSec SA replaces the old IPsec SA. ● receive invalid spi notify: The device receives an invalid SPI notification. ● dns resolution status change: DNS resolution status changes. ● ikev1 phase1-phase2 sa dependent offline: The device deletes the associated IPSec SA when deleting an IKEv1 SA. ● exchange timeout: Packet interaction timeout.
version	IKE version.
offline-time	IPSec tunnel deletion time.

10.3.7 display ike sa

Function

The **display ike sa** command displays information about SAs established through IKE negotiation.

Format

display ike sa [**remote** *ipv4-address*]

display ike sa [**remote-id-type** *remote-id-type*] **remote-id** *remote-id*

display ike sa verbose [**remote** *ipv4-address* | **connection-id** *connection-id* | [**remote-id-type** *remote-id-type*] **remote-id** *remote-id*]

Parameters

Parameter	Description	Value
remote *ipv4-address*	Specifies the IPv4 address of the remote peer.	The value is in dotted decimal notation.
remote-id-type *remote-id-type*	Specifies a remote ID type.	The remote ID type can be ip, key-id, fqdn, or user-fqdn.
remote-id *remote-id*	Specifies the remote ID.	The remote ID must be an existing one.
verbose	Displays detailed information about SAs. **NOTE** If only this parameter is specified (other parameters are not specified), the command displays detailed information about all SAs.	-
connection-id *connection-id*	Specifies the connection ID of an SA.	The value is an integer that ranges from 1 to 4294967295.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ike sa** command to check the following SA information: connection ID, peer IP address, VPN instance name, SA phase, remote ID type, remote ID, and SA status.

NOTE

After an IPSec tunnel is established successfully, the **display ike sa** command does not display the latest local ID or remote ID until the IPSec tunnel is re-negotiated if the local ID or remote ID is modified.

Example

Display IKE SAs and IPSec SAs.

```
<HUAWEI> display ike sa
IKE SA information :
   Conn-ID       Peer            VPN    Flag(s)    Phase    RemoteType   RemoteID
 ----------------------------------------------------------------------------------
   117477244     10.100.1.1/4500 vrf1   RD|M       v2:2     IP           10.100.1.1
   117477242     10.100.1.1/4500 vrf1   RD|M       v2:1     IP           10.100.1.1

  Number of IKE SA : 2
 ----------------------------------------------------------------------------------

 Flag Description:
 RD--READY   ST--STAYALIVE   RL--REPLACED   FD--FADING   TO--TIMEOUT
 HRT--HEARTBEAT   LKG--LAST KNOWN GOOD SEQ NO.   BCK--BACKED UP
 M--ACTIVE   S--STANDBY   A--ALONE  NEG--NEGOTIATING
```

Table 10-12 Description of the **display ike sa** command output

Item	Description
IKE SA information	Configuration of SAs.
Conn-ID	Connection ID of an SA.
Peer	IP address and UDP port number of the peer.
VPN	VPN instance bound to the interface where the IPSec policy was applied to.

Item	Description
Flag(s)	SA status: - RD--READY: The SA has been established successfully. - ST--STAYALIVE: This end is the initiator of tunnel negotiation. - RL--REPLACED: This SA has been replaced by a new one and will be deleted after a period of time. - FD--FADING: A soft timeout has occurred, but the SA is still in use. The SA will be deleted when the hard lifetime expires. - TO--TIMEOUT: This SA has not received any heartbeat packet after the last heartbeat timeout. The SA will be deleted if it still does not receive any heartbeat packet till the next heartbeat timeout. - HRT--HEARTBEAT: The local IKE SA sends heartbeat packets. - LKG--LAST KNOWN GOOD SEQ NO: It is the last known sequence number. - BCK--BACKED UP: The SA is backed up. - M--ACTIVE: The IPSec policy group is in active state. - S--STANDBY: The IPSec policy group is in standby state. - A--ALONE: The IPSec policy group is not backed up. - NEG--NEGOTIATING: The devices are negotiating an SA. - Empty: IKE SA negotiation is being performed because the settings at the two ends of the tunnel are inconsistent.
Phase	Phases of the SA: - v1:1 or v2:1: v1 and v2 are IKE versions. The digit 1 indicates the phase during which a security channel, that is IKE SA, is established. - v1:2 or v2:2: v1 and v2 are IKE versions. The digit 2 indicates the phase during which a security service, that is IPSec SA, is negotiated.
RemoteType	Remote ID type.
RemoteID	Remote ID.

Display detailed information about established IKE SAs and IPSec SAs when the peers use IKEv1 to negotiate IPSec SAs.

```
<HUAWEI> display ike sa verbose remote 10.100.1.1

Table 10-13 Description of the **display ike sa verbose** command output

Item	Description
Ike Sa phase	Phases of the SA: - 1: IKE peers establish an IPSec tunnel. An IKE SA is established in this phase. - 2: IKE peers negotiate security services. An IPSec SA is established in this phase.
Establish Time	Time when the SA was created.
PortCfg Index	Index of the interface where the IPSec policy was applied to.
IKE Peer Name	IKE peer name.

Item	Description
Connection Id	Connection ID of an SA.
Version	IKE version of the IKE peer: ● v1: IKEv1 is enabled. ● v2: IKEv2 is enabled. ● v1v2: Both IKEv1 and IKEv2 are enabled.
Exchange Mode	Negotiation mode of the IKEv1 phase 1. ● Main: main mode. ● Aggressive: aggressive mode.
Flow VPN	VPN to which the data flow belongs.
Peer VPN	VPN to which the peer belongs.
Initiator Cookie	Cookie of the initiator.
Responder Cookie	Cookie of the responder.
Local Address	Local IP address of an IPSec tunnel.
Remote Address	Remote IP address and UDP port number of an IPSec tunnel.
Encryption Algorithm	Encryption algorithm in the IKE proposal.
Authentication Algorithm	Authentication algorithm in the IKE proposal.
Authentication Method	Authentication method in the IKE proposal.
Integrity Algorithm	Integrity algorithm used in an IKEv2 proposal.
Prf Algorithm	Pseudo-random function (PRF) used in an IKEv2 proposal.
DPD Capability	Whether DPD capability is successfully negotiated. ● yes ● no
DPD Enable	Whether the DPD function is enabled. ● yes ● no
DPD Message Learning Enable	Whether automatic learning of the payload sequence of DPD packets is enabled. ● Yes ● No To configure the automatic learning function, run the **dpd msg notify-hash-sequence learning** command.

Item	Description
DPD Message Format	Sequence of the payload in DPD packets. ● Seq-Notify-Hash ● Seq-Hash-Notify
Reference Counter	Number of IPSec SAs negotiated by the IKE SA.
PFS	Perfect Forward Secrecy (PFS) when the local end initiates negotiation.
Flags	SA status: ● RD--READY: The SA has been established successfully. ● ST--STAYALIVE: This end is the initiator of tunnel negotiation. ● RL--REPLACED: This SA has been replaced by a new one and will be deleted after a period of time. ● FD--FADING: A soft timeout has occurred, but the SA is still in use. The SA will be deleted when the hard lifetime expires. ● TO--TIMEOUT: This SA has not received any heartbeat packet after the last heartbeat timeout. The SA will be deleted if it still does not receive any heartbeat packet till the next heartbeat timeout. ● HRT--HEARTBEAT: The local IKE SA sends heartbeat packets. ● LKG--LAST KNOWN GOOD SEQ NO: It is the last known sequence number. ● BCK--BACKED UP: The SA is backed up. ● M--ACTIVE: The IPSec policy group is in active state. ● S--STANDBY: The IPSec policy group is in standby state. ● A--ALONE: The IPSec policy group is not backed up. ● NEG--NEGOTIATING: The devices are negotiating an SA. ● Empty: IKE SA negotiation is being performed because the settings at the two ends of the tunnel are inconsistent.
Local Id Type	Local ID type.
Local Id	Local ID for IKE negotiation.
Remote Id Type	Remote ID type.
Remote Id	Remote ID for IKE negotiation.
DH Group	DH group in the IKE proposal.

Item	Description
NAT Traversal Version	Version of NAT traversal. - draft-ietf-ipsec-nat-t-ike-00 - draft-ietf-ipsec-nat-t-ike-02 - RFC3947
Re-authentication remaining time (sec)	Remaining time for IKEv2 to initiate re-authentication, in seconds.
SA Remaining Soft Timeout (sec)	Soft remaining lifetime of an IKE SA, in seconds.
SA Remaining Hard Timeout (sec)	Hard remaining lifetime of an IKE SA, in seconds.
Number of IKE SA	Total number of IKE SAs and IPSec SAs.

10.3.8 display ike statistics

Function

The **display ike statistics** command displays IKE statistics.

Format

display ike statistics { **v1** | **v2** }

Parameters

Parameter	Description	Value
v1	Displays IKEv1 statistics.	-
v2	Displays IKEv2 statistics.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

When a fault occurs on the IPSec tunnel that is established through IKE negotiation, you can check statistics about IKE peers, IKE SAs, and DPD packets to diagnose and locate the fault.

Example

Display IKEv1 statistics.

```
<HUAWEI> display ike statistics v1
--------------------------------------------------------------------------------
 IKE V1 statistics information

Table 10-14 Description of the **display ike statistics** command output

Item	Description
IKE V1 statistics information	IKEv1 statistics.
IKE V2 statistics information	IKEv2 statistics.
Number of total peers	Total number of peers.
Maximum of total peers in history	Historical maximum number of IKE peers.
Begin time of total peers	Time when the system started to count the number of IKE peers.
Maximum time of total peers	Time when the total number of IKE peers reached the maximum value.
Number of proposals	Number of IKE proposals.
Number of established V1/V2 phase 1 SAs	Total number of IKE SAs that have been established successfully.
Number of established V1/V2 phase 2 SAs	Total number of IPSec SAs that have been established successfully.
Number of total V1/V2 phase 1 SAs	Total number of IKE SAs.
Number of total V1/V2 phase 2 SAs	Total number of IPSec SAs.
Number of total SAs	Total number of SAs.
Maximum of V1/V2 phase 1 SAs in history	Maximum number of IKE SAs in the history.
Begin time of V1/V2 phase 1 SAs	Time when the system started to count the number of IKE SAs.

Item	Description
Maximum time of V1/V2 phase 1 SAs	Time when the total number of IKE SAs reaches the maximum value.
Maximum of V1/V2 phase 2 SAs in history	Maximum number of IPSec SAs in the history.
Begin time of V1/V2 phase 2 SAs	Time when the system started to count the number of IPSec SAs.
Maximum time of V1/V2 phase 2 SAs	Time when the total number of IPSec SAs reached the maximum value.
Maximum of total SAs in history	Maximum number of total SAs in the history.
Begin time of total SAs	Time when the system started to count the total number of SAs.
Maximum time of total SAs	Time when the total number of SAs reached the maximum value.
Number of messages in V1/V2 fast queue	Number of IKE messages in high-priority queues.
Number of messages in V1/V2 slow queue	Number of IKE messages in low-priority queues.
Number of DPD request sent	Number of DPD request packets sent from the local end.
Number of DPD ack received	Number of DPD ack packets received by the local end.
Number of DPD request received	Number of DPD request packets received by the local end.
Number of DPD ack sent	Number of DPD ack packets sent from the local end.
Number of DPD request receive dropped	Number of received DPD request packets that are dropped.
Number of DPD ack receive dropped	Number of received DPD response packets that are dropped.

10.3.9 display ikev2 statistics

Function

The **display ikev2 statistics** command displays statistics on IPSec tunnels negotiated using IKEv2.

Format

display ikev2 statistics { **error** | **notify-info** | **packet** | **sa** }

Parameters

Parameter	Description	Value
error	Displays error statistics on IPSec tunnels negotiated using IKEv2.	-
notify-info	Displays notification message statistics on IPSec tunnels negotiated using IKEv2.	-
packet	Displays packet statistics on IPSec tunnels negotiated using IKEv2.	-
sa	Displays SA statistics on IPSec tunnels negotiated using IKEv2.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to view error, packet, SA, and notification message statistics on IPSec tunnels negotiated using IKEv2.

Example

Display error statistics on IPSec tunnels negotiated using IKEv2.

```
<HUAWEI> display ikev2 statistics error

Error statistics:
--------------------------------------------------------------------------------
```

```
Config error:
Version error            :0
Peer address can not match with any ike peer config                  :0
Phase1 proposal mismatch :0           Phase2 proposal or pfs mismatch:0
Responder dh mismatch    :0           Initiator dh mismatch          :0
Flow mismatch            :1
ID can not match with any ike peer config                            :0
Construct local id fail                                              :0
Authentication fail (may be pre-shared-key error)                    :0
Peer's flow netmask range is too wide                                :0
-----------------------------------------------------------------------------
Packet or payload error:
Invalid length           :0
Message-id unordered     :0
Unknown exchange type    :0
Invalid cookie           :6
Shortpacket              :0
Malformed message        :4
Malformed payload        :0
Rekey, not find old child:0           Rekey, old child close         :14
Exchange-type or role(initiator or responder) mismatch               :0
Unexpected critical payload, drop                                    :0
Unexpected uncritical payload, ignore                                :0
-----------------------------------------------------------------------------
Maybe ddos attack:
Responder request IKEV2_COOKIE                                       :0
Responder receive invalid cookie for IKEV2_COOKIE request            :0
Responder receive no cookie for IKEV2_COOKIE request                 :0
-----------------------------------------------------------------------------
System abnormal:
Fail decrypt             :0           Fail encrypt                   :0
Fail integrity check     :0
No memory, fail send packet                                          :0
No memory, fail process packet                                       :0
-----------------------------------------------------------------------------
System limited:
First packet speed limited :0             License limited          :0
-----------------------------------------------------------------------------
```

Table 10-15 Description of the **display ikev2 statistics error** command output

Item	Description
Error statistics	Error statistics.
Config error	Configurations are incorrect.
Version error	The IKE version does not match.
Peer address can not match with any ike peer config	The corresponding IKE peer is not found based on the peer address.
Phase1 proposal mismatch	The phase 1 IPSec proposal does not match.
Phase2 proposal or pfs mismatch	The phase 2 IPSec proposal or PFS does not match.

Item	Description
Responder dh mismatch	DH group match on the responder failed. (If a matching DH group is available in the algorithm list of the initiator, the responder will send an information message to the initiator to instruct the initiator to start negotiation using the matching DH group. If the initiator accepts the information message, the negotiation succeeds.)
Initiator dh mismatch	DH group match on the initiator failed. (The initiator failed to process the message requesting a matching DH group.)
Flow mismatch	The data flow does not match.
ID can not match with any ike peer config	The peer ID does not match that configured in the IKE peer.
Construct local id fail	Local ID construction failed.
Authentication fail (may be pre-shared-key error)	Authentication failed. The possible cause is that the pre-shared key does not match.
Peer's flow netmask range is too wide	The mask length of the peer flow is too large.
Packet or payload error	Incorrect packet or payload.
Invalid length	Invalid length.
Message-id unordered	Message ID out of order.
Unknown exchange type	Unknown exchange type.
Invalid cookie	Invalid cookie: ● The corresponding SA does not exist in the received IKEv2 message that does not trigger negotiation. ● The cookie in the IKEv2 message that triggers negotiation is 0.
Shortpacket	The packet is too short.
Malformed message	Invalid message.
Malformed payload	Invalid payload.
Rekey, not find old child	The old IPSec SA is not found for re-negotiation.
Rekey, old child close	The old IPSec SA is offline for re-negotiation.

Item	Description
Exchange-type or role(initiator or responder) mismatch	The exchange type or role (initiator or responder) does not match.
Unexpected critical payload, drop	The unidentified key payload is dropped.
Unexpected uncritical payload, ignore	The unidentified key payload is ignored.
Maybe ddos attack	Maybe DDoS attacks occur.
Responder request IKEV2_COOKIE	The device requests a cookie when the SA in negotiation status exceeds the threshold.
Responder receive invalid cookie for IKEV2_COOKIE request	The received cookie is invalid.
Responder receive no cookie for IKEV2_COOKIE request	No cookie is received.
System abnormal	The system is abnormal.
Fail decrypt	Decryption failed.
Fail encrypt	Encryption failed.
Fail integrity check	Integrity check failed.
No memory, fail send packet	Packet sending failed due to insufficient memory.
No memory, fail process packet	Packet parsing failed due to insufficient memory.
System limited	System restriction.
First packet speed limited	The rate of the first packet is limited.
License limited	License restriction.

Display notification message statistics on IPSec tunnels negotiated using IKEv2.

```
<HUAWEI> display ikev2 statistics notify-info

Ikev2 notification statistics:
------------------------------------------------------------------------------
Notification:
INVALID_IKE_SPI notification              send:0          receive:0
```

```
INVALID_MAJOR_VERSION notification          send:0          receive:0
INVALID_SYNTAX notification                 send:0          receive:0
INVALID_IPSEC_SPI notification              send:0          receive:0
INVALID_KE_PAYLOAD notification             send:0          receive:0
SINGLE_PAIR_REQUIRED notification           send:0          receive:0
NO_ADDITIONAL_SA notification               send:0          receive:0
TS_UNACCEPTABLE notification                send:0          receive:0
INVALID_IPSEC_SELECTORS notification        send:0          receive:0
INITIAL_CONTACT payload                     send:0          receive:0
SET_WINDOW_SIZE payload                     send:0          receive:0
NAT_DETECTION_SOURCE_IP payload             send:0          receive:0
NAT_DETECTION_DESTINATION_IP payload        send:0          receive:0
USE_TRANSPORT_MODE notification             send:0          receive:0
REKEY_SA notification                       send:0          receive:0
ESP_TFC_PADDING_NOT_SUPPORTED payload       send:0          receive:0
AUTH_LIFETIME payload                       send:0          receive:0
REDIRECT payload                            send:0          receive:0
DELETE_OLD_CHILDSA notification             send:0          receive:0
DSCP payload                                send:0          receive:0
IKEV2_FRAGMENTATION_SUPPORTED payload       send:0          receive:0
------------------------------------------------------------------------------
```

Table 10-16 Description of the **display ikev2 statistics notify-info** command output

Item	Description
Ikev2 notification statistics	IKEv2 notification message statistics.
Notification	IKEv2 notification message.
INVALID_IKE_SPI notification	Invalid IKE SPI notification message.
INVALID_MAJOR_VERSION notification	Invalid Major version number notification message.
INVALID_SYNTAX notification	Invalid syntax notification message.
INVALID_IPSEC_SPI notification	Invalid IPSec SPI notification message.
INVALID_KE_PAYLOAD notification	Incorrect KE payload.
SINGLE_PAIR_REQUIRED notification	Single_Pair_Required notification message.
NO_ADDITIONAL_SA notification	No additional SA notification message.
TS_UNACCEPTABLE notification	Invalid TS payload.
INVALID_IPSEC_SELECTORS notification	Invalid IPSec Selectors notification message.
INITIAL_CONTACT payload	Initial_Contact notification message.

Item	Description
SET_WINDOW_SIZE payload	Set_Window_Size notification message.
NAT_DETECTION_SOURCE_IP payload	NAT source IP notification message.
NAT_DETECTION_DESTINATION_IP payload	NAT destination IP notification message.
USE_TRANSPORT_MODE notification	Transport mode notification message.
REKEY_SA notification	SA re-negotiation notification message.
ESP_TFC_PADDING_NOT_SUPPORTED payload	ESP_TFC_Padding_Not_Supported notification message.
AUTH_LIFETIME payload	Auth_Lifetime notification message.
REDIRECT payload	Redirection notification message.
DELETE_OLD_CHILDSA notification	Delete_Old_ChildSa notification message.
DSCP payload	DSCP notification message.
IKEV2_FRAGMENTATION_SUPPORTED payload	IKEV2_FRAGMENTATION_SUPPORTED notify payload message.
send	Number of sent messages.
receive	Number of received messages.

Display packet statistics on IPSec tunnels negotiated using IKEv2.

```
<HUAWEI> display ikev2 statistics packet

Packet statistics:
-----------------------------------------------------------------------------
Ike_init request  send   :0           Ike_init request   recv   :0
Ike_init response recv   :0           Ike_init response  send   :0
Ike_auth request  send   :0           Ike_auth request   recv   :0
Ike_auth response recv   :0           Ike_auth response  send   :0
Create_child req  send   :0           Create_child req   recv   :0
Create_child resp recv   :0           Create_child resp  send   :0
Ike_info request  send   :0           Ike_info request   recv   :0
Ike_info response recv   :0           Ike_info response  send   :0
Del_info request  send   :0           Del_info request   recv   :0
Del_info response recv   :0           Del_info response  send   :0
DPD_info request  send   :0           DPD_info request   recv   :0
DPD_info response recv   :0           DPD_info response  send   :0
DPD_info req recv drop   :0           DPD_info resp recv drop   :0
Fragment message  send   :0           Fragment message   recv   :0
```

```
Fragment packet   send   :0           Fragment packet    recv   :0

Ike_init request resend  :0
Ike_auth request resend  :0
Create_child req resend  :0
Ike_info request resend  :0
--------------------------------------------------------------------------------
```

Table 10-17 Description of the **display ikev2 statistics packet** command output

Item	Description
Packet statistics	IPSec packet statistics.
Ike_init request send	Number of sent IKE SA initialization exchange (ike_init) request packets.
Ike_init request recv	Number of received ike_init request packets.
Ike_init response recv	Number of received ike_init response packets.
Ike_init response send	Number of sent ike_init response packets.
Ike_auth request send	Number of sent IKE authentication exchange (ike_auth) request packets.
Ike_auth request recv	Number of received ike_auth request packets.
Ike_auth response recv	Number of received ike_auth response packets.
Ike_auth response send	Number of sent ike_auth response packets.
Create_child req send	Number of sent IPSec SA for sub-tunnel creation (create_child) request packets.
Create_child req recv	Number of received create_child request packets.
Create_child resp recv	Number of received create_child response packets.
Create_child resp send	Number of sent create_child response packets.
Ike_info request send	Number of sent IKE notification exchange (ike_info) request packets.
Ike_info request recv	Number of received ike_info request packets.
Ike_info response recv	Number of received ike_info response packets.
Ike_info response send	Number of sent ike_info response packets.

Item	Description
Del_info request send	Number of sent tunnel information deletion (del_info) request packets.
Del_info request recv	Number of received del_info request packets.
Del_info response recv	Number of received del_info response packets.
Del_info response send	Number of sent del_info response packets.
Dpd_info request send	Number of sent DPD information (dpd_info) request packets.
Dpd_info request recv	Number of received dpd_info request packets.
Dpd_info response recv	Number of received dpd_info response packets.
Dpd_info response send	Number of sent dpd_info response packets.
Dpd_info req recv drop	Number of received dpd_info request packets that are dropped.
Dpd_info resp recv drop	Number of received dpd_info response packets that are dropped.
Fragment message send	Number of sent fragment messages.
Fragment message recv	Number of received fragment messages.
Fragment packet send	Number of sent fragment packets.
Fragment packet recv	Number of received fragment packets.
Ike_init request resend	Number of retransmitted ike_init requests.
Ike_auth request resend	Number of retransmitted ike_auth requests.
Create_child req resend	Number of retransmitted create_child requests.
Ike_info request resend	Number of retransmitted ike_info requests.

Display SA statistics on IPSec tunnels negotiated using IKEv2.

```
<HUAWEI> display ikev2 statistics sa

Sa establish and offline statistic:
------------------------------------------------------------------------------
Establish:
Initiator request phase1 negotiation                         :33
Initiator request phase2 negotiation                         :16
Initiator request and success phase1 negotiation             :10
Initiator request and success phase2 negotiation             :41
Responder response phase1 negotiation                        :0
Responder response phase2 negotiation                        :0
Responder response and success phase1 negotiation            :0
Responder response and success phase2 negotiation            :0
Offline:
Receive delete info      :1          Config modify           :0
Manual reset             :1          Dpd timeout             :0
Phase1 hardware expire   :0          Phase2 hardware expire  :0
Phase1 replace           :0          Phase2 replace          :0
Aaa cut user             :0          Reauth timeout          :0
Flow overlap             :0          IP address syn failed   :0
Port mismatch            :0          Kick old SA             :0
CPU table updated        :0          SPI conflict            :0
EAP delete old sa        :0          Hash gene adjusted      :0
------------------------------------------------------------------------------
```

Table 10-18 Description of the **display ikev2 statistics sa** command output

Item	Description
Sa establish and offline statistic	SA establishment and deletion information.
Establish	Statistics on established IPSec tunnels.
Initiator request phase1 negotiation	Number of times that the initiator requests phase 1 negotiation.
Initiator request phase2 negotiation	Number of times that the initiator requests phase 2 negotiation.
Initiator request and success phase1 negotiation	Number of times that the initiator succeeds in requesting phase 1 negotiation.
Initiator request and success phase2 negotiation	Number of times that the initiator succeeds in requesting phase 2 negotiation.
Responder response phase1 negotiation	Number of times that the responder responds to phase 1 negotiation.
Responder response phase2 negotiation	Number of times that the responder responds to phase 2 negotiation.
Responder response and success phase1 negotiation	Number of times that the responder succeeds in responding to phase 1 negotiation.
Responder response and success phase2 negotiation	Number of times that the responder succeeds in responding to phase 2 negotiation.

Item	Description
Offline	Statistics on deleted IPSec tunnels.
Receive delete info	Number of times that the device receives tunnel deletion messages.
Config modify	Number of times that the tunnel is deleted by modifying the configuration.
Manual reset	Number of times that the tunnel is deleted manually.
Phase1 hardware expire	Number of times that the phase 1 tunnel is deleted due to hard timeout.
Phase2 hardware expire	Number of times that the phase 2 tunnel is deleted due to hard timeout.
Phase1 replace	Number of phase 1 tunnel re-negotiation times.
Phase2 replace	Number of phase 2 tunnel re-negotiation times.
Aaa cut user	Number of tunnel deletion times caused by forced user offline.
Dpd timeout	Number of tunnel deletion times caused by DPD timeout.
Reauth timeout	Number of tunnel deletion times caused by re-authentication timeout.
Flow overlap	Number of tunnel deletion times caused by the conflict between the IP address in the encrypted flow and remote IP address.
IP address syn failed	Number of tunnel deletion times caused by the failure to synchronize IP addresses.
Port mismatch	Number of tunnel deletion times caused by the UDP port mismatch.
Kick old SA	Number of tunnel deletion times caused by a flow conflict.
CPU table updated	Number of tunnel deletion times caused by a CPU table update.
SPI conflict	Number of tunnel deletion times caused by an SPI conflict.
EAP delete old sa	Number of times the device deletes the old SA during EAP authentication.
Hash gene adjusted	Number of tunnel deletion times caused by hash factor adjustment.

10.3.10 display ipsec efficient-vpn

Function

The **display ipsec efficient-vpn** command displays Efficient VPN policy information.

Format

display ipsec efficient-vpn [**brief** | **capability** | **name** *efficient-vpn-name*]

Parameters

Parameter	Description	Value
brief	Displays brief information about Efficient VPN policies.	-
capability	Displays the IPSec configuration supported by an Efficient VPN policy.	-
name *efficient-vpn-name*	Displays information about a specified Efficient VPN policy.	The value is an existing Efficient VPN policy name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After the Efficient VPN policy is configured, you can run this command to know the configuration information of the Efficient VPN policy, such as the name, interface, authentication method, IKE version, DH algorithm, and PFS algorithm of the Efficient VPN.

Example

Display brief information about Efficient VPN policies.

```
<HUAWEI> display ipsec efficient-vpn brief
 Total number of IPSec efficient-vpn: 1

 Efficient-vpn name       Efficient-vpn mode
 ------------------------------------------
 v1                       client
```

Display information about the Efficient VPN policy named **easyvpn_1**.

```
<HUAWEI> display ipsec efficient-vpn name easyvpn_1
===========================================IPSec efficient-vpn name: easyvpn_1
Using interface         : Vlanif27
===========================================
 IPSec Efficient-vpn Mode  : 1 (1:Client 2:Network 3:Network-plus)
 ACL Number                :
 Auth Method               : 8 (8:PSK)
 VPN name                  : wbh
 Local ID Type             : 11 (1:IP 2:Name 3:User-fqdn 11:Key-id)
 IKE Version               : 2 (1:IKEv1 2:IKEv2)
 Remote Address            : 10.10.10.1
 Pre Shared Key Cipher     : ******
 DH Group                  : DH group 14
 PFS Type                  : DH group 14 Remote Name               :
 Re-auth interval          : 400 seconds
 Anti-replay window size   : 0
 Service-scheme name       : ser
 DPD message  type         : seq-notify-hash
 DPD message  learning     : enable
 Interface loopback        : LoopBack0
 Interface loopback IP     : 1.1.1.1/32
```

Table 10-19 Description of the **display ipsec efficient-vpn** command output

Item	Description
Total number of IPSec efficient-vpn	Total number of the Efficient VPN policy.
Efficient-vpn name/IPSec Efficient-vpn Name	Name of the Efficient VPN policy. To configure an Efficient VPN policy, run the **ipsec efficient-vpn (system view)** command.
Using interface	Interface to which an Efficient VPN policy is applied.
Efficient-vpn mode/IPSec Efficient-vpn Mode	Mode used by the Efficient VPN policy. ● 1: client ● 2: network ● 3: network-plus To configure an Efficient VPN policy, run the **ipsec efficient-vpn (system view)** command.
ACL Number	ACL used by the Efficient VPN policy. To configure an ACL referenced by an Efficient VPN policy, run the **security acl** command.
Auth Method	Authentication method used by the Efficient VPN policy is pre-shared key authentication (8).
VPN name	Name of the VPN instance bound to the Efficient VPN policy. To bind a VPN instance to an Efficient VPN policy, run the **sa binding vpn-instance (Efficient VPN policy view)** command.

Item	Description
Local ID Type	Local ID type in IKE negotiation. ● 1: IP ● 2: Name ● 3: User-fqdn ● 11: Key-id To set the local ID type, run the **local-id-type** command.
IKE Version	Configured IKE version: ● 1: IKEv1 ● 2: IKEv2
Remote Address	IP address of the remote IKE peer. To configure the remote IP address, run the **remote-address** command.
Pre Shared Key Cipher	Pre-shared key. To configure a pre-shared key, run the **pre-shared-key** (Efficient VPN policy view) command.
DH Group	DH group used in IKE negotiation. To specify a DH group, run the **dh** command.
PFS Type	Perfect Forward Secrecy (PFS) used in IKE negotiation. To specify a PFS, run the **pfs** command.
Remote Name	Remote name used in IKE negotiation.
Re-auth interval	IKEv2 re-authentication interval. To configure an IKEv2 re-authentication interval, run the **re-authentication interval** command.
Anti-replay window size	IPSec anti-replay window size. This field is available only when the IPSec anti-replay function is enabled. To set the IPSec anti-replay window size, run the **anti-replay window** command. When the value is 0, the IPSec anti-replay function is enabled in the system view. To enable this function, run the **ipsec anti-replay enable** command.
Service-scheme name	Name of the bound service scheme. To configure the name of the bound service scheme, run the **service-scheme** command.

Item	Description
DPD message type	Sequence of the payload in DPD packets. - seq-notify-hash - seq-hash-notify To configure the sequence of the payload, run the **dpd msg** command.
DPD message learning	Whether automatic learning of the payload sequence of DPD packets is enabled. - enable - disable To configure the automatic learning function, run the **dpd msg notify-hash-sequence learning** command.
Interface loopback	Number of the loopback interface. The loopback interface is dynamically created on the remote device and is used to establish an IPSec tunnel with the Efficient VPN server.
Interface loopback IP	IP address of the loopback interface, which is allocated by the Efficient VPN server to the remote device.

Display the IPSec configuration supported by an Efficient VPN policy.

```
<HUAWEI> display ipsec efficient-vpn capability

  IKEv1 Global Supported Algorithms
------------------------------------------------------
  Supported DH Groups:
    DH_GROUP1 | DH_GROUP2 | DH_GROUP5 | DH_GROUP14 | DH_GROUP19 | DH_GROUP20 |
DH_GROUP21
  Supported Encryption Algorithms:
    DES | 3DES | AES128 | AES192 | AES256
  Supported Authentication Algorithms:
    MD5 | SHA1 | SHA2-256 | SHA2-384 | SHA2-512
  Supported Authentication Methods:
    Pre Shared Key

  IKEv2 Global Supported Algorithms
------------------------------------------------------
  Supported DH Groups:
    DH_GROUP1 | DH_GROUP2 | DH_GROUP5 | DH_GROUP14 | DH_GROUP19 | DH_GROUP20 |
DH_GROUP21
  Supported Encryption Algorithms:
    DES | 3DES | AES128 | AES192 | AES256
  Supported Integrity Algorithms:
    MD5 | SHA1 | AES-XCBC-96 | SHA2-256 | SHA2-384 | SHA2-512
  Supported PRF:
    PRF-MD5 | PRF-SHA1 | PRF-AES-XCBC-128 | PRF-SHA2-256 | PRF-SHA2-384 |
    PRF-SHA2-512

  IPSEC Global Supported Algorithms
------------------------------------------------------
  Supported Security Protocols:
    ESP
```

```
Supported Encapsulation Modes:
  TUNNEL
Supported Authentication Algorithms:
  MD5 | SHA1 | SHA256 | SHA384 | SHA512
Supported Encryption Algorithms:
  DES | 3DES | AES128 | AES192 | AES256
```

NOTE

- The MD5 and SHA-1 authentication algorithms have security risks; therefore, you are advised to use SHA-2 preferentially.
- The DES and 3DES encryption algorithms have security risks; therefore, you are advised to use AES preferentially.
- The PRF-MD5 and PRF-SHA1 algorithms have security risks; therefore, you are advised to use PRF-AES-XCBC-128 or SHA-2 preferentially.

Table 10-20 Description of the **display ipsec efficient-vpn capability** command output

Item	Description
IKEv1 Global Supported Algorithms	Supported algorithms when IKEv1 is specified in the Efficient VPN policy. The server can use only the supported algorithms to negotiate with the remote device.
Supported DH Groups	Supported DH groups when IKEv1 or IKEv2 is used.
Supported Encryption Algorithms	Supported encryption algorithms when IKEv1 or IKEv2 is used.
Supported Authentication Algorithms	Supported authentication algorithms when IKEv1 is used. To configure an authentication algorithm on the server.
Supported Authentication Methods	Supported authentication algorithms when IKEv1 is used: Pre Shared Key (pre-shared key authentication).
IKEv2 Global Supported Algorithms	Supported algorithms when IKEv2 is specified in the Efficient VPN policy. The server can use only the supported algorithms to negotiate with the remote device.
Supported Integrity Algorithms	Supported integrity algorithms when IKEv2 is used. To configure an integrity algorithm on the server.
Supported PRF	Supported PRF algorithms when IKEv2 is used.
IPSEC Global Supported Algorithms	Algorithms supported by the system.
Supported Security Protocols	Security protocol supported by IPSec: ESP.

Item	Description
Supported Encapsulation Modes	Encapsulation mode supported by IPSec: tunnel mode.
Supported Authentication Algorithms	Authentication algorithm supported by IPSec.
Supported Encryption Algorithms	Encryption algorithm supported by IPSec.

10.3.11 display ipsec global config

Function

The **display ipsec global config** command displays IPSec global configurations.

Format

display ipsec global config

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To view IPSec global configurations, run the **display ipsec global config** command. The global configurations include the global SA lifetime and whether the anti-replay function is enabled.

Example

Display IPSec global configurations.

```
<HUAWEI> display ipsec global config
IPSec Global Config:
-----------------------------------------------------------------
  IPSec sa global-duration time-based(seconds)        : 3600
  IPSec sa global-duration traffic-based(kbytes)      : 1843200
  IPSec anti-replay                                   : enable
-----------------------------------------------------------------
```

Table 10-21 Description of the **display ipsec global config** command output

Item	Description
IPSec Global Config	IPSec global configurations.
IPSec sa global-duration time-based(seconds)	Time-based global SA lifetime, in seconds. To set the time-based global SA lifetime, run the **ipsec sa global-duration time-based** command.
IPSec sa global-duration traffic-based(kbytes)	Traffic-based global SA lifetime, in kilobytes. To set the traffic-based global SA lifetime, run the **ipsec sa global-duration traffic-based** command.
IPSec anti-replay	Whether the anti-replay function is enabled. To configure the anti-replay function, run the **ipsec anti-replay enable** command.

10.3.12 display ipsec interface brief

Function

The **display ipsec interface brief** command displays IPSec policies bound to an interface.

Format

display ipsec interface brief

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After an IPSec policy is bound to an interface, you can run this command to view information about the bound IPSec policy, such as the policy name and interface to which the policy is bound.

Example

Display IPSec policies bound to an interface.

```
<HUAWEI> display ipsec interface brief
------------------------------------------------
```

```
 IPSec policy        : evpn_client
 Using interface     : Vlanif100
 IPSec policy number : -
 IPSec policy Type   : efficient-vpn
------------------------------------------------
```

Table 10-22 Description of the **display ipsec interface brief** command output

Item	Description
IPSec policy	Sequence number of the IPSec policy bound to the interface. Name of the IPSec policy bound to an interface. To apply an IPSec policy to an interface, run the **ipsec efficient-vpn (interface view)** command.
Using interface	Interface to which an IPSec policy is applied.
IPSec policy number	Sequence number of the IPSec policy bound to the interface.
IPSec policy Type	Type of the IPSec policy bound to an interface.

10.3.13 display ipsec history record

Function

The **display ipsec history record** command displays history information about IPSec tunnels.

Format

display ipsec history record [**remote-address** *remote-address*]

Parameters

Parameter	Description	Value
remote-address *remote-address*	Displays history information about the IPSec tunnel with the specified remote IP address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ipsec history record** command to view the reason and time of the last teardown of the IPSec tunnel.

Example

Display history information about IPSec tunnels.

```
<HUAWEI> display ipsec history record
IPSec history record:
Current record number: 1
===============================
Interface              : Vlanif100
remote-address         : 2.1.1.1
remote-port            : 500
VPN instance           : huawei
flow-source            : 10.1.1.1/255.255.255.255
flow-destination       : 10.2.2.2/255.255.255.255
last-offline-reason    : peer request
last-offline-time      : 2017-07-17 20:25:31
offline-times-in-24Hour: 1
```

Table 10-23 Description of the **display ipsec history record** command output

Item	Description
IPSec history record	Display history information about IPSec tunnels.
Current record number	Current record number of the teardown of the IPSec tunnel.
Interface	Interface to which an IPSec policy is applied.
remote-address	Remote IP address of an IPSec tunnel.
remote-port	Remote UDP port number.
VPN instance	Name of a VPN instance.
flow-source	Source address segment of data flows.
flow-destination	Destination address segment of data flows.

Item	Description
last-offline-reason	Reason of the last teardown of an IPSec tunnel. ● dpd timeout: Dead peer detection (DPD) times out. ● peer request: The remote end has sent a message, asking the local end to tear down the tunnel. ● config modify or manual offline: An SA is deleted due to configuration modification or an SA is manually deleted. ● phase1 hard expiry: Hard lifetime expires in phase 1 (no new SA negotiation success message is received). ● phase2 hard expiry: Hard lifetime expires in phase 2. ● heartbeat timeout: heartbeat detection times out. ● modecfg address soft expiry: The IP address lease applied by the remote end from the server expires. ● re-auth timeout: An SA is deleted due to reauthentication timeout. ● aaa cut user: The AAA module disconnects users. ● hard expiry triggered by port mismatch: A hard timeout occurs due to mismatch NAT port number. ● spi conflict: An SPI conflict occurs. ● phase1 sa replace: The new IKE SA replaces the old IKE SA. ● phase2 sa replace: The new IPSec SA replaces the old IPsec SA. ● receive invalid spi notify: The device receives an invalid SPI notification. ● dns resolution status change: DNS resolution status changes. ● ikev1 phase1-phase2 sa dependent offline: The device deletes the associated IPSec SA when deleting an IKEv1 SA. ● exchange timeout: Packet interaction timeout.
last-offline-time	Last time an IPSec tunnel was torn down.
offline-times-in-24Hour	Number of times an IPSec tunnel was torn down within 24 hours.

10.3.14 display ipsec sa efficient-vpn

Function

The **display ipsec sa efficient-vpn** command displays IPSec SA information.

Format

display ipsec sa efficient-vpn *efficient-vpn-name*

Parameters

Parameter	Description	Value
efficient-vpn-name	Displays SA information of an Efficient VPN policy with a specified name.	The value is an existing Efficient VPN policy name.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check Efficient VPN SA information, such as the local and remote addresses of IPSec tunnels, source and destination addresses of data flows, and SA lifetime.

Example

Display information about the IPSec SA of Efficient VPN policy.

```
<HUAWEI> display ipsec sa efficient-vpn evpn

ipsec sa information:

===============================
Interface: Vlanif20
===============================

  -----------------------------
  IPSec efficient-vpn name: "evpn"
  Mode                 : EFFICIENTVPN-CLIENT MODE
  -----------------------------
    Connection ID     : 268435456
    Tunnel index      : 4026531842
    Encapsulation mode: Tunnel
    Holding time      : 0d 0h 4m 29s
    Tunnel local      : 10.10.10.1/500
    Tunnel remote     : 10.2.1.2/500
    Flow source       : 10.10.10.6/255.255.255.255 0/0
    Flow destination  : 0.0.0.0/0.0.0.0 0/0
    Flow dscp         : af11

    [Outbound ESP SAs]
      SPI: 2703436139 (0xa123296b)
      Proposal: ESP-ENCRYPT-3DES-192 ESP-AUTH-SHA1
      SA remaining key soft duration (kilobytes/sec): 4666163/2960
      SA remaining key hard duration (kilobytes/sec): 5242880/3355
      Max sent sequence-number: 0
      UDP encapsulation used for NAT traversal: N
      SA encrypted packets (number/bytes): 0/0
```

```
[Inbound ESP SAs]
  SPI: 2303751342 (0x895074ae)
  Proposal: ESP-ENCRYPT-3DES-192 ESP-AUTH-SHA1
  SA remaining key soft duration (kilobytes/sec): 4666163/2960
  SA remaining key hard duration (kilobytes/sec): 5242880/3355
  Max received sequence-number: 0
  UDP encapsulation used for NAT traversal: N
  SA decrypted packets (number/bytes): 0/0
  Anti-replay : Enable
  Anti-replay window size: 1024
```

Table 10-24 Description of the **display ipsec sa efficient-vpn** command output

Item	Description
ipsec sa information	Information about the IPSec SA.
Interface	Interface to which the Efficient VPN policy is applied.
IPSec efficient-vpn name	Name of the Efficient VPN policy. To configure the Efficient VPN policy name, run the **ipsec efficient-vpn** command in the system view.
Mode	Mode in which an Efficient VPN policy is created.
Connection ID	ID of the IPSec SA connection.
Tunnel index	Tunnel index.
Encapsulation mode	Encapsulation mode in an IPSec proposal.
Holding time	Time elapsed since an IPSec tunnel was created.
Tunnel local	IP address and NAT traversal port of the local interface. To configure the IP address of the local interface, run the **tunnel local** command.
Tunnel remote	IP address and NAT traversal port of the remote interface. To configure the IP address of the remote interface, run the **remote-address** command in the Efficient VPN policy view.
Flow source	Source IP address segment of the data flow sent from the local end and the protocol number and port number of the ACL.
Flow destination	Destination IP address segment of the data flow sent from the local end and the protocol number and port number of the ACL.
Flow dscp	DSCP value of the data flow sent from the local end.
Outbound ESP SAs	Outbound IPSec SA information using ESP.
SPI	SPI of an SA.
Proposal	IPSec proposal.

Item	Description
SA remaining key soft duration (kilobytes/sec)	Remaining soft lifetime of an IPSec SA, in kilobytes or seconds.
SA remaining key hard duration (kilobytes/sec)	Remaining hard lifetime of an IPSec SA, in kilobytes or seconds. To set the SA lifetime, run the **ipsec sa global-duration** command.
Max sent sequence-number	Maximum sequence number of sent packets. The sequence number increases during communication and is used for anti-replay.
UDP encapsulation used for NAT traversal	Whether NAT traversal is enabled: ● Y ● N
SA encrypted packets (number/bytes)	Number of packets that are successfully encrypted using the IPSec SA.
Inbound ESP SAs	Inbound IPSec SA information using ESP.
Max received sequence-number	Maximum sequence number of received packets.
SA decrypted packets (number/bytes)	Number of packets that are successfully decrypted using the IPSec SA.
Anti-replay	Whether the anti-replay function is enabled for an IPSec tunnel: ● Enable ● disable To configure the anti-replay function for an IPSec tunnel, run the **ipsec anti-replay enable** command.
Anti-replay window size	IPSec anti-replay window size. This field is valid only when the IPSec anti-replay function is enabled. To set the IPSec anti-replay window size, run the **anti-replay window** or **ipsec anti-replay window** command.

10.3.15 display ipsec packet statistics

Function

The **display ipsec packet statistics** command displays IPSec packet statistics.

Format

display ipsec packet statistics

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

You can run the **display ipsec packet statistics** command to view IPSec packet statistics, including statistics about incoming or outgoing packets that are protected, statistics about encrypted and decrypted packets, detailed statistics about discarded packets that are protected, and statistics about IKE negotiation related packets. The IPSec packet statistics facilitate IPSec fault diagnosis and maintenance.

Precautions

The **display ipsec packet statistics** command only displays the number of plaintext bytes.

Example

Display statistics about all IPSec packets.

```
<HUAWEI> display ipsec packet statistics
 IPSec statistics information:
 Number of IPSec tunnels: 1
 Number of standby IPSec tunnels: 0
 the security packet statistics:
   input/output security packets: 0/0
   input/output security bytes: 0/0
   input/output dropped security packets: 0/0
   the encrypt packet statistics:
     send chip: 0, recv chip: 0, send err: 0
     local cpu: 0, other cpu: 0, recv other cpu: 0
     intact packet: 0, first slice: 0, after slice: 0
   the decrypt packet statistics:
     send chip: 0, recv chip: 0, send err: 0
     local cpu: 0, other cpu: 0, recv other cpu: 0
     reass  first slice: 0, after slice: 0
   dropped security packet detail:
     can not find SA: 0, wrong SA: 0
     authentication: 0, replay: 0
     front recheck: 0, after recheck: 0
     change cpu enc: 0, dec change cpu: 0
     fib search: 0, output l3: 0
     flow err: 0, slice err: 0, byte limit: 0
  negotiate about packet statistics:
```

```
IKE fwd packet ok: 0, err: 0
IKE ctrl packet inbound ok: 0, outbound ok: 0
SoftExpr: 0, HardExpr: 0, DPDOper: 0
trigger ok: 0, switch sa: 0, sync sa: 0
recv IKE nat keepalive: 0, IKE input: 0
```

Table 10-25 Description of the **display ipsec packet statistics** command output

Item	Description
IPSec statistics information	Statistics about IPSec packets.
Number of IPSec tunnels	Number of the IPSec tunnels.
Number of standby IPSec tunnels	Number of the standby IPSec tunnels.
the security packet statistics	Statistics about packets that are protected.
input/output security packets	Number of incoming or outgoing packets that are protected.
input/output security bytes	Number of incoming or outgoing bytes that are protected.
input/output dropped security packets	Number of discarded incoming or outgoing packets that are protected.
the encrypt packet statistics	Statistics about encrypted packets.
send chip	Number of packets sent to the hardware for encryption and decryption.
recv chip	Number of packets encrypted and decrypted by hardware.
send err	Number of packets that fail to be sent to hardware for encryption and decryption.
local cpu	Number of packets encrypted and decrypted by the local CPU.
other cpu	Number of packets forwarded to another CPU for encryption and decryption.
recv other cpu	Number of packets received from another CPU for encryption and decryption.
intact packet	Number of non-fragmented encrypted packets.
first slice	Number of initial fragmented packets.
after slice	Number of non-initial fragmented packets.

Item	Description
the decrypt packet statistics	Statistics about decrypted packets.
reass first slice	Number of initial packets that are reassembled.
after slice	Number of non-initial packets that are reassembled.
dropped security packet detail	Detailed statistics about discarded packets that are protected.
can not find SA	Number of packets for which SAs are not found.
wrong SA	Number of packets with invalid SAs.
authentication	Number of packets that fail to be authenticated.
replay	Number of discarded packets due to replay check.
front recheck	Number of discarded packets due to IPSec pre-check.
after recheck	Number of discarded packets due to IPSec post-check.
change cpu enc	Number of encrypted packets that fail to be forwarded.
dec change cpu	Number of decrypted packets that fail to be forwarded.
fib search	Number of encrypted packets that are discarded due to route searching failure.
output l3	Number of encrypted packets that fail to be sent.
flow err	Number of packets discarded because negotiation is triggered.
slice err	Number of IPSec packets that fail to be fragmented.
byte limit	Number of discarded packets due to traffic limit.
negotiate about packet statistics	Statistics about IKE negotiation packets.
IKE fwd packet ok	Number of IKE packets sent to the IKE process.

Item	Description
err	Number of IKE packets that fail to be sent to the IKE process.
IKE ctrl packet inbound ok	Number of IKE packets received by the control plane.
outbound ok	Number of IKE packets sent by the control plane.
SoftExpr	Number of traffic soft timeouts.
HardExpr	Number of traffic hard timeouts.
DPDOper	Number of times DPD is performed in on-demand DPD mode.
trigger ok	Number of times that negotiation is triggered.
switch sa	Number of times the local device receives data encrypted with the new SA and instructs the IKE process to replace the SA.
sync sa	Number of times the active device notifies the IKE process that the SA 3-tuple (remote address, SPI, protocol ID) does not exist on the standby device.
recv IKE nat keepalive	Number of received IKE nat keepalive packets.
IKE input	Number of received IKE packets.

10.3.16 display ipsec statistics tunnel-number

Function

The **display ipsec statistics tunnel-number** command displays the number of IPSec tunnels.

Format

display ipsec statistics tunnel-number

Parameters

None.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run this command to check the number of IPSec tunnels.

Example

Display the number of IPSec tunnels.

```
<HUAWEI> display ipsec statistics tunnel-number
  IPSec tunnel totals: 0
  IPSec tunnel specifications: 4000
```

Table 10-26 Description of the **display ipsec statistics tunnel-number** command output

Item	Description
IPSec tunnel totals	Number of IPSec tunnels.
IPSec tunnel specifications	IPSec tunnel specifications.

10.3.17 dpd msg

Function

The **dpd msg** command configures the payload sequence of DPD packets on the specified IKE peer.

The **undo dpd msg** command restores the default payload sequence of DPD packets on the specified IKE peer.

By default, the payload sequence of DPD packets on an IKE peer is **seq-notify-hash**.

Format

dpd msg { **seq-hash-notify** | **seq-notify-hash** }

undo dpd msg

Parameters

Parameter	Description	Value
seq-hash-notify	Indicates that in a DPD packet, the hash payload is before the notify payload.	-
seq-notify-hash	Indicates that in a DPD packet, the notify payload is before the hash payload.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

DPD packets carrying the notify payload and hash payload are exchanged bidirectionally. The notify payload sent by the initiator carries an R-U-THERE message equivalent to a Hello packet, and the notify payload sent by the responder carries an R-U-THERE-ACK message equivalent to an ACK packet.

The payload sequence of DPD packets sent by different devices may be different. IKE peers on both ends must send DPD packets with the same payload sequence; otherwise, DPD does not take effect. In this case, run the **dpd msg** command to set the same payload sequence of DPD packets on both ends.

Precautions

This command applies only when an IKE peer uses IKEv1.

Example

Set the payload sequence of DPD packets to **hash-notify**.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] dpd msg seq-hash-notify
```

10.3.18 dpd msg notify-hash-sequence learning

Function

The **dpd msg notify-hash-sequence learning** command enables automatic learning of the payload sequence of DPD packets.

The **undo dpd msg notify-hash-sequence learning** command disables automatic learning of the payload sequence of DPD packets.

By default, automatic learning of the payload sequence of DPD packets is enabled.

Format

dpd msg notify-hash-sequence learning

undo dpd msg notify-hash-sequence learning

Parameters

None

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

When DPD is used to detect the IKEv1 peer status, the payload sequence of DPD packets on both ends must be consistent. Otherwise, DPD does not take effect, and even the IPSec tunnel between both ends flaps.

If the local end does not know the payload sequence of DPD packets sent from the remote end, run the **dpd msg notify-hash-sequence learning** command on the local end to enable automatic learning of the payload sequence of DPD packets. When the local end receives a DPD packet from the remote end, the local end learns the payload sequence of the DPD packet and sends a DPD packet in the same payload sequence.

Example

Enable automatic learning of the payload sequence of DPD packets.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] dpd msg notify-hash-sequence learning
```

10.3.19 ike dscp

Function

The **ike dscp** command sets a global DSCP priority of IKE packets.

The **undo ike dscp** command cancels the DSCP priority configuration.

By default, the global DSCP priority of IKE packets is 0.

Format

ike dscp *dscp-value*

undo ike dscp

Parameters

Parameter	Description	Value
dscp-value	Specifies the global DSCP priority of IKE packets.	The value can be an integer or a string of characters. That is, the value can be an integer that ranges from 0 to 63, or a string of AF11 to AF13, AF21 to AF23, AF31 to AF33, AF41 to AF43, CS1 to CS7, EF, or default.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

IKE packets are used for IKE SA and IPSec SA negotiation or DPD. When IKE packets are lost during transmission, IPSec SAs may fail to be negotiated. As a result, packets that need to be protected by IPSec are not protected. The DSCP priority of IKE packets can be improved so that IKE packets are processed preferentially. IKE packet transmission reliability is therefore improved.

To configure the DSCP priority for IKE packets of all IKE peers, run this command.

Example

Set a global DSCP priority of IKE packets to CS2.

```
<HUAWEI> system-view
[HUAWEI] ike dscp cs2
```

10.3.20 ike heartbeat

Function

The **ike heartbeat** command sets heartbeat parameters.

The **undo ike heartbeat** command restores the default configuration.

By default, a heartbeat packet uses old type sequence number mechanism and does not carry the SPI list.

Format

ike heartbeat { **seq-num** { **new** | **old** } | **spi-list** }

undo ike heartbeat { **seq-num** | **spi-list** }

Parameters

Parameter	Description	Value
seq-num { **new** | **old** }	Configures the sequence number mechanism for heartbeat packets. ● **new**: The sequence number mechanism conforms to draft-ietf-ipsec-heartbeats-00.txt. ● **old**: The sequence number mechanism conforms to the standard that before draft-ietf-ipsec-heartbeats-00.txt emerges.	-
spi-list	Configures heartbeat packets to carry the SPI list.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In IPSec communication, if the local end becomes faulty and the remote end does not detect the fault because of system failures, the remote end still sends IPSec packets to the local end, causing traffic loss. Heartbeat detection solves this problem. After heartbeat detection is enabled, the local end periodically sends detection packets to the remote end. If the remote end does not receive packets after the heartbeat timer expires, the remote end considers the local end faulty. IKE can send heartbeat packets to detect IKE peer faults and maintain the IKE SA link status.

Precautions

The two ends must use the same heartbeat parameters.

If you run the **ike heartbeat** { **seq-num** { **new** | **old** } | **spi-list** } command multiple times, only the latest configuration takes effect.

Example

Configure the sequence number mechanism for heartbeat packets to **new**.

```
<HUAWEI> system-view
[HUAWEI] ike heartbeat seq-num new
```

10.3.21 ike heartbeat-timer interval

Function

The **ike heartbeat-timer interval** command sets the interval for sending heartbeat packets through an IKE SA.

The **undo ike heartbeat-timer interval** command cancels the configuration.

By default, an IKE SA does not send heartbeat packets.

Format

ike heartbeat-timer interval *interval*

undo ike heartbeat-timer interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending heartbeat packets through an IKE SA.	The value is an integer that ranges from 20 to 28800, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After heartbeat detection is enabled, the local end periodically sends detection packets to the remote end. If the remote end does not receive packets after the heartbeat timer expires, the remote end considers the local end faulty. IKE can send heartbeat packets to detect IKE peer faults and maintain the IKE SA link status. This command sets the interval for sending heartbeat packets through an IKE SA.

The interval at which heartbeat packets are sent (configured using the **ike heartbeat-timer timeout** command) at the local end must be used with the timeout interval of heartbeat packets (configured using the **ike heartbeat-timer timeout** command) at the remote end. If the remote end does not receive any heartbeat packet within the timeout interval, it deletes the IKE SA with a timeout tag along with its corresponding IPSec SA. If the IKE SA does not have a timeout tag, it is marked as timeout.

Precautions

When the **ike heartbeat-timer interval** command is configured at one end, the **ike heartbeat-timer timeout** command must be used at the other end.

The timeout interval of heartbeat packets must be longer than the interval at which heartbeat packets are sent. On a network, packet loss seldom occurs more than three consecutive times. Therefore, it is recommended that the timeout interval of heartbeat packets be three times the interval at which heartbeat packets are sent.

Example

Set the interval for sending heartbeat packets to 20 seconds.

```
<HUAWEI> system-view
[HUAWEI] ike heartbeat-timer interval 20
```

10.3.22 ike heartbeat-timer timeout

Function

The **ike heartbeat-timer timeout** command sets the timeout interval during which an IKE SA waits for a heartbeat packet.

The **undo ike heartbeat-timer timeout** command cancels the configuration.

By default, the timeout interval during which an IKE SA waits for a heartbeat packet is not configured.

Format

ike heartbeat-timer timeout *seconds*

undo ike heartbeat-timer timeout

Parameters

Parameter	Description	Value
seconds	Specifies the timeout interval during which an IKE SA waits for a heartbeat packet.	The value is an integer that ranges from 30 to 28800, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After heartbeat detection is enabled, the local end periodically sends detection packets to the remote end. If the remote end does not receive packets after the heartbeat timer expires, the remote end considers the local end faulty. IKE can send heartbeat packets to detect IKE peer faults and maintain the IKE SA link status. This command sets the timeout interval during which an IKE SA waits for a heartbeat packet.

Precautions

When the **ike heartbeat-timer interval** command is configured at one end, the **ike heartbeat-timer timeout** command must be used at the other end.

The timeout interval of heartbeat packets must be longer than the interval at which heartbeat packets are sent. On a network, packet loss seldom occurs more than three consecutive times. Therefore, it is recommended that the timeout interval of heartbeat packets be three times the interval at which heartbeat packets are sent.

Example

Set the timeout interval during which an IKE SA waits for a heartbeat packet to 60 seconds.

```
<HUAWEI> system-view
[HUAWEI] ike heartbeat-timer timeout 60
```

10.3.23 ike local-name

Function

The **ike local-name** command configures the local name for IKE negotiation.

The **undo ike local-name** command deletes the local name for IKE negotiation.

By default, no local name is configured for IKE negotiation.

Format

ike local-name *local-name*

undo ike local-name

Parameters

Parameter	Description	Value
local-name	Specifies a local name for IKE negotiation.	The value is a string of 1 to 255 case-sensitive characters without question marks (?).

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When identity authentication, If the ID type of an IKE peer is fully qualified domain name (FQDN), or USER-FQDN, the IKE peer uses the name for identity authentication. In this case, you need to run the **ike local-name** command to configure the local name.

Example

Set the local ID for IKE negotiation to **Huawei**.

```
<HUAWEI> system-view
[HUAWEI] ike local-name Huawei
```

10.3.24 ike nat-keepalive-timer interval

Function

The **ike nat-keepalive-timer interval** command configures the interval for sending NAT Keepalive packets.

The **undo ike nat-keepalive-timer interval** command restores the default setting.

By default, the interval for sending NAT Keepalive packets is 20 seconds.

Format

ike nat-keepalive-timer interval *interval*

undo ike nat-keepalive-timer interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for sending NAT Keepalive packets.	The value is an integer that ranges from 5 to 300, in seconds.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

When an NAT gateway exists between two IKE peers, to prevent NAT entries from being aged, the device on the private network side of the NAT gateway sends NAT Keepalive packets to its peer at a certain interval to maintain the NAT session.

Example

Configure the interval for sending NAT Keepalive packets to 30 seconds.

```
<HUAWEI> system-view
[HUAWEI] ike nat-keepalive-timer interval 30
```

10.3.25 ikev1 phase1-phase2 sa dependent

Function

The **ikev1 phase1-phase2 sa dependent** command enables dependency between IPSec SA and IKE SA during IKEv1 negotiation.

The **undo ikev1 phase1-phase2 sa dependent** command cancels dependency between IPSec SA and IKE SA during IKEv1 negotiation.

By default, no dependency exists between IPSec SA and IKE SA during IKEv1 negotiation.

Format

ikev1 phase1-phase2 sa dependent

undo ikev1 phase1-phase2 sa dependent

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

During IKEv1 negotiation, an IKE SA is established during phase 1, and an IPSec SA is established during phase 2. By default, no dependency exists between IPSec SA and IKE SA, that is, the two SAs can be deleted separately. If the IKE SA is deleted but the corresponding IPSec SA still exists, traffic forwarding will be effected. To prevent this problem, you can run this command to enable dependency between IPSec SA and IKE SA.

Prerequisites

Before running this command, you need to install the weak encryption algorithm plug-in and run the **version 1** command in the IKE peer view to enable IKEv1. Otherwise, the command configuration does not take effect. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Example

Enable dependency between IPSec SA and IKE SA during IKEv1 negotiation.

```
<HUAWEI> system-view
[HUAWEI] ikev1 phase1-phase2 sa dependent
```

10.3.26 ikev2 delete old child-sa enable

Function

The **ikev2 delete old child-sa enable** command enables the function of instructing the peer device to delete the old child SA.

The **undo ikev2 delete old child-sa enable** command disables the function of instructing the peer device to delete the old child SA.

By default, the function of instructing the peer device to delete the old child SA is enabled.

Format

ikev2 delete old child-sa enable

undo ikev2 delete old child-sa enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

In an IKEv2 scenario, when the local device deletes the child SA and initiates IKEv2 negotiation to the peer device again, the default negotiation message carries the IKEV2_NOTIFY_DELETE_OLD_CHILDSA payload, instructing the peer device to delete the old child SA. If the peer device does not support the processing of this payload, IKEv2 negotiation between the two ends fails. To prevent this problem, run the **undo ikev2 delete old child-sa enable** command on the local device to disable it from instructing the peer device to delete the old child SA so that the IKEv2 negotiation message does not carry this payload.

Example

Enable the function of instructing the peer device to delete the old child SA.

```
<HUAWEI> system-view
[HUAWEI] ikev2 delete old child-sa enable
```

10.3.27 ikev2 initial-contact enable

Function

The **ikev2 initial-contact enable** command enables the device to send the INITIAL_CONTACT notify payload in the first IKE_AUTH request.

The **undo ikev2 initial-contact enable** command disables the device from sending the INITIAL_CONTACT notify payload in the first IKE_AUTH request.

By default, the device is disabled to send the INITIAL_CONTACT notify payload in the first IKE_AUTH request.

Format

ikev2 initial-contact enable

undo ikev2 initial-contact enable

Parameters

None

Views

System View

Default Level

2: Configuration level

Usage Guidelines

The INITIAL_CONTACT notify payload asserts that an IKE SA is the only active IKE SA between a pair of IKE peers. By default, the device will delete the old IKE SA without the INITIAL_CONTACT notify payload after the new IKE SA is created. When the remote end requires the INITIAL_CONTACT notify payload to delete the old IKE SA, configure this command.

When the local device restarts or expects to use the current IKE SA for establishing an IPSec tunnel only, run this command to enable the device to send the INITIAL_CONTACT notify payload in the first IKE_AUTH request so that the remote device deletes the old IKE SA.

Example

Enable the device to send the INITIAL_CONTACT notify payload in the first IKE_AUTH request.

```
<HUAWEI> system-view
[HUAWEI] ikev2 initial-contact enable
```

10.3.28 ipsec anti-replay enable

Function

The **ipsec anti-replay enable** command enables the anti-replay function globally.

The **undo ipsec anti-replay enable** command disables the anti-replay function globally.

By default, the anti-replay function is enabled globally.

Format

ipsec anti-replay enable

undo ipsec anti-replay enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Replayed packets refer to the packets that have been processed by the device. IPSec uses the sliding window (anti-replay window) to detect replayed packets. AH and ESP packet headers carry 32-bit sequence numbers. The sequence numbers carried in the AH or ESP packet headers of the same SA are in ascending order. If the sequence number of an authenticated packet is the same as that of a decapsulated packet or the sequence number is outside the sliding window, the packet is considered a replayed packet.

Decapsulating replayed packets consumes many resources and makes system performance deteriorate. Therefore, attackers may use replayed packets to initiate a DoS attack. After the anti-replay function is enabled, the system discards replayed packets to save system resources.

Precautions

In some situations, for example, network congestion occurs or QoS is performed for packets, the sequence numbers of some service data packets may be different from those in common data packets. The device that has IPSec anti-replay enabled considers the packets replayed and discards them. You can disable global IPSec anti-replay to prevent packets from being discarded incorrectly or adjust the IPSec anti-replay window size to meet service requirements.

Example

Enable the anti-replay function globally.

```
<HUAWEI> system-view
[HUAWEI] ipsec anti-replay enable
```

10.3.29 ipsec anti-replay window

Function

The **ipsec anti-replay window** command sets the global IPSec anti-replay window size.

The **undo ipsec anti-replay window** command restores the default global IPSec anti-replay window size.

By default, the global IPSec anti-replay window size is 1024 bits.

Format

ipsec anti-replay window *window-size*

undo ipsec anti-replay window

Parameters

Parameter	Description	Value
window-size	Specifies the global IPSec anti-replay window size.	The value can be 32, 64, 128, 256, 512, or 1024, in bits.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In some situations, for example, network congestion occurs or QoS is performed for packets, the sequence numbers of some service data packets may be unusual. The device that has IPSec anti-replay enabled considers the packets replayed and discards them. To prevent packets from being discarded incorrectly, you can disable global IPSec anti-replay or adjust the IPSec anti-replay window size to meet service requirements.

Prerequisites

The anti-replay function has been enabled. By default, the anti-replay function is enabled (through **ipsec anti-reply enable** command).

Precautions

When both **anti-replay window** and **ipsec anti-replay window** are used, the **anti-replay window** command takes effect. When **anti-replay window** is not configured, the **ipsec anti-replay window** command takes effect.

Example

Set the global IPSec anti-replay window size to 128 bits.

```
<HUAWEI> system-view
[HUAWEI] ipsec anti-replay window 128
```

10.3.30 ipsec efficient-vpn (interface view)

Function

The **ipsec efficient-vpn** command binds an Efficient VPN policy to an interface.

The **undo ipsec efficient-vpn** command deletes the Efficient VPN policy from an interface.

By default, no Efficient VPN policy is applied to an interface.

Format

ipsec efficient-vpn *efficient-vpn-name*

undo ipsec efficient-vpn

Parameters

Parameter	Description	Value
efficient-vpn-name	Specifies the name of an Efficient VPN policy.	The value is an existing Efficient VPN policy name.

Views

VLANIF interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When many branches and traveling staff connect to the headquarters over IPSec tunnels, similar or duplicate IPSec configurations and other network resource configurations must be configured on the branch and headquarters gateways. The Efficient VPN solution uses centralized IPSec configurations on the headquarters gateway and simplified IPSec configuration on each branch gateway. This solution reduces the manual configuration workload, and facilitates IPSec VPN configuration and maintenance.

Prerequisites

An Efficient VPN policy has been created using the **ipsec efficient-vpn (system view)** command.

Precautions

If an Efficient VPN policy is used to establish an IPSec tunnel between the enterprise branch and headquarters, apply the Efficient VPN policy to the branch gateway and use an IPSec policy template on the headquarters gateway to create an IPSec policy.

Example

Apply the Efficient VPN policy named **evpn** to **VLANIF10**.

```
<HUAWEI> system-view
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ipsec efficient-vpn evpn
```

10.3.31 ipsec efficient-vpn (system view)

Function

The **ipsec efficient-vpn** command creates an IPSec Efficient VPN policy and displays the IPSec Efficient VPN policy view.

The **undo ipsec efficient-vpn** command deletes an IPSec Efficient VPN policy.

By default, no IPSec Efficient VPN policy is created in the system.

Format

ipsec efficient-vpn *efficient-vpn-name* [**mode** { **client** | **network** | **network-plus** }]

undo ipsec efficient-vpn *efficient-vpn-name*

Parameters

Parameter	Description	Value
efficient-vpn-name	Specifies the name of an Efficient VPN policy.	The value is a string of 1 to 12 case-sensitive characters without question marks (?) or spaces.
mode	Specifies the mode of the Efficient VPN policy.	-
client	Indicates the client mode.	-
network	Indicates the network mode.	-
network-plus	Indicates the network-plus mode.	-

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When many branches and traveling staff connect to the headquarters over IPSec tunnels, similar or duplicate IPSec configurations and other network resource configurations must be configured on the branch and headquarters gateways. The Efficient VPN solution uses centralized IPSec configurations on the headquarters gateway and simplified IPSec configuration on each branch gateway. This solution reduces the manual configuration workload, and facilitates IPSec VPN configuration and maintenance.

The Efficient VPN policy has the following modes:

- Client mode

  When a remote device requests an IP address from the Efficient VPN server, a loopback interface is dynamically created on the remote device and the IP address obtained from the server is assigned to the loopback interface. The remote device uses this IP address to establish an IPSec tunnel with the headquarters.

  The client mode applies to scenarios where small-scale branches connect to the headquarters network through private networks. In client mode, devices connected to the Efficient VPN server or remote devices can use the same IP address. However, the number of devices allowed depends on the number of IP addresses assigned by the Efficient VPN server.
- Network mode

  In network mode, a remote device does not apply to the Efficient VPN server for an IP address. Instead, the remote device uses the original IP address to establish an IPSec tunnel with the headquarters.

  The network mode applies to scenarios where IP addresses of the headquarters and branches are planned uniformly. Ensure that IP addresses do not conflict.
- Network-plus mode

  Compared with the network mode, the remote device applies to the Efficient VPN server for an IP address in network-plus mode. IP addresses of branches and headquarters are configured beforehand. A remote device applies to the Efficient VPN server for an IP address. The Efficient VPN server uses the IP address to perform ping, Telnet, or other management and maintenance operations on the remote device.

Follow-up Procedure

Configure negotiation parameters of Efficient VPN in the Efficient VPN policy view, and use the **ipsec efficient-vpn (interface view)** command to bind the Efficient VPN policy to an interface.

Example

Create the Efficient VPN policy named **vpn1** in client mode.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn vpn1 mode client
[HUAWEI-ipsec-efficient-vpn-vpn1]
```

10.3.32 ipsec sa global-duration

Function

The **ipsec sa global-duration** command sets the global hard lifetime of IPSec SAs.

The **undo ipsec sa global-duration** command restores the default global hard lifetime of IPSec SAs.

By default, the global time-based SA hard lifetime is 3600 seconds and the global traffic-based SA hard lifetime is 1843200 Kbytes.

Format

ipsec sa global-duration { **time-based** *interval* | **traffic-based** *size* }

undo ipsec sa global-duration { **time-based** | **traffic-based** }

Parameters

Parameter	Description	Value
time-based *interval*	Specifies the time-based global IPSec SA hard lifetime. When a large number of IPSec tunnels are established between two devices, you are advised to set the global IPSec SA hard lifetime to a value larger than or equivalent to 1800s.	It is an integer that ranges from 30 to 604800, in seconds.
traffic-based *size*	Specifies the traffic-based global IPSec SA hard lifetime. It is recommended that the traffic volume be equal to or larger than the size of IPSec traffic forwarded in 1 hour.	The value is 0 or an integer from 256 to 200000000, in Kbytes. ● IKEv1 for IPSec negotiation: If the traffic hard lifetime is set to 0 on either device, both the local and remote devices disable the traffic timeout function. ● IKEv2 for IPSec negotiation: If the traffic hard lifetime is set to 0 on either device, the local device disables the traffic timeout function.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

For a dynamic SA, configure the SA hard lifetime so that the SA can be updated in real time, reducing the crash risk and improving security.

There are two methods to measure the lifetime:

- Time-based lifetime

  The period from when an SA is set up to when the SA is expired.
- Traffic-based lifetime

  The maximum volume of traffic that this SA can process.

The lifetime is classified as follows:

- Hard lifetime: specifies the lifetime of an IPSec SA.

  When two devices negotiate an IPSec SA, the actual hard lifetime is the smaller of the two values configured on the two devices.
- Soft lifetime: specifies the time after which a new IPSec SA is negotiated so that the new IPSec SA will be ready before the hard lifetime of the original IPSec SA expires.

  Table 10-27 lists the default soft lifetime values.

Table 10-27 Soft lifetime values

Soft Lifetime Type	Description
Time-based soft lifetime (soft timeout period)	The value is 70% of the actual hard lifetime (hard timeout period).
Traffic-based soft lifetime (soft timeout traffic)	• For IKEv1, the value is 70% of the actual hard lifetime (hard timeout traffic). • For IKEv2, the value is 65% to 75% of the actual hard lifetime (hard timeout traffic) plus or minus a random value.

Before an IPSec SA becomes invalid, IKE negotiates a new IPSec SA for the remote end. The remote end uses the new IPSec SA to protect IPSec communication immediately after the new IPSec SA is negotiated. If service traffic is transmitted, the original IPSec SA is deleted immediately. If no service traffic is transmitted, the original IPSec SA will be deleted after 10s or the hard lifetime expires.

If the time-based lifetime and traffic-based lifetime are both set for an IPSec SA, the IPSec SA becomes invalid when either lifetime expires.

Precautions

During IKEv1 negotiation:

- The responder cannot initiate IPSec SA renegotiation after the IPSec SA soft lifetime expires.
- The initiator cannot initiate IPSec SA renegotiation when its IKE SA is deleted and the IPSec SA soft lifetime expires.

During IKEv2 negotiation, the initiator or responder cannot initiate IPSec SA renegotiation if the IKE SA is deleted and the IPSec SA soft lifetime expires.

Example

Set the time-based global SA hard lifetime to 7200s.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa global-duration time-based 7200
```

Set the traffic-based global SA hard lifetime to 10 MB.

```
<HUAWEI> system-view
[HUAWEI] ipsec sa global-duration traffic-based 10240
```

10.3.33 local-id-type

Function

The **local-id-type** command sets the type of the local ID used in IKE negotiation.

The **undo local-id-type** command restores the default type of the local ID used in IKE negotiation.

By default, the local ID type used by IKE negotiation is IP.

Format

local-id-type { **fqdn** | **ip** | **key-id** | **user-fqdn** }

undo local-id-type

Parameters

Parameter	Description	Value
fqdn	Specifies the name as the local ID.	-
ip	Specifies the IP address as the local ID.	-
key-id	Specifies the key-id as the local ID.	-
user-fqdn	Specifies the USER-FQDN as the local ID.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Identity authentication is a protection mechanism for IKE negotiation. The device ensures security by confirming identities of communication parties. IKE peers can use different types. This command configures the type of the local ID of an IKE peer.

Precautions

- The local ID type can be different from the remote ID type. You can use commands to specify the local and remote ID types.
- For pre-shared key authentication, the local ID type on the local end must be the same as the remote ID type on the remote end, and the local ID on the local end must be the same as the remote ID on the remote end.

Different authentication methods support different ID types, as shown in **Table 10-28**.

Table 10-28 Relationship between local IKE ID types, local ID, and authentication methods

Authentication Method	IP	FQDN	USER-FQDN	key-id
pre-share	Supported The IP address is the local IP address used for IKE negotiation by default.	Supported The ID specified by the **ike local-name** command, indicating that all peers on the device use this ID for identity authentication.	Supported The ID specified by the **ike local-name** command, indicating that all peers on the device use this ID for identity authentication.	Supported This parameter is often used when the device using the Efficient VPN policy functions as a remote end to communicate with Cisco devices.

Example

Set the local ID type of Efficient VPN to FQDN.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] local-id-type fqdn
```

10.3.34 pfs

Function

The **pfs** command enables PFS when the local end initiates IPSec tunnel negotiation.

The **undo pfs** command disables PFS when the local end initiates IPSec tunnel negotiation.

By default, PFS is not used when the local end initiates IPSec tunnel negotiation.

Format

pfs { **dh-group14** | **dh-group19** | **dh-group20** | **dh-group21** }

undo pfs

Parameters

Parameter	Description	Value
dh-group14	Uses the 2048-bit DH group.	-
dh-group19	Uses the 256-bit Elliptic Curve Groups modulo a Prime (ECP) DH group.	-
dh-group20	Uses the 384-bit ECP DH group.	-
dh-group21	Uses the 521-bit ECP DH group.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When the local end initiates negotiation, there is an additional DH exchange in IKEv1 phase 2 or IKEv2 CREATE_CHILD_SA exchange. The additional DH exchange ensures security of the IPSec SA key and improves communication security.

Precautions

The system software does not support the **dh-group1**, **dh-group2**, and **dh-group5** parameters. To use these DH groups, you need to install the WEAKEA plug-in. For higher security purposes, you are advised to specify other DH groups.

For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Example

Enable the PFS feature in the IPSec Efficient VPN policy **evpn**.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] pfs dh-group14
```

10.3.35 pre-shared-key (Efficient VPN policy view)

Function

The **pre-shared-key** command configures the pre-shared key used by IKE peers to perform pre-shared key authentication.

The **undo pre-shared-key** command deletes the pre-shared key used by IKE peers to perform pre-shared key authentication.

By default, the pre-shared key used by IKE peers to perform pre-shared key authentication is not configured.

Format

pre-shared-key cipher *key*

undo pre-shared-key

Parameters

Parameter	Description	Value
cipher	Indicates the pre-shared key in cipher text. You can enter a pre-shared key in plain text or cipher text, but the pre-shared key is displayed in cipher text in the configuration file.	-
key	Specifies the pre-shared key used by IKE peers to perform pre-shared key authentication.	The value is a string of case-sensitive characters without spaces. A plaintext key contains 1 to 128 characters, and a ciphertext key contains 48 to 188 characters. If the character string is enclosed in double quotation marks (" "), the character string can contain spaces. **NOTE** For security purposes, it is recommended that the pre-shared key contain at least three types of lowercase letters, uppercase letters, digits, and special characters and contain at least 8 characters.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During IKE negotiation, IPSec can use pre-shared key authentication to verify identities of communication parties. After pre-shared key authentication is configured, the initiator encrypts data using the pre-shared key before transmitting the data, and the receiver decrypts the data using the same pre-shared key. If the receiver succeeds in data decryption, the initiator passes the identity verification.

Precautions

Both ends of IKE negotiation must be configured with the same pre-shared key.

Example

Configure pre-shared key authentication in the Efficient VPN policy **evpn** and set the pre-shared key to YsHsjx_202206 in cipher text.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] pre-shared-key cipher YsHsjx_202206
```

10.3.36 re-authentication interval

Function

The **re-authentication interval** command sets the IKEv2 re-authentication interval.

The **undo re-authentication interval** command cancels the configuration.

By default, the device does not perform IKEv2 re-authentication.

Format

re-authentication interval *interval*

undo re-authentication interval

Parameters

Parameter	Description	Value
interval	Specifies the IKEv2 re-authentication interval. When about 70% of the time interval has elapsed, the device initiates IKEv2 re-authentication.	The value is an integer that ranges from 60 to 604800, in seconds.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the remote access scenario, third-party attacks may occur during communications of peers. To improve IPSec network security, you can run this command to enable the peers to periodically re-authenticate each other.

Precautions

Only IKEv2 supports re-authentication.

Example

Set the re-authentication interval to 400 seconds in the IPSec Efficient VPN policy.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] re-authentication interval 400
```

10.3.37 remote-address (Efficient VPN policy view)

Function

The **remote-address** command configures an IP address or domain name for the remote IKE peer during IKE negotiation.

The **undo remote-address** command deletes an IP address or domain name for the remote IKE peer during IKE negotiation.

By default, no IP address or domain name is configured for the remote IKE peer during IKE negotiation.

Format

remote-address { *ip-address* | **host-name** *host-name* } { **v1** | **v2** }

undo remote-address [*ip-address* | **host-name** *host-name*]

NOTE

The **v1** parameter is supported only when the WEAKEA plug-in is installed. For details about how to install the WEAKEA plug-in, see "WEAKEA Configuration" in the *CLI-based Configuration Guide*.

Parameters

Parameter	Description	Value
ip-address	Specifies the IP address of the remote IKE peer.	The value is in dotted decimal notation.
host-name *host-name*	Specifies the domain name of the remote IKE peer.	The value is an existing remote IKE peer domain name.
v1	Indicates that both ends use IKEv1.	-
v2	Indicates that both ends use IKEv2.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **remote-address** command configures an IP address or domain name for the remote IKE peer in an Efficient VPN policy. If the domain name is configured for the remote IKE peer, the IP address of the remote IKE peer is obtained in either of the following modes:

- Static mode: The IP address of the remote IKE peer is obtained based on the mapping between the domain name and IP address.
- Dynamic mode: The IP address of the remote IKE peer is obtained from the DNS server.

To improve network reliability, two devices can be deployed at the headquarters to connect to the branch gateway. In an Efficient VPN solution, two IP addresses or domain names of the remote IKE peer can be configured on the branch gateway. The branch gateway first attempts to use the first configured IP address or domain name to establish an IKE connection with the headquarters gateway. If establishing an IKE connection fails, the branch gateway uses the second IP address or domain name to establish an IKE connection.

Precautions

When you configure IP addresses or domain names for two remote IKE peers, ensure that the value type of **remote-address** and the IKE version are respectively the same. Generally, only one device is deployed at the headquarters to connect to the branch gateway. Therefore, only one remote address is configured.

Example

Assign the IP addresses 10.1.1.1 and 10.1.2.1 to the remote peer in the Efficient VPN policy view.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] remote-address 10.1.1.1 v2
[HUAWEI-ipsec-efficient-vpn-evpn] remote-address 10.1.2.1 v2
```

Set the domain name of the remote peer to **mypeer** in the Efficient VPN policy view.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] remote-address host-name mypeer v2
```

10.3.38 remote-id

Function

The **remote-id** command specifies the remote ID for IKE negotiation.

The **undo remote-id** command deletes the remote ID for IKE negotiation.

By default, the remote ID for IKE negotiation is not configured.

Format

remote-id *id*

undo remote-id

Parameters

Parameter	Description	Value
id	Specifies the remote ID.	The value is a string of 1 to 255 case-sensitive characters including special characters, such as the exclamation point (!), at sign (@), number sign (#), dollar sign ($), and percent (%).

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the remote ID type of the IKE peer is FQDN or USER-FQDN, you can run this command to set a value for the remote ID.

If the remote ID type of the IKE peer is DN, FQDN, or USER-FQDN, you can run this command to set a value for the remote ID.

During IKE negotiation, you can run the **remote-id** commands to configure the remote ID for authentication.

Precautions

- In IKEv1, the configured remote ID is used to authenticate only the peer.
- In IKEv2, the configured remote ID can be sent to the peer to check whether the local name of the peer is the same as this remote ID.

Example

Set the remote peer name to **Huawei** in the Efficient VPN policy view.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn name mode client
[HUAWEI-ipsec-efficient-vpn-name] remote-id Huawei
```

10.3.39 reset ike error-info

Function

The **reset ike error-info** command clears information about IPSec tunnel negotiation failures using IKE.

Format

reset ike error-info

Parameters

None.

Views

User view

Default Level

3: Management level

Usage Guidelines

NOTICE

Statistics cannot be restored after being cleared.

You can run the **display ike error-info** command to view information about IPSec tunnel negotiation failures using IKE.

Example

Clear information about IPSec tunnel negotiation failures using IKE.

```
<HUAWEI> reset ike error-info
```

10.3.40 reset ike offline-info

Function

The **reset ike offline-info** command clears information about deleted IPSec tunnels established through IKE negotiation.

Format

reset ike offline-info

Parameters

None.

Usage Guidelines

NOTICE

Statistics cannot be restored after being cleared.

You can run the **display ike offline-info** command to check the reasons why IPSec tunnels established through IKE negotiation have been deleted.

Example

Clear information about deleted IPSec tunnels established using IKE negotiation.

```
<HUAWEI> reset ike offline-info
```

10.3.41 reset ike sa

Function

The **reset ike sa** command clears information about SAs established through IKE negotiation.

Format

reset ike sa [**conn-id** *conn-id* | **remote** *ipv4-address*]

Parameters

Parameter	Description	Value
conn-id *conn-id*	Specifies the connection ID of an SA.	The value is an integer that ranges from 1 to 4294967295.
remote *ipv4-address*	Specifies the IPv4 address of the remote end.	The value is in dotted decimal notation.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

To clear an IPSec tunnel established through IKE negotiation, run the **reset ike sa** command to clear the IKE SA that is used to negotiate the IPSec tunnel.

There are two types of SAs established by IKE negotiation: IKE SAs in phase 1 and IPSec SAs in phase 2. IKE SAs in phase 1 are used for IKE negotiation. Under the protection of these IKE SAs, IPSec SAs in phase 2 are used to protect data flows.

- If the specified *conn-id* parameter corresponds to an IKE SA in phase 1, IKE peers do not automatically negotiate an IKE SA after the IKE SA is cleared. The IKE peers re-negotiate an IKE SA in phase 1 only when data flows match ACL rules in the IPSec policy again.
- If the specified *conn-id* parameter corresponds to an IPSec SA in phase 2, either of the following will occur:

  - Automatic triggering mode: The IKE peers re-negotiate an IPSec SA in phase 2 under the protection of the IKE SA in phase 1 after the IPSec SA is cleared.
  - Traffic-based triggering mode: The IKE peers do not automatically negotiate an IPSec SA after the IPSec SA is cleared. They re-negotiate an IPSec SA in phase 2 under the protection of the IKE SA in phase 1 only when data flows match ACL rules in the IPSec policy again.
- If the *conn-id* parameter is not specified, all IKE SAs in phase 1 are cleared, and IKE negotiation process is similar to that described above.

Precautions

After dependency between IPSec SA and IKE SA during IKEv1 negotiation is disabled using the **undo ikev1 phase1-phase2 sa dependent** command, running the **reset ike sa** *conn-id* command to delete an IKE SA will also delete the corresponding IPSec SA.

Example

Clear IKE SAs in both phases.

```
<HUAWEI> reset ike sa
```

10.3.42 reset ike statistics

Function

The **reset ike statistics** command clears IKE statistics.

Format

reset ike statistics

Parameters

None.

Views

User view

Default Level

3: Management level

Usage Guidelines

NOTICE

Statistics cannot be restored after being cleared.

To diagnose and locate faults of IPSec tunnels established using IKE, you can collect IKE statistics in a given period of time. You can run the **reset ike statistics** command to clear historical IKE statistics before starting statistics collection. You can then run the **display ike statistics** command to check IKE statistics.

Example

Clear IKE statistics.

```
<HUAWEI> reset ike statistics
```

10.3.43 reset ipsec history record

Function

The **reset ipsec history record** command clears history information about IPSec tunnels.

Format

reset ipsec history record

Parameters

None.

Views

User view

Default Level

3: Management level

Usage Guidelines

NOTICE

Statistics cannot be restored once being cleared.

You can run the **display ipsec history record** command to view history information about the current IPSec tunnel.

Example

Clear history information about IPSec tunnels.

```
<HUAWEI> reset ipsec history record
```

10.3.44 reset ipsec sa

Function

The **reset ipsec sa** command deletes IPSec SAs.

Format

reset ipsec sa [**remote** *ipv4-address* | **parameters** *ipv4-address* **esp** *spi* | **efficient-vpn** *efficient-vpn-name*]

Parameters

Parameter	Description	Value
remote *ipv4-address*	Specifies the IPv4 address of the remote end.	The value is in dotted decimal notation.
parameters *ipv4-address* **esp** *spi*	Specifies the three elements that uniquely identify an IPSec SA. The three elements are *ipv4-address* (destination address), *protocol* (ESP), and Security Parameter Index (SPI). To reset an SA, the three elements must be specified.	The three elements are described as follows: ● *ipv4-address*: IPv4 address. ● *protocol*: ESP. ● *spi*: an integer that ranges from 256 to 4294967295.
efficient-vpn *efficient-vpn-name*	Specifies the name of an Efficient VPN policy.	The value is an existing Efficient VPN policy name.

Views

User view

Default Level

3: Management level

Usage Guidelines

When you run the **reset ipsec sa** command to delete IPSec SAs, note the following points:

- If no parameter is specified, all IPSec SAs are deleted.
- If **parameters** is specified, the IPSec SAs in two directions are deleted simultaneously.
- To delete IPSec SAs established through IKE negotiation, you must run the **reset ipsec sa** and **reset ike sa** commands in sequence. Otherwise, IPSec SAs established through IKE negotiation fail to be deleted. After the IPSec SAs are deleted, IKE peers re-negotiate IPSec SAs only when packets trigger IKE negotiation.

Example

Delete the IPSec SA created through Efficient VPN policy **evpn**.

```
<HUAWEI> reset ipsec sa efficient-vpn evpn
```

10.3.45 reset ipsec packet statistics

Function

The **reset ipsec packet statistics** command deletes statistics about IPSec packets.

Format

reset ipsec packet statistics

Parameters

None.

Views

User view

Default Level

3: Management level

Usage Guidelines

Usage Scenario

Before collecting statistics about IPSec packets within a given period of time, run this command to delete existing statistics.

Precautions

The deleted statistics about IPSec packets cannot be restored. Exercise caution when you run this command.

Example

Delete statistics about all IPSec packets.

```
<HUAWEI> reset ipsec packet statistics
```

10.3.46 sa binding vpn-instance (Efficient VPN policy view)

Function

The **sa binding vpn-instance** command binds a VPN instance to an IPSec tunnel.

The **undo sa binding vpn-instance** command unbinds a VPN instance from an IPSec tunnel.

By default, no VPN instance is bound to an IPSec tunnel.

Format

sa binding vpn-instance *vpn-instance-name*

undo sa binding vpn-instance

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of the VPN instance bound to an IPSec tunnel.	The value is an existing VPN instance name.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Applicable environment

On an VPN with small VPN sites, if CEs and PEs are connected through the Internet but not leased lines, hosts connected to a CE can access resources on another VPN site only through the insecure Internet. To enhance access security, these hosts can connect to the backbone network of the VPN through an IPSec tunnel.

This command specifies the VPN that the remote end of the IPSec tunnel belongs to. The tunnel initiator then can obtain the outbound interface and send packets through the outbound interface.

Prerequisites

A VPN instance has been created using the **ip vpn-instance** command.

A route distinguisher (RD) for the VPN instance has been configured using the **route-distinguisher** command.

Example

Bind the VPN instance **vpna** to the Efficient VPN policy **evpn**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpna
[HUAWEI-vpn-instance-vpna] ipv4-family
[HUAWEI-vpn-instance-vpna-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpna-af-ipv4] vpn-target 100:100
[HUAWEI-vpn-instance-vpna-af-ipv4] quit
```

```
[HUAWEI-vpn-instance-vpna] quit
[HUAWEI] ipsec efficient-vpn evpn mode client
[HUAWEI-ipsec-efficient-vpn-evpn] sa binding vpn-instance vpna
```

10.3.47 security acl

Function

The **security acl** command specifies an ACL to be referenced in an IPSec policy or IPSec policy template.

The **undo security acl** command cancels the configuration.

By default, an IPSec policy or IPSec policy template does not reference an ACL.

Format

security acl *acl-number*

undo security acl

Parameters

Parameter	Description	Value
acl-number	Specifies the number of an ACL.	The value is an integer that ranges from 3000 to 3999.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The **security acl** command references an ACL that defines data flows to be protected by IPSec. In practice, you need to configure rules in an ACL to define data flows to be protected and apply the ACL to an IPSec policy to protect the data flows.

When an IPSec policy is created using an IPSec policy template, you can determine whether to define data flows to be protected by IPSec on the responder.

- If data flows to be protected by IPSec are not specified on the responder, the responder accepts the range of data flows to be protected by IPSec defined on the initiator.
- If data flows to be protected by IPSec are specified on the responder, the configuration on the responder must mirror that on the initiator or the range

of protected data flows on the responder must contain the range of protected data flows on the initiator.

Precautions

To reference an ACL in an IPSec policy, ensure that rules must be configured in this ACL view and the number of rules configured in this ACL view does not exceed 32. Otherwise, this ACL cannot be referenced in this IPSec policy.

Example

Reference ACL 3101 in an Efficient VPN policy.

```
<HUAWEI> system-view
[HUAWEI] acl number 3101
[HUAWEI-acl-adv-3101] rule permit tcp source 10.1.1.1 0.0.0.0 destination 10.1.1.2 0.0.0.0
[HUAWEI-acl-adv-3101] quit
[HUAWEI] ipsec efficient-vpn name mode network
[HUAWEI-ipsec-efficient-vpn-name] security acl 3101
```

10.3.48 service-scheme (Efficient VPN policy view)

Function

The **service-scheme** command configures a server-end service scheme in an Efficient VPN policy.

The **undo service-scheme** command deletes a server-end service scheme from an Efficient VPN policy.

By default, no server-end service scheme is configured in an Efficient VPN policy.

Format

service-scheme *service-scheme-name*

undo service-scheme

Parameters

Parameter	Description	Value
service-scheme-name	Specifies the name of a service scheme on the server end.	The service scheme name must already exist.

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

In an Efficient VPN scenario, the customer wants to deploy network resources including the DNS domain name, DNS server address, WINS server address, and IP addresses on the server end (headquarters gateway). The server end pushes network resource information to remote ends (branch gateways) to simplify configuration and maintenance of network resources on them.

Remote ends are authorized based on network resource information pushed by the server end or the server-end AAA service scheme specified in an Efficient VPN policy. To use the AAA service scheme, run the **service-scheme** command to configure a server-end service scheme in an Efficient VPN policy and run the **local-id-type** command to specify the **key-id** parameter. Otherwise, the configuration does not take effect.

Example

Configure the server-end service scheme **service** in an Efficient VPN policy.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn name mode network
[HUAWEI-ipsec-efficient-vpn-name] service-scheme service
```

10.3.49 tunnel local

Function

The **tunnel local** command specifies the local address of an IPSec tunnel.

The **undo tunnel local** command cancels the configuration.

By default, no local IP address is configured for the IPSec tunnel.

Format

tunnel local { *ipv4-address* | **applied-interface** }

undo tunnel local

Parameters

Parameter	Description	Value
ipv4-address	Specifies an IPv4 address for the local end of an IPSec tunnel.	The value is in dotted decimal notation.
applied-interface	Indicates the primary IP address of the IPSec-enabled interface is used as the local address of an IPSec tunnel.	-

Views

Efficient VPN policy view

Default Level

2: Configuration level

Usage Guidelines

You can run this command to specify a start point for an IPSec tunnel.

You do not need to configure an IP address for the local end of an IPSec tunnel. During SA negotiation, the device will select a proper address based on route information. The local address needs to be configured in the following situations:

- If the IP address of the interface to which an IPSec policy is applied varies or is unknown, run the **tunnel local** *ipv4-address* command to specify the IP address of another interface (such as the loopback interface) on the device as the IP address for the local end of an IPSec tunnel. Otherwise, run the **tunnel local applied-interface** command to specify the IP address of the interface to which an IPSec policy is applied as the local address of an IPSec tunnel.
- If the interface to which an IPSec policy is applied has multiple IP addresses (one primary IP address and several secondary IP addresses), run the **tunnel local** *ipv4-address* command to specify one of these IP addresses as the IP address for the local end of an IPSec tunnel. Otherwise, run the **tunnel local applied-interface** command to specify the primary IP address of the interface as the local address of an IPSec tunnel.
- If equal-cost routes exist between the local and remote ends, run the **tunnel local** command to specify a local IP address for an IPSec tunnel.

Example

Set the primary IP address of the interface to which the Efficient VPN policy in IKE negotiation mode is applied as the local IP address of the IPSec tunnel.

```
<HUAWEI> system-view
[HUAWEI] ipsec efficient-vpn name mode network
[HUAWEI-ipsec-efficient-vpn-name] tunnel local applied-interface
```

10.4 BGP/MPLS IP VPN Configuration Commands

10.4.1 Command Support

- Only the following switch models support working as a PE:

  S5731-H, S5731S-H, S5732-H, S5731-S, S6730-S, S6720-EI, S6720S-EI, S6730S-H, and S6730-H
- S1720GW-E and S1720GWR-E switches support working as an MCE. All models of S300, S500, S2700, S5700, and S6700 series switches (except the S5731-L and S5731S-L) support working as an MCE.

10.4.2 apply tunnel-policy (tunnel-selector view)

Function

The **apply tunnel-policy** command applies a tunnel policy to routes filtered by the **if-match** clause.

The **undo apply tunnel-policy** command cancels the setting.

By default, no tunnel policy is configured for filtered routes.

Format

apply tunnel-policy *tunnel-policy-name*

undo apply tunnel-policy

Parameters

Parameter	Description	Value
tunnel-policy-name	Specifies the name of a tunnel policy to be applied to the routes that match the **if-match** clause.	The value is a string of 1 to 39 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Tunnel selector view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In BGP/MPLS IP VPN networking, by default, LSPs are selected for VPNv4 and BGP labeled routes without performing load balancing. If you want to select other types of tunnels or configure load balancing for VPNv4 or BGP labeled routes, run the **apply tunnel-policy** command to apply a tunnel policy. The **apply tunnel-policy** command can be used in the following situations:

- The RR on the backbone network of a VPN needs to apply a tunnel policy to VPNv4 routes learned from PEs.

If you want to apply a tunnel policy to only specific VPNv4 or BGP labeled routes in the situations mentioned above, first use the **if-match** clause to filter routes. The **if-match** commands that can be used are listed below:

- **if-match ip next-hop (tunnel-selector view)**

  The command filters IPv4 routes by next hop.
- **if-match ipv6 next-hop (tunnel-selector view)**

  The command filters IPv6 routes by next hop.
- **if-match rd-filter**

  The command filters routes by RD.

Prerequisite

The **tunnel-selector** command is run to create a tunnel selector; **if-match** clauses are configured as needed.

Follow-up Procedure

If the tunnel policy specified in the **apply tunnel-policy** command does not exist in the system, run the **tunnel-policy** command to create the tunnel policy.

Example

Select policy1 for the VPN routes that are filtered by RD in the tunnel selector view.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy policy1
[HUAWEI-tunnel-policy-policy1] tunnel select-seq cr-lsp lsp load-balance-number 1
[HUAWEI-tunnel-policy-policy1] quit
[HUAWEI] tunnel-selector tps permit node 10
[HUAWEI-tunnel-selector] if-match rd-filter 1
[HUAWEI-tunnel-selector] apply tunnel-policy policy1
```

10.4.3 apply-label per-instance

Function

The **apply-label per-instance** command sets the label allocation mode to one label per instance. In this mode, all the routes of the VPN instance address family destined for the remote PE are assigned the same label.

The **undo apply-label per-instance** command restores the default configuration.

By default, the VPN instance address family assigns the same label to all routes to be sent to the peer PE.

Format

apply-label per-instance

undo apply-label per-instance

Parameters

None

Views

VPN instance view, VPN instance IPv4 address family view, VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In BGP/MPLS IP VPN networking, if VPN routes on PE are numerous but MPLS label resources are insufficient, the **apply-label per-instance** command can be run to minimize MPLS label consumption on PE.

When a large number of routes of the VPN instance IPv4 address family need to apply for labels, the **apply-label per-instance** command saves label resources of PEs and lowers the requirements for PE capacities.

By default, the system applies for a label for each route in a VPN instance enabled with the IPv4 or IPv6 address family. After the **apply-label per-instance** command is run in the IPv4 or IPv6 address family view of the VPN instance, the routes of the VPN instance enabled with the corresponding address family will be allocated the same label. For example, a PE is configured with two VPN instances that have 20000 routes in total. By default, 20000 MPLS labels will be allocated to the routes. If the **apply-label per-instance** command is run, only two MPLS labels will be allocated to the routes.

You can run the **display fib statistics** command to check the number of VPN routes.

Prerequisites

1. The **ip vpn-instance** command has been executed to create a VPN instance and enter the VPN instance view.
2. The **ipv4-family** or **ipv6-family** command has been executed to enter the IPv4 or IPv6 VPN instance address family view.
3. The **route distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

The change of the label allocation mode leads to the re-advertising of VPN routes. The services may be interrupted temporarily. Therefore, use the **apply-label per-instance** and **undo apply-label per-instance** commands with caution.

NOTE

If there are a large number of VPN routes in the system, frequently executing this command will cause flapping of many routes. Route flapping results in a high CPU usage but does not affect real-time services in the system.

Example

Assign one label to all routes of the IPv4 address family of the VPN instance named vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] apply-label per-instance
```

10.4.4 apply-label per-nexthop

Function

The **apply-label per-nexthop** command enables the ASBR to allocate labels for IPv4 VPN routes or IPv6 VPN routes based on the next hop.

The **undo apply-label per-nexthop** command disables the ASBR from allocating labels for IPv4 VPN routes or IPv6 VPN routes based on the next hop.

By default, next-hop-based label allocation for VPN routes is disabled on the ASBR, and a label is allocated to each VPN instance.

Format

apply-label per-nexthop

undo apply-label per-nexthop

Parameters

None

Views

BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In inter-AS VPN Option B or HoVPN networking, if MPLS label resources on the ASBR or SPE are insufficient for the advertised VPNv4 or VPNv6 routes to use, the **apply-label per-nexthop** command can be run to minimize MPLS label consumption on the ASBR or SPE.

By default, the ASBR or SPE allocates a label to each VPNv4 or VPNv6 route when advertising it to an MP-BGP peer. If the **apply-label per-nexthop** command is run, the ASBR or SPE will allocate one label to all the routes with the same next hop and outgoing label. To make the routes learned from the same next hop have the same outgoing label, run the **apply-label per-instance** command on the PE. Otherwise, the effect of the **apply-label per-nexthop** command will be affected.

Configuration Impact

After next-hop-based label allocation is enabled or disabled, the label allocated by the ASBR to a route changes, which leads to a transient loss of VPN packets.

Example

In the BGP-VPNv4 view, enable the ASBR to allocate labels to IPv4 VPN routes based on the next hop.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] apply-label per-nexthop
```

10.4.5 apply-label per-route

Function

The **apply-label per-route** command enables the one-label-per-route mode. The VPN instance address family assigns a unique label to each route to be sent to the peer PE.

The **undo apply-label per-route** command disables the one-label-per-route mode.

By default, the VPN instance address family assigns the same label to all routes to be sent to the peer PE.

Format

apply-label per-route

undo apply-label per-route

Parameters

None

Views

VPN instance view, VPN instance IPv4 address family view, VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If you want to change the label allocation mode from one-label-per-instance to one-label-per-route, run the **apply-label per-route** command.

Prerequisite

The **route-distinguisher** command is run to configure an RD for the VPN instance enabled with the IPv4 or IPv6 address family.

Configuration Impact

The change of the label allocation mode leads to the re-advertising of VPN routes. The services may be interrupted temporarily. Exercise caution when running the **apply-label per-route** or **undo apply-label per-route** command.

The **apply-label per-instance** and **apply-label per-route** commands are mutually exclusive. If both commands are run, the latest configuration overrides the previous one.

Example

Enable the one-label-per-route mode for routes of **vpn1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] apply-label per-route
```

10.4.6 arp vpn-cross enable

Function

The **arp vpn-cross enable** command enables direct ARP entry delivery for mutual access between local VPNs.

The **undo arp vpn-cross enable** command disables direct ARP entry delivery for mutual access between local VPNs.

By default, direct ARP entry delivery is disabled for mutual access between local VPNs.

NOTE

Only the S5720I-SI, S5731-S, S5731S-S, S5731-H, S5732-H, S5735-S, S500, S5735S-S, S5735-S-I, S5736-S, S5735S-H, S6720S-S, S6720S-EI, S6735-S, S6720-EI, S6730-S, S6730S-S, S6730S-H, and S6730-H support this command.

Format

arp vpn-cross enable

undo arp vpn-cross enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

The initial traffic between two local VPNs triggers ARP Miss messages and ARP learning. If a PE device fails to timely process the ARP Miss messages due to some reasons, mutual access traffic between the VPNs cannot be transmitted.

After direct ARP entry delivery is enabled on the PE device, the PE device delivers ARP entries before the mutual access traffic triggers ARP Miss messages and ARP learning. This ensures normal traffic transmission between local VPNs.

Precautions

ARP entry delivery before triggering of ARP Miss messages and ARP learning consumes ARP entries. Configure this command only when required.

Example

Enable direct ARP entry delivery for mutual access between local VPNs.

```
<HUAWEI> system-view
[HUAWEI] arp vpn-cross enable
Warning: After this function is enabled, a large number of ARP entries will be occupied.
```

10.4.7 as-number

Function

The **as-number** command configures an AS number for a VPN instance.

The **undo as-number** command restores the default setting.

By default, a VPN instance uses the AS number of BGP.

Format

as-number { *as-number-plain* | *as-number-dot* }

undo as-number

Parameters

Parameter	Description	Value
as-number-plain	Integral AS number	The value is an integer ranging from 1 to 4294967295.
as-number-dot	AS number in dotted notation	The value is in the format of *x.y*, where *x* and *y* are integers that range from 1 to 65535 and from 0 to 65535, respectively.

Views

BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

During network transfer or service identification, a device needs to be simulated as multiple BGP devices logically. In this case, you can run the **as-number** command to configure an AS number for each VPN instance.

After the **as-number** command is used:

- BGP peer relationships in the VPN instance are established by using the configured AS number.
- The configured AS number is used to generate the aggregator attribute during route aggregation.
- When advertising routes to an EBGP peer, the local device carries the AS number configured in the VPN instance.

Prerequisites

If a BGP peer or a BGP peer group is configured in the VPN instance, you need to delete the configuration of the BGP peer or peer group before configuring or deleting an AS number.

Precautions

A VPN instance configured with an AS number cannot be configured with BGP confederation. Conversely, a VPN instance configured with BGP confederation cannot be configured with an AS number.

NOTE

The AS number configured in the BGP-VPN instance view cannot be the same as the AS number configured in the BGP view.

Example

Set the AS number of the VPN instance named **vpna** to 65001.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vpna
[HUAWEI-bgp-vpna] as-number 65001
```

10.4.8 auto-frr

Function

The **auto-frr** command enables BGP Auto FRR.

The **undo auto-frr** command disables BGP Auto FRR.

By default, BGP Auto FRR is disabled.

Format

auto-frr

undo auto-frr

Parameters

None

Views

BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This function is applicable to networks that require a low packet loss ratio and a short delay.

Using BGP Auto FRR together with BFD is recommended. They can rapidly detect a link fault and switch traffic to a standby link if a fault occurs.

Example

Enable BGP Auto FRR for unicast routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vpna
[HUAWEI-bgp-vpna] auto-frr
```

10.4.9 auto-frr (BGP-VPNv4 address family view)

Function

The **auto-frr** command enables VPNv4 FRR.

The **undo auto-frr** command restores the default configuration.

By default, VPNv4 FRR is disabled.

Format

auto-frr

undo auto-frr

Parameters

None.

Views

BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

Running the **auto-frr** command in the BGP-VPNv4 address family view enables VPNv4 FRR and improves network reliability. After VPNv4 FRR is configured, traffic can be switched to the backup LSP (Label Switched Path) immediately after the primary LSP to which a VPNv4 route recurses becomes faulty. VPNv4 FRR applies to HVPN scenarios.

- In an HVPN scenario, VPNv4 FRR is deployed on SPEs.

Prerequisites

BGP has been enabled.

Precautions

If used with BFD, VPNv4 FRR can rapidly detect link faults and switch services to the standby link for transmission.

Do not configure the **apply-label per-nexthop** command in the BGP-VPNv4 address family view if VPNv4 FRR is enabled, or VPNv4 FRR will fail to take effect.

If the **auto-frr** command is configured in the BGP-VPNv4 address family view, the **bestroute nexthop-resolved tunnel** command must also be configured, so that packets will not get lost during traffic switchback.

Example

Enable VPNv4 FRR.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] auto-frr
```

10.4.10 description (VPN instance view)

Function

The **description** command specifies the description of the current VPN instance.

The **undo description** command deletes the description of the current VPN instance.

By default, no description is specified for a VPN instance.

Format

description *description-information*

undo description

Parameters

Parameter	Description	Value
description-information	Specifies the description of a VPN instance.	The value is a string of 1 to 242 case-sensitive characters with spaces.

Views

VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To record the purpose of creating a VPN instance and the CEs with which the VPN instance is associated, you can run the **description** command to specify the description of the VPN instance.

To check the description of a VPN instance, run the **display ip vpn-instance** command.

Precautions

If you run the **description** command several times, the latest configuration overrides the previous configurations.

Example

Specify the description of a VPN instance named vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] description OnlyForAB
```

10.4.11 description (tunnel interface view)

Function

The **description** command sets the description of the current tunnel interface.

The **undo description** command deletes the description of the current tunnel interface.

By default, a tunnel interface does not have a description.

Format

description *text*

undo description

Parameters

Parameter	Description	Value
text	Specifies the description of a tunnel interface.	The value is a string of 1 to 242 case-sensitive characters, with spaces supported.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

After using the **interface tunnel** command to create a tunnel interface, you can run the **description** command to configure a description of the tunnel interface to facilitate later query.

To check the description of a tunnel interface, run the **display this interface** command in the tunnel interface view or the **display interface tunnel** command.

Example

Configure the description of Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] description This is a tunnel from 10.1.1.1 to 10.2.2.2
```

Delete the description of Tunnel 1.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] undo description
```

10.4.12 description (tunnel-policy view)

Function

The **description** command configures the description of the current tunnel policy.

The **undo description** command cancels the setting.

By default, a tunnel policy does not have a description.

Format

description *description-information*

undo description

Parameters

Parameter	Description	Value
description-information	Specifies the description of the tunnel policy.	The value is a string of 1 to 80 case-sensitive characters with spaces.

Views

Tunnel policy view

Default Level

2: Configuration level

Usage Guidelines

After using the **tunnel-policy** command to create a tunnel policy, you can run the **description** command to configure a description of the tunnel policy to facilitate later query.

To check tunnel policy configurations, run the **display tunnel-policy-config** command.

Example

Configure the description of the tunnel policy named test1.

```
<HUAWEI> system-view
[HUAWEI] tunnel-policy test1
[HUAWEI-tunnel-policy-test1] description two TE tunnels are used
```

10.4.13 destination

Function

The **destination** command specifies the destination IP address of a tunnel interface.

The **undo destination** command deletes the destination IP address of a tunnel interface.

By default, no destination address is configured.

Format

destination [**vpn-instance** *vpn-instance-name*] *dest-ip-address*

undo destination

Parameters

Parameter	Description	Value
vpn-instance *vpn-instance-name*	Specifies the name of the VPN instance that the destination address of a tunnel belongs to. When the tunnel interface uses GRE, you can specify **vpn-instance** *vpn-instance-name*.	The value is the name of an existing VPN instance.
dest-ip-address	Specifies the destination IP address of a tunnel interface.	The IPv4 address is in dotted decimal notation. The IPv6 address is a 32-digit hexadecimal number, in the format X:X:X:X:X:X:X:X.

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When configuring a GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, create a tunnel interface. After a tunnel interface is created, run the **destination** command to specify the destination IP address for the tunnel interface.

When using the **destination** command on a PE to specify the destination address of a GRE tunnel bound for a CE, you need to set **vpn-instance** *vpn-instance-name* in the command to specify the name of the VPN instance to which the destination address belongs.

Prerequisites

A tunnel interface has been created using the **interface tunnel** command, and the encapsulation mode is set to GRE, MPLS TE, IPv4 over IPv6 or IPv6 over IPv4 of manual mode using the **tunnel-protocol** command.

Precautions

Two tunnel interfaces with the same encapsulation mode, source address, and destination address cannot be configured simultaneously.

You can configure a main interface working in Layer 3 mode as the source tunnel interface.

On the GRE, MPLS TE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, the destination address of the local tunnel interface is the source address of the remote tunnel interface, and the source address of the local tunnel interface is the destination address of the remote tunnel interface.

Example

Establish a manual IPv6 over IPv4 tunnel between VLANIF 10 at 10.1.1.1 on switch HUAWEI1 and VLANIF 20 at 10.2.1.1 on switch HUAWEI2.

```
<HUAWEI1> system-view
[HUAWEI1] interface tunnel 1
[HUAWEI1-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI1-Tunnel1] source 10.1.1.1
[HUAWEI1-Tunnel1] destination 10.2.1.1
<HUAWEI2> system-view
[HUAWEI2] interface tunnel 1
[HUAWEI2-Tunnel1] tunnel-protocol ipv6-ipv4
[HUAWEI2-Tunnel1] source 10.2.1.1
[HUAWEI2-Tunnel1] destination 10.1.1.1
```

Set the destination address of the GRE tunnel Tunnel1 to 10.1.1.1 that belongs to vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] quit
[HUAWEI-vpn-instance-vpn1] quit
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol gre
[HUAWEI-Tunnel1] destination vpn-instance vpn1 10.1.1.1
```

10.4.14 display default-parameter l3vpn

Function

The **display default-parameter l3vpn** command displays the default configuration of L3VPN during initialization.

Format

display default-parameter l3vpn

Parameters

None

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Scenario

You can run this command to check the default configuration of L3VPN during initialization, for example, default label allocation mode in a VPN instance.

Precautions

This command displays only the default configuration of L3VPN during initialization. The command output shows the default configuration of L3VPN during initialization even when the default configuration is changed.

Example

Display the default configuration of L3VPN during initialization.

```
<HUAWEI> display default-parameter l3vpn
 Apply label mode          :
    IPv4-family           : label per instance
    IPv6-family           : label per instance
```

Table 10-29 Description of the display default-parameter l3vpn command output

Item	Description
Apply label mode	Default label allocation mode.
IPv4-family	IPv4 address family.
IPv6-family	IPv6 address family.
label per instance	The default label allocation mode is label per instance.

10.4.15 display ip prefix-limit statistics

Function

The **display ip prefix-limit statistics** command displays the statistics of the prefix limits of VPN instances.

Format

display ip prefix-limit { **all-vpn-instance** | **vpn-instance** *vpn-instance-name* } **statistics**

Parameters

Parameter	Description	Value
all-vpn-instance	Indicates all VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of a VPN instance.	The value is the name of an existing VPN instance.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

You can run the **display ip prefix-limit statistics** command to view the number of times that a protocol re-adds or deletes routes according to the prefix limit of a specified VPN instance.

Example

Display the statistics of the prefix limits of all VPN instances.

```
<HUAWEI> display ip prefix-limit all-vpn-instance statistics
-------------------------------------------------------------------------------
VPN instance name: vrf1
         DenyAdd TryAddInDelState NotifyDelAll NotifyDelFinish NotifyAddRoute

```

Table 10-30 Description of the display ip prefix-limit statistics command output

Item	Description
DenyAdd	Number of routes that the protocol fails to add to the RIB because of the prefix limit.
TryAddInDelState	Number of routes that the protocol fails to add to the RIB because the RIB is in the process of deleting routes.
NotifyDelAll	Number of times that the RIB notifies the protocol of deleting routes when the prefix limit is decreased.
NotifyDelFinish	Number of times that the protocol notifies the RIB of completion of deleting routes.
NotifyAddRoute	Number of times that the RIB notifies the protocol of re-adding routes.

10.4.16 display ipv6 prefix-limit statistics

Function

The **display ipv6 prefix-limit statistics** command displays the statistics of the prefix limits of IPv6 VPN instances.

Format

display ipv6 prefix-limit { **all-vpn-instance** | **vpn-instance** *vpn-instance-name* } **statistics**

Parameters

Parameter	Description	Value
all-vpn-instance	Indicates all IPv6 VPN instances.	-
vpn-instance *vpn-instance-name*	Specifies the name of an IPv6 VPN instance.	The value is the name of an existing IPv6 VPN instance.

Views

Item	Description
NotifyAddRoute	Number of times that the RIB notifies the protocol of re-adding routes.

10.4.17 display ip vpn-instance

Function

The **display ip vpn-instance** command displays configurations of VPN instances.

Format

display ip vpn-instance [**verbose**] [*vpn-instance-name*]

display ip vpn-instance [*vpn-instance-name*] **interface**

display ip vpn-instance [*vpn-instance-name*] **tunnel-info**

Parameters

Parameter	Description	Value
verbose	Displays detailed information about VPN instances.	-
vpn-instance-name	Specifies the name of a VPN instance.	The value is the name of an existing VPN instance.
interface	Displays information about the interfaces bound to the VPN instance.	-
tunnel-info	Displays information about the LSP associated with the VPN instance.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If you want to check the configurations of VPN instances, interfaces bound to them, and LSPs associated with them, run the **display ip vpn-instance** command.

Since VPN instances support both IPv4 and IPv6 address families, the **display ip vpn-instance** command displays the information of different address families separately.

If *vpn-instance-name* is not specified, the **display ip vpn-instance** command displays information about all configured VPN instances on the device.

If **interface** is specified, the display ip vpn-instance command displays all interfaces bound to the specified VPN instance.

If **tunnel-info** is specified, the **display ip vpn-instance** command displays information about the LSPs to which the routes of the VPN instance enabled with the IPv4 or IPv6 address family recurse (in other words, information about the LSPs between PEs). If the tunnels between PEs are not LSPs, the **display ip vpn-instance** command does not display tunnel information.

Precautions

If the VPN instance to be displayed is not created, the system prompts that the VPN instance does not exist.

Example

Display brief information about all VPN instances.

```
<HUAWEI> display ip vpn-instance
 Total VPN-Instances configured      : 2
 Total IPv4 VPN-Instances configured : 2
 Total IPv6 VPN-Instances configured : 0

  VPN-Instance Name              RD                  Address-family
  vpn1
  vpna                         100:1               IPv4
  vpnb                         100:2               IPv4
```

Table 10-32 Description of the display ip vpn-instance command output

Item	Description
Total VPN-Instances configured	Total number of VPN instances configured on the local end.
Total IPv4 VPN-Instances configured	Total number of locally configured VPN instances for which IPv4 address families are enabled.
Total IPv6 VPN-Instances configured	Total number of locally configured VPN instances for which IPv6 address families are enabled.
VPN-Instance Name	Name of the VPN instance.
RD	RD of the VPN instance IPv4 address family or IPv6 address family.

Item	Description
Address-family	Address family enabled for the VPN instance. The address family can be: ● Null, if no address family is enabled. ● IPv4, if only the IPv4 address family is enabled. ● IPv6, if only the IPv6 address family is enabled.

Display detailed information about all VPN instances.

```
<HUAWEI> display ip vpn-instance verbose
 Total VPN-Instances configured      : 1

```

Table 10-33 Description of the display ip vpn-instance verbose command output

Item	Description
Total VPN-Instances configured	Total number of VPN instances configured on the local end.
Total IPv4 VPN-Instances configured	Total number of locally configured VPN instances for which IPv4 address families are enabled.

Item	Description
Total IPv6 VPN-Instances configured	Total number of locally configured VPN instances for which IPv6 address families are enabled.
VPN-Instance Name and ID	Name and ID of the VPN instance. The ID is assigned by the system, which facilitates indexing.
Description	Description of the VPN instance. This field is displayed in the command output only when the **description (VPN instance view)**command is used.
Service ID	Service ID of the VPN instance. This item is displayed only after the **service-id (VPN instance view)** command is run in the VPN instance view.
Interfaces	Interfaces bound to the VPN instance. This field is displayed only after the **ip binding vpn-instance** command is configured on these interfaces.
Address family ipv4	Information about the IPv4 address family enabled for the VPN instance.
Address family ipv6	Information about the IPv6 address family enabled for the VPN instance.
Create date	Time when the VPN instance is created.
Up time	Period during which the VPN instance maintains in the Up state.
Route Distinguisher	RD of the VPN instance IPv4 address family or IPv6 address family. To specify an RD, run the **route-distinguisher** command.
Export VPN Targets	Route Target list in the outbound direction. To set the VPN target, run the **vpn-target** command.
Import VPN Targets	Route Target list in the inbound direction. To set the VPN target, run the **vpn-target** command.

Item	Description
Label Policy	Label policy: ● label per instance: indicates that the same label is allocated to routes of a VPN instance. This field is displayed in the command output only when the **apply-label per-instance** command is run in the VPN instance view. ● label per route: indicates that each route of a VPN instance is assigned a label.
Per-Instance Label	Label value used when all VPN routes of the VPN instance address family share one label. This field is displayed only after the **apply-label per-instance** command is run in the VPN instance address family view.
IP FRR Route Policy	IP FRR route policy used for the address family. This item is displayed only after the **ip frr** command is run in the VPN instance IPv4 address family view.
VPN FRR Route Policy	VPN FRR route policy used for the address family. This item is displayed only after the **vpn frr** command is run in the VPN instance IPv4 address family view.
Import Route Policy	Import Route-Policy applied to the VPN instance. This field is displayed only after the **import route-policy** command is run in the VPN instance address family view.
Export Route Policy	Export Route-Policy applied to the VPN instance. This field is displayed only after the **export route-policy** command is run in the VPN instance address family view.
Tunnel Policy	Tunnel policy applied to the VPN instance. This field is displayed only after the **tnl-policy** command is run in the VPN instance address family view.

Item	Description
Maximum Routes Limit	Maximum number of routes supported by the current address family. This field is displayed only after the **routing-table limit** command is run in the VPN instance address family view.
Threshold Routes Limit	Percentage of the maximum number of routes specified for the current address family. When the maximum number of routes reaches the percentage threshold, an alarm is generated. This field is displayed only after the **routing-table limit** command is run in the VPN instance address family view.
Maximum Prefixes Limit	Maximum number of prefixes supported by the current address family of the VPN instance. This field is displayed only after the **prefix limit** command is run in the VPN instance address family view.
Threshold Prefixes Limit	Percentage of the maximum number of prefixes specified for the current address family of the VPN instance. When the maximum number of prefixes reaches the percentage threshold, an alarm is generated. This field is displayed only after the **prefix limit** command is run in the VPN instance address family view.
Install Mode	Method of processing routes. The **prefix limit** command can be used to specify the route processing method when the threshold is lowered due to the number of route prefixes exceeding the upper threshold. ● If **route-unchanged** is configured, routes in the routing information base (RIB) table remain unchanged. ● If **route-unchanged** is not configured, all routes in the RIB table are deleted and the routes are re-installed in the RIB table.

Item	Description
Log Interval	Interval for displaying log messages when the number of VPN instance routes exceeds the maximum value. The default interval is 5 seconds. The value can be set by the command **limit-log-interval**.

Display information about the interface bound to the VPN instance named **vrf1**.

```
<HUAWEI> display ip vpn-instance vrf1 interface
 VPN-Instance Name and ID : vrf1, 1
  Interface Number : 1
  Interface list : Vlanif40
```

Table 10-34 Description of the display ip vpn-instance interface command output

Item	Description
Interface Number	Number of interfaces bound to the VPN instance
Interface list	List of interfaces bound to the VPN instance

Display information about the LSP associated with the vrf1 VPN instance.

```
<HUAWEI> display ip vpn-instance vrf1 tunnel-info
 VPN-Instance Name and ID : vrf1, 1
 Address family ipv4
  Nexthop Address              Tunnel ID
  1.1.1.1                    0x3
 Address family ipv6
  Nexthop Address              Tunnel ID
  1.1.1.1                    0x3
```

Table 10-35 Description of the display ip vpn-instance tunnel-info command output

Item	Description
Nexthop Address	Indicates the next-hop address of the route learned by the VPN instance from the peer PE.
Tunnel ID	Indicates the ID of the LSP corresponding to the next-hop address of the route learned by the VPN instance from the peer PE.

10.4.18 display ip vpn-instance import-vt

Function

The **display ip vpn-instance import-vt** command displays all VPN instances with the specified import vpn-target attribute.

Format

display ip vpn-instance import-vt *ivt-value*

Parameters

Parameter	Description	Value
ivt-value	Specifies the value of the import VPN-target attribute. The forms of VPN targets are as follows: ● 2-byte AS number: 4-byte user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a VPN target cannot be 0:0. ● IPv4-address: 2-byte user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a VPN target cannot be 0.0:0.	-

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

If a PE is configured with multiple VPN instances, the **display ip vpn-instance import-vt** command can be run on the PE to check into which VPN instances a VPNv4 route with a specified VPN target can be imported.

The VPN target controls route learning between VPN instances. A VPN target may be either an import VPN target or an export VPN target. An export VPN target is contained in a VPNv4 route to be advertised to a remote MP-BGP peer. Receiving a VPNv4 route, an MP-BGP peer compares the received export VPN target with the local import VPN target to determine whether the VPNv4 route can be added to the routing table of the local VPN instance IPv4 address family.

Precautions

At present, this command cannot be used to view the VPN instance with multiple import VPN-target attributes specified.

Example

Display the VPN instance with the import VPN-target attribute being 1:1.

```
<HUAWEI> display ip vpn-instance import-vt 1:1
The number of ipv4-family matched the import-vt : 3
 VPN-Instance Name and ID : vrf1, 1
 VPN-Instance Name and ID : vrf4, 5
 VPN-Instance Name and ID : vrf5, 4

The number of ipv6-family matched the import-vt : 2
 VPN-Instance Name and ID : vrf1, 1
 VPN-Instance Name and ID : vrf5, 4
```

Table 10-36 Description of the display ip vpn-instance import-vt command output

Item	Description
The number of ipv4-family matched the import-vt	Number of VPN instances with the specified import VPN-target attribute in the VPN instance IPv4 address family view.
The number of ipv6-family matched the import-vt	Number of VPN instances with the specified import VPN-target attribute in the VPN instance IPv6 address family view.
VPN-Instance Name and ID	Name and ID of the VPN instance.

10.4.19 display interface tunnel

Function

The **display interface tunnel** command displays details of the tunnel interface.

Format

display interface tunnel [*interface-number* | **main**]

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface. If this parameter is not specified, the command displays information about all tunnel interfaces.	The value must be the number a tunnel interface that has been created.
main	Displays status and traffic statistics about main interface. The interface has no sub-interfaces. Status and traffic statistics about the interface are displayed whether you specify the main parameter or not.	-

1: Monitoring level

Usage Guidelines

Usage Scenario

To check status of tunnels or diagnose the fault in these tunnels, run the **display interface tunnel** command. You can run this command to obtain tunnel interface information when configuring tunnels or when locating the fault on these tunnels.

Prerequisites

Before run **display interface tunnel**, please ensure that tunnel interface has been created using the **interface tunnel** command.

Example

Display the details of the tunnel interface.

```
<HUAWEI> display interface tunnel 1
Tunnel1 current state : UP
Line protocol current state : UP
Last line protocol up time : 2012-11-16 19:16:33 UTC+08:00
Description:
Route Port,The Maximum Transmit Unit is 1500
Internet Address is 10.3.1.2/24
```

```
Encapsulation is TUNNEL, loopback not set
Tunnel source 10.2.1.2 (Vlanif1234), destination 10.2.1.1
Tunnel protocol/transport GRE/IP, key disabled
keepalive enable period 5 retry-times 3
Checksumming of packets disabled
Current system time: 2012-11-16 19:17:39+08:00
Last 300 seconds input rate 16 bits/sec, 0 packets/sec
Last 300 seconds output rate 0 bits/sec, 0 packets/sec
Input:  5 packets, 650 bytes
Output:  0 packets, 0 bytes
    Input bandwidth utilization  :    0%
    Output bandwidth utilization :    0%
```

Table 10-37 Description of the display interface tunnel command output

Item	Description
Tunnel1 current state	Physical layer status of the tunnel interface: ● UP: The interface is in normal state. ● Administratively DOWN: The network administrator executes the **shutdown** command on the interface. After a tunnel interface is created, its physical layer status is Up.
Line protocol current state	Link protocol status: ● UP: The link layer protocol of the tunnel interface works normally. ● Down: The link layer protocol of the tunnel interface is abnormal.
Last line protocol up time	Last time the link layer protocol of the tunnel interface goes UP. **NOTE** This field is displayed only when the link layer protocol status of the tunnel interface is UP.
Description	Description of the tunnel interface.
Route Port	Indicates the Layer 3 interface.
The Maximum Transmit Unit is 1500	MTU of tunnel interfaces, which is 1500 bytes by default. Any packet larger than the MTU is fragmented before being sent. If non-fragmentation is configured, the packet is discarded.
Internet Address is 10.3.1.2/24	IP address of the tunnel interface is 10.3.1.2. The mask is 24 bits, that is, 255.255.255.0.
Encapsulation is TUNNEL,	Encapsulation type of packets on a tunnel interface. Packet encapsulation protects a whole IP packet.
loopback not set	The tunnel interface does not support a loopback test.
Tunnel source 10.2.1.2 (Vlanif1234)	The source address of the tunnel is 10.2.1.2. That is, the IP address of the VLANIF 1234 interface sending packets at the source side is 10.2.1.2.

Item	Description
destination 10.2.1.1	Destination address of the tunnel.
Tunnel protocol/ transport GRE/IP, key disabled	The tunnel encapsulation protocol is the GRE protocol, and the transport protocol is the IP protocol. Encapsulation protocol types of a tunnel are as follows: ● GRE: indicates Generic Routing Encapsulation. ● MPLS: encapsulates packets into MPLS packets. ● IPv6 over IPv4: encapsulates IPv6 packets into IPv4 packets. ● IPv4 over IPv6: encapsulates IPv4 packets into IPv6 packets. ● none: indicates no encapsulation. This is the default mode of the tunnel interface. key disabled: the key word recognition function of GRE is not enabled.
keepalive enable period 5 retry-times 3	The keepalive function of GRE.
Checksumming of packets disabled	The check sum function of GRE is not enabled.
Current system time	Current system time. If the time zone is configured and the daylight saving time is used, the time is in YYYY/MM/DD HH:MM:SS UTC±HH:MM DST format.
Last 300 seconds input rate	Incoming packet rate (bits per second and packets per second) within the last 300 seconds.
Last 300 seconds output rate	Outgoing packet rate (bits per second and packets per second) within the last 300 seconds.
Input	Total number of received packets.
Output	Total number of sent packets.
Input bandwidth utilization : --	Input bandwidth usage.
Output bandwidth utilization : --	Output bandwidth usage.

10.4.20 display l3vpn vpn-list tunnel-policy

Function

The **display l3vpn vpn-list tunnel-policy** command displays all the VPN instances to which a specified tunnel policy is applied.

Format

display l3vpn vpn-list tunnel-policy *tunnel-policy-name*

Parameters

Parameter	Description	Value
tunnel-policy-name	Specifies the name of a tunnel policy.	The value is the name of an existing tunnel policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

To have its routes recursing to tunnels, a VPN instance needs to apply a tunnel policy. If the tunnel policy used by a VPN instance is changed or the status of tunnels selected based on the tunnel policy changes, the recursive tunnels may change. The **display l3vpn vpn-list tunnel-policy** command displays all the VPN instances to which a specified tunnel policy is applied. The command output will show the VPN instances that will be affected by changes in the tunnel policy.

Example

Display the referential relationship between a tunnel policy and a VPN instance.

```
<HUAWEI> display l3vpn vpn-list tunnel-policy p1
Codes: *(Tunnel policy is not configured)
Tunnel Policy Name: p1
Total VPN Instance(s) number: 1
VPN(s) using the tunnel policy:
vrf1
```

Table 10-38 Description of the **display l3vpn vpn-list tunnel-policy** command output

Item	Description
Codes	Comments

Item	Description
Tunnel Policy Name	Name of a tunnel policy
Total VPN Instance(s) number	Number of VPN instances specified with tunnel policies
VPN(s) using the tunnel policy	Name of VPN instances specified with tunnel policies

10.4.21 display mpls label-stack vpn-instance

Function

The **display mpls label-stack vpn-instance** command displays information about L3VPN label stacks.

Format

display mpls label-stack vpn-instance *vpn-instance-name ip-address*

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance.	The value is the name of an existing VPN instance.
ip-address	Specifies a private IPv4 address.	The value is in dotted decimal notation.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

In a non-inter-AS L3VPN scenario, this command allows you to query label stack information on PEs based on VPN instance names and private IP addresses.

Example

Display label stack information about the VPN instance named **vpna**.

```
<HUAWEI> display mpls label-stack vpn-instance vpna 10.12.12.1
Label-stack  : 1
Level        : 1
Type         : VPN
```

```
Label       : 1033
Level       : 2
Type        : LDP
Label       : 1041
OutInterface : Vlanif100
```

Table 10-39 Description of the **display mpls label-stack vpn-instance** command output

Item	Description
Label-stack	Number of label stacks
Level	Number of labels
Type	Tunnel type
Label	Value of the outgoing label
OutInterface	Outbound interface

10.4.22 display tunnel-info

Function

The **display tunnel-info** command displays the tunnel information.

Format

display tunnel-info { **tunnel-id** *tunnel-id* | **all** | **statistics** [**slots**] }

Parameters

Parameter	Description	Value
tunnel-id *tunnel-id*	Specifies the tunnel ID. If the specified ID does not exist, the system prompts errors.	A hexadecimal integer ranging from 1 to FFFFFFFE.
all	Displays information about all the tunnels.	-
statistics	Displays statistics about all tunnels.	-
slots	Displays tunnel statistics in the order of slots.	-

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

The **display tunnel-info all** command displays existing tunnel IDs, tunnel types, destination IP addresses, and Token information about all tunnels.

The **display tunnel-info tunnel-id** *tunnel-id* command displays detailed information about a tunnel when you only know the tunnel ID.

The **display tunnel-info statistics** command displays the number of tunnels configured on the switch.

Example

View information about the tunnel.

```
<HUAWEI> display tunnel-info tunnel-id 2
Tunnel ID:                    0x2
Tunnel Token:                 2
Type:                         cr lsp
Destination:                  1.1.1.1
Out Slot:                     0
Instance ID:                  0
Interface:                    Tunnel1
Sub Tunnel ID:                0x0
<HUAWEI> display tunnel-info tunnel-id 3
Tunnel ID:                    0x3
Tunnel Token:                 3
Type:                         lsp
Destination:                  10.20.10.10
Out Slot:                     0
Instance ID:                  0
Out Interface:                Vlanif1024
Out Label:                    3
Next Hop:                     10.24.10.200
Lsp Index:                    2048
<HUAWEI> display tunnel-info tunnel-id 10006
Tunnel ID:                    0x10006
Tunnel Token:                 2
Type:                         lsp
Destination:                  6.6.6.6
Out Slot:                     0
Instance ID:                  0
Out Interface:                Vlanif15
Lsp Index:                    0
SubTunnel Type:               L2VPN QoS Token
```

Table 10-40 Description of the **display tunnel-info tunnel-id** command output

Item	Description
Tunnel ID	Tunnel ID in hexadecimal notation that is assigned by the system.
Tunnel Token	Token value used for MPLS forwarding that is a part of tunnel ID and is assigned by the system.

Item	Description
Type	Type of a tunnel, such as GRE, MPLS LSP, or CR-LSP. The command output varies according to the tunnel type.
Destination	Destination IP address of the tunnel.
Out Slot	Number of the slot that is used when the switch sends packets.
Instance ID	VPN instance ID (0 indicates that a tunnel is a public network tunnel).
Interface	Local tunnel interface.
Sub Tunnel ID	Sub-tunnel ID of VPN QoS in hexadecimal notation that is automatically assigned by the system.
Out Label	Out label value.
Next Hop	Next hop.
Lsp Index	LSP index, which is allocated by MPLS.
Out Interface	Local outbound interface of the tunnel.
SubTunnel Type	Types of tokens of sub-tunnels: ● LDP LSP over TE QoS Token ● LDP LSP QoS Token ● BGP LSP over TE QoS Token ● BGP LSP QoS Token ● Static LSP QoS Token ● CR-LSP over TE QoS Token ● L2VPN over TE QoS Token ● L2VPN QoS Token This field is displayed only for sub-tunnels.

Display all tunnel information.

```
<HUAWEI> display tunnel-info all
 * -> Allocated VC Token
Tunnel ID           Type                Destination           Token
----------------------------------------------------------------------
0x10006             lsp                 10.2.1.1              6
```

Display tunnel statistics.

```
<HUAWEI> display tunnel-info statistics
LSP/32bit LSP :                     0/0
GRE :                               2
CRLSP :                             0
LOCAL IFNET :                       0
MPLS LOCAL IFNET :                  0
VPN QOS LSP :                       0
```

```
Reserved :                        0
Vxlan :                         0
```

Table 10-41 Description of the **display tunnel-info statistics** command output

Item	Description
LSP/32bit LSP	Number of LSP tunnels created in the system view/Number of LSP tunnels triggered by the route of host with the 32-bit mask address.
GRE	Number of tunnel IDs allocated to the GRE tunnels.
CRLSP	Number of tunnel IDs allocated to the CR-LSP tunnels.
LOCAL IFNET	Number of tunnels used by the VPN internal module.
MPLS LOCAL IFNET	Number of tunnels used by the MPLS internal module.
VPN QOS LSP	Number of the tunnel ID allocated to the LSP used in VPN QoS.
Reserved	Number of the tunnel ID allocated to the product.
Vxlan	Number of tunnel IDs allocated to the Vxlan tunnels.

Display tunnel statistics in the order of slots.

```
<HUAWEI> display tunnel-info statistics slots
--------------------------------------------------------------------
Slot      LSP     CR     GRE      LCL     MPLS-L  VPN     VXLAN
Num               LSP           IFNET    IFNET   QOS
--------------------------------------------------------------------
0         0     0      0      0      0      0      0
Logic Slot: 0                  Total:  0
```

Table 10-42 Description of the display tunnel-info statistics slots command output

Item	Description
Slot Num	Slot number used by the device to send packets.
LSP	Total LSP tunnels set up by the device.
CR LSP	Number of CR-LSPs created on the device.
GRE	Number of GRE tunnels created on the device.
LCL IFNET	Number of tunnels used by the VPN module.
MPLS-L IFNET	Number of tunnels used by the MPLS module.

Item	Description
VPN QOS	Number of tunnels used for VPN QoS.
VXLAN	Number of VXLAN tunnels created on the device.

10.4.23 display tunnel-policy

Function

The **display tunnel-policy** command displays the configurations of tunnel policies.

Format

display tunnel-policy [*tunnel-policy-name*]

Parameters

Parameter	Description	Value
tunnel-policy-name	Specifies the name of tunnel policy. If *tunnel-policy-name* is specified, information about the specified tunnel policy is displayed.	The value is the name of an existing tunnel policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Using the **display tunnel-policy** command, you can check the configured tunnel policy and information about a tunnel policy before applying it.

Example

Display information about all the tunnel policies.

```
<HUAWEI> display tunnel-policy
Total   tunnel policy num:            3
Sel-Seq tunnel policy num:            1
Binding tunnel policy num:            1
Invalid tunnel policy num:            1

Tunnel Policy Name                    Select-Seq                    Load balance No
-------------------------------------------------------------------------------------------
po2                              CR-LSP LSP                    3
```

```
Tunnel Policy Name                    Destination      Tunnel Intf       Ignore-dest-check   Down switch
------------------------------------------------------------------------------------------------------------------
po2                            1.1.1.9         Tunnel2           Disable             Enable
```

Table 10-43 Description of the display tunnel-policy command output

Item	Description
Total tunnel policy num	Total number of tunnel policies.
Sel-Seq tunnel policy num	Total number of tunnel policies in select-sequence mode.
Binding tunnel policy num	Total number of tunnel policies in tunnel binding mode.
Invalid tunnel policy num	Total number of invalid tunnel policies.
Tunnel Policy Name	Name of tunnel policies.
Select-Seq	Priorities of tunnel types in descending order.
Load balance No	Number of tunnels for load balancing. The default value is 1.
Destination	Destination IP addresses of the bound tunnels, that is, IP addresses of the peer interfaces that receive packets.
Tunnel Intf	Local tunnel interface of the bound tunnel.
Ignore-dest-check	Check is disabled regardless of whether the destination IP address specified in a tunnel policy is consistent with the actual destination address of the tunnel to be bound to the tunnel policy.
Down switch	Tunnel switch over status: ● Enable indicates that the function is enabled ● Disable indicates that the function is disabled

Display information about the tunnel policy.

```
<HUAWEI> display tunnel-policy p1
The number of binding:1
Tunnel Policy Name                    Destination      Tunnel Intf       Ignore-dest-check   Down Switch
------------------------------------------------------------------------------------------------------------------
p1                             1.1.1.1         Tunnel2           Disable             Enable
```

Table 10-44 Description of the display tunnel-policy tunnel-policy-name command output

Item	Description
The number of binding	Number of the bound destination addresses.

10.4.24 display tunnel-policy-config

Function

The **display tunnel-policy-config** command displays the configuration of tunnel policies.

Format

display tunnel-policy-config [*tunnel-policy-name*]

Parameters

Parameter	Description	Value
tunnel-policy-name	Indicates the name of the tunnel policy.	The value is the name of an existing tunnel policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

After tunnel policies are configured, you can view the configuration of a tunnel policy by using the **display tunnel-policy-config** command. If you do not specify the tunnel policy to be displayed, the configurations of all tunnel policies are displayed.

Example

Display the configurations of all tunnel policies.

```
<HUAWEI> display tunnel-policy-config
#
tunnel-policy whm1
 description 1.1.1.1
#
tunnel-policy whm2
 description 1.1.1.1
```

```
 tunnel select-seq cr-lsp lsp load-balance-number 3
#
tunnel-policy whm3
 tunnel binding destination 1.1.1.1 te Tunnel2
#
return
```

Display the configuration of the tunnel policy named p1.

```
<HUAWEI> display tunnel-policy-config p1
#
tunnel-policy p1
 tunnel select-seq cr-lsp lsp load-balance-number 1
#
return
```

10.4.25 display tunnel-policy subscriber statistics

Function

The **display tunnel-policy subscriber statistics** command displays the number of times a tunnel policy is used by external services.

Format

display tunnel-policy *tunnel-policy-name* **subscriber statistics**

Parameters

Parameter	Description	Value
tunnel-policy-name	Specify the name of a tunnel policy.	The value is the name of an existing tunnel policy.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

Usage Scenario

A system has many tunnel policies that can be used by different services. The **display tunnel-policy subscriber statistics** command can be used to view the number of times a tunnel policy is used by external services. This prevents the tunnel policy from being deleted mistakenly.

Example

View the number of times a tunnel policy is used by external services.

```
<HUAWEI> display tunnel-policy nms-vrf-vpna subscriber statistics
The specified tunnel policy does not exist.
Total 0 applications subscribed the tunnel policy.
```

View the number of times a tunnel policy is used by external services.

```
<HUAWEI> display tunnel-policy nms-vrf-vpna subscriber statistics
Total 200 applications subscribed the tunnel policy.
```

Table 10-45 Description of the **display tunnel-policy subscriber statistics** command output

Item	Description
The specified tunnel policy does not exist. Total 0 applications subscribed the tunnel policy.	The tunnel policy does not exist and is not used by applications.
Total 200 applications subscribed the tunnel policy.	The tunnel policy exists and is used by 200 applications.

10.4.26 display tunnel-selector

Function

The **display tunnel-selector** command displays the configurations of tunnel selectors of a system.

Format

display tunnel-selector [*tunnel-selector-name*]

Parameters

Parameter	Description	Value
tunnel-selector-name	Specifies the name of a tunnel selector.	The value is the name of an existing tunnel selector.

Views

All views

Default Level

1: Monitoring level

Usage Guidelines

If *tunnel-selector-name* is not specified in the command, the command displays the configurations of all the tunnel selectors of the system.

Example

Display information about a tunnel selector named tps.

```
<HUAWEI> display tunnel-selector tps
Tunnel-selector : tps
  permit : 10 (matched counts: 0)
    Match clauses :
      if-match ip next-hop ip-prefix ipv4prefix
    Apply clauses :
      apply tunnel-policy policy1
```

Table 10-46 Description of the **display tunnel-selector** command output

Item	Description
Tunnel-selector	Name of a tunnel selector
permit : 10	Matching mode and number of the node of the tunnel selector
Match clauses	**if-match** clauses
Apply clauses	**apply** causes

10.4.27 export route-policy

Function

The **export route-policy** command associates the current VPN instance address family with an export Route-Policy.

The **undo export route-policy** command disassociates the current VPN instance address family from the export Route-Policy.

By default, the current VPN instance address family is not associated with any export Route-Policy.

Format

export route-policy *policy-name*

undo export route-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of the export Route-Policy to be associated with the VPN instance address family.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN instance IPv4 address family view, VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

You can implement a more accurate advertisement of the routes of the VPN instance address family based on the export Route-Policy than that based on the extended community attribute. The export Route-Policy is used to filter the routing information and to set the routing attributes of the routes that pass the filtering.

The **export route-policy** command advertises local routes of the VPN instance address family to other VPN instances address family. The **peer route-policy** command or the **filter-policy** command run in the BGP VPN instance address family view filters routes of the VPN instance address family advertised to or received from CE neighbors.

In local cross scenarios, you can run the **export route-policy** command to filter out locally crossed routes and set the attributes of these routes. Locally crossed routes include both locally imported routes and routes learned from VPN peers.

Prerequisites

The **route-distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

The current VPN instance address family can be associated with only one export Route-Policy. If the **export route-policy** command is run several times, the latest configuration overrides the previous configurations.

If the route policy does not exist, you need to configure the route policy.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the route-policy nonexistent-config-check disable command is run in the system view and a nonexistent route-policy is referenced using the current command in the VPN instance view or BGP-VPN instance IPv4 address family view, all routes in the VPN instance address family can be crossed to the VPNv4 address family. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command in the BGP-VPN instance IPv6 address family view, all routes in the BGP-VPN instance IPv6 address family can be crossed to the VPNv6 address family.

Example

Apply an export Route-Policy named poly-1 to the IPv4 address family of the VPN instance named vrf1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] export route-policy poly-1
```

10.4.28 if-match ip next-hop (tunnel-selector view)

Function

The **if-match ip next-hop** command configures route filtering based on the next hop.

The **undo if-match ip next-hop** command cancels the setting.

By default, route filtering based on the next hop is not configured.

Format

if-match ip next-hop { **acl** { *acl-number* | *acl-name* } | **ip-prefix** *ip-prefix-name* }

undo if-match ip next-hop [**acl** { *acl-number* | *acl-name* } | **ip-prefix** *ip-prefix-name*]

Parameters

Parameter	Description	Value
acl *acl-number*	Specifies the number of a basic ACL.	The value is an integer ranging from 2000 to 2999.
acl *acl-name*	Specifies the name of a named ACL.	The value is a string of 1 to 64 case-sensitive characters without spaces. The value must start with a letter.
ip-prefix *ip-prefix-name*	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Tunnel selector view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

This command can be run in the tunnel selector view on the SPE in HVPN networking needs to apply a tunnel policy to VPNv4 routes to, for example, have the VPNv4 routes recursing to MPLS TE tunnels.

The **if-match ip next-hop** command is used to apply a tunnel policy to the VPNv4 or BGP-IPv4 labeled routes with a specified next hop, not all VPNv4 or BGP-IPv4 labeled routes.

Either an ACL or IP prefix list can be used to filter routes by next hop.

Prerequisite

The **tunnel-selector** command is run to create a tunnel selector.

An IP prefix list is configured using the **ip ip-prefix** command, or an ACL is configured using the **acl** command in the system view or the **acl name** command to specify the next hop.

Follow-up Procedure

Run the **apply tunnel-policy** command in the tunnel selector view to apply a tunnel policy to the routes that pass the filtering.

Precautions

Creating an ACL before it is referenced is recommended. If a nonexistent ACL is referenced using the command, all routes match the ACL.

Creating an IP prefix list before it is referenced is recommended. By default, nonexistent IP prefix lists cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent IP prefix list is referenced using the current command, all routes match the IP prefix list.

Example

Configure route filtering based on the next hop.

```
<HUAWEI> system-view
[HUAWEI] tunnel-selector abc permit node 10
[HUAWEI-tunnel-selector] if-match ip next-hop acl 2000
```

10.4.29 if-match ip-prefix (tunnel-selector view)

Function

The **if-match ip-prefix** command configures a tunnel selector to use an IP prefix list as a route filtering rule.

The **undo if-match ip-prefix** command restores the default configuration.

By default, a tunnel selector does not use any IP prefix list as a route filtering rule.

Format

if-match ip-prefix *ip-prefix-name*

undo if-match ip-prefix *ip-prefix-name*

Parameters

Parameter	Description	Value
ip-prefix-name	Specifies the name of an IP prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

Tunnel-selector view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To enable a device to match routes against a specified IP prefix list and determine whether to permit or deny the routes based on matching results, run the **if-match ip-prefix** command to configure a tunnel selector to use the IP prefix list as a route filtering rule.

The **if-match ip-prefix** command must be used with the **ip ip-prefix** command. For example:

If the **if-match ip-prefix aa** and **ip ip-prefix aa permit 1.1.1.1 32** commands are both configured, BGP routes with IP prefix 1.1.1.1/32 will be permitted.

Prerequisites

A tunnel selector has been configured using the **tunnel-selector** command.

The IPv4 prefix list has been created by running the **ip ip-prefix** command.

Precautions

Routes are filtered by IP prefix. Only routes matching the specified IP prefix list are permitted.

Example

Configure a tunnel selector to use IP prefix list **p1** as a route filtering rule.

```
<HUAWEI> system-view
[HUAWEI] ip ip-prefix p1 permit 10.0.0.0 8 greater-equal 17 less-equal 18
[HUAWEI] tunnel-selector policy permit node 10
[HUAWEI-tunnel-selector] if-match ip-prefix p1
```

10.4.30 if-match ipv6 next-hop (tunnel-selector view)

Function

The **if-match ipv6 next-hop** command configures the filtering of IPv6 routes based on the next hop.

The **undo if-match ipv6 next-hop** command cancels the setting.

By default, the filtering of IPv6 routes based on the next hop is not configured.

Format

if-match ipv6 next-hop prefix-list *ipv6-prefix-name*

undo if-match ipv6 next-hop prefix-list *ipv6-prefix-name*

Parameters

Parameter	Description	Value
prefix-list *ipv6-prefix-name*	Specifies the name of an IPv6 prefix list.	The name is a string of 1 to 169 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

tunnel selector view

Default Level

2: Configuration level

Usage Guidelines

You can run the **if-match ipv6 next-hop** command if it is required to filter IPv6 routes based on the next hop. When you run the **if-match ipv6 next-hop** command in the tunnel selector view, you can use an **apply** clause to apply a tunnel policy to the IPv6 routes filtered based on the next hop.

The next hop can be specified by the IPv6 prefix list.

Example

Configure filtering of IPv6 routes based on the next hop.

```
<HUAWEI> system-view
[HUAWEI] tunnel-selector abc permit node 10
[HUAWEI-tunnel-selector] if-match ipv6 next-hop prefix-list ipv6prefix
```

10.4.31 import route-policy

Function

The **import route-policy** command associates the current VPN instance address family with an import Route-Policy.

The **undo import route-policy** command disassociates the current VPN instance address family from an import Route-Policy.

By default, the current VPN instance address family is not associated with any import Route-Policy.

Format

import route-policy *policy-name*

undo import route-policy

Parameters

Parameter	Description	Value
policy-name	Specifies the name of the import Route-Policy to be associated with the VPN instance address family.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN instance IPv4 address family view, or VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When no import Route-Policy is configured, routes that match the export VPN target attribute of the received routes and the import VPN target attribute of the local VPN instance address family are added to the VPN instance address family.

To control the import of the routes into the VPN instance address family more accurately, you can use the import Route-Policy. The import Route-Policy is used to filter the imported routing information and to set the routing attributes of the routes that pass the filtering.

The **import route-policy** command controls the VPN routes that are cross added to the VPN instance address family. The **peer route-policy** command or the **filter-policy** command run in the BGP VPN instance address family view filters routes of the VPN instance address family advertised to or received from CE neighbors.

Prerequisites

The **route-distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

The current VPN instance address family can be associated with only one import Route-Policy. If the **import route-policy** command is run several times, the latest configuration overrides the previous configurations.

If the route policy to be associated with the VPN instance address family does not exist, you need to configure the route policy.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command in the VPN instance view or BGP-VPN instance IPv4 address family view, all routes in the VPNv4 address family can be crossed to the VPN instance address family. If the route-policy nonexistent-config-check disable command is run in the system view and a nonexistent route-policy is referenced using the current command in the BGP-VPN instance IPv6 address family view, all routes in the VPNv6 address family can be crossed to the VPN instance address family.

Example

Apply an import Route-Policy named poly-1 to the IPv4 address family of the VPN instance named vrf1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] import route-policy poly-1
```

10.4.32 ingress-lsp trigger

Function

The **ingress-lsp trigger** command specifies a routing policy to control the creation of ingress LSPs based on BGP labeled routes.

The **undo ingress-lsp trigger** command restores the default setting.

By default, ingress LSPs are created based on all received BGP labeled routes.

NOTE

This command is not supported by the S5731S-S, S6730S-S, and S6735-S.

Format

ingress-lsp trigger route-policy *route-policy-name*

undo ingress-lsp trigger

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of a routing policy to be used to create ingress LSPs based on BGP labeled routes.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

BGP view, BGP-IPv4 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a MAN where the hybrid access mode is used, a large number of BGP labeled routes are used to establish end-to-end LSPs. On certain intermediate nodes where VPN services do not need to be supported, excessive ingress LSPs are created, causing the waste of network resources. In this case, you can run the **ingress-lsp trigger** command to create ingress LSPs based on a routing policy to save network resources.

Precautions

If the **ingress-lsp trigger** command is run more than once, the latest configuration overrides the previous ones.

Creating a route-policy before it is referenced is recommended. By default, nonexistent route-policies cannot be referenced using the command. If the **route-policy nonexistent-config-check disable** command is run in the system view and a nonexistent route-policy is referenced using the current command, ingress LSPs are established for all labeled routes.

Example

Specify a routing policy named test-policy to control the creation of ingress LSPs based on labeled IPv4 routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family unicast
[HUAWEI-bgp-af-ipv4] ingress-lsp trigger route-policy test-policy
```

10.4.33 interface tunnel

Function

The **interface tunnel** command creates a tunnel interface.

The **undo interface tunnel** command deletes the configured tunnel interface.

By default, no tunnel interface is configured.

Format

interface tunnel *interface-number*

undo interface tunnel *interface-number*

Parameters

Parameter	Description	Value
interface-number	Specifies the number of the tunnel interface.	The value is an integer that ranges from 0 to 2047 .

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

To forward data over a tunnel, ensure that the tunnel has been created. The system supports the following types of tunnels:

- LSP (Static LSP, BGP LSP, LDP LSP)
- MPLS TE
- GRE

- IPv6 over IPv4
- IPv4 over IPv6

You must use the **interface tunnel** command to create a tunnel interface when creating a tunnel except for LSP tunnels.

Precautions

Tunnel interface numbers are valid on the local device only. You can configure different numbers for the tunnel interfaces on the two ends.

Follow-up Procedure

After a tunnel interface is created, you need to configure an IP address and encapsulation type for the tunnel interface.

To save IP addresses, run the **ip address unnumbered** command to configure the tunnel interface to borrow an IP address of another interface.

The **tunnel-protocol** command configures an encapsulation protocol for the tunnel interface. Then basic configurations are performed based on the encapsulation protocol:

- On an MPLS TE tunnel, run the **destination**, **mpls te tunnel-id**, **mpls te signal-protocol**, and **mpls te commit** commands.
- On the GRE, IPv4 over IPv6 tunnel or manual IPv6 over IPv4 tunnel, run the **source** and **destination** commands.

Example

Create a tunnel interface.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1]
```

10.4.34 ip binding vpn-instance

Function

The **ip binding vpn-instance** command associates an interface on a PE with a VPN instance.

The **undo ip binding vpn-instance** command disables the association between a VPN instance and an interface.

By default, an interface is a public network interface and is not associated with any VPN instance.

Format

ip binding vpn-instance *vpn-instance-name*

undo ip binding vpn-instance *vpn-instance-name*

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of the VPN instance that is associated with the interface.	The value must be an existing VPN instance name.

Views

Interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a VPN instance is created, you need to associate the PE interface connecting to the VPN with the VPN instance. Then, the interface is used as a private network interface on which a private network address and a private network routing protocol can be configured.

Prerequisites

The **ip vpn-instance** command has been executed to create a VPN instance.

Precautions

Binding an interface to a VPN instance or deleting the binding will result in the deletion of the IP address, Layer 3 features, and IP-related routing protocols of the interface as well as IGMP snooping and MLD snooping configurations of the VLAN to which the interface is added. These features must be re-configured if needed.

An interface cannot be bound to any VPN instance that is not enabled with any address family.

Using the **undo ipv4-family** or **undo ipv6-family** command to disable the IPv4 or IPv6 address family also deletes the IPv4 or IPv6 configurations of the interfaces bound to the VPN instance.

The binding relationship between an interface and a VPN instance with a BFD session bound is removable using the **undo ip binding vpn-instance** command only after the bound BFD session is removed.

Example

Associate the VLANIF 10 interface with the VPN instance named **vrf1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] quit
[HUAWEI-vpn-instance-vrf1] quit
```

```
[HUAWEI] interface vlanif 10
[HUAWEI-Vlanif10] ip binding vpn-instance vrf1
```

Associate the GE0/0/1 interface with the VPN instance named **vrf1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vrf1-af-ipv4] quit
[HUAWEI-vpn-instance-vrf1] quit
[HUAWEI] interface gigabitethernet 0/0/1
[HUAWEI-GigabitEthernet0/0/1] undo portswitch
[HUAWEI-GigabitEthernet0/0/1] ip binding vpn-instance vrf1
```

10.4.35 ip frr (VPN instance view)

Function

The **ip frr** command enables IP FRR of a private network in the VPN instance IPv4 address family view.

The **undo ip frr** command disables IP FRR of a private network in the VPN instance IPv4 address family view.

By default, IP FRR of a private network is disabled in the VPN instance IPv4 address family view.

Format

ip frr route-policy *route-policy-name*

undo ip frr

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Enables IP FRR for the private routes matching the specified route-policy.	The name is a string of 1 to 40 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

VPN instance view, VPN instance IPv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the development of the network, services such as audio, online video, and finance have more requirements for real time. Generally, active/standby links are deployed on the network to ensure service stability.

However, under traditional forwarding modes, when multiple routes to the same destination exist, the system selects the optimal route, which is delivered to FIB table to direct data forwarding. When the optimal link is faulty, the system waits for the completion of route convergence, then selects another optimal route, and then deliver the route to the FIB table. Then the service is recovered. This process leads to a long-time service interruption and cannot meet service requirements.

Using the **ip frr** command, you can enable IP FRR of the private network. IP FRR can specify a backup next hop and a backup interface and set backup forwarding information for IPv4 routes. When the active link is faulty, the system can switch the traffic immediately to the backup link. This process is irrelevant to route convergence and therefore services are interrupted for short time.

Pre-configuration Tasks

You are advised to use the **route-policy** command to create Route-Policy at first, in which the **apply backup-interface** command and the **apply backup-nexthop** command are used to set a backup outbound interface and a backup next hop for IPv4 route of the private network.

The **ip frr** command should be used with the **apply backup-interface** command and the **apply backup-nexthop** command.

- To configure IP FRR for a private network, you need to run the **route-policy** command to create Route-Policy first. Then set a backup outbound interface and next hop for IPv4 routes of the private network using the **apply backup-interface** and **apply backup-nexthop** commands.
- To configure IP+VPN hybrid FRR, you need to run the **route-policy** command to create Route-Policy first. Then set a backup next hop for IPv4 routes of the private network using the **apply backup-nexthop** command.

NOTE

The differences between the IP FRR configuration and IP+VPN hybrid FRR configuration is as follows:

- If the backup next hop and the backup outgoing interface are specified at the same time, the configurations are for IP FRR.
- If only the backup next hop is specified, the configurations are for IP+VPN hybrid FRR. Based on the backup next hop, a matched VPNv4 route from another PE is found. Then a hybrid FRR entry is formed according to the fields of Token, BackupToken, and Label in the route.
- It is invalid to only specify the backup outgoing interface.

Precautions

Only one policy can be used at one time. New configuration will replace the previous one if another policy is configured. Configuration in the system view and that in the VPN instance view will not interfere each other.

Example

Specify a backup outbound interface and a backup next hop in route-policy **ip_frr_rp** and enable IP FRR for private routes in the VPN instance view.

```
<HUAWEI> system-view
[HUAWEI] route-policy ip_frr_rp permit node 10
[HUAWEI-route-policy] apply backup-interface vlanif 100
[HUAWEI-route-policy] apply backup-nexthop 192.168.20.2
[HUAWEI-route-policy] quit
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ip frr route-policy ip_frr_rp
```

10.4.36 ipv6 frr (VPN instance IPv6 address family view)

Function

The **ipv6 frr** command enables IPv6 FRR of the private network in the VPN instance IPv6 address family view.

The **undo ipv6 frr** command disables IPv6 FRR of the private network.

By default, IPv6 FRR of the private network is disabled.

NOTE

Only the S5720I-SI, S5735-S, S5735S-S, S5735-S-I, S5735S-H, S5736-S, S5731-H, S5731-S, S5731S-H, S5731S-S, S5732-H, S6735-S, S6720-EI, S6720S-EI, S6720S-S, S6730-H, S6730S-H, S6730-S, and S6730S-S support this function.

Format

ipv6 frr route-policy *route-policy-name*

undo ipv6 frr

Parameters

Parameter	Description	Value
route-policy *route-policy-name*	Specifies the name of the Route-Policy used by IPv6 FRR.	The name must be unique. The value is a string of 1 to 40 case-sensitive characters.

Views

VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

With the development of the network, services such as audio, online video, and finance have more requirements for real time. Generally, active/standby links are deployed on the network to ensure service stability.

However, under traditional forwarding modes, when multiple routes to the same destination exist, the system selects the optimal route, which is delivered to FIB table to direct data forwarding. When the optimal link is faulty, the system waits for the completion of route convergence, then selects another optimal route, and then deliver the route to the FIB table. Then the service is recovered. This process leads to a long-time service interruption and cannot meet service requirements.

Using the **ipv6 frr** command enables IPv6 FRR of the private network. IPv6 FRR can specify a backup next hop and a backup interface and set backup forwarding information for IPv6 routes. When the active link is faulty, the system can switch the traffic immediately to the backup link. This process is irrelevant to route convergence and therefore services are interrupted for short time.

Pre-configuration Tasks

The **ipv6 frr** command should be used with the **apply ipv6 backup-interface** command and the **apply ipv6 backup-nexthop** command. You are advised to use the **route-policy** command to create Route-Policy at first, in which the **apply ipv6 backup-interface** command and the **apply ipv6 backup-nexthop** command are used to set a backup outbound interface and a backup next hop for IPv6 route of the private network.

Precautions

Only one policy can be used at one time. New configuration will replace the previous one if another policy is configured. Configuration in the system view and that in the VPN instance IPv6 address family view will not interfere each other.

Example

Specify a backup next hop in the Route-Policy named ipv6_frr_rp. Enable IPv6 FRR of the private network in the VPN instance IPv6 address family view.

```
<HUAWEI> system-view
[HUAWEI] route-policy ipv6_frr_rp permit node 10
[HUAWEI-route-policy] apply ipv6 backup-interface GigabitEthernet1/0/0
[HUAWEI-route-policy] apply ipv6 backup-nexthop 2001:db8:1::1
[HUAWEI-route-policy] quit
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv6-family
[HUAWEI-vpn-instance-vpn1-af-ipv6] route-distinguisher 100:100
[HUAWEI-vpn-instance-vpn1-af-ipv6] ipv6 frr route-policy ip_frr_rp
```

10.4.37 ip vpn-instance

Function

The **ip vpn-instance** command creates a VPN instance and displays the VPN instance view.

The **undo ip vpn-instance** command deletes a specified VPN instance.

By default, no VPN instance is configured.

Format

ip vpn-instance *vpn-instance-name*

undo ip vpn-instance *vpn-instance-name*

Parameters

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance.	The value is a string of 1 to 31 case-sensitive characters, spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

When private network data needs to travel across a public network, you need to configure a VPN instance on the PE of the public network. The public network mentioned here is an MPLS backbone network.

A multi-VPN-instance CE (MCE) device can connect to multiple VPNs. The MCE solution isolates services of different VPNs while reducing cost of network devices. Before configuring an MCE device, configure a VPN instance on the MCE device.

VPN instances are required for all L3VPN configurations.

Precautions

After the ip vpn-instance command is run, a virtual routing table is created on the PE or MCE and consumes resources on the PE or MCE.

After the **undo ip vpn-instance** command is used to delete a VPN instance, all configurations of this VPN instance are deleted.

A VPN instance with a BFD session bound can be deleted using the **undo ip vpn-instance** command only after the bound BFD session is deleted.

When you run the **undo ip vpn-instance** command to delete the VPN instance, if this instance is specified by the **source ip** (NETCONF view) command, you need to delete the bound VPN instance using the **undo source ip** (NETCONF view) command, and then delete the VPN instance.

Follow-up Procedure

After creating a VPN instance, perform the following configurations in the VPN instance view:

- Enable the IPv4 or IPv6 address family for the VPN instance. A VPN instance supports both the IPv4 and IPv6 address families. You need to run the **ipv4-family (VPN instance view)** or **ipv6-family (VPN instance view)** command to enable the IPv4 or IPv6 address family based on the type of the protocol stack used to advertise VPN routes in the VPN instance.

- Configure an RD for the IPv4 address family of the VPN instance. You are allowed to perform VPN configurations in the address family view only after using the **route-distinguisher** command to configure an RD for the address family.
- Configure a VPN target for the VPN instance using the **vpn-target** command. The VPN target controls route learning between VPN instances.
- Bind the VPN instance to the PE or MCE interface connected to the VPN using the **ip binding vpn-instance** command. After an interface is bound to a VPN instance, the interface becomes a part of the VPN. Packets entering the interface will be forwarded based on the VRF table of the VPN.

Example

Create a VPN instance named **vrf1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1]
```

10.4.38 ipv4-family (VPN instance view)

Function

The **ipv4-family** command enables the IPv4 address family for a VPN instance and displays the VPN instance IPv4 address family view.

The **undo ipv4-family** command disables the IPv4 address family for a VPN instance.

By default, VPN instances are disabled with the IPv4 address family.

Format

ipv4-family

undo ipv4-family

Parameters

None.

Views

VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In BGP/MPLS IP VPN networking, after running the **ip vpn-instance** command to create a VPN instance, you can run the **ipv4-family** command to enable the IPv4 address family for the VPN instance. You can then perform VPN configurations in the address family view to advertise IPv4 VPN routes and allow IPv4 VPN data to be forwarded.

Follow-up Procedure

Run the **route-distinguisher** command to configure an RD for the IPv4 address family of the VPN instance. Before performing VPN configurations in the IPv4 address family view, configure an RD for the IPv4 address family of the VPN instance.

Precautions

Configurations of the commands run in the VPN instance view, except the **description** and **service id** command, are automatically synchronized to the VPN instance IPv4 address family view.

The IPv4 address family for a VPN instance with a BFD session bound can be disabled using the **undo ipv4-family** command only after the bound BFD session is deleted.

Example

Enable the IPv4 address family for a VPN instance.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv4-family
[HUAWEI-vpn-instance-vrf1-af-ipv4]
```

10.4.39 ipv6-family (VPN instance view)

Function

The **ipv6-family** command enables the IPv6 address family for a VPN instance and displays the VPN instance IPv6 address family view.

The **undo ipv6-family** command disables the IPv6 address family for a VPN instance.

By default, the IPv6 address family is disabled for a VPN instance.

Format

ipv6-family

undo ipv6-family

Parameters

None

Views

VPN instance view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In BGP/MPLS IPv6 VPN networking, after running the **ip vpn-instance** command to create a VPN instance, you can run the **ipv6-family** command to enable the IPv6 address family for the VPN instance and perform VPN configurations in the address family view if you want to have IPv6 VPN routes advertised and IPv6 VPN data forwarded.

Follow-up Procedure

Run the **route-distinguisher** command to configure an RD for the IPv6 address family of the VPN instance. VPN configurations can be performed in the IPv6 address family view only after an RD is configured for the IPv6 address family of the VPN instance.

Precautions

The IPv6 address family for a VPN instance with a BFD session bound can be disabled using the **undo ipv6-family** command only after the bound BFD session is deleted.

Example

Enable the IPv6 address family for the VPN instance named vrf1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vrf1
[HUAWEI-vpn-instance-vrf1] ipv6-family
[HUAWEI-vpn-instance-vrf1-af-ipv6]
```

10.4.40 limit-log-interval

Function

The **limit-log-interval** command configures the interval for displaying logs when the number of routes exceeds the threshold.

The **undo limit-log-interval** command restores the default setting.

By default, the interval for displaying logs when the number of routes exceeds the threshold is 5 seconds.

Format

limit-log-interval *interval*

undo limit-log-interval

Parameters

Parameter	Description	Value
interval	Specifies the interval for displaying logs when the number of routes exceeds the threshold.	An integer ranging from 1 to 60, in seconds.

Views

VPN instance view, VPN instance IPv4 address family view or VPN instance IPv6 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If the routes or prefixes in the IPv4 or IPv6 address family of a VPN instance reach the maximum, the system will generate logs at intervals (defaulting to 5 seconds). To prevent logs from being displayed frequently, run the **limit-log-interval** command to prolong the interval of log generation.

The maximum number of routes or prefixes that the IPv4 or IPv6 address family of a VPN instance supports can be configured using the **routing-table limit** or **prefix limit** command.

Prerequisites

1. The **ip vpn-instance** command has been executed to create a VPN instance and enter the VPN instance view.
2. The **ipv4-family** or **ipv6-family** command has been executed to create a VPN instance and enter the VPN instance IPv4 or IPv6 address family view.
3. The **route distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

If a log is generated to record the event that routes or prefixes in the IPv4 or IPv6 address family of a VPN instance reach the maximum, no more routes can be added to the routing table of the IPv4 or IPv6 address family of the VPN instance. Instead, the routes will be discarded.

Example

Set the interval for displaying logs to 8 seconds when the number of routes in the IPv4 address family of the VPN instance named vpn1 exceeds the threshold.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] limit-log-interval 8
```

10.4.41 mpls te reserved-for-binding

Function

The **mpls te reserved-for-binding** command reserves an MPLS TE tunnel for VPN binding.

The **undo mpls te reserved-for-binding** command removes the configuration.

By default, an MPLS TE tunnel can be selected based on any type of tunnel policy.

Format

mpls te reserved-for-binding

undo mpls te reserved-for-binding

Parameters

None

Views

Tunnel interface view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

If a VPN has high requirements for bandwidth, you can apply a tunnel binding policy to the VPN to have the routes of the VPN recursing to MPLS TE tunnels. Before applying that tunnel binding policy to the VPN, you need to run the **mpls te reserved-for-binding** command to reserve MPLS TE tunnels for VPN binding.

Prerequisites

MPLS TE tunnels are available in the system.

Configuration Impact

After the **mpls te reserved-for-binding** command is configured on an MPLS TE tunnel, the tunnel can be selected based on a tunnel binding policy only. Even if no tunnel binding policy is configured, a tunnel type prioritizing policy created using the **tunnel select-seq** command will not select the MPLS TE tunnel for which the **mpls te reserved-for-binding** command has been configured.

Follow-up Procedure

Run the **tunnel-policy** command to create a tunnel policy and the **tunnel binding** command to bind the policy to the MPLS TE tunnel.

Example

Reserve Tunnel1 for VPN binding.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] tunnel-protocol mpls te
[HUAWEI-Tunnel1] mpls te reserved-for-binding
```

Delete the configuration of a tunnel that is reserved for VPN binding.

```
<HUAWEI> system-view
[HUAWEI] interface tunnel 1
[HUAWEI-Tunnel1] undo mpls te reserved-for-binding
```

10.4.42 nd vpn-cross enable

Function

The **nd vpn-cross enable** command enables direct ND entry delivery for mutual access between IPv6 VPNs.

The **undo nd vpn-cross enable** command disables direct ND entry delivery for mutual access between IPv6 VPNs.

By default, direct ND entry delivery for mutual access between IPv6 VPNs is disabled.

NOTE

Only the S5731-S, S5731S-S, S5731-H, S5731S-H, S5732-H, S6720S-EI, S6720-EI, S6730-S, S6730S-S, and S6730-H support this command.

Format

nd vpn-cross enable

undo nd vpn-cross enable

Parameters

None

Views

System view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a scenario of mutual access between IPv6 VPNs, traffic initiated during mutual access for the first time will trigger ND Miss messages and ND entry learning. If a PE device fails to process the ND Miss messages in time (for example, when a new card is installed), mutual access traffic between the VPNs cannot be transmitted.

After direct ND entry delivery for mutual access between IPv6 VPNs is enabled on the PE device, the device delivers ND entries in advance when a new card is installed without the need to trigger mutual access traffic. This ensures proper transmission of mutual access traffic between local VPNs.

Precautions

After direct ND entry delivery for mutual access between IPv6 VPNs is enabled, the ND entries delivered by the device in advance will consume some ND entry resources. Therefore, configure this function only when required.

Example

Enable direct ND entry delivery for mutual access between IPv6 VPNs.

```
<HUAWEI> system-view
[HUAWEI] nd vpn-cross enable
Warning: After this function is enabled, a large number of ND entries will be occupied.
```

10.4.43 peer default-originate vpn-instance

Function

The **peer default-originate vpn-instance** command configures BGP to advertise all default routes related to the specified VPN instance to the specified VPNv4 peer or peer group.

The **undo peer default-originate vpn-instance** command removes the configuration.

By default, BGP does not advertise its default route to the VPNv4 peer or peer group.

Format

peer { *ipv4-address* | *group-name* } **default-originate vpn-instance** *vpn-instance-name*

undo peer { *ipv4-address* | *group-name* } **default-originate vpn-instance** *vpn-instance-name*

Parameters

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
group-name	Specifies the name of the peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
vpn-instance-name	Specifies the name of a VPN instance.	The value must be an existing VPN instance name.

Views

BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

HoVPN refers to a hierarchical VPN, with multiple PEs functioning as different roles to form a hierarchical architecture and provide functions of a single PE. In this manner, the performance requirement on PEs is lowered. If the **peer default-originate vpn-instance** command is used, SPE sends the default route with the address of the next hop as the local address, regardless of whether there is a default route in the local routing table. The UPE then only needs to maintain the local VPN routes, whereas all remote routes are replaced by the default route. The workload of the UPE is reduced.

Precautions

If an SPE does not have an active default route, either of the following methods can be used to generate a default route on the SPE and allow the SPE to advertise the route to the UPE:

- Method 1: Run the **peer default-originate vpn-instance** command to enable the SPE to automatically generate a default route and advertise it to the UPE.
- Method 2: Run the **ip route-static vpn-instance** command to configure a default route on the SPE, run the **default-route imported** command to enable the SPE to import the default route to the BGP routing table, and then run the **import-route static** or **network** command in the BGP-VPN instance IPv4 address family view to import the default route to the BGP IPv4 VPN instance routing table.

Either of the preceding methods can be used to advertise a default route to the UPE. The priority of the default route generated through method 1 is higher than that generated through method 2. If method 1 is used, the default route generated through method 2 will be suppressed, and no Update messages will be sent for a route change or withdrawal. If the SPE has an active default route, the SPE can advertise the route to the UPE without the need for either of the preceding methods.

Example

Advertise default routes of vpn1 to VPNv4 peer 1.1.1.1.

```
<HUAWEI> system-view
```

```
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 1.1.1.1 as-number 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] peer 1.1.1.1 enable
[HUAWEI-bgp-af-vpnv4] peer 1.1.1.1 upe
[HUAWEI-bgp-af-vpnv4] peer 1.1.1.1 default-originate vpn-instance vpn1
```

10.4.44 peer mpls-local-ifnet disable

Function

The **peer mpls-local-ifnet disable** command disables EBGP peers from establishing an MPLS local ifnet tunnel between them.

The **undo peer mpls-local-ifnet disable** command enables EBGP peers to establish an MPLS local ifnet tunnel between them.

By default, EBGP peers can automatically establish MPLS local ifnet tunnels between them if one of the following conditions is met:

- EBGP peers are enabled to exchange labeled routes.
- EBGP peers are configured in the BGP-VPLS address families.
- EBGP peers are configured in the BGP-VPNv4 or BGP-VPNv6 address family.

Format

peer { *group-name* | *ipv4-address* } **mpls-local-ifnet disable**

undo peer { *group-name* | *ipv4-address* } **mpls-local-ifnet disable**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a BGP peer.	The value is in dotted decimal notation.

Views

BGP view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

MPLS local ifnet tunnel: In inter-AS VPN Option B or Option C scenarios, the VPN routes with L2VPN label block information that ASBRs advertise to BGP peers must contain public-network tunnel information. However, no tunnels are configured between ASBRs. To allow EBGP routes to be advertised to IBGP peers, an MPLS local ifnet tunnel is generated between MPLS interfaces of ASBRs.

In the L3VPN over inter-as seamless MPLS or VPLS scenario, EBGP peer relationships are established between BGP peers. The BGP peers can be endpoint PEs in the VPLS scenario or the CSG and MASG in the inter-AS seamless MPLS scenario. These EBGP peers automatically establish MPLS local ifnet tunnels between them. The E2E MPLS local ifnet tunnel fails to transmit traffic if the two peers are indirectly connected.

If a fault occurs on a tunnel between the two EBGP peers, the route recurses to the MPLS local ifnet tunnel, not an FRR bypass tunnel. As the MPLS local ifnet tunnel cannot forward traffic, traffic is interrupted. To prevent the traffic interruption, run this command to disable the establishment of an MPLS local ifnet tunnel between the EBGP peers.

Prerequisites

The EBGP peer relationship must be in the Established between PEs.

Example

Disable EBGP peers from establishing an MPLS local ifnet tunnel.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 10.1.1.1 as-number 200
[HUAWEI-bgp] peer 10.1.1.1 mpls-local-ifnet disable
```

10.4.45 peer upe

Function

The **peer upe** command specifies a BGP peer or peer group as UPE of HoVPN.

The **undo peer upe** command cancels the configuration.

Format

peer { *group-name* | *ipv4-address* } **upe**

undo peer { *group-name* | *ipv4-address* } **upe**

Parameters

Parameter	Description	Value
group-name	Specifies the name of the peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.

Parameter	Description	Value
ipv4-address	Specifies the IPv4 address of a peer.	-

Views

BGP-VPNv4 address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

After a UPE is specified on the SPE through the **peer upe** command, the SPE does not send a specific route to the UPE. If the **peer route-policy export** command is run on the SPE to configure routing policies for the UPE and certain specific routes can pass the filtration of routing policies, these specific routes can be sent to the UPE.

Prerequisites

Before you run the peer upe command, the **peer as-number** command should be used to create a peer or peer group.

Precautions

The BGP peer relationship is interrupted after you run the **peer upe** command. So, confirm the action before you use the command.

If an SPE does not have an active default route, either of the following methods can be used to generate a default route on the SPE and allow the SPE to advertise the route to the UPE:

- Method 1: Run the **peer default-originate vpn-instance** command to enable the SPE to automatically generate a default route and advertise it to the UPE.
- Method 2: Run the **ip route-static vpn-instance** command to configure a default route on the SPE, run the **default-route imported** command to enable the SPE to import the default route to the BGP routing table, and then run the **import-route static** or **network** command in the BGP-VPN instance IPv4 address family view to import the default route to the BGP IPv4 VPN instance routing table.

Either of the preceding methods can be used to advertise a default route to the UPE. The priority of the default route generated through method 1 is higher than that generated through method 2. If method 1 is used, the default route generated through method 2 will be suppressed, and no Update messages will be sent for a route change or withdrawal. If the SPE has an active default route, the SPE can advertise the route to the UPE without the need for either of the preceding methods.

Follow-up Procedure

After the **peer upe** command is configured, to send the default route 0.0.0.0 to the UPE, you need to run the **peer default-originate vpn-instance** command on the SPE.

Example

Specify the peer 1.1.1.2 as UPE.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] peer 1.1.1.2 as-number 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] peer 1.1.1.2 enable
[HUAWEI-bgp-af-vpnv4] peer 1.1.1.2 upe
```

10.4.46 peer soo

Function

The **peer soo** command configures the Site of Origin (SoO) attribute for an EBGP peer in a BGP VPN instance.

The **undo peer soo** command deletes the SoO.

By default, no SoO attribute is configured for an EBGP peer in a BGP VPN instance.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **soo** *site-of-origin*

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **soo**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a BGP peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a BGP peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a BGP peer.	The address is in the format of X:X:X:X:X:X:X:X.

Parameter	Description	Value
Site-of-origin	Specifies the SoO attribute, which is a BGP extended community attribute and can be expressed in any of the following formats: ● 2-byte AS number: 4-byte user-defined number, for example, 1:3. The AS number ranges from 0 to 65535. The user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot both be 0. That is, a SoO cannot be 0:0. ● IPv4-address: 2-byte user-defined number, for example, 192.168.122.15:1. The IP address ranges from 0.0.0.0 to 255.255.255.255. The user-defined number ranges from 0 to 65535. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a SoO cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, a SoO cannot be 0.0:0.	-

BGP-VPN instance IPv4 address family view, BGP-VPN instance IPv6 address family view, BGP view, BGP-IPv4 unicast address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a BGP/MPLS IP VPN scenario, if the ASs to which two VPN sites belong use private AS numbers, the AS numbers of the two VPN sites may be the same. As a result, different sites of the same VPN cannot communicate. The **peer substitute-**

as command can be used to enable AS number substitution on PEs to address this problem.

Enabling AS number substitution will cause another problem. Several CEs at a VPN site may establish EBGP connections with different PEs of a BGP/MPLS IP VPN backbone network, and a routing protocol has been configured on the CEs. If AS number substitution is enabled on PEs, the AS numbers carried by VPN routes of this site will be replaced on the PEs. As a result, routes advertised from a CE to a PE may be re-advertised to this VPN site after the routes traverse the backbone network, causing a routing loop. The **peer soo** command can be run on the PEs to address this problem.

After the **peer soo** command is run on a PE to configure the SoO attribute for a specified CE, the PE adds the attribute to a route sent from the CE and advertises the route to the remote PE. The remote PE checks the SoO attribute of the route before sending it to its attached CE. If the SoO attribute is the same as the local SoO attribute on the remote PE, the remote PE does not send the route to its attached CE, preventing a routing loop in a VPN site.

Precautions

The **peer soo** command is used only in the scenarios where PEs and CEs establish EBGP peer relationships.

Example

Configure the SoO attribute for EBGP peers in a BGP VPN instance.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vpna
[HUAWEI-bgp-vpna] peer 192.168.15.2 soo 10.2.2.2:45
```

10.4.47 peer substitute-as

Function

The **peer substitute-as** command enables AS number substitution. This command enables a device to replace the AS number of the peer specified in the AS_Path attribute with the local AS number.

The **undo peer substitute-as** command disables AS number substitution.

By default, AS number substitution is disabled.

Format

peer { *group-name* | *ipv4-address* | *ipv6-address* } **substitute-as**

undo peer { *group-name* | *ipv4-address* | *ipv6-address* } **substitute-as**

Parameters

Parameter	Description	Value
group-name	Specifies the name of a peer group.	The name is a string of 1 to 47 case-sensitive characters, with spaces not supported. When double quotation marks are used around the string, spaces are allowed in the string.
ipv4-address	Specifies the IPv4 address of a peer.	It is in dotted decimal notation.
ipv6-address	Specifies the IPv6 address of a peer.	The address is in the format of X:X:X:X:X:X:X:X.

Views

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In a BGP/MPLS IP VPN scenario, if the ASs to which two VPN sites belong use private AS numbers, the AS numbers of the two VPN sites may be the same. If a CE in a VPN site sends a VPN route to the connected PE using EBGP and the PE then sends the route to the remote PE, the remote CE will discard the route because the AS number carried by the route is the same as the local AS number. As a result, different sites of the same VPN cannot communicate. The **peer substitute-as** command can be used on the PE to enable AS number substitution to address this problem. After that, the PE replaces the AS number carried in the VPN route with the local AS number. As a result, the remote CE will not discard the route due to identical AS numbers.

Pre-configuration Tasks

Run the **peer as-number** command to create a peer or configure an AS number for a specified peer group.

Example

Configure a device to replace the AS number of a specified peer in the AS_Path of a route with the local AS number.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpn-instance vpn1
```

```
[HUAWEI-bgp-vpn1] peer 10.1.1.2 as-number 200
[HUAWEI-bgp-vpn1] peer 10.1.1.2 substitute-as
```

10.4.48 policy vpn-target

Function

The **policy vpn-target** command configures a device to implement VPN target-based filtering for received routes.

The **undo policy vpn-target** command cancels VPN target-based filtering.

By default, the VPN-Target filtering is enabled.

Format

policy vpn-target

undo policy vpn-target

Parameters

None

Views

BGP-VPNv4 address family view, BGP-VPNv6 address family view, BGP-MDT address family view, BGP-MVPN address family view

Default Level

2: Configuration level

Usage Guidelines

Usage Scenario

In the networking of BGP/MPLS IP VPN, Kompella VLL, and Kompella VPLS, VPN target attributes are used to filter received VPN routes or label blocks. If VPN target attributes are not configured, received VPN routes or label blocks are discarded.

VPNs and VPN target attributes are not configured on the following devices in certain networking scenarios:

- RRs in BGP/MPLS IP VPN, Kompella VPLS, or Kompella VLL
- ASBRs (not functioning as PEs) in inter-AS BGP/MPLS IP VPN OptionB

In this case, VPN routes or label blocks are not saved on the RRs or ASBRs.

The RRs or ASBRs, however, need to save all VPN routes or label blocks sent from PEs. Therefore, the **undo policy vpn-target** command can be configured on the RRs or ASBRs to disable the filtering of VPN routes or label blocks.

Precautions

Running the **undo policy vpn-target** makes all VPN routes or label blocks from PEs received. Therefore, this command is configured only on devices of particular roles (RRs or ASBRs)

Example

Configure a device to implement VPN target-based filtering for received VPNv4 routes.

```
<HUAWEI> system-view
[HUAWEI] bgp 100
[HUAWEI-bgp] ipv4-family vpnv4
[HUAWEI-bgp-af-vpnv4] policy vpn-target
```

10.4.49 prefix limit

Function

The **prefix limit** command sets a limit on the maximum number of prefixes supported in the existing VPN instance address family, preventing the PE from importing excessive VPN route prefixes.

The **undo prefix limit** command restores the default setting.

By default, the maximum number of VPN route prefixes is not limited.

Format

prefix limit *number* { *alert-percent* [**route-unchanged**] | **simply-alert** }

undo prefix limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of prefixes supported in the VPN instance address family.	The value is an integer, and the minimum value is 1. The maximum number is determined by the license file.

Parameter	Description	Value
alert-percent	Specifies the proportion of the alarm threshold to the maximum number of prefixes. When the number of prefixes in the VPN instance address family exceeds *number* x *alert-percent*/100, alarms are displayed. The VPN route prefixes, however, can still join the VPN routing table. When the number of the prefixes exceeds the *number*, the subsequent prefixes are discarded.	The value is an integer ranging from 1 to 100.
route-unchanged	Indicates that the routing table remains unchanged. By default, **route-unchanged** is not configured. When the number of prefixes in the routing table is greater than the value of the parameter number, routes are processed as follows: ● If **route-unchanged** is configured, routes in the routing table remain unchanged. ● If **route-unchanged** is not configured, all routes in the routing table are deleted and then re-added.	-
simply-alert	Indicates that when the number of VPN route prefixes exceeds *number*, prefixes can still join the VPN routing table and alarms are displayed. On the device, however, the subsequent VPN route prefixes are discarded after the total number of the unicast prefixes of the private network and the public network reaches the upper limit.	-

Usage Guidelines

Usage Scenario

If many useless route prefixes imported into a VPN instance constitute a large proportion of the route prefixes on a device, run the **prefix limit** command to set a limit on the maximum number of prefixes supported by the VPN instance. After the **prefix limit** command is run in the current VPN instance address family, if the number of route prefixes reaches the set limit, the system will generate an alarm to instruct the user to check the validity of route prefixes of the VPN instance.

The **prefix limit** command enables the system to display a message when the number of route prefixes added to the routing table of the VPN instance IPv6 address family exceeds the limit. If you run the **prefix limit** command to increase the maximum number of route prefixes in the VPN instance IPv6 address family or run the **undo prefix limit** command to cancel the limit, the system adds the excess route prefixes to the VPN IP routing table.

When the number of route prefixes exceeds the limit, direct routes and static routes can still be added to the routing table of the VPN instance IPv6 address family.

Prerequisites

The **route-distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

The **prefix limit** command can prevent the routing table of the current VPN instance address family on a PE from importing too many route prefixes, but cannot prevent the PE from importing excessive route prefixes from other PEs. Therefore, configuring both the **prefix limit** and **peer route-limit** commands is recommended.

Do not run both the **routing-table limit** (the command restricts the number of routes) and **prefix limit** (the command restricts the number of route prefixes) commands in the current VPN instance address family. Configure either one of them based on your need.

Example

Configure the system to only generate alarms when the number of prefixes exceeds the maximum number 1000 in the VPN instance named vpn1.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] prefix limit 1000 simply-alert
```

10.4.50 route-distinguisher

Function

The **route-distinguisher** command configures a route distinguisher (RD) for a VPN instance address family.

By default, no RD is configured for the VPN instance address family.

Format

route-distinguisher *route-distinguisher*

Parameters

Parameter	Description	Value
route-distinguisher	Specifies the value of an RD. The forms of RD are as follows: ● 2-byte AS number:4-byte user-defined number, for example, 101:3. An AS number ranges from 0 to 65535. A user-defined number ranges from 0 to 4294967295. The AS number and the user-defined number cannot be 0s at the same time. That is, an RD cannot be 0:0. ● Integral 4-byte AS number:2-byte user-defined number, for example, 65537:3. An AS number ranges from 65536 to 4294967295. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0:0. ● 4-byte AS number in dotted notation:2-byte user-defined number, for example, 0.0:3 or 0.1:0. A 4-byte AS number in dotted notation is in the format of *x.y*, where *x* and *y* are integers that range from 0 to 65535 and from 0 to 65535, respectively. A user-defined number ranges from 0 to 65535. The AS number and user-defined number cannot be both 0s. That is, an RD cannot be 0.0:0. ● IPv4-address:2-byte user-defined number, for example, 192.168.122.15:1. An IP address ranges from 0.0.0.0 to 255.255.255.255. A user-defined number ranges from 0 to 65535.	-

Usage Guidelines

Usage Scenario

After creating a VPN instance and enabling the IPv4 or IPv6 address family for the VPN instance, you need to run the **route-distinguisher** command to configure an RD for the address family.

Different VPN instances may have the same route prefix. To allow a PE to determine to which VPN instance a route belongs, run the **route-distinguisher** command to configure an RD for an address family of a VPN instance on the PE. After the configuration, the PE will add an RD to the route received from the VPN instance, and then the route prefix becomes a globally unique VPNv4 or VPNv6 route.

Configuration Impact

An RD configured for the IPv4 or IPv6 address family of a VPN instance cannot be directly modified or deleted. Before modifying an RD, you need to disable the IPv4 or IPv6 address family of the VPN instance or delete the VPN instance and then reconfigure the address family or the VPN instance.

Precautions

Configuring a unique RD for the IPv4 or IPv6 address family of a VPN instance is recommended; otherwise, route overlap may occur.

When the **route-distinguisher** command is run in the VPN instance view, an **ipv4-family** command is created at the same time by default. The command results are equivalent to running the **ipv4-family** command in the VPN instance view and then running the **route-distinguisher** command in the VPN instance IPv4 address family view. For example:

```
[HUAWEI-vpn-instance-vpn1] route-distinguisher 200:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] display this
#
 ipv4-family
  route-distinguisher 200:1
#
return
```

Example

Configure an RD for the VPN instance named **vpn1**.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 22:1
```

10.4.51 routing-table limit

Function

The **routing-table limit** command sets the maximum number of routes that the current VPN instance address family supports.

The **undo routing-table limit** command restores the maximum number of routes that the current VPN instance address family can support to the default setting.

By default, there is no limit on the maximum number of routes that the current VPN instance address family can support, but the total number of private network and public network routes on a device cannot exceed the allowed maximum number of unicast routes.

Format

routing-table limit *number* { *alert-percent* | **simply-alert** }

undo routing-table limit

Parameters

Parameter	Description	Value
number	Specifies the maximum number of routes supported by a VPN instance.	The value is an integer, and the minimum value is 1. The maximum number is determined by the license file.
alert-percent	Specifies the percentage of the maximum number of routes. When the maximum number of routes that join the VPN instance is up to the value (*number***alert-percent*)/100, the system prompts alarms. The VPN routes can be still added to the routing table, but after the number of routes reaches *number*, the subsequent routes are dropped.	An integer ranging from 1 to 100.
simply-alert	Indicates that when VPN routes exceed *number*, routes can still be added into the routing table, but the system prompts alarms. However, after the total number of VPN routes and network public routes reaches the unicast route limit specified in the License, the subsequent VPN routes are dropped.	-

Usage Guidelines

Usage Scenario

If many useless routes imported into a VPN instance constitute a large proportion of the routes on a device, run the **routing-table limit** command to set a limit on the maximum number of routes supported by the VPN instance. After the **routing-table limit** command is run in the current VPN instance address family, if the number of routes of the VPN instance reaches the set limit, the system will generate an alarm to instruct the user to check the validity of routes of the VPN instance.

The **routing-table limit** command enables the system to display a message when the number of routes added to the routing table of the VPN instance IPv6 address family exceeds the limit. If you run the **routing-table limit** command to increase the maximum number of routes in the VPN instance IPv6 address family or run the **undo routing-table limit** command to cancel the limit, the system adds the excess routes to the VPN IP routing table.

Prerequisites

1. The **ip vpn-instance** command has been executed to create a VPN instance and enter the VPN instance view.
2. The **ipv4-family** or **ipv6-family** command has been executed to enter the IPv4 or IPv6 VPN instance address family view.
3. The **route distinguisher** command has been executed to set the RD of the VPN instance.

Precautions

Using the **routing-table limit** command prevents the routing table of the current VPN instance address family on a PE from importing too many routes, but cannot prevent the PE from importing excessive routes from other PEs. Therefore, configuring both the **routing-table limit** and **peer route-limit** commands is recommended.

Do not run both the **routing-table limit** (the command restricts the number of routes) and **prefix limit** (the command restricts the number of route prefixes) commands in the current VPN instance address family. Configure either one of them based on your need.

If the remote cross routes learned using MP-IBGP and the BGP routes learned from CEs failed to be added to the routing table, the system automatically refreshes the routing table to add these routes.

Example

Configure the maximum number of routes for the IPv4 address family of the VPN instance named vpn1 to 1000, and when VPN routes exceed 1000, routes can still be added into the routing table, but the system prompts alarms.

```
<HUAWEI> system-view
[HUAWEI] ip vpn-instance vpn1
[HUAWEI-vpn-instance-vpn1] ipv4-family
[HUAWEI-vpn-instance-vpn1-af-ipv4] route-distinguisher 100:1
[HUAWEI-vpn-instance-vpn1-af-ipv4] routing-table limit 1000 simply-alert
```
